$$\begin{aligned} \mathrm{wt}(b_N \otimes \cdots \otimes b_1) &= \mathrm{wt}(b_N) + \cdots + \mathrm{wt}(b_1), \\ \varepsilon_i(b_N \otimes \cdots \otimes b_1) &= \max_{1 \leq k \leq n} \left(\sum_{j=1}^{k} \varepsilon_i(b_j) - \sum_{j=1}^{k-1} \varphi_i(b_j) \right) \\ &= \max_{1 \leq k \leq N} \big(a_i(k)\big), \\ \varphi_i(b_N \otimes \cdots \otimes b_1) &= \max_{1 \leq k \leq N} \left(\varphi_i(b_N) + \sum_{j=k}^{N-1} \big(\varphi_i(b_j) - \varepsilon_i(b_{j+1})\big) \right) \\ &= \max_{1 \leq k \leq N} \big(\lambda_i + a_i(k)\big) \end{aligned}$$

where $\lambda_i = \langle \alpha_i^\vee, \mathrm{wt}(b_N \otimes \cdots \otimes b_1) \rangle$. Then for $k = 1, \ldots, N$ the action of the Kashiwara operators is determined as follows.

- If $a_i(k) > a_i(j)$ for $1 \leq j < k$ and $a_i(k) \geq a_i(j)$ for $k < j \leq N$:

$$e_i(b_N \otimes \cdots \otimes b_1) = b_N \otimes \cdots \otimes e_i b_k \otimes \cdots \otimes b_1.$$

- If $a_i(k) \geq a_i(j)$ for $1 \leq j < k$ and $a_i(k) > a_i(j)$ for $k < j \leq N$:

$$f_i(b_N \otimes \cdots \otimes b_1) = b_N \otimes \cdots \otimes f_i b_k \otimes \cdots \otimes b_1.$$

Note that this is just recursively applying the definition of the tensor product on two crystals. Recall that $\langle \alpha_i^\vee, \mathrm{wt}(b_j) \rangle = \varphi_i(b_j) - \varepsilon_i(b_j)$ by the definition of a crystal.

Regular crystals

Now if all crystals B_k are regular crystals, all ε_i and φ_i are nonnegative and we can define tensor product by the *signature rule*. We start by writing a word in $+$ and $-$ as follows:

$$\underbrace{-\cdots-}_{\varphi_i(b_N)\text{ times}}\ \underbrace{+\cdots+}_{\varepsilon_i(b_N)\text{ times}}\ \cdots\ \underbrace{-\cdots-}_{\varphi_i(b_1)\text{ times}}\ \underbrace{+\cdots+}_{\varepsilon_i(b_1)\text{ times}},$$

and then canceling ordered pairs of $+-$ until the word is in the reduced form:

$$\underbrace{-\cdots-}_{\varphi_i\text{ times}}\ \underbrace{+\cdots+}_{\varepsilon_i\text{ times}}.$$

Here e_i acts on the factor corresponding to the leftmost $+$ and f_i on the factor corresponding to the rightmost $-$. If there is no $+$ or $-$ respectively, then the result is 0 (`None`).

EXAMPLES:

We construct the type A_2-crystal generated by $2 \otimes 1 \otimes 1$:

```
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C,C,generators=[[C(2),C(1),C(1)]])
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(2)])
>>> T = crystals.TensorProduct(C,C,C,generators=[[C(Integer(2)),C(Integer(1)),
↪C(Integer(1))]])
```

It has 8 elements:

```
sage: T.list()
[[2, 1, 1], [2, 1, 2], [2, 1, 3], [3, 1, 3],
 [3, 2, 3], [3, 1, 1], [3, 1, 2], [3, 2, 2]]
```

```
>>> from sage.all import *
>>> T.list()
[[2, 1, 1], [2, 1, 2], [2, 1, 3], [3, 1, 3],
 [3, 2, 3], [3, 1, 1], [3, 1, 2], [3, 2, 2]]
```

One can also check the Cartan type of the crystal:

```
sage: T.cartan_type()
['A', 2]
```

```
>>> from sage.all import *
>>> T.cartan_type()
['A', 2]
```

Other examples include crystals of tableaux (which internally are represented as tensor products obtained by reading the tableaux columnwise):

```
sage: C = crystals.Tableaux(['A',3], shape=[1,1,0])
sage: D = crystals.Tableaux(['A',3], shape=[1,0,0])
sage: T = crystals.TensorProduct(C,D, generators=[[C(rows=[[1], [2]]),␣
↪D(rows=[[1]])], [C(rows=[[2], [3]]), D(rows=[[1]])]])
```

(continues on next page)

(continued from previous page)

```
sage: T.cardinality()
24
sage: TestSuite(T).run()
sage: T.module_generators
([[[1], [2]], [[1]]], [[[2], [3]], [[1]]])
sage: [x.weight() for x in T.module_generators]
[(2, 1, 0, 0), (1, 1, 1, 0)]
```

```
>>> from sage.all import *
>>> C = crystals.Tableaux(['A',Integer(3)], shape=[Integer(1),Integer(1),
↪Integer(0)])
>>> D = crystals.Tableaux(['A',Integer(3)], shape=[Integer(1),Integer(0),
↪Integer(0)])
>>> T = crystals.TensorProduct(C,D, generators=[[C(rows=[[Integer(1)],␣
↪[Integer(2)]]), D(rows=[[Integer(1)]])], [C(rows=[[Integer(2)], [Integer(3)]]),␣
↪D(rows=[[Integer(1)]])]])
>>> T.cardinality()
24
>>> TestSuite(T).run()
>>> T.module_generators
([[[1], [2]], [[1]]], [[[2], [3]], [[1]]])
>>> [x.weight() for x in T.module_generators]
[(2, 1, 0, 0), (1, 1, 1, 0)]
```

If no module generators are specified, we obtain the full tensor product:

```
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C)
sage: T.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
sage: T.cardinality()
9
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(2)])
>>> T = crystals.TensorProduct(C,C)
>>> T.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
>>> T.cardinality()
9
```

For a tensor product of crystals without module generators, the default implementation of `module_generators` contains all elements in the tensor product of the crystals. If there is a subset of elements in the tensor product that still generates the crystal, this needs to be implemented for the specific crystal separately:

```
sage: T.module_generators.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
```

```
>>> from sage.all import *
>>> T.module_generators.list()
[[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1], [3, 2], [3, 3]]
```

For classical highest weight crystals, it is also possible to list all highest weight elements:

```
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C,C,generators=[[C(2),C(1),C(1)],[C(1),C(2),
↪C(1)]])
sage: T.highest_weight_vectors()
([2, 1, 1], [1, 2, 1])
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(2)])
>>> T = crystals.TensorProduct(C,C,C,generators=[[C(Integer(2)),C(Integer(1)),
↪C(Integer(1))],[C(Integer(1)),C(Integer(2)),C(Integer(1))]])
>>> T.highest_weight_vectors()
([2, 1, 1], [1, 2, 1])
```

Examples with non-regular and infinite crystals (these did not work before Issue #14402):

```
sage: B = crystals.infinity.Tableaux(['D',10])
sage: T = crystals.TensorProduct(B,B)
sage: T
Full tensor product of the crystals
[The infinity crystal of tableaux of type ['D', 10],
 The infinity crystal of tableaux of type ['D', 10]]

sage: B = crystals.infinity.GeneralizedYoungWalls(15)
sage: T = crystals.TensorProduct(B,B,B)
sage: T
Full tensor product of the crystals
[Crystal of generalized Young walls of type ['A', 15, 1],
 Crystal of generalized Young walls of type ['A', 15, 1],
 Crystal of generalized Young walls of type ['A', 15, 1]]

sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_
↪weights()
sage: B = crystals.GeneralizedYoungWalls(2,La[0]+La[1])
sage: C = crystals.GeneralizedYoungWalls(2,2*La[2])
sage: D = crystals.GeneralizedYoungWalls(2,3*La[0]+La[2])
sage: T = crystals.TensorProduct(B,C,D)
sage: T
Full tensor product of the crystals
[Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and␣
↪highest weight Lambda[0] + Lambda[1],
 Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and␣
↪highest weight 2*Lambda[2],
 Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and␣
↪highest weight 3*Lambda[0] + Lambda[2]]
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['D',Integer(10)])
>>> T = crystals.TensorProduct(B,B)
>>> T
Full tensor product of the crystals
[The infinity crystal of tableaux of type ['D', 10],
```

(continues on next page)

(continued from previous page)

```
 The infinity crystal of tableaux of type ['D', 10]]

>>> B = crystals.infinity.GeneralizedYoungWalls(Integer(15))
>>> T = crystals.TensorProduct(B,B,B)
>>> T
Full tensor product of the crystals
[Crystal of generalized Young walls of type ['A', 15, 1],
 Crystal of generalized Young walls of type ['A', 15, 1],
 Crystal of generalized Young walls of type ['A', 15, 1]]

>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=True).
↪fundamental_weights()
>>> B = crystals.GeneralizedYoungWalls(Integer(2),La[Integer(0)]+La[Integer(1)])
>>> C = crystals.GeneralizedYoungWalls(Integer(2),Integer(2)*La[Integer(2)])
>>> D = crystals.GeneralizedYoungWalls(Integer(2),
↪Integer(3)*La[Integer(0)]+La[Integer(2)])
>>> T = crystals.TensorProduct(B,C,D)
>>> T
Full tensor product of the crystals
[Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and␣
↪highest weight Lambda[0] + Lambda[1],
 Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and␣
↪highest weight 2*Lambda[2],
 Highest weight crystal of generalized Young walls of Cartan type ['A', 2, 1] and␣
↪highest weight 3*Lambda[0] + Lambda[2]]
```

There is also a global option for setting the convention (by default Sage uses anti-Kashiwara):

```
sage: C = crystals.Letters(['A',2])
sage: T = crystals.TensorProduct(C,C)
sage: elt = T(C(1), C(2)); elt
[1, 2]
sage: crystals.TensorProduct.options.convention = "Kashiwara"
sage: elt
[2, 1]
sage: crystals.TensorProduct.options._reset()
```

```
>>> from sage.all import *
>>> C = crystals.Letters(['A',Integer(2)])
>>> T = crystals.TensorProduct(C,C)
>>> elt = T(C(Integer(1)), C(Integer(2))); elt
[1, 2]
>>> crystals.TensorProduct.options.convention = "Kashiwara"
>>> elt
[2, 1]
>>> crystals.TensorProduct.options._reset()
```

options = Current options for TensorProductOfCrystals - convention: antiKashiwara

class sage.combinat.crystals.tensor_product.**TensorProductOfCrystalsWithGenerators**(*crystals*, *generators*, *cartan_type*)

Bases: *TensorProductOfCrystals*

Tensor product of crystals with a generating set.

Todo

Deprecate this class in favor of using `subcrystal()`.

class sage.combinat.crystals.tensor_product.**TensorProductOfRegularCrystalsWithGenerators**(*crystals*, *generators*, *cartan_type*)

Bases: *TensorProductOfCrystalsWithGenerators*

Tensor product of regular crystals with a generating set.

class Element

Bases: *TensorProductOfRegularCrystalsElement*

Virtual crystals

These are the crystals that are subsets of a larger ambient crystal with virtual crystal operators.

AUTHORS:

- Travis Scrimshaw (2013-10-16): initial implementation

class sage.combinat.crystals.virtual_crystal.**VirtualCrystal**(*ambient*, *virtualization*, *scaling_factors*, *contained*, *generators*, *cartan_type*, *index_set*, *category*)

Bases: *Subcrystal*

A virtual crystal V of an ambient crystal $\widehat{B}$ is a crystal formed by taking a subset of $\widehat{B}$ and whose crystal structure is given by

$$e_i = \prod_{j \in \sigma_i} \widehat{e}_j^{\gamma_i}, \quad f_i = \prod_{j \in \sigma_i} \widehat{f}_j^{\gamma_i},$$

$$\varepsilon_i = \frac{\widehat{\varepsilon}_j}{\gamma_j}, \quad \varphi_i = \frac{\widehat{\varphi}_j}{\gamma_j}, \quad \mathrm{wt} = \Psi^{-1} \circ \widehat{\mathrm{wt}}$$

where σ_i is a subset of the index set of B, $\gamma_i \in \mathbf{Z}$ are the *scaling factors*, and $\Psi : P \to \widehat{P}$ is an embedding of the weight lattices. We note that for the crystal to be well-defined, we must have

$$\widehat{\varepsilon}_j = \widehat{\varepsilon|j'}, \quad \widehat{\varphi}_j = \widehat{\varphi}_{j'}$$

for all $j, j' \in \sigma_i$ and that the order that the Kashiwara operators in the ambient space are applied does not affect the result.

INPUT:

- `ambient` – the ambient crystal
- `virtualization` – dictionary whose key i corresponds to the set σ_i
- `scaling_factors` – dictionary whose key i corresponds to the scaling factor γ_i
- `contained` – (optional) a set (or function) which specifies when an element is contained in the subcrystal; the default is everything possible is included
- `generators` – (optional) the generators for the virtual crystal; the default is the generators for the ambient crystal
- `cartan_type` – (optional) the Cartan type for the virtual crystal; the default is the Cartan type for the ambient crystal
- `index_set` – (optional) the index set for the virtual crystal; the default is the index set for the Cartan type
- `category` – (optional) the category for the virtual crystal; the default is the `Crystals` category

EXAMPLES:

We construct an example from a natural virtualization map of type C_n in type A_{2n-1}:

```
sage: C = crystals.Tableaux(['C',2], shape=[1])
sage: A = crystals.Tableaux(['A',3], shape=[2,1,1])
sage: psi = C.crystal_morphism(A.module_generators)
sage: V = psi.image()
sage: list(V)
[[[1, 1], [2], [3]],
 [[1, 2], [2], [4]],
 [[1, 3], [3], [4]],
 [[2, 4], [3], [4]]]
sage: V.digraph().is_isomorphic(C.digraph(), edge_labels=True)
True
```

```
>>> from sage.all import *
>>> C = crystals.Tableaux(['C',Integer(2)], shape=[Integer(1)])
>>> A = crystals.Tableaux(['A',Integer(3)], shape=[Integer(2),Integer(1),
...Integer(1)])
>>> psi = C.crystal_morphism(A.module_generators)
>>> V = psi.image()
>>> list(V)
[[[1, 1], [2], [3]],
 [[1, 2], [2], [4]],
 [[1, 3], [3], [4]],
 [[2, 4], [3], [4]]]
>>> V.digraph().is_isomorphic(C.digraph(), edge_labels=True)
True
```

We construct the virtualization of a $U_q'(\mathfrak{g})$-crystal $B^{r,s}$ of type $C_n^{(1)}$ in type $A_{2n+1}^{(2)}$. Here it is not a default folding known to Sage, so we have to explicitly state the folding (since the scaling factors are not specified, they are all assumed to be 1):

```
sage: K = crystals.KirillovReshetikhin(['C',2,1], 1,1)
sage: VK = crystals.KirillovReshetikhin(['A',5,2], 1,1)
sage: target = VK.module_generator().f(1); target
[[2]]
sage: psi = K.crystal_morphism({K.module_generator(): target},
....:                          virtualization={0:[0,1], 1:[2], 2:[3]})
sage: V = psi.image()
sage: list(V)
[[[2]], [[3]], [[-2]], [[-3]]]
sage: V.digraph().is_isomorphic(K.digraph(), edge_labels=True)
True
```

```
>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['C',Integer(2),Integer(1)], Integer(1),
↪Integer(1))
>>> VK = crystals.KirillovReshetikhin(['A',Integer(5),Integer(2)], Integer(1),
↪Integer(1))
>>> target = VK.module_generator().f(Integer(1)); target
[[2]]
>>> psi = K.crystal_morphism({K.module_generator(): target},
...                          virtualization={Integer(0):[Integer(0),Integer(1)],␣
↪Integer(1):[Integer(2)], Integer(2):[Integer(3)]})
>>> V = psi.image()
>>> list(V)
[[[2]], [[3]], [[-2]], [[-3]]]
>>> V.digraph().is_isomorphic(K.digraph(), edge_labels=True)
True
```

We create an example of $B(\Lambda_n)$ of type B_n inside of $B(2\Lambda_n)$ using the doubling map through the (virtual) subcrystal method:

```
sage: BB = crystals.Tableaux(['B',3], shape=[1,1,1])
sage: S = BB.subcrystal(scaling_factors={1:2, 2:2, 3:2})
sage: B = crystals.Tableaux(['B',3], shape=[1/2,1/2,1/2])
sage: S.digraph().is_isomorphic(B.digraph(), edge_labels=True)
True
```

```
>>> from sage.all import *
>>> BB = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1),Integer(1),
↪Integer(1)])
>>> S = BB.subcrystal(scaling_factors={Integer(1):Integer(2),␣
↪Integer(2):Integer(2), Integer(3):Integer(2)})
>>> B = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1)/Integer(2),
↪Integer(1)/Integer(2),Integer(1)/Integer(2)])
>>> S.digraph().is_isomorphic(B.digraph(), edge_labels=True)
True
```

We can also directly construct a virtual crystal using *VirtualCrystal* (however it is recommended to use either crystal_morphism() or subcrystal()):

```
sage: from sage.combinat.crystals.virtual_crystal import VirtualCrystal
sage: A = crystals.Tableaux(['A',3], shape=[2,1,1])
sage: V = VirtualCrystal(A, {1:(1,3), 2:(2,)}, {1:1, 2:2}, cartan_type=['C',2])
```

(continues on next page)

(continued from previous page)

```
sage: G = crystals.Tableaux(['C',2], shape=[1]).digraph()
sage: V.digraph().is_isomorphic(G, edge_labels=True)
True

sage: C1 = crystals.Tableaux(['A',3], shape=[1])
sage: C2 = crystals.Tableaux(['A',3], shape=[1,1,1])
sage: T = C1.tensor(C2)
sage: mg = T(C1.module_generators[0], C2.module_generators[0])
sage: V = VirtualCrystal(A, {1:(1,3), 2:(2,)}, {1:1, 2:2},
....:                    cartan_type=['C',2], generators=[mg])
sage: V.digraph().is_isomorphic(G, edge_labels=True)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.crystals.virtual_crystal import VirtualCrystal
>>> A = crystals.Tableaux(['A',Integer(3)], shape=[Integer(2),Integer(1),
↪Integer(1)])
>>> V = VirtualCrystal(A, {Integer(1):(Integer(1),Integer(3)),␣
↪Integer(2):(Integer(2),)}, {Integer(1):Integer(1), Integer(2):Integer(2)},␣
↪cartan_type=['C',Integer(2)])
>>> G = crystals.Tableaux(['C',Integer(2)], shape=[Integer(1)]).digraph()
>>> V.digraph().is_isomorphic(G, edge_labels=True)
True

>>> C1 = crystals.Tableaux(['A',Integer(3)], shape=[Integer(1)])
>>> C2 = crystals.Tableaux(['A',Integer(3)], shape=[Integer(1),Integer(1),
↪Integer(1)])
>>> T = C1.tensor(C2)
>>> mg = T(C1.module_generators[Integer(0)], C2.module_generators[Integer(0)])
>>> V = VirtualCrystal(A, {Integer(1):(Integer(1),Integer(3)),␣
↪Integer(2):(Integer(2),)}, {Integer(1):Integer(1), Integer(2):Integer(2)},
...                    cartan_type=['C',Integer(2)], generators=[mg])
>>> V.digraph().is_isomorphic(G, edge_labels=True)
True
```

REFERENCES:

- [FOS2009]
- [OSS03]
- [OSS2003]

class Element

Bases: *Element*

An element of a virtual (sub)crystal. Wraps an element in the ambient crystal.

e(i)

Return e_i of `self`.

EXAMPLES:

```
sage: B = crystals.Tableaux(['B',3], shape=[1])
sage: C = crystals.Tableaux(['D',4], shape=[2])
```

(continues on next page)

(continued from previous page)

```
sage: psi = B.crystal_morphism(C.module_generators)
sage: V = psi.image()
sage: mg = V.module_generators[0]
sage: mg.e(1)
sage: b = psi(B.module_generators[0].f(1))
sage: V(b).e(1)
[[1, 1]]
```

```
>>> from sage.all import *
>>> B = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1)])
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(2)])
>>> psi = B.crystal_morphism(C.module_generators)
>>> V = psi.image()
>>> mg = V.module_generators[Integer(0)]
>>> mg.e(Integer(1))
>>> b = psi(B.module_generators[Integer(0)].f(Integer(1)))
>>> V(b).e(Integer(1))
[[1, 1]]
```

epsilon(i)

Return ε_i of `self`.

EXAMPLES:

```
sage: B = crystals.Tableaux(['B',3], shape=[1])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: psi = B.crystal_morphism(C.module_generators)
sage: V = psi.image()
sage: mg = V.module_generators[0]
sage: mg.epsilon(2)
0
sage: mg.f(1).epsilon(1)
1
```

```
>>> from sage.all import *
>>> B = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1)])
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(2)])
>>> psi = B.crystal_morphism(C.module_generators)
>>> V = psi.image()
>>> mg = V.module_generators[Integer(0)]
>>> mg.epsilon(Integer(2))
0
>>> mg.f(Integer(1)).epsilon(Integer(1))
1
```

f(i)

Return f_i of `self`.

EXAMPLES:

```
sage: B = crystals.Tableaux(['B',3], shape=[1])
sage: C = crystals.Tableaux(['D',4], shape=[2])
```

(continues on next page)

(continued from previous page)

```
sage: psi = B.crystal_morphism(C.module_generators)
sage: V = psi.image()
sage: mg = V.module_generators[0]
sage: mg.f(1)
[[2, 2]]
sage: mg.f(2)
```

```
>>> from sage.all import *
>>> B = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1)])
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(2)])
>>> psi = B.crystal_morphism(C.module_generators)
>>> V = psi.image()
>>> mg = V.module_generators[Integer(0)]
>>> mg.f(Integer(1))
[[2, 2]]
>>> mg.f(Integer(2))
```

phi(*i*)

Return φ_i of `self`.

EXAMPLES:

```
sage: B = crystals.Tableaux(['B',3], shape=[1])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: psi = B.crystal_morphism(C.module_generators)
sage: V = psi.image()
sage: mg = V.module_generators[0]
sage: mg.phi(1)
1
sage: mg.phi(2)
0
```

```
>>> from sage.all import *
>>> B = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1)])
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(2)])
>>> psi = B.crystal_morphism(C.module_generators)
>>> V = psi.image()
>>> mg = V.module_generators[Integer(0)]
>>> mg.phi(Integer(1))
1
>>> mg.phi(Integer(2))
0
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: B = crystals.Tableaux(['B',3], shape=[1])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: psi = B.crystal_morphism(C.module_generators)
sage: V = psi.image()
```

(continues on next page)

(continued from previous page)

```
sage: mg = V.module_generators[0]
sage: mg.weight()
(1, 0, 0)
sage: mg.f(1).weight()
(0, 1, 0)
sage: all(V(psi(x)).weight() == x.weight() for x in B)
True
```

```
>>> from sage.all import *
>>> B = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1)])
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(2)])
>>> psi = B.crystal_morphism(C.module_generators)
>>> V = psi.image()
>>> mg = V.module_generators[Integer(0)]
>>> mg.weight()
(1, 0, 0)
>>> mg.f(Integer(1)).weight()
(0, 1, 0)
>>> all(V(psi(x)).weight() == x.weight() for x in B)
True
```

scaling_factors()

Return the scaling factors γ_i.

EXAMPLES:

```
sage: B = crystals.Tableaux(['B',3], shape=[1])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: psi = B.crystal_morphism(C.module_generators)
sage: V = psi.image()
sage: V.scaling_factors()
Finite family {1: 2, 2: 2, 3: 1}
```

```
>>> from sage.all import *
>>> B = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1)])
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(2)])
>>> psi = B.crystal_morphism(C.module_generators)
>>> V = psi.image()
>>> V.scaling_factors()
Finite family {1: 2, 2: 2, 3: 1}
```

virtualization()

Return the virtualization sets σ_i.

EXAMPLES:

```
sage: B = crystals.Tableaux(['B',3], shape=[1])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: psi = B.crystal_morphism(C.module_generators)
sage: V = psi.image()
sage: V.virtualization()
Finite family {1: (1,), 2: (2,), 3: (3, 4)}
```

```
>>> from sage.all import *
>>> B = crystals.Tableaux(['B',Integer(3)], shape=[Integer(1)])
>>> C = crystals.Tableaux(['D',Integer(4)], shape=[Integer(2)])
>>> psi = B.crystal_morphism(C.module_generators)
>>> V = psi.image()
>>> V.virtualization()
Finite family {1: (1,), 2: (2,), 3: (3, 4)}
```

$\mathcal{B}(\infty)$ crystal of PBW monomials

See also

For information on PBW datum, see *PBW data*.

AUTHORS:

- Dinakar Muthiah (2015-05-11): initial version

class sage.combinat.crystals.pbw_crystal.**PBWCrystal**(*cartan_type*)

Bases: Parent, UniqueRepresentation

Crystal of $\mathcal{B}(\infty)$ given by PBW monomials.

A model of the crystal $\mathcal{B}(\infty)$ whose elements are PBW datum up to equivalence by the tropical Plücker relations. The crystal structure on Lusztig data $x = (x_1, \ldots, x_m)$ for the reduced word $s_{i_1} \cdots s_{i_m} = w_0$ is given as follows. Suppose $i_1 = j$, then $f_j x = (x_1 + 1, x_2, \ldots, x_m)$. If $i_1 \neq j$, then we use the tropical Plücker relations to change the reduced expression such that $i'_1 = j$ and then we change back to the original word.

EXAMPLES:

```
sage: PBW = crystals.infinity.PBW(['B', 3])
sage: hw = PBW.highest_weight_vector()
sage: x = hw.f_string([1,2,2,3,3,1,3,3,2,3,2,1,3,1,2,3,1,2,1,3,2]); x
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

```
>>> from sage.all import *
>>> PBW = crystals.infinity.PBW(['B', Integer(3)])
>>> hw = PBW.highest_weight_vector()
>>> x = hw.f_string([Integer(1),Integer(2),Integer(2),Integer(3),Integer(3),
...Integer(1),Integer(3),Integer(3),Integer(2),Integer(3),Integer(2),Integer(1),
...Integer(3),Integer(1),Integer(2),Integer(3),Integer(1),Integer(2),Integer(1),
...Integer(3),Integer(2)]); x
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

Elements are expressed in terms of Lusztig datum for a fixed reduced expression of w_0:

```
sage: PBW.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: PBW.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: x
PBW monomial with Lusztig datum (3, 1, 1, 0, 1, 0, 1, 3, 4)
sage: PBW.set_default_long_word([1, 3, 2, 3, 1, 2, 3, 1, 2])
```

```
>>> from sage.all import *
>>> PBW.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
>>> PBW.set_default_long_word([Integer(2),Integer(1),Integer(3),Integer(2),
↪Integer(1),Integer(3),Integer(2),Integer(3),Integer(1)])
>>> x
PBW monomial with Lusztig datum (3, 1, 1, 0, 1, 0, 1, 3, 4)
>>> PBW.set_default_long_word([Integer(1), Integer(3), Integer(2), Integer(3),␣
↪Integer(1), Integer(2), Integer(3), Integer(1), Integer(2)])
```

We can construct elements by giving it Lusztig data (with respect to the default long word):

```
sage: PBW([1,1,1,3,1,0,0,1,1])
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

```
>>> from sage.all import *
>>> PBW([Integer(1),Integer(1),Integer(1),Integer(3),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1)])
PBW monomial with Lusztig datum (1, 1, 1, 3, 1, 0, 0, 1, 1)
```

We can also construct elements by passing in a reduced expression for a long word:

```
sage: x = PBW([1,1,1,3,1,0,0,1,1], [3,2,1,3,2,3,2,1,2]); x
PBW monomial with Lusztig datum (1, 1, 1, 0, 1, 0, 5, 1, 1)
sage: x.to_highest_weight()[1]
[1, 2, 2, 2, 2, 2, 1, 3, 3, 3, 3, 2, 3, 2, 3, 3, 2, 3, 3, 2, 1, 3]
```

```
>>> from sage.all import *
>>> x = PBW([Integer(1),Integer(1),Integer(1),Integer(3),Integer(1),Integer(0),
↪Integer(0),Integer(1),Integer(1)], [Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3),Integer(2),Integer(1),Integer(2)]); x
PBW monomial with Lusztig datum (1, 1, 1, 0, 1, 0, 5, 1, 1)
>>> x.to_highest_weight()[Integer(1)]
[1, 2, 2, 2, 2, 2, 1, 3, 3, 3, 3, 2, 3, 2, 3, 3, 2, 3, 3, 2, 1, 3]
```

Element

alias of *PBWCrystalElement*

default_long_word()

Return the default long word used to express elements of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['E', 6])
sage: B.default_long_word()
[1, 3, 4, 5, 6, 2, 4, 5, 3, 4, 1, 3, 2, 4, 5, 6, 2, 4,
 5, 3, 4, 1, 3, 2, 4, 5, 3, 4, 1, 3, 2, 4, 1, 3, 2, 1]
```

```
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['E', Integer(6)])
>>> B.default_long_word()
[1, 3, 4, 5, 6, 2, 4, 5, 3, 4, 1, 3, 2, 4, 5, 6, 2, 4,
 5, 3, 4, 1, 3, 2, 4, 5, 3, 4, 1, 3, 2, 4, 1, 3, 2, 1]
```

set_default_long_word(*word*)

Set the default long word used to express elements of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['C', 3])
sage: B.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
sage: x = B.highest_weight_vector().f_string([2,1,3,2,3,1,2,3,3,1])
sage: x
PBW monomial with Lusztig datum (1, 2, 2, 0, 0, 0, 0, 0, 1)
sage: B.set_default_long_word([2,1,3,2,1,3,2,3,1])
sage: B.default_long_word()
[2, 1, 3, 2, 1, 3, 2, 3, 1]
sage: x
PBW monomial with Lusztig datum (2, 0, 0, 0, 0, 0, 1, 3, 2)
```

```
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['C', Integer(3)])
>>> B.default_long_word()
[1, 3, 2, 3, 1, 2, 3, 1, 2]
>>> x = B.highest_weight_vector().f_string([Integer(2),Integer(1),Integer(3),
...Integer(2),Integer(3),Integer(1),Integer(2),Integer(3),Integer(3),
...Integer(1)])
>>> x
PBW monomial with Lusztig datum (1, 2, 2, 0, 0, 0, 0, 0, 1)
>>> B.set_default_long_word([Integer(2),Integer(1),Integer(3),Integer(2),
...Integer(1),Integer(3),Integer(2),Integer(3),Integer(1)])
>>> B.default_long_word()
[2, 1, 3, 2, 1, 3, 2, 3, 1]
>>> x
PBW monomial with Lusztig datum (2, 0, 0, 0, 0, 0, 1, 3, 2)
```

class sage.combinat.crystals.pbw_crystal.**PBWCrystalElement**(*parent*, *lusztig_datum*, *long_word=None*)

Bases: `Element`

A crystal element in the PBW model.

e(*i*)

Return the action of e_i on `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['B', 3])
sage: b = B.highest_weight_vector()
sage: c = b.f_string([2,1,3,2,1,3,2,2]); c
PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 2)
sage: c.e(2)
PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 1)
sage: c.e_string([2,2,1,3,2,1,3,2]) == b
True
```

```
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['B', Integer(3)])
>>> b = B.highest_weight_vector()
>>> c = b.f_string([Integer(2),Integer(1),Integer(3),Integer(2),Integer(1),
↪Integer(3),Integer(2),Integer(2)]); c
PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 2)
>>> c.e(Integer(2))
PBW monomial with Lusztig datum (0, 1, 0, 1, 0, 0, 0, 1, 1)
>>> c.e_string([Integer(2),Integer(2),Integer(1),Integer(3),Integer(2),
↪Integer(1),Integer(3),Integer(2)]) == b
True
```

epsilon(i)

Return ε_i of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(["A2"])
sage: s = B((3,0,0), (1,2,1))
sage: s.epsilon(1)
3
sage: s.epsilon(2)
0
```

```
>>> from sage.all import *
>>> B = crystals.infinity.PBW(["A2"])
>>> s = B((Integer(3),Integer(0),Integer(0)), (Integer(1),Integer(2),
↪Integer(1)))
>>> s.epsilon(Integer(1))
3
>>> s.epsilon(Integer(2))
0
```

f(i)

Return the action of f_i on `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW("D4")
sage: b = B.highest_weight_vector()
sage: c = b.f_string([1,2,3,1,2,3,4]); c
PBW monomial with Lusztig datum (0, 1, 0, 0, 0, 0, 0, 2, 0, 0, 2, 0)
sage: c == b.f_string([1,2,4,1,2,3,3])
True
```

```
>>> from sage.all import *
>>> B = crystals.infinity.PBW("D4")
>>> b = B.highest_weight_vector()
>>> c = b.f_string([Integer(1),Integer(2),Integer(3),Integer(1),Integer(2),
↪Integer(3),Integer(4)]); c
PBW monomial with Lusztig datum (0, 1, 0, 0, 0, 0, 0, 2, 0, 0, 2, 0)
>>> c == b.f_string([Integer(1),Integer(2),Integer(4),Integer(1),Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(3),Integer(3)])
True
```

lusztig_datum(*word=None*)

Return the Lusztig datum of `self` with respect to the reduced expression of the long word `word`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['A', 2])
sage: u = B.highest_weight_vector()
sage: b = u.f_string([2,1,2,2,2,2,1,1,2,1,2,1,2,1,2,2])
sage: b.lusztig_datum()
(6, 0, 10)
sage: b.lusztig_datum(word=[2,1,2])
(4, 6, 0)
```

```
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['A', Integer(2)])
>>> u = B.highest_weight_vector()
>>> b = u.f_string([Integer(2),Integer(1),Integer(2),Integer(2),Integer(2),
↪Integer(2),Integer(1),Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1),Integer(2),Integer(1),Integer(2),Integer(2)])
>>> b.lusztig_datum()
(6, 0, 10)
>>> b.lusztig_datum(word=[Integer(2),Integer(1),Integer(2)])
(4, 6, 0)
```

phi(*i*)

Return φ_i of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['A', 2])
sage: s = B((3,0,0), (1,2,1))
sage: s.phi(1)
-3
sage: s.phi(2)
3
```

```
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['A', Integer(2)])
>>> s = B((Integer(3),Integer(0),Integer(0)), (Integer(1),Integer(2),
↪Integer(1)))
>>> s.phi(Integer(1))
-3
>>> s.phi(Integer(2))
3
```

star()

Return the starred crystal element corresponding to `self`.

Let b be an element of `self` with Lusztig datum $(b_1, \ldots, b_N)$ with respect to $w_0 = s_{i_1} \cdots s_{i_N}$. Then b^* is the element with Lusztig datum $(b_N, \ldots, b_1)$ with respect to $w_0 = s_{i_N^*} \cdots s_{i_1^*}$, where $i_j^* = \omega(i_j)$ with ω being the *automorphism* given by the action of w_0 on the simple roots.

EXAMPLES:

```
sage: P = crystals.infinity.PBW(['A', 2])
sage: P((1,2,3), (1,2,1)).star() == P((3,2,1), (2,1,2))
True

sage: B = crystals.infinity.PBW(['E', 6])
sage: b = B.highest_weight_vector()
sage: c = b.f_string([1,2,6,3,4,2,5,2,3,4,1,6])
sage: c == c.star().star()
True
```

```
>>> from sage.all import *
>>> P = crystals.infinity.PBW(['A', Integer(2)])
>>> P((Integer(1),Integer(2),Integer(3)), (Integer(1),Integer(2),Integer(1))).
↪star() == P((Integer(3),Integer(2),Integer(1)), (Integer(2),Integer(1),
↪Integer(2)))
True

>>> B = crystals.infinity.PBW(['E', Integer(6)])
>>> b = B.highest_weight_vector()
>>> c = b.f_string([Integer(1),Integer(2),Integer(6),Integer(3),Integer(4),
↪Integer(2),Integer(5),Integer(2),Integer(3),Integer(4),Integer(1),
↪Integer(6)])
>>> c == c.star().star()
True
```

weight()

Return weight of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.PBW(['A', 2])
sage: s = B((2,2,2), (1,2,1))
sage: s.weight()
(-4, 0, 4)
```

```
>>> from sage.all import *
>>> B = crystals.infinity.PBW(['A', Integer(2)])
>>> s = B((Integer(2),Integer(2),Integer(2)), (Integer(1),Integer(2),
↪Integer(1)))
>>> s.weight()
(-4, 0, 4)
```

$\mathcal{B}(\infty)$ crystals of tableaux in nonexceptional types and G_2

A tableau model for $\mathcal{B}(\infty)$. For more information, see *InfinityCrystalOfTableaux*.

AUTHORS:

- Ben Salisbury: initial version
- Travis Scrimshaw: initial version

class sage.combinat.crystals.infinity_crystals.**DualInfinityQueerCrystalOfTableaux**(*cartan_type*)

Bases: *CrystalOfWords*

Initialize `self`.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['A',2])
sage: TestSuite(B).run() # long time
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['A',Integer(2)])
>>> TestSuite(B).run() # long time
```

class Element

Bases: *InfinityQueerCrystalOfTableauxElement*

index_set()

Return the index set of `self`.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(["Q",3])
sage: B.index_set()
(1, 2, -1)
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(["Q",Integer(3)])
>>> B.index_set()
(1, 2, -1)
```

module_generator()

Return the module generator (or highest weight element) of `self`.

The module generator is the unique semistandard hook tableau of shape $(n, n-1, \ldots, 2, 1)$ with weight 0.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(["Q",5])
sage: B.module_generator()
[[5, 5, 5, 5, 5], [4, 4, 4, 4], [3, 3, 3], [2, 2], [1]]
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(["Q",Integer(5)])
>>> B.module_generator()
[[5, 5, 5, 5, 5], [4, 4, 4, 4], [3, 3, 3], [2, 2], [1]]
```

class sage.combinat.crystals.infinity_crystals.**InfinityCrystalOfTableaux**(*cartan_type*)

Bases: *CrystalOfWords*

$\mathcal{B}(\infty)$ crystal of tableaux.

A tableaux model $\mathcal{T}(\infty)$ for the crystal $\mathcal{B}(\infty)$ is introduced by Hong and Lee in [HL2008]. This model is currently valid for types A_n, B_n, C_n, D_n, and G_2, and builds on the tableaux model given by Kashiwara and Nakashima [KN1994] in types A_n, B_n, C_n, and D_n, and by Kang and Misra [KM1994] in type G_2.

> **Note**
>
> We are using the English convention for our tableaux.

We say a tableau T is *marginally large* if:

- for each $1 \leq i \leq n$, the leftmost box in the i-th row from the top in T is an i-box,
- for each $1 \leq i \leq n$, the number of i-boxes in the i-th row from the top in T is greater than the total number of boxes in the $(i+1)$-th row by exactly one.

We now will describe this tableaux model type-by-type.

Type A_n

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly n rows over the alphabet $\{1 \prec 2 \prec \cdots \prec n+1\}$.

Type B_n

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly n rows over the alphabet $\{1 \prec \cdots \prec n \prec 0 \prec \overline{n} \prec \cdots \prec \overline{1}\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the i-th row are $\preceq \overline{i}$,
- the entry 0 can appear at most once in a single row.

Type C_n

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly n rows over the alphabet $\{1 \prec \cdots \prec n \prec \overline{n} \prec \cdots \prec \overline{1}\}$ and for each $1 \leq i \leq n$, the contents of the boxes in the i-th row are $\preceq \overline{i}$.

Type D_n

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly $n-1$ rows over the alphabet $\{1 \prec \cdots \prec n, \overline{n} \prec \cdots \prec \overline{1}\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the i-th row are $\preceq \overline{i}$,
- the entries n and $\overline{n}$ may not appear simultaneously in a single row.

Type G_2

$\mathcal{T}(\infty)$ is the set of marginally large semistandard tableaux with exactly 2 rows over the ordered alphabet $\{1 \prec 2 \prec 3 \prec 0 \prec \overline{3} \prec \overline{2} \prec \overline{1}\}$ and subject to the following constraints:

- the contents of the boxes in the first row are $\preceq \overline{i}$,
- the contents of the boxes in the second row are $\preceq 3$,
- the entry 0 can appear at most once in the first row and not at all in the second row.

In particular, the shape of the tableaux is not fixed in any instance of $\mathcal{T}(\infty)$; the row lengths of a tableau can be arbitrarily long.

INPUT:

- `cartan_type` – one of `['A',n]`, `['B',n]`, `['C',n]`, `['D',n]`, or `['G',2]`, where `n` is a positive integer

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['A',2])
sage: b = B.highest_weight_vector(); b.pp()
1  1
2
sage: b.f_string([2,1,1,2,2,2]).pp()
1  1  1  1  1  2  3
2  3  3  3

sage: B = crystals.infinity.Tableaux(['G',2])
sage: b = B(rows=[[1,1,1,1,1,2,3,3,0,-3,-1,-1,-1],[2,3,3,3]])
sage: b.e_string([2,1,1,1,1,1,1]).pp()
1  1  1  1  2  3  3  3  3 -2 -2 -2
2  3  3
sage: b.e_string([2,1,1,1,1,1,1,1])
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['A',Integer(2)])
>>> b = B.highest_weight_vector(); b.pp()
1  1
2
>>> b.f_string([Integer(2),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(2)]).pp()
1  1  1  1  1  2  3
2  3  3  3

>>> B = crystals.infinity.Tableaux(['G',Integer(2)])
>>> b = B(rows=[[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(2),Integer(3),Integer(3),Integer(0),-Integer(3),-Integer(1),-Integer(1),
↪-Integer(1)],[Integer(2),Integer(3),Integer(3),Integer(3)]])
>>> b.e_string([Integer(2),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1)]).pp()
1  1  1  1  2  3  3  3  3 -2 -2 -2
2  3  3
>>> b.e_string([Integer(2),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1),Integer(1)])
```

We check that a few classical crystals embed into $\mathcal{T}(\infty)$:

```
sage: def crystal_test(B, C):
....:     T = crystals.elementary.T(C.cartan_type(), C.module_generators[0].
↪weight())
....:     TP = crystals.TensorProduct(T, B)
....:     mg = TP(T[0], B.module_generators[0])
....:     g = {C.module_generators[0]: mg}
....:     f = C.crystal_morphism(g, category=HighestWeightCrystals())
....:     G = B.digraph(subset=[f(x) for x in C])
....:     return G.is_isomorphic(C.digraph(), edge_labels=True)
sage: B = crystals.infinity.Tableaux(['A',2])
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['A',2], shape=[6,2])
sage: crystal_test(B, C)
```

(continues on next page)

(continued from previous page)

```
True
sage: B = crystals.infinity.Tableaux(['B',2])
sage: C = crystals.Tableaux(['B',2], shape=[3])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['B',2], shape=[2,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['C',3])
sage: C = crystals.Tableaux(['C',3], shape=[2,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['D',4])
sage: C = crystals.Tableaux(['D',4], shape=[2])
sage: crystal_test(B, C)
True
sage: C = crystals.Tableaux(['D',4], shape=[1,1,1,1])
sage: crystal_test(B, C)
True
sage: B = crystals.infinity.Tableaux(['G',2])
sage: C = crystals.Tableaux(['G',2], shape=[3])
sage: crystal_test(B, C)
True
```

```
>>> from sage.all import *
>>> def crystal_test(B, C):
...     T = crystals.elementary.T(C.cartan_type(), C.module_
↪generators[Integer(0)].weight())
...     TP = crystals.TensorProduct(T, B)
...     mg = TP(T[Integer(0)], B.module_generators[Integer(0)])
...     g = {C.module_generators[Integer(0)]: mg}
...     f = C.crystal_morphism(g, category=HighestWeightCrystals())
...     G = B.digraph(subset=[f(x) for x in C])
...     return G.is_isomorphic(C.digraph(), edge_labels=True)
>>> B = crystals.infinity.Tableaux(['A',Integer(2)])

>>> C = crystals.Tableaux(['G',Integer(2)], shape=[Integer(3)])
>>> crystal_test(B, C)
True
```

class Element

Bases: *InfinityCrystalOfTableauxElement*

Elements in $\mathcal{B}(\infty)$ crystal of tableaux.

content()

Return the content of `self`.

The content $|T|$ of $T \in \mathcal{B}(\infty)$ is the number of blocks added to the highest weight to obtain T with any $\bar{\imath}$-boxes in the i-th row counted with multiplicity 2 provided the underlying Cartan type is of type B, D, or G.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("D5")
sage: b = B.highest_weight_vector().f_string([5,4,3,1,1,3,4,5,3,4,5,1,4,5,
↪2,3,5,3,2,4])
sage: b.content()
13

sage: B = crystals.infinity.Tableaux("B2")
sage: b = B(rows=[[1,1,1,1,1,1,2,2,2,-2,-2],[2,0,-2,-2,-2]])
sage: b.content()
12

sage: B = crystals.infinity.Tableaux("C2")
sage: b = B(rows=[[1,1,1,1,1,1,2,2,2,-2,-2],[2,-2,-2,-2]])
sage: b.content()
8
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("D5")
>>> b = B.highest_weight_vector().f_string([Integer(5),Integer(4),
↪Integer(3),Integer(1),Integer(1),Integer(3),Integer(4),Integer(5),
↪Integer(3),Integer(4),Integer(5),Integer(1),Integer(4),Integer(5),
↪Integer(2),Integer(3),Integer(5),Integer(3),Integer(2),Integer(4)])
>>> b.content()
13

>>> B = crystals.infinity.Tableaux("B2")
```

(continues on next page)

(continued from previous page)

```
>>> b = B(rows=[[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1),Integer(2),Integer(2),Integer(2),-Integer(2),-Integer(2)],
↪[Integer(2),Integer(0),-Integer(2),-Integer(2),-Integer(2)]])
>>> b.content()
12

>>> B = crystals.infinity.Tableaux("C2")
>>> b = B(rows=[[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1),Integer(2),Integer(2),Integer(2),-Integer(2),-Integer(2)],
↪[Integer(2),-Integer(2),-Integer(2),-Integer(2)]])
>>> b.content()
8
```

phi(i)

Return φ_i of `self`.

Let $T \in \mathcal{B}(\infty)$ Define $\varphi_i(T) := \varepsilon_i(T) + \langle h_i, \mathrm{wt}(T) \rangle$, where h_i is the i-th simple coroot and $\mathrm{wt}(T)$ is the *weight()* of T.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("A3")
sage: [B.highest_weight_vector().f_string([1,3,2,3,1,3,2,1]).phi(i) for i␣
↪in B.index_set()]
[-3, 4, -3]

sage: B = crystals.infinity.Tableaux("G2")
sage: [B.highest_weight_vector().f_string([2,2,1,2,1,1,1,2]).phi(i) for i␣
↪in B.index_set()]
[5, -3]
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("A3")
>>> [B.highest_weight_vector().f_string([Integer(1),Integer(3),Integer(2),
↪Integer(3),Integer(1),Integer(3),Integer(2),Integer(1)]).phi(i) for i␣
↪in B.index_set()]
[-3, 4, -3]

>>> B = crystals.infinity.Tableaux("G2")
>>> [B.highest_weight_vector().f_string([Integer(2),Integer(2),Integer(1),
↪Integer(2),Integer(1),Integer(1),Integer(1),Integer(2)]).phi(i) for i␣
↪in B.index_set()]
[5, -3]
```

reduced_form()

Return the reduced form of `self`.

The reduced form of a tableaux $T \in \mathcal{T}(\infty)$ is the (not necessarily semistandard) tableaux obtained from T by removing all i-boxes in the i-th row, subject to the condition that if the row is empty, a $*$ is put as a placeholder. This is described in [BN2010] and [LS2012].

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['A',3])
sage: b = B.highest_weight_vector().f_string([2,2,2,3,3,3,3,3])
sage: b.pp()
1  1  1  1  1  1  1  1
2  2  2  2  4  4  4
3  4  4
sage: b.reduced_form()
[['*'], [4, 4, 4], [4, 4]]
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['A',Integer(3)])
>>> b = B.highest_weight_vector().f_string([Integer(2),Integer(2),
↪Integer(2),Integer(3),Integer(3),Integer(3),Integer(3),Integer(3)])
>>> b.pp()
1  1  1  1  1  1  1  1
2  2  2  2  4  4  4
3  4  4
>>> b.reduced_form()
[['*'], [4, 4, 4], [4, 4]]
```

seg()

Return the statistic seg of `self`.

More precisely, following [LS2012], define a k-segment of a tableau T in $\mathcal{B}(\infty)$ to be a maximal string of k-boxes in a single row of T. Set $\mathrm{seg}'(T)$ to be the number of k-segments in T, as k varies over all possible values. Then $\mathrm{seg}(T)$ is determined type-by-type.

- In types A_n and C_n, define $\mathrm{seg}(T) := \mathrm{seg}'(T)$.
- In types B_n and G_2, set $e(T)$ to be the number of rows in T which contain both a 0-box and an $\bar{\imath}$-box. Define $\mathrm{seg}(T) := \mathrm{seg}'(T) - e(T)$.
- In type D_n, set $d(T)$ to be the number of rows in T which contain an $\bar{\imath}$-box, but no n-box nor $\overline{n}$-box. Define $\mathrm{seg}(T) := \mathrm{seg}'(T) + d(T)$.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux(['A',3])
sage: b = B.highest_weight_vector().f_string([1,3,2,2,3,1,1,3])
sage: b.pp()
1  1  1  1  1  2  2  4
2  2  2  3
3  4  4
sage: b.seg()
4

sage: B = crystals.infinity.Tableaux(['D',4])
sage: b = B(rows=[[1,1,1,1,1,1,3,-2,-1],[2,2,2,4,-2],[3,3],[4]])
sage: b.pp()
1  1  1  1  1  1  3 -2 -1
2  2  2  4 -2
3  3
4
sage: b.seg()
6

sage: B = crystals.infinity.Tableaux(['G',2])
```

(continues on next page)

(continued from previous page)

```
sage: b = B.highest_weight_vector().f_string([2,1,1,1,2,1,2,2,1,2,2,2,1,2,
↪2,1])
sage: b.pp()
1  1  1  1  1  1  1  1  2  3  0 -3
2  3  3  3  3  3  3
sage: b.seg()
5
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux(['A',Integer(3)])
>>> b = B.highest_weight_vector().f_string([Integer(1),Integer(3),
↪Integer(2),Integer(2),Integer(3),Integer(1),Integer(1),Integer(3)])
>>> b.pp()
1  1  1  1  1  1  2  2  4
2  2  2  2  3
3  4  4
>>> b.seg()
4

>>> B = crystals.infinity.Tableaux(['D',Integer(4)])
>>> b = B(rows=[[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1),Integer(3),-Integer(2),-Integer(1)],[Integer(2),Integer(2),
↪Integer(2),Integer(4),-Integer(2)],[Integer(3),Integer(3)],
↪[Integer(4)]])
>>> b.pp()
1  1  1  1  1  1  3 -2 -1
2  2  2  4 -2
3  3
4
>>> b.seg()
6

>>> B = crystals.infinity.Tableaux(['G',Integer(2)])
>>> b = B.highest_weight_vector().f_string([Integer(2),Integer(1),
↪Integer(1),Integer(1),Integer(2),Integer(1),Integer(2),Integer(2),
↪Integer(1),Integer(2),Integer(2),Integer(2),Integer(1),Integer(2),
↪Integer(2),Integer(1)])
>>> b.pp()
1  1  1  1  1  1  1  1  2  3  0 -3
2  3  3  3  3  3  3
>>> b.seg()
5
```

weight()

Return the weight of `self`.

From the definition of a crystal and that the highest weight element b_∞ of $\mathcal{B}(\infty)$ is 0, the weight of $T \in \mathcal{B}(\infty)$ can be defined as $\mathrm{wt}(T) := -\sum_j \alpha_{i_j}$ where $\widetilde{e}_{i_1} \cdots \widetilde{e}_{i_\ell} T = b_\infty$ and $\{\alpha_i\}$ is the set of simple roots. (Note that the weight is independent of the path chosen to get to the highest weight.)

However we can also take advantage of the fact that $\rho\colon R_\lambda \otimes \mathcal{B}(\infty) \longrightarrow B(\lambda)$, where λ is the shape of T, preserves the tableau representation of T. Therefore

$$\mathrm{wt}(T) = \mathrm{wt}\big(\rho(T)\big) - \lambda$$

where $\mathrm{wt}\big(\rho(T)\big)$ is just the usual weight of the tableau T.

Let Λ_i be the i-th fundamental weight. In type D, the height $n-1$ columns corresponds to $\Lambda_{n-1}+\Lambda_n$ and the in type B, the height n columns corresponds to $2\Lambda_n$.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("C7")
sage: b = B.highest_weight_vector().f_string([1,6,4,7,4,2,4,6,2,4,6,7,1,2,
↪4,7])
sage: b.weight()
(-2, -1, 3, -5, 5, -3, -3)
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("C7")
>>> b = B.highest_weight_vector().f_string([Integer(1),Integer(6),
↪Integer(4),Integer(7),Integer(4),Integer(2),Integer(4),Integer(6),
↪Integer(2),Integer(4),Integer(6),Integer(7),Integer(1),Integer(2),
↪Integer(4),Integer(7)])
>>> b.weight()
(-2, -1, 3, -5, 5, -3, -3)
```

Check that the definitions agree:

```
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
sage: b.weight() == -2*alpha[1] - 3*alpha[2] - 5*alpha[4] - 3*alpha[6] -␣
↪3*alpha[7]
True
```

```
>>> from sage.all import *
>>> P = B.weight_lattice_realization()
>>> alpha = P.simple_roots()
>>> b.weight() == -Integer(2)*alpha[Integer(1)] -␣
↪Integer(3)*alpha[Integer(2)] - Integer(5)*alpha[Integer(4)] -␣
↪Integer(3)*alpha[Integer(6)] - Integer(3)*alpha[Integer(7)]
True
```

Check that it works for type B:

```
sage: B = crystals.infinity.Tableaux("B2")
sage: B.highest_weight_vector().weight()
(0, 0)
sage: b = B.highest_weight_vector().f_string([1,2,2,2,1,2])
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
sage: b.weight() == -2*alpha[1] - 4*alpha[2]
True
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("B2")
>>> B.highest_weight_vector().weight()
(0, 0)
>>> b = B.highest_weight_vector().f_string([Integer(1),Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2),Integer(2),Integer(1),Integer(2)])
>>> P = B.weight_lattice_realization()
>>> alpha = P.simple_roots()
>>> b.weight() == -Integer(2)*alpha[Integer(1)] -␣
↪Integer(4)*alpha[Integer(2)]
True
```

Check that it works for type D:

```
sage: B = crystals.infinity.Tableaux("D4")
sage: B.highest_weight_vector().weight()
(0, 0, 0, 0)
sage: b = B.highest_weight_vector().f_string([1,4,4,2,4,3,2,4,1,3,2,4])
sage: P = B.weight_lattice_realization()
sage: alpha = P.simple_roots()
sage: b.weight() == -2*alpha[1] - 3*alpha[2] - 2*alpha[3] - 5*alpha[4]
True
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("D4")
>>> B.highest_weight_vector().weight()
(0, 0, 0, 0)
>>> b = B.highest_weight_vector().f_string([Integer(1),Integer(4),
↪Integer(4),Integer(2),Integer(4),Integer(3),Integer(2),Integer(4),
↪Integer(1),Integer(3),Integer(2),Integer(4)])
>>> P = B.weight_lattice_realization()
>>> alpha = P.simple_roots()
>>> b.weight() == -Integer(2)*alpha[Integer(1)] -␣
↪Integer(3)*alpha[Integer(2)] - Integer(2)*alpha[Integer(3)] -␣
↪Integer(5)*alpha[Integer(4)]
True
```

module_generator()

Return the module generator (or highest weight element) of `self`.

The module generator is the unique tableau of shape $(n, n-1, \ldots, 2, 1)$ with weight 0.

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux(['A',3])
sage: T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

```
>>> from sage.all import *
>>> T = crystals.infinity.Tableaux(['A',Integer(3)])
>>> T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

class sage.combinat.crystals.infinity_crystals.**InfinityCrystalOfTableauxTypeD**(*cartan_type*)

Bases: *InfinityCrystalOfTableaux*

$\mathcal{B}(\infty)$ crystal of tableaux for type D_n.

This is the set $\mathcal{T}(\infty)$ of marginally large semistandard tableaux with exactly $n-1$ rows over the alphabet $\{1 \prec \cdots \prec n, \overline{n} \prec \cdots \prec \overline{1}\}$ and subject to the following constraints:

- for each $1 \leq i \leq n$, the contents of the boxes in the i-th row are $\preceq \overline{i}$,
- the entries n and $\overline{n}$ may not appear simultaneously in a single row.

For more information, see *InfinityCrystalOfTableaux*.

EXAMPLES:

```
sage: B = crystals.infinity.Tableaux("D4")
sage: b = B.highest_weight_vector().f_string([4,3,2,1,4])
sage: b.pp()
1  1  1  1  1  1  2
2  2  2  2  3
3 -4 -3
sage: b.weight()
(-1, 0, -2, -1)
```

```
>>> from sage.all import *
>>> B = crystals.infinity.Tableaux("D4")
>>> b = B.highest_weight_vector().f_string([Integer(4),Integer(3),Integer(2),
↪Integer(1),Integer(4)])
>>> b.pp()
1  1  1  1  1  1  2
2  2  2  2  3
3 -4 -3
>>> b.weight()
(-1, 0, -2, -1)
```

class Element

Bases: *InfinityCrystalOfTableauxElementTypeD*, *Element*

Elements in $\mathcal{B}(\infty)$ crystal of tableaux for type D_n.

module_generator()

Return the module generator (or highest weight element) of `self`.

The module generator is the unique tableau of shape $(n-1, \ldots, 2, 1)$ with weight 0.

EXAMPLES:

```
sage: T = crystals.infinity.Tableaux(['D',4])
sage: T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

```
>>> from sage.all import *
>>> T = crystals.infinity.Tableaux(['D',Integer(4)])
>>> T.module_generator()
[[1, 1, 1], [2, 2], [3]]
```

4.1.5 sage.combinat.designs

Balanced incomplete block designs (BIBD)

This module gathers everything related to Balanced Incomplete Block Designs. One can build a BIBD (or check that it can be built) with *balanced_incomplete_block_design()*:

```
sage: BIBD = designs.balanced_incomplete_block_design(7,3,1)                    #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> BIBD = designs.balanced_incomplete_block_design(Integer(7),Integer(3),Integer(1))␣
↪                        # needs sage.schemes
```

In particular, Sage can build a $(v, k, 1)$-BIBD when one exists for all $k \leq 5$. The following functions are available:

balanced_incomplete_block_design()	Return a BIBD of parameters v, k, λ.
BIBD_from_TD()	Return a BIBD through TD-based constructions.
BIBD_from_difference_family()	Return the BIBD associated to the difference family D on the group G.
BIBD_from_PBD()	Return a $(v, k, 1)$-BIBD from a (r, K)-PBD where $r = (v-1)/(k-1)$.
PBD_from_TD()	Return a $(kt, \{k, t\})$-PBD if $u = 0$ and a $(kt+u, \{k, k+1, t, u\})$-PBD otherwise.
steiner_triple_system()	Return a Steiner Triple System.
v_5_1_BIBD()	Return a $(v, 5, 1)$-BIBD.
v_4_1_BIBD()	Return a $(v, 4, 1)$-BIBD.
PBD_4_5_8_9_12()	Return a $(v, \{4, 5, 8, 9, 12\})$-PBD on v elements.
BIBD_5q_5_for_q_prime_pow	Return a $(5q, 5, 1)$-BIBD with $q \equiv 1 \pmod 4$ a prime power.

Construction of BIBD when $k = 4$

Decompositions of K_v into K_4 (i.e. $(v, 4, 1)$-BIBD) are built following Douglas Stinson's construction as presented in [Stinson2004] page 167. It is based upon the construction of $(v\{4, 5, 8, 9, 12\})$-PBD (see the doc of *PBD_4_5_8_9_12()*), knowing that a $(v\{4, 5, 8, 9, 12\})$-PBD on v points can always be transformed into a $((k-1)v+1, 4, 1)$-BIBD, which covers all possible cases of $(v, 4, 1)$-BIBD.

Construction of BIBD when $k = 5$

Decompositions of K_v into $K_5 (i.e.`(v, 5, 1)$-BIBD) are built following Clayton Smith's construction [ClaytonSmith].

Functions

sage.combinat.designs.bibd.**BIBD**

alias of *BalancedIncompleteBlockDesign*

sage.combinat.designs.bibd.**BIBD_5q_5_for_q_prime_power**(*q*)

Return a $(5q, 5, 1)$-BIBD with $q \equiv 1 \pmod 4$ a prime power.

See Theorem 24 [ClaytonSmith].

INPUT:

- q – integer; a prime power such that $q \equiv 1 \pmod 4$

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import BIBD_5q_5_for_q_prime_power
sage: for q in [25, 45, 65, 85, 125, 145, 185, 205, 305, 405, 605]: # long time
....:     _ = BIBD_5q_5_for_q_prime_power(q/5)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import BIBD_5q_5_for_q_prime_power
>>> for q in [Integer(25), Integer(45), Integer(65), Integer(85), Integer(125),␣
↪Integer(145), Integer(185), Integer(205), Integer(305), Integer(405),␣
↪Integer(605)]: # long time
...     _ = BIBD_5q_5_for_q_prime_power(q/Integer(5))
```

sage.combinat.designs.bibd.**BIBD_from_PBD**(*PBD*, *v*, *k*, *check=True*, *base_cases=None*)

Return a $(v, k, 1)$-BIBD from a (r, K)-PBD where $r = (v-1)/(k-1)$.

This is Theorem 7.20 from [Stinson2004].

INPUT:

- `v`, `k` – integers
- `PBD` – a PBD on $r = (v-1)/(k-1)$ points, such that for any block of `PBD` of size s there must exist a $((k-1)s+1, k, 1)$-BIBD
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `base_cases` – caching system, for internal use

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import PBD_4_5_8_9_12
sage: from sage.combinat.designs.bibd import BIBD_from_PBD
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: PBD = PBD_4_5_8_9_12(17)                                                  #␣
↪needs sage.schemes
sage: bibd = is_pairwise_balanced_design(BIBD_from_PBD(PBD,52,4),52,[4])        #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import PBD_4_5_8_9_12
>>> from sage.combinat.designs.bibd import BIBD_from_PBD
>>> from sage.combinat.designs.bibd import is_pairwise_balanced_design
>>> PBD = PBD_4_5_8_9_12(Integer(17))                                           ␣
↪     # needs sage.schemes
>>> bibd = is_pairwise_balanced_design(BIBD_from_PBD(PBD,Integer(52),Integer(4)),
↪Integer(52),[Integer(4)])        # needs sage.schemes
```

sage.combinat.designs.bibd.**BIBD_from_TD**(*v*, *k*, *existence=False*)

Return a BIBD through TD-based constructions.

INPUT:

- `v`, `k` – integers; computes a $(v, k, 1)$-BIBD
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design

- `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
- `False` – meaning that the design does not exist

This method implements three constructions:

- If there exists a $TD(k,v)$ and a $(v,k,1)$-BIBD then there exists a $(kv,k,1)$-BIBD.

  The BIBD is obtained from all blocks of the TD, and from the blocks of the $(v,k,1)$-BIBDs defined over the k groups of the TD.

- If there exists a $TD(k,v)$ and a $(v+1,k,1)$-BIBD then there exists a $(kv+1,k,1)$-BIBD.

  The BIBD is obtained from all blocks of the TD, and from the blocks of the $(v+1,k,1)$-BIBDs defined over the sets $V_1\cup\infty,\dots,V_k\cup\infty$ where the $V_1,\dots,V_k$ are the groups of the TD.

- If there exists a $TD(k,v)$ and a $(v+k,k,1)$-BIBD then there exists a $(kv+k,k,1)$-BIBD.

  The BIBD is obtained from all blocks of the TD, and from the blocks of the $(v+k,k,1)$-BIBDs defined over the sets $V_1\cup\{\infty_1,\dots,\infty_k\},\dots,V_k\cup\{\infty_1,\dots,\infty_k\}$ where the $V_1,\dots,V_k$ are the groups of the TD. By making sure that all copies of the $(v+k,k,1)$-BIBD contain the block $\{\infty_1,\dots,\infty_k\}$, the result is also a BIBD.

These constructions can be found in http://www.argilo.net/files/bibd.pdf.

EXAMPLES:

First construction:

```
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(25,5,existence=True)                                 #␣
↪needs sage.schemes
True
sage: _ = BlockDesign(25,BIBD_from_TD(25,5))                            #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import BIBD_from_TD
>>> BIBD_from_TD(Integer(25),Integer(5),existence=True)                  ␣
↪              # needs sage.schemes
True
>>> _ = BlockDesign(Integer(25),BIBD_from_TD(Integer(25),Integer(5)))    ␣
↪                       # needs sage.schemes
```

Second construction:

```
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(21,5,existence=True)                                 #␣
↪needs sage.schemes
True
sage: _ = BlockDesign(21,BIBD_from_TD(21,5))                            #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import BIBD_from_TD
>>> BIBD_from_TD(Integer(21),Integer(5),existence=True)                  ␣
↪              # needs sage.schemes
```

(continues on next page)

(continued from previous page)

```
True
>>> _ = BlockDesign(Integer(21),BIBD_from_TD(Integer(21),Integer(5)))          ␣
↪                        # needs sage.schemes
```

Third construction:

```
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(85,5,existence=True)                                        #␣
↪needs sage.schemes
True
sage: _ = BlockDesign(85,BIBD_from_TD(85,5))                                   #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import BIBD_from_TD
>>> BIBD_from_TD(Integer(85),Integer(5),existence=True)                        ␣
↪               # needs sage.schemes
True
>>> _ = BlockDesign(Integer(85),BIBD_from_TD(Integer(85),Integer(5)))          ␣
↪                        # needs sage.schemes
```

No idea:

```
sage: from sage.combinat.designs.bibd import BIBD_from_TD
sage: BIBD_from_TD(20,5,existence=True)
Unknown
sage: BIBD_from_TD(20,5)
Traceback (most recent call last):
...
NotImplementedError: I do not know how to build a (20,5,1)-BIBD!
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import BIBD_from_TD
>>> BIBD_from_TD(Integer(20),Integer(5),existence=True)
Unknown
>>> BIBD_from_TD(Integer(20),Integer(5))
Traceback (most recent call last):
...
NotImplementedError: I do not know how to build a (20,5,1)-BIBD!
```

sage.combinat.designs.bibd.**BIBD_from_arc_in_desarguesian_projective_plane**(*n*, *k*, *existence=False*)

Return a $(n, k, 1)$-BIBD from a maximal arc in a projective plane.

This function implements a construction from Denniston [Denniston69], who describes a maximal *arc* in a *Desarguesian Projective Plane* of order 2^k. From two powers of two n, q with $n < q$, it produces a $((n-1)(q+1)+1, n, 1)$-BIBD.

INPUT:

- `n`, `k` – integers; must be powers of two (among other restrictions)
- `existence` – boolean; whether to return the BIBD obtained through this construction (default), or to merely indicate with a boolean return value whether this method *can* build the requested BIBD.

EXAMPLES:

A $(232, 8, 1)$-BIBD:

```
sage: from sage.combinat.designs.bibd import BIBD_from_arc_in_desarguesian_
↪projective_plane
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: D = BIBD_from_arc_in_desarguesian_projective_plane(232,8)                #␣
↪needs sage.libs.gap sage.modules sage.rings.finite_rings
sage: BalancedIncompleteBlockDesign(232,D)                                     #␣
↪needs sage.libs.gap sage.modules sage.rings.finite_rings
(232,8,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import BIBD_from_arc_in_desarguesian_
↪projective_plane
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> D = BIBD_from_arc_in_desarguesian_projective_plane(Integer(232),Integer(8))  ␣
↪              # needs sage.libs.gap sage.modules sage.rings.finite_rings
>>> BalancedIncompleteBlockDesign(Integer(232),D)                              ␣
↪     # needs sage.libs.gap sage.modules sage.rings.finite_rings
(232,8,1)-Balanced Incomplete Block Design
```

A $(120, 8, 1)$-BIBD:

```
sage: D = BIBD_from_arc_in_desarguesian_projective_plane(120,8)                #␣
↪needs sage.libs.gap sage.modules sage.rings.finite_rings
sage: BalancedIncompleteBlockDesign(120,D)                                     #␣
↪needs sage.libs.gap sage.modules sage.rings.finite_rings
(120,8,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> D = BIBD_from_arc_in_desarguesian_projective_plane(Integer(120),Integer(8))  ␣
↪              # needs sage.libs.gap sage.modules sage.rings.finite_rings
>>> BalancedIncompleteBlockDesign(Integer(120),D)                              ␣
↪     # needs sage.libs.gap sage.modules sage.rings.finite_rings
(120,8,1)-Balanced Incomplete Block Design
```

Other parameters:

```
sage: all(BIBD_from_arc_in_desarguesian_projective_plane(n,k,existence=True)
....:     for n,k in
....:       [(120, 8), (232, 8), (456, 8), (904, 8), (496, 16),
....:        (976, 16), (1936, 16), (2016, 32), (4000, 32), (8128, 64)])
True
```

```
>>> from sage.all import *
>>> all(BIBD_from_arc_in_desarguesian_projective_plane(n,k,existence=True)
...     for n,k in
...       [(Integer(120), Integer(8)), (Integer(232), Integer(8)), (Integer(456),␣
↪Integer(8)), (Integer(904), Integer(8)), (Integer(496), Integer(16)),
...        (Integer(976), Integer(16)), (Integer(1936), Integer(16)),␣
↪(Integer(2016), Integer(32)), (Integer(4000), Integer(32)), (Integer(8128),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(64))])
True
```

Of course, not all can be built this way:

```
sage: BIBD_from_arc_in_desarguesian_projective_plane(7,3,existence=True)
False
sage: BIBD_from_arc_in_desarguesian_projective_plane(7,3)
Traceback (most recent call last):
...
ValueError: This function cannot produce a (7,3,1)-BIBD
```

```
>>> from sage.all import *
>>> BIBD_from_arc_in_desarguesian_projective_plane(Integer(7),Integer(3),
↪existence=True)
False
>>> BIBD_from_arc_in_desarguesian_projective_plane(Integer(7),Integer(3))
Traceback (most recent call last):
...
ValueError: This function cannot produce a (7,3,1)-BIBD
```

sage.combinat.designs.bibd.**BIBD_from_difference_family**(*G*, *D*, *lambd=None*, *check=True*)

Return the BIBD associated to the difference family `D` on the group `G`.

Let G be a group. A (G, k, λ)-*difference family* is a family $B = \{B_1, B_2, \ldots, B_b\}$ of k-subsets of G such that for each element of $G\backslash\{0\}$ there exists exactly λ pairs of elements (x, y), x and y belonging to the same block, such that $x - y = g$ (or x y^{-1} = g` in multiplicative notation).

If $\{B_1, B_2, \ldots, B_b\}$ is a (G, k, λ)-difference family then its set of translates $\{B_i \cdot g; i \in \{1, \ldots, b\}, g \in G\}$ is a (v, k, λ)-BIBD where v is the cardinality of G.

INPUT:

- `G` – a finite additive Abelian group
- `D` – a difference family on `G` (short blocks are allowed)
- `lambd` – the λ parameter (optional, only used if `check` is `True`)
- `check` – boolean (default: `True`); whether or not we check the output

EXAMPLES:

```
sage: G = Zmod(21)
sage: D = [[0,1,4,14,16]]
sage: sorted(G(x-y) for x in D[0] for y in D[0] if x != y)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20]

sage: from sage.combinat.designs.bibd import BIBD_from_difference_family
sage: BIBD_from_difference_family(G, D)
[[0, 1, 4, 14, 16],
 [1, 2, 5, 15, 17],
 [2, 3, 6, 16, 18],
 [3, 4, 7, 17, 19],
 [4, 5, 8, 18, 20],
 [5, 6, 9, 19, 0],
```

(continues on next page)

(continued from previous page)

```

 [18, 19, 1, 11, 13],
 [19, 20, 2, 12, 14],
 [20, 0, 3, 13, 15]]
```

class sage.combinat.designs.bibd.**BalancedIncompleteBlockDesign**(*points*, *blocks*, *k=None*, *lambd=1*, *check=True*, *copy=True*, ***kwds*)

Bases: *PairwiseBalancedDesign*

Balanced Incomplete Block Design (BIBD).

INPUT:

- `points` – the underlying set. If `points` is an integer v, then the set is considered to be $\{0, ..., v-1\}$
- `blocks` – collection of blocks
- `k` – integer; size of the blocks. Set to `None` (automatic guess) by default
- `lambd` – integer; value of λ, set to 1 by default
- `check` – boolean; whether to check that the design is a PBD with the right parameters
- `copy` – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the instance's internal data.

EXAMPLES:

```
sage: b=designs.balanced_incomplete_block_design(9,3); b
(9,3,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> b=designs.balanced_incomplete_block_design(Integer(9),Integer(3)); b
(9,3,1)-Balanced Incomplete Block Design
```

arc(*s*, *solver=2*, *verbose=None*, *integrality_tolerance=0*)

Return the `s`-arc with maximum cardinality.

A s-arc is a subset of points in a BIBD that intersects each block on at most s points. It is one possible generalization of independent set for graphs.

A simple counting shows that the cardinality of a s-arc is at most $(s-1)*r+1$ where r is the number of blocks incident to any point. A s-arc in a BIBD with cardinality $(s-1)*r+1$ is called maximal and is characterized by the following property: it is not empty and each block either contains 0 or s points of this arc. Equivalently, the trace of the BIBD on these points is again a BIBD (with block size s).

For more informations, see Wikipedia article Arc_(projective_geometry).

INPUT:

- `s` – (default: 2) the maximum number of points from the arc in each block
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – integer (default: 0); sets the level of verbosity. Set to 0 by default, which means quiet.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

EXAMPLES:

```
sage: # needs sage.schemes
sage: B = designs.balanced_incomplete_block_design(21, 5)
sage: a2 = B.arc(); a2  # random
[5, 9, 10, 12, 15, 20]
sage: len(a2)
6
sage: a4 = B.arc(4); a4  # random
[0, 1, 2, 5, 6, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 20]
```

(continues on next page)

(continued from previous page)

```
sage: len(a4)
16
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> B = designs.balanced_incomplete_block_design(Integer(21), Integer(5))
>>> a2 = B.arc(); a2  # random
[5, 9, 10, 12, 15, 20]
>>> len(a2)
6
>>> a4 = B.arc(Integer(4)); a4  # random
[0, 1, 2, 5, 6, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 20]
>>> len(a4)
16
```

The 2-arc and 4-arc above are maximal. One can check that they intersect the blocks in either 0 or s points. Or equivalently that the traces are again BIBD:

```
sage: r = (21-1)//(5-1)
sage: 1 + r*1
6
sage: 1 + r*3
16

sage: B.trace(a2).is_t_design(2, return_parameters=True)                    #␣
↪needs sage.schemes
(True, (2, 6, 2, 1))
sage: B.trace(a4).is_t_design(2, return_parameters=True)                    #␣
↪needs sage.schemes
(True, (2, 16, 4, 1))
```

```
>>> from sage.all import *
>>> r = (Integer(21)-Integer(1))//(Integer(5)-Integer(1))
>>> Integer(1) + r*Integer(1)
6
>>> Integer(1) + r*Integer(3)
16

>>> B.trace(a2).is_t_design(Integer(2), return_parameters=True)              ␣
↪     # needs sage.schemes
(True, (2, 6, 2, 1))
>>> B.trace(a4).is_t_design(Integer(2), return_parameters=True)              ␣
↪     # needs sage.schemes
(True, (2, 16, 4, 1))
```

Some other examples which are not maximal:

```
sage: # needs sage.numerical.mip
sage: B = designs.balanced_incomplete_block_design(25, 4)
sage: a2 = B.arc(2)
sage: r = (25-1)//(4-1)
sage: len(a2), 1 + r
```

(continues on next page)

(continued from previous page)

```
(8, 9)
sage: sa2 = set(a2)
sage: set(len(sa2.intersection(b)) for b in B.blocks())
{0, 1, 2}
sage: B.trace(a2).is_t_design(2)
False

sage: # needs sage.numerical.mip
sage: a3 = B.arc(3)
sage: len(a3), 1 + 2*r
(15, 17)
sage: sa3 = set(a3)
sage: set(len(sa3.intersection(b)) for b in B.blocks()) == set([0,3])
False
sage: B.trace(a3).is_t_design(3)
False
```

```
>>> from sage.all import *
>>> # needs sage.numerical.mip
>>> B = designs.balanced_incomplete_block_design(Integer(25), Integer(4))
>>> a2 = B.arc(Integer(2))
>>> r = (Integer(25)-Integer(1))//(Integer(4)-Integer(1))
>>> len(a2), Integer(1) + r
(8, 9)
>>> sa2 = set(a2)
>>> set(len(sa2.intersection(b)) for b in B.blocks())
{0, 1, 2}
>>> B.trace(a2).is_t_design(Integer(2))
False

>>> # needs sage.numerical.mip
>>> a3 = B.arc(Integer(3))
>>> len(a3), Integer(1) + Integer(2)*r
(15, 17)
>>> sa3 = set(a3)
>>> set(len(sa3.intersection(b)) for b in B.blocks()) == set([Integer(0),
↪Integer(3)])
False
>>> B.trace(a3).is_t_design(Integer(3))
False
```

sage.combinat.designs.bibd.**BruckRyserChowla_check**(*v*, *k*, *lambd*)

Check whether the parameters passed satisfy the Bruck-Ryser-Chowla theorem.

For more information on the theorem, see the corresponding Wikipedia entry.

INPUT:

- `v`, `k`, `lambd` – integers; parameters to check

OUTPUT: `True` – the parameters satisfy the theorem

- `False` – the theorem fails for the given parameters
- `Unknown` – the preconditions of the theorem are not met

EXAMPLES:

sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(22,7,2) False

Nonexistence of projective planes of order 6 and 14

sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(43,7,1) # needs sage.schemes False sage: BruckRyserChowla_check(211,15,1) # needs sage.schemes False

Existence of symmetric BIBDs with parameters $(79, 13, 2)$ and $(56, 11, 2)$

sage: from sage.combinat.designs.bibd import BruckRyserChowla_check sage: BruckRyserChowla_check(79,13,2) # needs sage.schemes True sage: BruckRyserChowla_check(56,11,2) True

sage.combinat.designs.bibd.**PBD_4_5_8_9_12**(*v*, *check=True*)

Return a $(v, \{4, 5, 8, 9, 12\})$-PBD on v elements.

A $(v, \{4, 5, 8, 9, 12\})$-PBD exists if and only if $v \equiv 0, 1 \pmod 4$. The construction implemented here appears page 168 in [Stinson2004].

INPUT:

- `v` – integer congruent to 0 or 1 modulo 4
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

EXAMPLES:

```
sage: designs.balanced_incomplete_block_design(40,4).blocks()  # indirect doctest␣
↪          # needs sage.schemes
[[0, 1, 2, 12], [0, 3, 6, 9], [0, 4, 8, 10],
 [0, 5, 7, 11], [0, 13, 26, 39], [0, 14, 25, 28],
 [0, 15, 27, 38], [0, 16, 22, 32], [0, 17, 23, 34],
...
```

```
>>> from sage.all import *
>>> designs.balanced_incomplete_block_design(Integer(40),Integer(4)).blocks()  #␣
↪indirect doctest           # needs sage.schemes
[[0, 1, 2, 12], [0, 3, 6, 9], [0, 4, 8, 10],
 [0, 5, 7, 11], [0, 13, 26, 39], [0, 14, 25, 28],
 [0, 15, 27, 38], [0, 16, 22, 32], [0, 17, 23, 34],
...
```

Check that Issue #16476 is fixed:

```
sage: from sage.combinat.designs.bibd import PBD_4_5_8_9_12
sage: for v in (0,1,4,5,8,9,12,13,16,17,20,21,24,25):                          #␣
↪needs sage.schemes
....:     _ = PBD_4_5_8_9_12(v)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import PBD_4_5_8_9_12
>>> for v in (Integer(0),Integer(1),Integer(4),Integer(5),Integer(8),Integer(9),
↪Integer(12),Integer(13),Integer(16),Integer(17),Integer(20),Integer(21),
↪Integer(24),Integer(25)):                          # needs sage.schemes
...     _ = PBD_4_5_8_9_12(v)
```

sage.combinat.designs.bibd.**PBD_from_TD**(k, t, u)

Return a $(kt, \{k, t\})$-PBD if $u = 0$ and a $(kt + u, \{k, k + 1, t, u\})$-PBD otherwise.

This is theorem 23 from [ClaytonSmith]. The PBD is obtained from the blocks a truncated $TD(k+1, t)$, to which are added the blocks corresponding to the groups of the TD. When $u = 0$, a $TD(k, t)$ is used instead.

INPUT:

- k, t, u – integers such that $0 \leq u \leq t$

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import PBD_from_TD
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: PBD = PBD_from_TD(2,2,1); PBD
[[0, 2, 4], [0, 3], [1, 2], [1, 3, 4], [0, 1], [2, 3]]
sage: is_pairwise_balanced_design(PBD,2*2+1,[2,3])
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import PBD_from_TD
>>> from sage.combinat.designs.bibd import is_pairwise_balanced_design

[[0, 2, 4], [0, 3], [1, 2], [1, 3, 4], [0, 1], [2, 3]]
>>> is_pairwise_balanced_design(PBD,Integer(2)*Integer(2)+Integer(1),[Integer(2),
↪Integer(3)])
True
```

class sage.combinat.designs.bibd.**PairwiseBalancedDesign**(*points*, *blocks*, *K=None*, *lambd=1*, *check=True*, *copy=True*, ***kwds*)

Bases: *GroupDivisibleDesign*

Pairwise Balanced Design (PBD).

A Pairwise Balanced Design, or (v, K, λ)-PBD, is a collection $\mathcal{B}$ of blocks defined on a set X of size v, such that any block pair of points $p_1, p_2 \in X$ occurs in exactly λ blocks of $\mathcal{B}$. Besides, for every block $B \in \mathcal{B}$ we must have $|B| \in K$.

INPUT:

- points – the underlying set; if points is an integer v, then the set is considered to be $\{0, ..., v - 1\}$
- blocks – collection of blocks
- K – list of integers of which the sizes of the blocks must be elements; set to None (automatic guess) by default
- lambd – integer; value of λ, set to 1 by default
- check – boolean; whether to check that the design is a PBD with the right parameters
- copy – (use with caution) if set to False then blocks must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your blocks object will become the instance's internal data.

sage.combinat.designs.bibd.**balanced_incomplete_block_design**(*v*, *k*, *lambd=1*, *existence=False*, *use_LJCR=False*)

Return a BIBD of parameters v, k, λ.

A Balanced Incomplete Block Design of parameters v, k, λ is a collection $\mathcal{C}$ of k-subsets of $V = \{0, \ldots, v - 1\}$ such that for any two distinct elements $x, y \in V$ there are λ elements $S \in \mathcal{C}$ such that $x, y \in S$.

For more information on BIBD, see the corresponding Wikipedia entry.

INPUT:

- `v`, `k`, `lambd` – integers
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist
- `use_LJCR` – boolean; whether to query the La Jolla Covering Repository for the design when Sage does not know how to build it (see *best_known_covering_design_www()*). This requires internet.

```

sage.combinat.designs.bibd.**biplane**(*n*, *existence=False*)

Return a biplane of order n.

A biplane of order n is a symmetric $(1+\frac{(n+1)(n+2)}{2}, n+2, 2)$-BIBD. A symmetric (or square) (v,k,λ)-BIBD is a (v,k,λ)-BIBD with v blocks.

INPUT:

- `n` – integer; order of the biplane
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

See also

- *balanced_incomplete_block_design()*

EXAMPLES:

```
sage: designs.biplane(4)                                                 #␣
↪needs sage.rings.finite_rings
(16,6,2)-Balanced Incomplete Block Design

↪     # needs sage.schemes
True
```

(continues on next page)

(continued from previous page)

```
>>> designs.biplane(Integer(11))                                              ␣
↪     # needs sage.schemes
(79,13,2)-Balanced Incomplete Block Design
```

sage.combinat.designs.bibd.**steiner_triple_system**(*n*, *algorithm=None*, *seed=None*, *check=True*)

Return a Steiner Triple System.

A Steiner Triple System (STS) of a set $\{0, ..., n-1\}$ is a family S of 3-sets such that for any $i \neq j$ there exists exactly one set of S in which they are both contained.

It can alternatively be thought of as a factorization of the complete graph K_n with triangles.

A Steiner Triple System of an n-set exists if and only if $n \equiv 1 \pmod 6$ or $n \equiv 3 \pmod 6$, in which case one can be found through Bose's and Skolem's constructions, respectively [AndHonk97]. A randomized construction using Stinson's algorithm [KreherStinson98] is also available.

INPUT:

- `n` – return a Steiner Triple System of $\{0, ..., n-1\}$
- `algorithm` – string (default: `None`); can be one of the following:
  - `None` or `"bose-skolem"` – use Bose and Skolem's deterministic construction
  - `"stinson"` – use Stinson's randomized algorithm
- `seed` – (default: `None`) a seed for the random number generator; only used when `algorithm="stinson"`
- `check` – boolean (default: `True`); whether to check that the output of Stinson's randomized algorithm has the correct BIBD parameters

EXAMPLES:

A Steiner Triple System on 9 elements

```
sage: sts = designs.steiner_triple_system(9)
sage: sts
(9,3,1)-Balanced Incomplete Block Design
sage: list(sts)
[[0, 1, 5], [0, 2, 4], [0, 3, 6], [0, 7, 8], [1, 2, 3],
 [1, 4, 7], [1, 6, 8], [2, 5, 8], [2, 6, 7], [3, 4, 8],
 [3, 5, 7], [4, 5, 6]]
```

```
>>> from sage.all import *
>>> sts = designs.steiner_triple_system(Integer(9))
>>> sts
(9,3,1)-Balanced Incomplete Block Design
>>> list(sts)
[[0, 1, 5], [0, 2, 4], [0, 3, 6], [0, 7, 8], [1, 2, 3],
 [1, 4, 7], [1, 6, 8], [2, 5, 8], [2, 6, 7], [3, 4, 8],
 [3, 5, 7], [4, 5, 6]]
```

As any pair of vertices is covered once, its parameters are

```
sage: sts.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
```

```
>>> from sage.all import *
>>> sts.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
```

A Steiner Triple System using Stinson's randomized algorithm

```
sage: sts = designs.steiner_triple_system(9, algorithm='stinson', seed=0)
sage: sts.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
```

```
>>> from sage.all import *
>>> sts = designs.steiner_triple_system(Integer(9), algorithm='stinson',␣
↪seed=Integer(0))
>>> sts.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
```

An exception is raised for invalid values of `n`

```
sage: designs.steiner_triple_system(10)
Traceback (most recent call last):
...
EmptySetError: Steiner triple systems only exist for n = 1 mod 6 or n = 3 mod 6
```

```
>>> from sage.all import *
>>> designs.steiner_triple_system(Integer(10))
Traceback (most recent call last):
...
EmptySetError: Steiner triple systems only exist for n = 1 mod 6 or n = 3 mod 6
```

`sage.combinat.designs.bibd.`**`v_4_1_BIBD`**(*v*, *check=True*)

Return a $(v, 4, 1)$-BIBD.

A $(v, 4, 1)$-BIBD is an edge-decomposition of the complete graph K_v into copies of K_4. For more information, see *balanced_incomplete_block_design()*. It exists if and only if $v \equiv 1, 4 \pmod{12}$.

See page 167 of [Stinson2004] for the construction details.

See also

- *balanced_incomplete_block_design()*

INPUT:

- `v` – integer; number of points
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import v_4_1_BIBD  # long time
sage: for n in range(13,100):                            # long time
....:     if n%12 in [1,4]:
....:         _ = v_4_1_BIBD(n, check = True)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import v_4_1_BIBD  # long time
>>> for n in range(Integer(13),Integer(100)):                                # long␣
↪time
...     if n%Integer(12) in [Integer(1),Integer(4)]:
...         _ = v_4_1_BIBD(n, check = True)
```

sage.combinat.designs.bibd.**v_5_1_BIBD**(*v*, *check=True*)

Return a $(v, 5, 1)$-BIBD.

This method follows the construction from [ClaytonSmith].

INPUT:

- v – integer

See also

- *balanced_incomplete_block_design()*

EXAMPLES:

```
sage: from sage.combinat.designs.bibd import v_5_1_BIBD
sage: i = 0
sage: while i<200:                                                          #␣
↪needs sage.libs.pari sage.schemes
....:     i += 20
....:     _ = v_5_1_BIBD(i+1)
....:     _ = v_5_1_BIBD(i+5)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.bibd import v_5_1_BIBD
>>> i = Integer(0)
>>> while i<Integer(200):                                                    ␣
↪     # needs sage.libs.pari sage.schemes
...     i += Integer(20)
...     _ = v_5_1_BIBD(i+Integer(1))
...     _ = v_5_1_BIBD(i+Integer(5))
```

Block designs

A *block design* is a set together with a family of subsets (repeated subsets are allowed) whose members are chosen to satisfy some set of properties that are deemed useful for a particular application. See Wikipedia article Block_design.

REFERENCES:

- Block design from wikipedia: Wikipedia article Block_design

  This is a significantly modified form of the module block_design.py (version 0.6) written by Peter Dobcsanyi peter@designtheory.org. Thanks go to Robert Miller for lots of good design suggestions.

Todo

Implement more finite non-Desarguesian plane as in [We07] and Wikipedia article Non-Desarguesian_plane.

Functions and methods

sage.combinat.designs.block_design.**AffineGeometryDesign**(*n*, *d*, *F*, *point_coordinates=True*, *check=True*)

Return an affine geometry design.

The affine geometry design $AG_d(n, q)$ is the 2-design whose blocks are the d-vector subspaces in $\mathbf{F}_q^n$. It has parameters

$$v = q^n,\ k = q^d,\ \lambda = \binom{n-1}{d-1}_q$$

where the q-binomial coefficient $\binom{m}{r}_q$ is defined by

$$\binom{m}{r}_q = \frac{(q^m-1)(q^{m-1}-1)\cdots(q^{m-r+1}-1)}{(q^r-1)(q^{r-1}-1)\cdots(q-1)}$$

See also

ProjectiveGeometryDesign()

INPUT:

- `n` – integer; the Euclidean dimension. The number of points of the design is $v = |\mathbf{F}_q^n|$
- `d` – integer; the dimension of the (affine) subspaces of $\mathbf{F}_q^n$ which make up the blocks
- `F` – a finite field or a prime power
- `point_coordinates` – boolean (default: `True`); whether we use coordinates in $\mathbf{F}_q^n$ or plain integers for the points of the design
- `check` – boolean (default: `True`); whether to check the output

EXAMPLES:

```
sage: # needs sage.combinat
sage: BD = designs.AffineGeometryDesign(3, 1, GF(2))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 8, 2, 1))
sage: BD = designs.AffineGeometryDesign(3, 2, GF(4))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))
sage: BD = designs.AffineGeometryDesign(4, 2, GF(3))
sage: BD.is_t_design(return_parameters=True)
(True, (2, 81, 9, 13))
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> BD = designs.AffineGeometryDesign(Integer(3), Integer(1), GF(Integer(2)))
>>> BD.is_t_design(return_parameters=True)
(True, (2, 8, 2, 1))
>>> BD = designs.AffineGeometryDesign(Integer(3), Integer(2), GF(Integer(4)))
>>> BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))
>>> BD = designs.AffineGeometryDesign(Integer(4), Integer(2), GF(Integer(3)))
>>> BD.is_t_design(return_parameters=True)
(True, (2, 81, 9, 13))
```

With `F` an integer instead of a finite field:

```
sage: BD = designs.AffineGeometryDesign(3, 2, 4)
sage: BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))
```

```
>>> from sage.all import *
>>> BD = designs.AffineGeometryDesign(Integer(3), Integer(2), Integer(4))
>>> BD.is_t_design(return_parameters=True)
(True, (2, 64, 16, 5))
```

Testing the option `point_coordinates`:

```
sage: designs.AffineGeometryDesign(3, 1, GF(2),
....:                              point_coordinates=True).blocks()[0]
[(0, 0, 0), (0, 0, 1)]
sage: designs.AffineGeometryDesign(3, 1, GF(2),
....:                              point_coordinates=False).blocks()[0]
[0, 1]
```

```
>>> from sage.all import *
>>> designs.AffineGeometryDesign(Integer(3), Integer(1), GF(Integer(2)),
...                              point_coordinates=True).blocks()[Integer(0)]
[(0, 0, 0), (0, 0, 1)]
>>> designs.AffineGeometryDesign(Integer(3), Integer(1), GF(Integer(2)),
...                              point_coordinates=False).blocks()[Integer(0)]
[0, 1]
```

`sage.combinat.designs.block_design.`**`CremonaRichmondConfiguration`**`()`

Return the Cremona-Richmond configuration.

The Cremona-Richmond configuration is a set system whose incidence graph is equal to the `TutteCoxeterGraph()`. It is a generalized quadrangle of parameters $(2, 2)$.

For more information, see the Wikipedia article Cremona-Richmond_configuration.

EXAMPLES:

```
sage: H = designs.CremonaRichmondConfiguration(); H
Incidence structure with 15 points and 15 blocks
sage: g = graphs.TutteCoxeterGraph()
```

(continues on next page)

(continued from previous page)

```
sage: H.incidence_graph().is_isomorphic(g)
True
```

```
>>> from sage.all import *
>>> H = designs.CremonaRichmondConfiguration(); H
Incidence structure with 15 points and 15 blocks
>>> g = graphs.TutteCoxeterGraph()
>>> H.incidence_graph().is_isomorphic(g)
True
```

sage.combinat.designs.block_design.**DesarguesianProjectivePlaneDesign**(*n*, *point_coordinates=True*, *check=True*)

Return the Desarguesian projective plane of order `n` as a 2-design.

The Desarguesian projective plane of order n can also be defined as the projective plane over a field of order n. For more information, have a look at Wikipedia article Projective_plane.

INPUT:

- `n` – integer which must be a power of a prime number
- `point_coordinates` – boolean (default: `True`); whether to label the points with their homogeneous coordinates (default) or with integers
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

Traceback (most recent call last):
...
ValueError: the order of a finite field must be a prime power
```

sage.combinat.designs.block_design.**Hadamard3Design**(n)

Return the Hadamard 3-design with parameters $3-(n, \frac{n}{2}, \frac{n}{4}-1)$.

This is the unique extension of the Hadamard 2-design (see *HadamardDesign()*). We implement the description from pp. 12 in [CvL].

INPUT:

- n – integer; a multiple of 4 such that $n > 4$

EXAMPLES:

```
sage: # needs sage.combinat sage.modules
sage: designs.Hadamard3Design(12)
Incidence structure with 12 points and 22 blocks
```

```
>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> designs.Hadamard3Design(Integer(12))
Incidence structure with 12 points and 22 blocks
```

We verify that any two blocks of the Hadamard 3-design $3-(8,4,1)$ design meet in 0 or 2 points. More generally, it is true that any two blocks of a Hadamard 3-design meet in 0 or $\frac{n}{4}$ points (for $n > 4$).

```
sage: # needs sage.combinat sage.modules
sage: D = designs.Hadamard3Design(8)
sage: N = D.incidence_matrix()
sage: N.transpose()*N
[4 2 2 2 2 2 2 2 2 2 2 2 2 0]

REFERENCES:

sage.combinat.designs.block_design.**HadamardDesign**(n)

As described in Section 1, p. 10, in [CvL]. The input n must have the property that there is a Hadamard matrix of order $n + 1$ (and that a construction of that Hadamard matrix has been implemented…).

EXAMPLES:

```
sage: # needs sage.combinat sage.modules
sage: designs.HadamardDesign(7)
Incidence structure with 7 points and 7 blocks
sage: print(designs.HadamardDesign(7))
Incidence structure with 7 points and 7 blocks
```

```
>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> designs.HadamardDesign(Integer(7))
Incidence structure with 7 points and 7 blocks
>>> print(designs.HadamardDesign(Integer(7)))
Incidence structure with 7 points and 7 blocks
```

For example, the Hadamard 2-design with $n = 11$ is a design whose parameters are $2 - (11, 5, 2)$. We verify that $NJ = 5J$ for this design.

```
sage: # needs sage.combinat sage.modules
sage: D = designs.HadamardDesign(11); N = D.incidence_matrix()
sage: J = matrix(ZZ, 11, 11, [1]*11*11); N*J

sage.combinat.designs.block_design.**HughesPlane**(*q2*, *check=True*)

Return the Hughes projective plane of order `q2`.

Let q be an odd prime, the Hughes plane of order q^2 is a finite projective plane of order q^2 introduced by D. Hughes in [Hu57]. Its construction is as follows.

Let $K = GF(q^2)$ be a finite field with q^2 elements and $F = GF(q) \subset K$ be its unique subfield with q elements. We define a twisted multiplication on K as

$$x \circ y = \begin{cases} x\ y & \text{if y is a square in K} \\ x^q\ y & \text{otherwise} \end{cases}$$

The points of the Hughes plane are the triples (x, y, z) of points in $K^3 \backslash \{0, 0, 0\}$ up to the equivalence relation $(x, y, z) \sim (x \circ k, y \circ k, z \circ k)$ where $k \in K$.

For $a = 1$ or $a \in (K \backslash F)$ we define a block $L(a)$ as the set of triples (x, y, z) so that $x + a \circ y + z = 0$. The rest of the blocks are obtained by letting act the group $GL(3, F)$ by its standard action.

For more information, see Wikipedia article Hughes_plane and [We07].

See also

DesarguesianProjectivePlaneDesign() to build the Desarguesian projective planes

INPUT:

- `q2` – an even power of an odd prime number
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

EXAMPLES:

```
sage: H = designs.HughesPlane(9); H
(91,10,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> H = designs.HughesPlane(Integer(9)); H
(91,10,1)-Balanced Incomplete Block Design
```

We prove in the following computations that the Desarguesian plane `H` is not Desarguesian. Let us consider the two triangles $(0, 1, 10)$ and $(57, 70, 59)$. We show that the intersection points $D_{0,1} \cap D_{57,70}$, $D_{1,10} \cap D_{70,59}$ and $D_{10,0} \cap D_{59,57}$ are on the same line while $D_{0,70}$, $D_{1,59}$ and $D_{10,57}$ are not concurrent:

```
sage: blocks = H.blocks()
sage: line = lambda p,q: next(b for b in blocks if p in b and q in b)

sage: b_0_1 = line(0, 1)
sage: b_1_10 = line(1, 10)
sage: b_10_0 = line(10, 0)
sage: b_57_70 = line(57, 70)
sage: b_70_59 = line(70, 59)
sage: b_59_57 = line(59, 57)

sage: set(b_0_1).intersection(b_57_70)
{2}
sage: set(b_1_10).intersection(b_70_59)
{73}
sage: set(b_10_0).intersection(b_59_57)
{60}

sage: line(2, 73) == line(73, 60)
True

sage: b_0_57 = line(0, 57)
sage: b_1_70 = line(1, 70)
sage: b_10_59 = line(10, 59)

sage: p = set(b_0_57).intersection(b_1_70)
sage: q = set(b_1_70).intersection(b_10_59)
sage: p == q
False
```

```
>>> from sage.all import *
>>> blocks = H.blocks()
>>> line = lambda p,q: next(b for b in blocks if p in b and q in b)

>>> b_0_1 = line(Integer(0), Integer(1))
>>> b_1_10 = line(Integer(1), Integer(10))
>>> b_10_0 = line(Integer(10), Integer(0))
>>> b_57_70 = line(Integer(57), Integer(70))
>>> b_70_59 = line(Integer(70), Integer(59))
>>> b_59_57 = line(Integer(59), Integer(57))

>>> set(b_0_1).intersection(b_57_70)
```

(continues on next page)

(continued from previous page)

```
{2}
>>> set(b_1_10).intersection(b_70_59)
{73}
>>> set(b_10_0).intersection(b_59_57)
{60}

>>> line(Integer(2), Integer(73)) == line(Integer(73), Integer(60))
True

>>> b_0_57 = line(Integer(0), Integer(57))
>>> b_1_70 = line(Integer(1), Integer(70))
>>> b_10_59 = line(Integer(10), Integer(59))

>>> p = set(b_0_57).intersection(b_1_70)
>>> q = set(b_1_70).intersection(b_10_59)
>>> p == q
False
```

sage.combinat.designs.block_design.**ProjectiveGeometryDesign**(*n*, *d*, *F*, *algorithm=None*, *point_coordinates=True*, *check=True*)

Return a projective geometry design.

The projective geometry design $PG_d(n,q)$ has for points the lines of $\mathbf{F}_q^{n+1}$, and for blocks the $(d+1)$-dimensional subspaces of $\mathbf{F}_q^{n+1}$, each of which contains $\frac{|\mathbf{F}_q|^{d+1}-1}{|\mathbf{F}_q|-1}$ lines. It is a 2-design with parameters

$$v = \binom{n+1}{1}_q,\ k = \binom{d+1}{1}_q,\ \lambda = \binom{n-1}{d-1}_q$$

where the q-binomial coefficient $\binom{m}{r}_q$ is defined by

$$\binom{m}{r}_q = \frac{(q^m-1)(q^{m-1}-1)\cdots(q^{m-r+1}-1)}{(q^r-1)(q^{r-1}-1)\cdots(q-1)}$$

See also

AffineGeometryDesign()

INPUT:

- `n` – the projective dimension
- `d` – the dimension of the subspaces which make up the blocks
- `F` – a finite field or a prime power
- `algorithm` – set to `None` by default, which results in using Sage's own implementation. In order to use GAP's implementation instead (i.e. its `PGPointFlatBlockDesign` function) set `algorithm="gap"`. Note that GAP's "design" package must be available in this case, and that it can be installed with the `gap_packages` spkg.
- `point_coordinates` – `True` by default. Ignored and assumed to be `False` if `algorithm="gap"`. If `True`, the ground set is indexed by coordinates in $\mathbf{F}_q^{n+1}$. Otherwise the ground set is indexed by integers.

- `check` – boolean (default: `True`); whether to check the output

EXAMPLES:

The set of d-dimensional subspaces in a n-dimensional projective space forms 2-designs (or balanced incomplete block designs):

```
sage: PG = designs.ProjectiveGeometryDesign(4, 2, GF(2)); PG                    #␣
↪needs sage.combinat
Incidence structure with 31 points and 155 blocks
sage: PG.is_t_design(return_parameters=True)                                    #␣
↪needs sage.combinat
(True, (2, 31, 7, 7))

sage: PG = designs.ProjectiveGeometryDesign(3, 1, GF(4))                        #␣
↪needs sage.combinat
sage: PG.is_t_design(return_parameters=True)                                    #␣
↪needs sage.combinat
(True, (2, 85, 5, 1))
```

```
>>> from sage.all import *
>>> PG = designs.ProjectiveGeometryDesign(Integer(4), Integer(2), GF(Integer(2)));
↪ PG                    # needs sage.combinat
Incidence structure with 31 points and 155 blocks
>>> PG.is_t_design(return_parameters=True)                                       #␣
↪needs sage.combinat
(True, (2, 31, 7, 7))

>>> PG = designs.ProjectiveGeometryDesign(Integer(3), Integer(1), GF(Integer(4)))␣
↪                       # needs sage.combinat
>>> PG.is_t_design(return_parameters=True)                                       #␣
↪needs sage.combinat
(True, (2, 85, 5, 1))
```

Check with `F` being a prime power:

```
sage: PG = designs.ProjectiveGeometryDesign(3, 2, 4); PG
Incidence structure with 85 points and 85 blocks
```

```
>>> from sage.all import *
>>> PG = designs.ProjectiveGeometryDesign(Integer(3), Integer(2), Integer(4)); PG
Incidence structure with 85 points and 85 blocks
```

Use coordinates:

```
sage: PG = designs.ProjectiveGeometryDesign(2, 1, GF(3))
sage: PG.blocks()[0]
[(1, 0, 0), (1, 0, 1), (1, 0, 2), (0, 0, 1)]
```

```
>>> from sage.all import *
>>> PG = designs.ProjectiveGeometryDesign(Integer(2), Integer(1), GF(Integer(3)))
>>> PG.blocks()[Integer(0)]
[(1, 0, 0), (1, 0, 1), (1, 0, 2), (0, 0, 1)]
```

Use indexing by integers:

```
sage: PG = designs.ProjectiveGeometryDesign(2, 1, GF(3), point_coordinates=0)
sage: PG.blocks()[0]
[0, 1, 2, 12]
```

```
>>> from sage.all import *
>>> PG = designs.ProjectiveGeometryDesign(Integer(2), Integer(1), GF(Integer(3)),␣
↪point_coordinates=Integer(0))
>>> PG.blocks()[Integer(0)]
[0, 1, 2, 12]
```

Check that the constructor using gap also works:

```
sage: BD = designs.ProjectiveGeometryDesign(2, 1, GF(2), algorithm='gap')   #␣
↪optional - gap_package_design
sage: BD.is_t_design(return_parameters=True)                                #␣
↪optional - gap_package_design
(True, (2, 7, 3, 1))
```

```
>>> from sage.all import *
>>> BD = designs.ProjectiveGeometryDesign(Integer(2), Integer(1), GF(Integer(2)),␣
↪algorithm='gap')  # optional - gap_package_design
>>> BD.is_t_design(return_parameters=True)                                  #␣
↪optional - gap_package_design
(True, (2, 7, 3, 1))
```

sage.combinat.designs.block_design.**WittDesign**(*n*)

INPUT:

- n – integer in $9, 10, 11, 12, 21, 22, 23, 24$

Wraps GAP Design's WittDesign. If `n=24` then this function returns the large Witt design W_{24}, the unique (up to isomorphism) $5-(24,8,1)$ design. If `n=12` then this function returns the small Witt design W_{12}, the unique (up to isomorphism) $5-(12,6,1)$ design. The other values of n return a block design derived from these.

Note

Requires GAP's Design package (included in the gap_packages Sage spkg).

EXAMPLES:

```
sage: # optional - gap_package_design
sage: BD = designs.WittDesign(9)
sage: BD.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
sage: BD
Incidence structure with 9 points and 12 blocks
sage: print(BD)
Incidence structure with 9 points and 12 blocks
```

```
>>> from sage.all import *
>>> # optional - gap_package_design
>>> BD = designs.WittDesign(Integer(9))
```

(continues on next page)

(continued from previous page)

```
>>> BD.is_t_design(return_parameters=True)
(True, (2, 9, 3, 1))
>>> BD
Incidence structure with 9 points and 12 blocks
>>> print(BD)
Incidence structure with 9 points and 12 blocks
```

sage.combinat.designs.block_design.**are_hyperplanes_in_projective_geometry_parameters**(*v*, *k*, *lmbda*, *return_parameters=False*)

Return `True` if the parameters `(v,k,lmbda)` are the one of hyperplanes in a (finite Desarguesian) projective space.

In other words, test whether there exists a prime power `q` and an integer `d` greater than two such that:

- $v = (q^{d+1}-1)/(q-1) = q^d + q^{d-1} + ... + 1$
- $k = (q^{d}-1)/(q-1) = q^{d-1} + q^{d-2} + ... + 1$
- $lmbda = (q^{d-1}-1)/(q-1) = q^{d-2} + q^{d-3} + ... + 1$

If it exists, such a pair `(q,d)` is unique.

INPUT:

- `v`, `k`, `lmbda` – integers

OUTPUT:

- a boolean or, if `return_parameters` is set to `True` a pair `(True, (q,d))` or `(False, (None,None))`.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import are_hyperplanes_in_
↪projective_geometry_parameters
sage: are_hyperplanes_in_projective_geometry_parameters(40, 13, 4)
True
sage: are_hyperplanes_in_projective_geometry_parameters(40, 13, 4,
....:                                                   return_parameters=True)
(True, (3, 3))
sage: PG = designs.ProjectiveGeometryDesign(3, 2, GF(3))                    #␣
↪needs sage.combinat
sage: PG.is_t_design(return_parameters=True)                                #␣
↪needs sage.combinat
(True, (2, 40, 13, 4))

sage: are_hyperplanes_in_projective_geometry_parameters(15, 3, 1)
False
sage: are_hyperplanes_in_projective_geometry_parameters(15, 3, 1,
....:                                                   return_parameters=True)
(False, (None, None))
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.block_design import are_hyperplanes_in_projective_
↪geometry_parameters
>>> are_hyperplanes_in_projective_geometry_parameters(Integer(40), Integer(13),␣
↪Integer(4))
True
>>> are_hyperplanes_in_projective_geometry_parameters(Integer(40), Integer(13),␣
↪Integer(4),
...                                                 return_parameters=True)
(True, (3, 3))
>>> PG = designs.ProjectiveGeometryDesign(Integer(3), Integer(2), GF(Integer(3)))␣
↪                       # needs sage.combinat
>>> PG.is_t_design(return_parameters=True)                                    #␣
↪needs sage.combinat
(True, (2, 40, 13, 4))

>>> are_hyperplanes_in_projective_geometry_parameters(Integer(15), Integer(3),␣
↪Integer(1))
False
>>> are_hyperplanes_in_projective_geometry_parameters(Integer(15), Integer(3),␣
↪Integer(1),
...                                                 return_parameters=True)
(False, (None, None))
```

sage.combinat.designs.block_design.**normalize_hughes_plane_point**(*p*, *q*)

Return the normalized form of point `p` as a 3-tuple.

In the Hughes projective plane over the finite field K, all triples (xk, yk, zk) with $k \in K$ represent the same point (where the multiplication is over the nearfield built from K). This function chooses a canonical representative among them.

This function is used in *HughesPlane()*.

INPUT:

- `p` – point with the coordinates (x, y, z) (a list, a vector, a tuple…)
- `q` – cardinality of the underlying finite field

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import normalize_hughes_plane_point
sage: K = FiniteField(9,'x')
sage: x = K.gen()
sage: normalize_hughes_plane_point((x, x + 1, x), 9)
(1, x, 1)
sage: normalize_hughes_plane_point(vector((x,x,x)), 9)
(1, 1, 1)
sage: zero = K.zero()
sage: normalize_hughes_plane_point((2*x + 2, zero, zero), 9)
(1, 0, 0)
sage: one = K.one()
sage: normalize_hughes_plane_point((2*x, one, zero), 9)
(2*x, 1, 0)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.block_design import normalize_hughes_plane_point
>>> K = FiniteField(Integer(9),'x')
>>> x = K.gen()
>>> normalize_hughes_plane_point((x, x + Integer(1), x), Integer(9))
(1, x, 1)
>>> normalize_hughes_plane_point(vector((x,x,x)), Integer(9))
(1, 1, 1)
>>> zero = K.zero()
>>> normalize_hughes_plane_point((Integer(2)*x + Integer(2), zero, zero),␣
↪Integer(9))
(1, 0, 0)
>>> one = K.one()
>>> normalize_hughes_plane_point((Integer(2)*x, one, zero), Integer(9))
(2*x, 1, 0)
```

sage.combinat.designs.block_design.**projective_plane**(*n*, *check=True*, *existence=False*)

Return a projective plane of order `n` as a 2-design.

A finite projective plane is a 2-design with n^2+n+1 lines (or blocks) and n^2+n+1 points. For more information on finite projective planes, see the Wikipedia article Projective_plane#Finite_projective_planes.

If no construction is possible, then the function raises a `EmptySetError`, whereas if no construction is available, the function raises a `NotImplementedError`.

INPUT:

- `n` – the finite projective plane's order

EXAMPLES:

```
sage: # needs sage.schemes
sage: designs.projective_plane(2)
(7,3,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(3)
(13,4,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(4)
(21,5,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(5)
(31,6,1)-Balanced Incomplete Block Design
sage: designs.projective_plane(6)
Traceback (most recent call last):

projective planes of order 10" (1989), Canad. J. Math.
>>> designs.projective_plane(Integer(12))
Traceback (most recent call last):
...
NotImplementedError: If such a projective plane exists,
we do not know how to build it.
>>> designs.projective_plane(Integer(14))
Traceback (most recent call last):
...
EmptySetError: By the Bruck-Ryser theorem, no projective plane of order 14 exists.
```

sage.combinat.designs.block_design.**projective_plane_to_OA**(*pplane*, *pt=None*, *check=True*)

Return the orthogonal array built from the projective plane `pplane`.

The orthogonal array $OA(n+1, n, 2)$ is obtained from the projective plane `pplane` by removing the point `pt` and the $n+1$ lines that pass through it`. These $n+1$ lines form the $n+1$ groups while the remaining n^2+n lines form the transversals.

INPUT:

- `pplane` – a projective plane as a 2-design
- `pt` – a point in the projective plane `pplane`; if it is not provided, then it is set to n^2+n
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import projective_plane_to_OA
sage: p2 = designs.DesarguesianProjectivePlaneDesign(2, point_coordinates=False)
```

(continues on next page)

(continued from previous page)

```
sage: projective_plane_to_OA(p2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]
sage: p3 = designs.DesarguesianProjectivePlaneDesign(3, point_coordinates=False)
sage: projective_plane_to_OA(p3)
[[0, 0, 0, 0],
 [0, 1, 2, 1],
 [0, 2, 1, 2],
 [1, 0, 2, 2],
 [1, 1, 1, 0],
 [1, 2, 0, 1],
 [2, 0, 1, 1],
 [2, 1, 0, 2],
 [2, 2, 2, 0]]

sage: pp = designs.DesarguesianProjectivePlaneDesign(16, point_coordinates=False)
sage: _ = projective_plane_to_OA(pp, pt=0)
sage: _ = projective_plane_to_OA(pp, pt=3)
sage: _ = projective_plane_to_OA(pp, pt=7)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.block_design import projective_plane_to_OA
>>> p2 = designs.DesarguesianProjectivePlaneDesign(Integer(2), point_
↪coordinates=False)
>>> projective_plane_to_OA(p2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]
>>> p3 = designs.DesarguesianProjectivePlaneDesign(Integer(3), point_
↪coordinates=False)
>>> projective_plane_to_OA(p3)
[[0, 0, 0, 0],
 [0, 1, 2, 1],
 [0, 2, 1, 2],
 [1, 0, 2, 2],
 [1, 1, 1, 0],
 [1, 2, 0, 1],
 [2, 0, 1, 1],
 [2, 1, 0, 2],
 [2, 2, 2, 0]]

>>> pp = designs.DesarguesianProjectivePlaneDesign(Integer(16), point_
↪coordinates=False)
>>> _ = projective_plane_to_OA(pp, pt=Integer(0))
>>> _ = projective_plane_to_OA(pp, pt=Integer(3))
>>> _ = projective_plane_to_OA(pp, pt=Integer(7))
```

sage.combinat.designs.block_design.**q3_minus_one_matrix**(K)

Return a companion matrix in $GL(3, K)$ whose multiplicative order is $q^3 - 1$.

This function is used in *HughesPlane()*.

EXAMPLES:

```
sage: from sage.combinat.designs.block_design import q3_minus_one_matrix
sage: m = q3_minus_one_matrix(GF(3))
```

(continues on next page)

(continued from previous page)

```
sage: m.multiplicative_order() == 3**3 - 1
True

sage: m = q3_minus_one_matrix(GF(4, 'a'))
sage: m.multiplicative_order() == 4**3 - 1
True

sage: m = q3_minus_one_matrix(GF(5))
sage: m.multiplicative_order() == 5**3 - 1
True

sage: m = q3_minus_one_matrix(GF(9, 'a'))
sage: m.multiplicative_order() == 9**3 - 1
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.block_design import q3_minus_one_matrix
>>> m = q3_minus_one_matrix(GF(Integer(3)))
>>> m.multiplicative_order() == Integer(3)**Integer(3) - Integer(1)
True

>>> m = q3_minus_one_matrix(GF(Integer(4), 'a'))
>>> m.multiplicative_order() == Integer(4)**Integer(3) - Integer(1)
True

>>> m = q3_minus_one_matrix(GF(Integer(5)))
>>> m.multiplicative_order() == Integer(5)**Integer(3) - Integer(1)
True

>>> m = q3_minus_one_matrix(GF(Integer(9), 'a'))
>>> m.multiplicative_order() == Integer(9)**Integer(3) - Integer(1)
True
```

sage.combinat.designs.block_design.**tdesign_params**(t, v, k, L)

Return the design's parameters: (t, v, b, r, k, L). Note that t must be given.

EXAMPLES:

```
sage: BD = BlockDesign(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,
↪5]])
sage: from sage.combinat.designs.block_design import tdesign_params
sage: tdesign_params(2,7,3,1)
(2, 7, 7, 3, 3, 1)
```

```
>>> from sage.all import *
>>> BD = BlockDesign(Integer(7), [[Integer(0),Integer(1),Integer(2)],[Integer(0),
↪Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],[Integer(1),
↪Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],[Integer(2),
↪Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> from sage.combinat.designs.block_design import tdesign_params
>>> tdesign_params(Integer(2),Integer(7),Integer(3),Integer(1))
(2, 7, 7, 3, 3, 1)
```

Bounds on the number of mutually orthogonal Latin squares

This module contains known lower bounds on the number of mutually orthogonal Latin squares (MOLS) of a given size, and consists (almost) entirely of an internal, constant tuple of Python integers corresponding to Table 3.87 in the Handbook of Combinatorial Designs, 2nd edition, by Colbourn and Dinitz. One public function, *lower_bound()*, is provided to access it.

Make sure we have all of the entries:

```
sage: from sage.combinat.designs import MOLS_handbook_data
sage: len(MOLS_handbook_data._LOWER_BOUNDS)
10000
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import MOLS_handbook_data
>>> len(MOLS_handbook_data._LOWER_BOUNDS)
10000
```

Jeff Dinitz's website (at UVM) provides the following two updates to the table as printed in the second edition:

```
sage: from sage.combinat.designs import MOLS_handbook_data
sage: MOLS_handbook_data.lower_bound(60)
5
sage: MOLS_handbook_data.lower_bound(7968)
31
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import MOLS_handbook_data
>>> MOLS_handbook_data.lower_bound(Integer(60))
5
>>> MOLS_handbook_data.lower_bound(Integer(7968))
31
```

sage.combinat.designs.MOLS_handbook_data.**lower_bound**(*order*)

Return the best known lower bound on the number of MOLS of the given `order`.

The source of this information is Table 3.87 in the Handbook of Combinatorial Designs, 2nd edition, by Colbourn and Dinitz. A few updates have subsequently been provided on Jeff Dinitz's website.

Parameters

order
: [int] The order (also known as the side) for which you'd like a lower bound on the number of MOLS instances. In the language of the Handbook, this is `n`, and it should be between 0 and 9999.

Returns

int
: A lower bound on the number of MOLS.

Raises

IndexError
: If you ask for an order that isn't contained in the table.

Examples

There are no MOLS of order zero:

```
sage: from sage.combinat.designs import MOLS_handbook_data
sage: MOLS_handbook_data.lower_bound(0)
0
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import MOLS_handbook_data
>>> MOLS_handbook_data.lower_bound(Integer(0))
0
```

Catalog of designs

This module gathers all designs that can be reached through `designs.<tab>`. Example with the Witt design on 24 points:

```
sage: designs.WittDesign(24)                                    # optional - gap_package_
↪design
Incidence structure with 24 points and 759 blocks
```

```
>>> from sage.all import *
>>> designs.WittDesign(Integer(24))                              # optional - gap_
↪package_design
Incidence structure with 24 points and 759 blocks
```

Or a Steiner Triple System on 19 points:

```
sage: designs.steiner_triple_system(19)
(19,3,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> designs.steiner_triple_system(Integer(19))
(19,3,1)-Balanced Incomplete Block Design
```

La Jolla Covering Repository

The La Jolla Covering Repository (LJCR, see[1]) is an online database of covering designs. As it is frequently updated, it is not included in Sage, but one can query it through *designs.best_known_covering_design_from_LJCR*:

```
sage: C = designs.best_known_covering_design_from_LJCR(7, 3, 2)    # optional -␣
↪internet
sage: C                              # optional - internet
(7, 3, 2)-covering design of size 7
Lower bound: 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
sage: C.incidence_structure()        # optional - internet
Incidence structure with 7 points and 7 blocks
```

[1] La Jolla Covering Repository, https://dmgordon.org/cover

```
>>> from sage.all import *
>>> C = designs.best_known_covering_design_from_LJCR(Integer(7), Integer(3),␣
↪Integer(2))   # optional - internet
>>> C                            # optional - internet
(7, 3, 2)-covering design of size 7
Lower bound: 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
>>> C.incidence_structure()      # optional - internet
Incidence structure with 7 points and 7 blocks
```

Design constructors

This module gathers the following designs:

ProjectiveGeometryDesign()
DesarguesianProjectivePlaneDesign()
HughesPlane()
HigmanSimsDesign()
balanced_incomplete_block_design()
resolvable_balanced_incomplete_block_design()
kirkman_triple_system()
AffineGeometryDesign()
CremonaRichmondConfiguration()
WittDesign()
HadamardDesign()
Hadamard3Design()
mutually_orthogonal_latin_squares()
transversal_design()
orthogonal_array()
incomplete_orthogonal_array()
difference_family()
difference_matrix()
steiner_triple_system()
steiner_quadruple_system()
projective_plane()
biplane()
gen_quadrangles_with_spread()

And the *designs.best_known_covering_design_from_LJCR* function which queries the LJCR.

Todo

Implement DerivedDesign and ComplementaryDesign.

Covering arrays

A covering array, denoted $CA(N; t, k, v)$, is an N by k array with entries from a set of v elements with the property that in every selection of t columns, every sequence of t elements appears in at least one row.

An orthogonal array, denoted $OA(N; t, k, v)$ is a covering array with the property that every sequence of t-elements appears in exactly one row. (See `sage.combinat.designs.orthogonal_arrays`).

This module collects methods relating to covering arrays, some of which are inherited from orthogonal array methods. This module defines the following functions:

is_covering_array()	Check that an input list of lists is a $CA(N; t, k, v)$.
OA_relabel()	Return a relabelled version of the CA.
OA_standard_label()	Return a version of the CA relabelled to symbols $(0, \ldots, n-1)$.
truncate_columns()	Return an array with k columns from a larger one.
Kleitman_Spencer_Katona()	Return a $CA(N; 2, k, 2)$ using N as input.
column_Kleitman_Spencer_Katona()	Return a $CA(N; 2, k, 2)$ using k as input.
database_check()	Check if CA can be made from the database of combinatorial designs.
covering_array()	Return a CA with given parameters.

AUTHORS:

- Aaron Dwyer and brett stevens (2022): initial version

sage.combinat.designs.covering_array.**Kleitman_Spencer_Katona**(N)

Return a $CA(N; 2, k, 2)$ where $k = \binom{N-1}{\lceil N/2 \rceil}$.

INPUT:

- N – the number of rows in the array, must be an integer greater than 3 since any smaller would not produce enough columns for a strength 2 array.

This construction is referenced in [Colb2004] from [KS1973] and [Kat1973]

Construction

Take all distinct binary N-tuples of weight $N/2$ that have a 0 in the first position and place them as columns in an array.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_array import Kleitman_Spencer_Katona
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: C = Kleitman_Spencer_Katona(2)
Traceback (most recent call last):
...
ValueError: N must be greater than 3
sage: C = Kleitman_Spencer_Katona(5)
sage: is_covering_array(C,parameters=True)
(True, (5, 2, 4, 2))
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_array import Kleitman_Spencer_Katona
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> C = Kleitman_Spencer_Katona(Integer(2))
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: N must be greater than 3
>>> C = Kleitman_Spencer_Katona(Integer(5))
>>> is_covering_array(C,parameters=True)
(True, (5, 2, 4, 2))
```

sage.combinat.designs.covering_array.**column_Kleitman_Spencer_Katona**(k)

Return a covering array with k columns using the Kleitman-Spencer-Katona method.

See *Kleitman_Spencer_Katona()*

INPUT:

- `k` – the number of columns in the array, must be an integer greater than 3 since any smaller is a trivial array for strength 2.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.covering_array import column_Kleitman_Spencer_
↪Katona
sage: C = column_Kleitman_Spencer_Katona(20)
sage: is_covering_array(C,parameters=True)
(True, (8, 2, 20, 2))
sage: column_Kleitman_Spencer_Katona(25000)
Traceback (most recent call last):
...
NotImplementedError: not implemented for k > 24310
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.covering_array import column_Kleitman_Spencer_
↪Katona
>>> C = column_Kleitman_Spencer_Katona(Integer(20))
>>> is_covering_array(C,parameters=True)
(True, (8, 2, 20, 2))
>>> column_Kleitman_Spencer_Katona(Integer(25000))
Traceback (most recent call last):
...
NotImplementedError: not implemented for k > 24310
```

sage.combinat.designs.covering_array.**covering_array**(*strength*, *number_columns*, *levels*)

Build a $CA(N; t, k, v)$ using direct constructions, where N is the smallest size known.

INPUT:

- `strength` (integer) – the parameter t of the covering array, such that in any selection of t columns of the array, every t-tuple appears at least once.
- `levels` (integer) – the parameter v which is the number of unique symbols that appear in the covering array.
- `number_columns` (integer) – the number of columns desired for the covering array.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.covering_array import covering_array
sage: C1 = covering_array(2, 7, 3)
sage: is_covering_array(C1,parameters=True)
(True, (12, 2, 7, 3))
sage: C2 = covering_array(2, 11, 2)
sage: is_covering_array(C2,parameters=True)
(True, (7, 2, 11, 2))
sage: C3 = covering_array(2, 8, 7)
sage: is_covering_array(C3,parameters=True)
(True, (49, 2, 8, 7))
sage: C4 = covering_array(2, 50, 7)
No direct construction known and/or implemented for a CA(N; 2, 50, 7)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.covering_array import covering_array
>>> C1 = covering_array(Integer(2), Integer(7), Integer(3))
>>> is_covering_array(C1,parameters=True)
(True, (12, 2, 7, 3))
>>> C2 = covering_array(Integer(2), Integer(11), Integer(2))
>>> is_covering_array(C2,parameters=True)
(True, (7, 2, 11, 2))
>>> C3 = covering_array(Integer(2), Integer(8), Integer(7))
>>> is_covering_array(C3,parameters=True)
(True, (49, 2, 8, 7))
>>> C4 = covering_array(Integer(2), Integer(50), Integer(7))
No direct construction known and/or implemented for a CA(N; 2, 50, 7)
```

sage.combinat.designs.covering_array.**database_check**(*number_columns*, *strength*, *levels*)

Check if the database can be used to build a CA with the given parameters. If so return the CA, if not return False.

INPUT:

- `strength` (integer) – the parameter t of the covering array, such that in any selection of t columns of the array, every t-tuple appears at least once.
- `levels` (integer) – the parameter v which is the number of unique symbols that appear in the covering array.
- `number_columns` (integer) – the number of columns desired for the covering array.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.covering_array import database_check
sage: C = database_check(6, 2, 3)
sage: is_covering_array(C, parameters=True)
(True, (12, 2, 6, 3))
sage: database_check(6, 3, 3)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.covering_array import database_check
>>> C = database_check(Integer(6), Integer(2), Integer(3))
```

(continues on next page)

(continued from previous page)

```
>>> is_covering_array(C, parameters=True)
(True, (12, 2, 6, 3))
>>> database_check(Integer(6), Integer(3), Integer(3))
False
```

sage.combinat.designs.covering_array.**truncate_columns**(*array*, *k*)

Return a covering array with k columns, obtained by removing excess columns from a larger covering array.

INPUT:

- `array` – the array to be truncated.
- `k` – the number of columns desired. Must be less than the number of columns in `array`.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.covering_array import truncate_columns
sage: from sage.combinat.designs.database import ca_11_2_5_3
sage: C = ca_11_2_5_3()
sage: D = truncate_columns(C,7)
Traceback (most recent call last):
...
ValueError: array only has 5 columns
sage: E = truncate_columns(C,4)
sage: is_covering_array(E,parameters=True)
(True, (11, 2, 4, 3))
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.covering_array import truncate_columns
>>> from sage.combinat.designs.database import ca_11_2_5_3
>>> C = ca_11_2_5_3()
>>> D = truncate_columns(C,Integer(7))
Traceback (most recent call last):
...
ValueError: array only has 5 columns
>>> E = truncate_columns(C,Integer(4))
>>> is_covering_array(E,parameters=True)
(True, (11, 2, 4, 3))
```

Covering designs: coverings of t-element subsets of a v-set by k-sets

A (v, k, t) covering design C is an incidence structure consisting of a set of points P of order v, and a set of blocks B, where each block contains k points of P. Every t-element subset of P must be contained in at least one block.

If every t-set is contained in exactly one block of C, then we have a block design. Following the block design implementation, the standard representation of a covering design uses $P = [0, 1, ..., v - 1]$.

In addition to the parameters and incidence structure for a covering design from this database, we include extra information:

- Best known lower bound on the size of a (v, k, t)-covering design
- Name of the person(s) who produced the design
- Method of construction used

- Date when the design was added to the database

REFERENCES:

AUTHORS:

- Daniel M. Gordon (2008-12-22): initial version

Classes and methods

class sage.combinat.designs.covering_design.**CoveringDesign**(*v=0*, *k=0*, *t=0*, *size=0*, *points=None*, *blocks=None*, *low_bd=0*, *method=''*, *creator=''*, *timestamp=''*)

Bases: SageObject

Covering design.

INPUT:

- v, k, t – integer parameters of the covering design
- size – integer
- points – list of points (default: $[0, ..., v-1]$)
- blocks
- low_bd – integer; lower bound for such a design
- method, creator, timestamp – database information

creator()

Return the creator of the covering design.

This field is optional, and is used in a database to give attribution for the covering design It can refer to the person who submitted it, or who originally gave a construction

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:     [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6],
....:     [2, 4, 5]],0, 'Projective Plane', 'Gino Fano')
sage: C.creator()
'Gino Fano'
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...     [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)], [Integer(2), Integer(3), Integer(6)],
...     [Integer(2), Integer(4), Integer(5)]],Integer(0), 'Projective Plane',
↪'Gino Fano')
>>> C.creator()
'Gino Fano'
```

incidence_structure()

Return the incidence structure of this design, without extra parameters.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:     [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
....:     [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: D = C.incidence_structure()
sage: D.ground_set()
[0, 1, 2, 3, 4, 5, 6]
sage: D.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5],
[1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...     [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...     [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]], Integer(0), 'Projective Plane')
>>> D = C.incidence_structure()
>>> D.ground_set()
[0, 1, 2, 3, 4, 5, 6]
>>> D.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5],
[1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

is_covering()

Check all t-sets are in fact covered by the blocks of `self`.

Note

This is very slow and wasteful of memory.

EXAMPLES:

```
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:     [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
....:     [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.is_covering()
True
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:     [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6],
....:     [2, 4, 6]], 0, 'not a covering')   # last block altered
sage: C.is_covering()
False
```

```
>>> from sage.all import *
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...      [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...      [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]], Integer(0), 'Projective Plane')
>>> C.is_covering()
True
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...      [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)], [Integer(2), Integer(3), Integer(6)],
...      [Integer(2), Integer(4), Integer(6)]], Integer(0), 'not a covering') ␣
↪ # last block altered
>>> C.is_covering()
False
```

k()

Return k, the size of blocks of the covering design.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
....:      [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.k()
3
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...      [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...      [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]], Integer(0), 'Projective Plane')
>>> C.k()
3
```

low_bd()

Return a lower bound for the number of blocks a covering design with these parameters could have.

Typically this is the Schonheim bound, but for some parameters better bounds have been shown.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
```

(continues on next page)

(continued from previous page)

```
....:     [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.low_bd()
7
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...     [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...     [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]], Integer(0), 'Projective Plane')
>>> C.low_bd()
7
```

method()

Return the method used to create the covering design.

This field is optional, and is used in a database to give information about how coverings were constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:     [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
....:     [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.method()
'Projective Plane'
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...     [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...     [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]], Integer(0), 'Projective Plane')
>>> C.method()
'Projective Plane'
```

size()

Return the number of blocks in the covering design.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:     [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
....:     [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.size()
7
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...      [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...      [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]], Integer(0), 'Projective Plane')
>>> C.size()
7
```

t()

Return t, the size of sets which must be covered by the blocks of the covering design

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
....:      [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.t()
2
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...      [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...      [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]], Integer(0), 'Projective Plane')
>>> C.t()
2
```

timestamp()

Return the time that the covering was submitted to the database.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:      [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
....:      [2, 3, 6], [2, 4, 5]],0, 'Projective Plane',
....:      'Gino Fano', '1892-01-01 00:00:00')
sage: C.timestamp()  # No exact date known; in Fano's 1892 article
'1892-01-01 00:00:00'
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
```

(continues on next page)

(continued from previous page)

```
...      [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...      [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]],Integer(0), 'Projective Plane',
...      'Gino Fano', '1892-01-01 00:00:00')
>>> C.timestamp()  # No exact date known; in Fano's 1892 article
'1892-01-01 00:00:00'
```

v()

Return v, the number of points in the covering design.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import CoveringDesign
sage: C = CoveringDesign(7, 3, 2, 7, range(7), [[0, 1, 2],
....:     [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6],
....:     [2, 3, 6], [2, 4, 5]], 0, 'Projective Plane')
sage: C.v()
7
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import CoveringDesign
>>> C = CoveringDesign(Integer(7), Integer(3), Integer(2), Integer(7),␣
↪range(Integer(7)), [[Integer(0), Integer(1), Integer(2)],
...      [Integer(0), Integer(3), Integer(4)], [Integer(0), Integer(5),␣
↪Integer(6)], [Integer(1), Integer(3), Integer(5)], [Integer(1), Integer(4),␣
↪Integer(6)],
...      [Integer(2), Integer(3), Integer(6)], [Integer(2), Integer(4),␣
↪Integer(5)]], Integer(0), 'Projective Plane')
>>> C.v()
7
```

sage.combinat.designs.covering_design.**best_known_covering_design_www**(v, k, t, *verbose=False*)

Return the best known (v, k, t) covering design from an online database.

This uses the La Jolla Covering Repository, a database available at https://ljcr.dmgordon.org/cover.html

INPUT:

- `v` – integer; the size of the point set for the design
- `k` – integer; the number of points per block
- `t` – integer; the size of sets covered by the blocks
- `verbose` – boolean (default: `False`); print verbose message

OUTPUT:

A *CoveringDesign* object representing the `(v, k, t)`-covering design with smallest number of blocks available in the database.

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import (  # optional - internet
....:     best_known_covering_design_www)
```

(continues on next page)

(continued from previous page)

```
sage: C = best_known_covering_design_www(7, 3, 2)  # optional - internet
sage: print(C)                                     # optional - internet
C(7, 3, 2) = 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
0  1  2
0  3  4
0  5  6
1  3  5
1  4  6
2  3  6
2  4  5
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import (  # optional - internet
...     best_known_covering_design_www)
>>> C = best_known_covering_design_www(Integer(7), Integer(3), Integer(2))  #␣
↪optional - internet
>>> print(C)                                       # optional - internet
C(7, 3, 2) = 7
Method: lex covering
Submitted on: 1996-12-01 00:00:00
0  1  2
0  3  4
0  5  6
1  3  5
1  4  6
2  3  6
2  4  5
```

A `ValueError` is raised if the `(v, k, t)` parameters are not found in the database.

`sage.combinat.designs.covering_design.`**`schonheim`**`(`v, k, t`)`

Return the Schonheim lower bound for the size of such a covering design.

INPUT:

- `v` – integer; size of point set
- `k` – integer; cardinality of each block
- `t` – integer; cardinality of sets being covered

OUTPUT:

The Schonheim lower bound for such a covering design's size: $C(v,k,t) \leq \lceil (\frac{v}{k} \lceil \frac{v-1}{k-1} \cdots \lceil \frac{v-t+1}{k-t+1} \rceil \cdots \rceil \rceil$

EXAMPLES:

```
sage: from sage.combinat.designs.covering_design import schonheim
sage: schonheim(10, 3, 2)
17
sage: schonheim(32, 16, 8)
930
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.covering_design import schonheim
>>> schonheim(Integer(10), Integer(3), Integer(2))
17
>>> schonheim(Integer(32), Integer(16), Integer(8))
930
```

sage.combinat.designs.covering_design.**trivial_covering_design**(v, k, t)

Construct a trivial covering design.

INPUT:

- v – integer; size of point set
- k – integer; cardinality of each block
- t – integer; cardinality of sets being covered

OUTPUT:

A trivial (v, k, t) covering design

EXAMPLES:

```
sage: C = trivial_covering_design(8, 3, 1)
sage: print(C)
C(8, 3, 1) = 3
Method: Trivial
0   1   2
0   6   7
3   4   5
sage: C = trivial_covering_design(5, 3, 2)
sage: print(C)
4 <= C(5, 3, 2) <= 10
Method: Trivial
0   1   2
0   1   3
0   1   4
0   2   3
0   2   4
0   3   4
1   2   3
1   2   4
1   3   4
2   3   4
```

```
>>> from sage.all import *
>>> C = trivial_covering_design(Integer(8), Integer(3), Integer(1))
>>> print(C)
C(8, 3, 1) = 3
Method: Trivial
0   1   2
0   6   7
3   4   5
>>> C = trivial_covering_design(Integer(5), Integer(3), Integer(2))
>>> print(C)
```

(continues on next page)

(continued from previous page)

```
4 <= C(5, 3, 2) <= 10
Method: Trivial
0   1   2
0   1   3
0   1   4
0   2   3
0   2   4
0   3   4
1   2   3
1   2   4
1   3   4
2   3   4
```

Note

Cases are:

- $t = 0$: This could be empty, but it's a useful convention to have one block (which is empty if $k = 0$).
- $t = 1$: This contains $\lceil v/k \rceil$ blocks: $[0, ..., k-1], [k, ..., 2k-1], ...$. The last block wraps around if k does not divide v.
- anything else: Just use every k-subset of $[0, 1, ..., v-1]$.

Cython functions for combinatorial designs

This module implements the design methods that need to be somewhat efficient.

Functions

`sage.combinat.designs.designs_pyx.`**`is_covering_array`**(*array*, *strength=None*, *levels=None*, *verbose=False*, *parameters=False*)

Check if the input is a covering array with given strength.

See *sage.combinat.designs.covering_array* for a definition.

INPUT:

- `array` – the Covering Array to be tested
- `strength` – integer; the parameter t of the covering array, such that in any selection of t columns of the array, every t -tuple appears at least once. If set to None then all t > 0 are tested to and the maximal strength is used.
- `levels` – the number of symbols that appear in `array` If set to None, then each unique entry in `array` is counted
- `verbose` – boolean; whether to display some information about the covering array
- `parameters` – boolean; whether to return the parameters of the Covering Array. If set to `True`, the function returns a pair `(boolean_answer,(N,t,k,v))`.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: C = [[1, 1, 1, 0],
```

(continues on next page)

(continued from previous page)

```
....:       [1, 1, 0, 0],
....:       [0, 0, 0]]

sage.combinat.designs.designs_pyx.**is_difference_matrix**(*M*, *G*, *k*, *lmbda=1*, *verbose=False*)

Test if M is a (G, k, λ)-difference matrix.

A matrix M is a (G, k, λ)-difference matrix if its entries are element of G, and if for any two rows R, R' of M and $x \in G$ there are exactly λ values i such that $R_i - R'_i = x$.

INPUT:

- `M` – a matrix with entries from `G`
- `G` – a group
- `k` – integer
- `lmbda` – integer (default: 1)
- `verbose` – boolean; whether to print some information when the answer is `False`

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: q = 3**3
sage: F = GF(q,'x')                                                          #␣
↪needs sage.rings.finite_rings
sage: M = [[x*y for y in F] for x in F]                                      #␣
↪needs sage.rings.finite_rings
sage: is_difference_matrix(M,F,q,verbose=1)                                  #␣
↪needs sage.rings.finite_rings
True

sage: B = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
....:      [0, 1, 2, 3, 4, 2, 3, 4, 0, 1],
....:      [0, 2, 4, 1, 3, 3, 0, 2, 4, 1]]
sage: G = GF(5)
sage: B = [[G(b) for b in R] for R in B]
sage: is_difference_matrix(list(zip(*B)),G,3,2)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> q = Integer(3)**Integer(3)
```

(continues on next page)

(continued from previous page)

```
>>> F = GF(q,'x')                                                              #␣
↪needs sage.rings.finite_rings
>>> M = [[x*y for y in F] for x in F]                                          #␣
↪needs sage.rings.finite_rings
>>> is_difference_matrix(M,F,q,verbose=Integer(1))                               ␣
↪     # needs sage.rings.finite_rings
True

>>> B = [[Integer(0), Integer(0), Integer(0), Integer(0), Integer(0), Integer(0),␣
↪Integer(0), Integer(0), Integer(0), Integer(0)],
...      [Integer(0), Integer(1), Integer(2), Integer(3), Integer(4), Integer(2),␣
↪Integer(3), Integer(4), Integer(0), Integer(1)],
...      [Integer(0), Integer(2), Integer(4), Integer(1), Integer(3), Integer(3),␣
↪Integer(0), Integer(2), Integer(4), Integer(1)]]
>>> G = GF(Integer(5))
>>> B = [[G(b) for b in R] for R in B]
>>> is_difference_matrix(list(zip(*B)),G,Integer(3),Integer(2))
True
```

Bad input:

```
sage: # needs sage.rings.finite_rings
sage: for R in M: R.append(None)
sage: is_difference_matrix(M,F,q,verbose=1)
The matrix has 28 columns but k=27
False
sage: for R in M: _=R.pop(-1)
sage: M.append([None]*3**3)
sage: is_difference_matrix(M,F,q,verbose=1)
The matrix has 28 rows instead of lambda(|G|-1+2u)+mu=1(27-1+2.0)+1=27
False
sage: _= M.pop(-1)
sage: for R in M: R[-1] = 0
sage: is_difference_matrix(M,F,q,verbose=1)
Columns 0 and 26 generate 0 exactly 27 times instead of the expected mu(=1)
False
sage: for R in M: R[-1] = 1
sage: M[-1][-1] = 0
sage: is_difference_matrix(M,F,q,verbose=1)
Columns 0 and 26 do not generate all elements of G exactly lambda(=1) times.
The element x appeared 0 times as a difference.
False
```

```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> for R in M: R.append(None)
>>> is_difference_matrix(M,F,q,verbose=Integer(1))
The matrix has 28 columns but k=27
False
>>> for R in M: _=R.pop(-Integer(1))
>>> M.append([None]*Integer(3)**Integer(3))
>>> is_difference_matrix(M,F,q,verbose=Integer(1))
```

(continues on next page)

(continued from previous page)

```
The matrix has 28 rows instead of lambda(|G|-1+2u)+mu=1(27-1+2.0)+1=27
False
>>> _= M.pop(-Integer(1))
>>> for R in M: R[-Integer(1)] = Integer(0)
>>> is_difference_matrix(M,F,q,verbose=Integer(1))
Columns 0 and 26 generate 0 exactly 27 times instead of the expected mu(=1)
False
>>> for R in M: R[-Integer(1)] = Integer(1)
>>> M[-Integer(1)][-Integer(1)] = Integer(0)
>>> is_difference_matrix(M,F,q,verbose=Integer(1))
Columns 0 and 26 do not generate all elements of G exactly lambda(=1) times.
The element x appeared 0 times as a difference.
False
```

sage.combinat.designs.designs_pyx.**is_group_divisible_design**(*groups*, *blocks*, *v*, *G=None*, *K=None*, *lambd=1*, *verbose=False*)

Check that input is a Group Divisible Design on $\{0, \ldots, v-1\}$.

For more information on Group Divisible Designs, see *GroupDivisibleDesign*.

INPUT:

- `groups` – a partition of X. If set to `None` the groups are guessed automatically, and the function returns `(True, guessed_groups)` instead of `True`
- `blocks` – collection of blocks
- `v` – integers; size of the ground set assumed to be $X = \{0, ..., v-1\}$
- `G` – list of integers of which the sizes of the groups must be elements. Set to `None` (automatic guess) by default
- `K` – list of integers of which the sizes of the blocks must be elements. Set to `None` (automatic guess) by default
- `lambd` – value of λ. Set to 1 by default
- `verbose` – boolean; whether to display some information when the design is not a GDD

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_group_divisible_design
sage: TD = designs.transversal_design(4,10)                                    #␣
↪needs sage.modules
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: is_group_divisible_design(groups,TD,40,lambd=1)                          #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_group_divisible_design
>>> TD = designs.transversal_design(Integer(4),Integer(10))                    ␣
↪              # needs sage.modules
>>> groups = [list(range(i*Integer(10),(i+Integer(1))*Integer(10))) for i in␣
↪range(Integer(4))]
>>> is_group_divisible_design(groups,TD,Integer(40),lambd=Integer(1))          ␣
↪              # needs sage.modules
True
```

sage.combinat.designs.designs_pyx.**is_orthogonal_array**(*OA*, *k*, *n*, *t=2*, *verbose=False*, *terminology='OA'*)

Check that the integer matrix OA is an $OA(k, n, t)$.

See *orthogonal_array()* for a definition.

INPUT:

- `OA` – the Orthogonal Array to be tested
- `k`, `n`, `t` – integers; only implemented for $t = 2$
- `verbose` – boolean; whether to display some information when `OA` is not an orthogonal array $OA(k, n)$
- `terminology` – string; how to phrase the information when `verbose = True`. Possible values are "OA", "$MOLS$"

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: OA = designs.orthogonal_arrays.build(8,9)
sage: is_orthogonal_array(OA,8,9)
True
sage: is_orthogonal_array(OA,8,10)
False
sage: OA[4][3] = 1
sage: is_orthogonal_array(OA,8,9)
False
sage: is_orthogonal_array(OA,8,9,verbose=True)
Columns 0 and 3 are not orthogonal
False
sage: is_orthogonal_array(OA,8,9, verbose=True, terminology='MOLS')
Squares 0 and 3 are not orthogonal
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> OA = designs.orthogonal_arrays.build(Integer(8),Integer(9))
>>> is_orthogonal_array(OA,Integer(8),Integer(9))
True
>>> is_orthogonal_array(OA,Integer(8),Integer(10))
False
>>> OA[Integer(4)][Integer(3)] = Integer(1)
>>> is_orthogonal_array(OA,Integer(8),Integer(9))
False
>>> is_orthogonal_array(OA,Integer(8),Integer(9),verbose=True)
Columns 0 and 3 are not orthogonal
False
>>> is_orthogonal_array(OA,Integer(8),Integer(9), verbose=True, terminology='MOLS
↪')
Squares 0 and 3 are not orthogonal
False
```

sage.combinat.designs.designs_pyx.**is_pairwise_balanced_design**(*blocks*, *v*, *K=None*, *lambd=1*, *verbose=False*)

Check that input is a Pairwise Balanced Design (PBD) on $\{0, \ldots, v-1\}$.

For more information on Pairwise Balanced Designs (PBD), see *PairwiseBalancedDesign*.

INPUT:

- `blocks` – collection of blocks
- `v` – integers; size of the ground set assumed to be $X = \{0, ..., v-1\}$
- `K` – list of integers of which the sizes of the blocks must be elements; set to `None` (automatic guess) by default
- `lambd` – value of λ (default: 1)
- `verbose` – boolean; whether to display some information when the design is not a PBD

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_pairwise_balanced_design
sage: sts = designs.steiner_triple_system(9)
sage: is_pairwise_balanced_design(sts,9,[3],1)
True
sage: TD = designs.transversal_design(4,10).blocks()                          #␣
↪needs sage.modules
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: is_pairwise_balanced_design(TD + groups, 40, [4,10], 1, verbose=True)   #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_pairwise_balanced_design
>>> sts = designs.steiner_triple_system(Integer(9))
>>> is_pairwise_balanced_design(sts,Integer(9),[Integer(3)],Integer(1))
True
>>> TD = designs.transversal_design(Integer(4),Integer(10)).blocks()          ␣
↪              # needs sage.modules
>>> groups = [list(range(i*Integer(10),(i+Integer(1))*Integer(10))) for i in␣
↪range(Integer(4))]
>>> is_pairwise_balanced_design(TD + groups, Integer(40), [Integer(4),
↪Integer(10)], Integer(1), verbose=True)     # needs sage.modules
True
```

`sage.combinat.designs.designs_pyx.`**`is_projective_plane`**(*blocks*, *verbose=False*)

Test whether the blocks form a projective plane on $\{0, ..., v-1\}$.

A *projective plane* is an incidence structure that has the following properties:

1. Given any two distinct points, there is exactly one line incident with both of them.
2. Given any two distinct lines, there is exactly one point incident with both of them.
3. There are four points such that no line is incident with more than two of them.

For more informations, see Wikipedia article Projective_plane.

is_t_design() can also check if an incidence structure is a projective plane with the parameters $v = k^2+k+1$, $t = 2$ and $l = 1$.

INPUT:

- `blocks` – collection of blocks
- `verbose` – whether to print additional information

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_projective_plane
sage: p = designs.projective_plane(4)
sage: b = p.blocks()
sage: is_projective_plane(b, verbose=True)
True

sage: p = designs.projective_plane(2)
sage: b = p.blocks()
sage: is_projective_plane(b)
True
sage: b[0][2] = 5
sage: is_projective_plane(b, verbose=True)
the pair (0,5) has been seen 2 times but lambda=1
False

sage: is_projective_plane([[0,1,2],[1,2,4]], verbose=True)
the pair (0,3) has been seen 0 times but lambda=1
False

sage: is_projective_plane([[1]], verbose=True)
First block has less than 3 points.
False

sage: p = designs.projective_plane(2)
sage: b = p.blocks()
sage: b[2].append(4)
sage: is_projective_plane(b, verbose=True)
a block has size 4 while K=[3]
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_projective_plane
>>> p = designs.projective_plane(Integer(4))
>>> b = p.blocks()
>>> is_projective_plane(b, verbose=True)
True

>>> p = designs.projective_plane(Integer(2))
>>> b = p.blocks()
>>> is_projective_plane(b)
True
>>> b[Integer(0)][Integer(2)] = Integer(5)
>>> is_projective_plane(b, verbose=True)
the pair (0,5) has been seen 2 times but lambda=1
False

>>> is_projective_plane([[Integer(0),Integer(1),Integer(2)],[Integer(1),
↪Integer(2),Integer(4)]], verbose=True)
the pair (0,3) has been seen 0 times but lambda=1
False
```

(continues on next page)

(continued from previous page)

```
>>> is_projective_plane([[Integer(1)]], verbose=True)
First block has less than 3 points.
False

>>> p = designs.projective_plane(Integer(2))
>>> b = p.blocks()
>>> b[Integer(2)].append(Integer(4))
>>> is_projective_plane(b, verbose=True)
a block has size 4 while K=[3]
False
```

sage.combinat.designs.designs_pyx.**is_quasi_difference_matrix**(*M*, *G*, *k*, *lmbda*, *mu*, *u*, *verbose=False*)

Test if the matrix is a $(G, k; \lambda, \mu; u)$-quasi-difference matrix.

Let G be an abelian group of order n. A $(n, k; \lambda, \mu; u)$-quasi-difference matrix (QDM) is a matrix Q_{ij} with $\lambda(n-1+2u)+\mu$ rows and k columns, with each entry either equal to `None` (i.e. the 'missing entries') or to an element of G. Each column contains exactly λu empty entries, and each row contains at most one `None`. Furthermore, for each $1 \leq i < j \leq k$, the multiset

$$\{q_{li} - q_{lj} : 1 \leq l \leq \lambda(n-1+2u)+\mu, \text{ with } q_{li} \text{ and } q_{lj} \text{ not empty}\}$$

contains λ times every nonzero element of G and contains μ times 0.

INPUT:

- `M` – a matrix with entries from `G` (or equal to `None` for missing entries)
- `G` – a group
- `k`, `lmbda`, `mu`, `u` – integers
- `verbose` – boolean; whether to print some information when the answer is `False`

EXAMPLES:

Differences matrices:

```
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: q = 3**3
sage: F = GF(q,'x')                                                          #␣
↪needs sage.rings.finite_rings
sage: M = [[x*y for y in F] for x in F]                                      #␣
↪needs sage.rings.finite_rings
sage: is_quasi_difference_matrix(M,F,q,1,1,0,verbose=1)                      #␣
↪needs sage.rings.finite_rings
True

sage: B = [[0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
....:      [0, 1, 2, 3, 4, 2, 3, 4, 0, 1],
....:      [0, 2, 4, 1, 3, 3, 0, 2, 4, 1]]
sage: G = GF(5)
sage: B = [[G(b) for b in R] for R in B]
sage: is_quasi_difference_matrix(list(zip(*B)),G,3,2,2,0)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> q = Integer(3)**Integer(3)
>>> F = GF(q,'x')                                                    #␣
↪needs sage.rings.finite_rings
>>> M = [[x*y for y in F] for x in F]                                 #␣
↪needs sage.rings.finite_rings
>>> is_quasi_difference_matrix(M,F,q,Integer(1),Integer(1),Integer(0),
↪verbose=Integer(1))                          # needs sage.rings.finite_rings
True

>>> B = [[Integer(0), Integer(0), Integer(0), Integer(0), Integer(0), Integer(0),␣
↪Integer(0), Integer(0), Integer(0), Integer(0)],
...       [Integer(0), Integer(1), Integer(2), Integer(3), Integer(4), Integer(2),␣
↪Integer(3), Integer(4), Integer(0), Integer(1)],
...       [Integer(0), Integer(2), Integer(4), Integer(1), Integer(3), Integer(3),␣
↪Integer(0), Integer(2), Integer(4), Integer(1)]]
>>> G = GF(Integer(5))
>>> B = [[G(b) for b in R] for R in B]
>>> is_quasi_difference_matrix(list(zip(*B)),G,Integer(3),Integer(2),Integer(2),
↪Integer(0))
True
```

A quasi-difference matrix from the database:

```
sage: from sage.combinat.designs.database import QDM
sage: G,M = QDM[38,1][37,1,1,1][1]()
sage: is_quasi_difference_matrix(M,G,k=6,lmbda=1,mu=1,u=1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM
>>> G,M = QDM[Integer(38),Integer(1)][Integer(37),Integer(1),Integer(1),
↪Integer(1)][Integer(1)]()
>>> is_quasi_difference_matrix(M,G,k=Integer(6),lmbda=Integer(1),mu=Integer(1),
↪u=Integer(1))
True
```

Bad input:

```
sage: is_quasi_difference_matrix(M,G,k=6,lmbda=1,mu=1,u=3,verbose=1)
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.3)+1=43
False
sage: is_quasi_difference_matrix(M,G,k=6,lmbda=1,mu=2,u=1,verbose=1)
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.1)+2=40
False
sage: M[3][1] = None
sage: is_quasi_difference_matrix(M,G,k=6,lmbda=1,mu=1,u=1,verbose=1)
Row 3 contains more than one empty entry
False
sage: M[3][1] = 1
sage: M[6][1] = None
sage: is_quasi_difference_matrix(M,G,k=6,lmbda=1,mu=1,u=1,verbose=1)
```

(continues on next page)

(continued from previous page)

```
Column 1 contains 2 empty entries instead of the expected lambda.u=1.1=1
False
```

```
>>> from sage.all import *
>>> is_quasi_difference_matrix(M,G,k=Integer(6),lmbda=Integer(1),mu=Integer(1),
↪u=Integer(3),verbose=Integer(1))
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.3)+1=43
False
>>> is_quasi_difference_matrix(M,G,k=Integer(6),lmbda=Integer(1),mu=Integer(2),
↪u=Integer(1),verbose=Integer(1))
The matrix has 39 rows instead of lambda(|G|-1+2u)+mu=1(37-1+2.1)+2=40
False
>>> M[Integer(3)][Integer(1)] = None
>>> is_quasi_difference_matrix(M,G,k=Integer(6),lmbda=Integer(1),mu=Integer(1),
↪u=Integer(1),verbose=Integer(1))
Row 3 contains more than one empty entry
False
>>> M[Integer(3)][Integer(1)] = Integer(1)
>>> M[Integer(6)][Integer(1)] = None
>>> is_quasi_difference_matrix(M,G,k=Integer(6),lmbda=Integer(1),mu=Integer(1),
↪u=Integer(1),verbose=Integer(1))
Column 1 contains 2 empty entries instead of the expected lambda.u=1.1=1
False
```

Database of generalised quadrangles with spread

This module implements some construction of generalised quadrangles with spread.

EXAMPLES:

```
sage: GQ, S = designs.generalised_quadrangle_with_spread(4, 16, check=False)
sage: GQ
Incidence structure with 325 points and 1105 blocks
sage: GQ2, O = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: GQ2
Incidence structure with 1105 points and 325 blocks
sage: GQ3 = GQ.dual()
sage: set(GQ3._points) == set(GQ2._points)
True
sage: GQ2.is_isomorphic(GQ3) # long time
True
```

```
>>> from sage.all import *
>>> GQ, S = designs.generalised_quadrangle_with_spread(Integer(4), Integer(16),␣
↪check=False)
>>> GQ
Incidence structure with 325 points and 1105 blocks
>>> GQ2, O = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(4))
>>> GQ2
Incidence structure with 1105 points and 325 blocks
>>> GQ3 = GQ.dual()
>>> set(GQ3._points) == set(GQ2._points)
```

(continues on next page)

(continued from previous page)

```
True
>>> GQ2.is_isomorphic(GQ3) # long time
True
```

sage.combinat.designs.gen_quadrangles_with_spread.**dual_GQ_ovoid**(*GQ*, *O*)

Compute the dual incidence structure of GQ and return the image of O under the dual map

INPUT:

- `GQ` – IncidenceStructure; the generalised quadrangle we want the dual of
- `O` – iterable; the iterable of blocks we want to compute the dual

OUTPUT: a pair `(D, S)` where `D` is the dual of `GQ` and `S` is the dual of `O`

EXAMPLES:

```
sage: from sage.combinat.designs.gen_quadrangles_with_spread import \
....: dual_GQ_ovoid
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(3)
sage: t[0].is_generalized_quadrangle(parameters=True)
(9, 3)
sage: t = dual_GQ_ovoid(*t)
sage: t[0].is_generalized_quadrangle(parameters=True)
(3, 9)
sage: all(x in t[0] for x in t[1])
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.gen_quadrangles_with_spread import dual_GQ_ovoid
>>> t = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(3))
>>> t[Integer(0)].is_generalized_quadrangle(parameters=True)
(9, 3)
>>> t = dual_GQ_ovoid(*t)
>>> t[Integer(0)].is_generalized_quadrangle(parameters=True)
(3, 9)
>>> all(x in t[Integer(0)] for x in t[Integer(1)])
True
```

sage.combinat.designs.gen_quadrangles_with_spread.**generalised_quadrangle_hermitian_with_ovoid**(*q*)

Construct the generalised quadrangle $H(3, q^2)$ with an ovoid.

The GQ has order (q^2, q).

INPUT:

- `q` – integer; a prime power

OUTPUT:

A pair `(D, O)` where `D` is an IncidenceStructure representing the generalised quadrangle and `O` is a list of points of `D` which constitute an ovoid of `D`.

EXAMPLES:

```
sage: t = designs.generalised_quadrangle_hermitian_with_ovoid(4)
sage: t[0]
Incidence structure with 1105 points and 325 blocks
sage: len(t[1])
65
sage: G = t[0].intersection_graph([1])  # line graph
sage: G.is_strongly_regular(True)
(325, 68, 3, 17)
sage: set(t[0].block_sizes())
{17}
```

```
>>> from sage.all import *
>>> t = designs.generalised_quadrangle_hermitian_with_ovoid(Integer(4))
>>> t[Integer(0)]
Incidence structure with 1105 points and 325 blocks
>>> len(t[Integer(1)])
65
>>> G = t[Integer(0)].intersection_graph([Integer(1)])  # line graph
>>> G.is_strongly_regular(True)
(325, 68, 3, 17)
>>> set(t[Integer(0)].block_sizes())
{17}
```

REFERENCES:

For more on $H(3, q^2)$ and the construction implemented here see [PT2009] or [TP1994].

sage.combinat.designs.gen_quadrangles_with_spread.**generalised_quadrangle_symplectic_with_spread**(*q*, *check*=

Construct the symplectic generalised quadrangle $W(3, q)$ with a spread.

The GQ has order (q, q).

INPUT:

- `q` – integer; a prime power
- `check` – boolean; if `True`, then Sage checks that the object built is correct. (default: `True`)

OUTPUT:

A pair `(GQ, S)` where `GQ` is an `IncidenceStructure` representing $W(3, q)$ and `S` is a list of blocks of `GQ` representing a spread.

EXAMPLES:

```
sage: GQ, S = designs.generalised_quadrangle_symplectic_with_spread(2)
sage: GQ
Incidence structure with 15 points and 15 blocks
sage: len(S)
5
```

(continues on next page)

(continued from previous page)

```
sage: GQ.is_generalized_quadrangle(parameters=True)                             #␣
↪needs networkx
(2, 2)
```

```
>>> from sage.all import *
>>> GQ, S = designs.generalised_quadrangle_symplectic_with_spread(Integer(2))
>>> GQ
Incidence structure with 15 points and 15 blocks
>>> len(S)
5
>>> GQ.is_generalized_quadrangle(parameters=True)                               #␣
↪needs networkx
(2, 2)
```

sage.combinat.designs.gen_quadrangles_with_spread.**generalised_quadrangle_with_spread**(*s*, *t*, *existence=False*, *check=True*)

Construct a generalised quadrangle GQ of order (s, t) with a spread S.

INPUT:

- `s`, `t` – integers; order of the generalised quadrangle
- `existence` – boolean;
- `check` – boolean; if `True`, then Sage checks that the object built is correct. (default: `True`)

OUTPUT:

A pair (GQ, S) where GQ is a *IncidenceStructure* representing the generalised quadrangle and S is a list of blocks of GQ representing the spread of GQ.

EXAMPLES:

```
sage: t = designs.generalised_quadrangle_with_spread(2, 2)
sage: t[0]
Incidence structure with 15 points and 15 blocks
sage: len(t[1])
5
sage: t = designs.generalised_quadrangle_with_spread(3, 9)
sage: t[0]
Incidence structure with 112 points and 280 blocks
sage: designs.generalised_quadrangle_with_spread(5, 25, existence=True)
True
sage: (designs.generalised_quadrangle_with_spread(4, 16, check=False))[0]
Incidence structure with 325 points and 1105 blocks
sage: designs.generalised_quadrangle_with_spread(0, 2, existence=True)
False
```

```
>>> from sage.all import *
>>> t = designs.generalised_quadrangle_with_spread(Integer(2), Integer(2))
>>> t[Integer(0)]
```

(continues on next page)

(continued from previous page)

```
Incidence structure with 15 points and 15 blocks
>>> len(t[Integer(1)])
5
>>> t = designs.generalised_quadrangle_with_spread(Integer(3), Integer(9))
>>> t[Integer(0)]
Incidence structure with 112 points and 280 blocks
>>> designs.generalised_quadrangle_with_spread(Integer(5), Integer(25),␣
↪existence=True)
True
>>> (designs.generalised_quadrangle_with_spread(Integer(4), Integer(16),␣
↪check=False))[Integer(0)]
Incidence structure with 325 points and 1105 blocks
>>> designs.generalised_quadrangle_with_spread(Integer(0), Integer(2),␣
↪existence=True)
False
```

sage.combinat.designs.gen_quadrangles_with_spread.**is_GQ_with_spread**(*GQ*, *S*, *s=None*, *t=None*)

Check if GQ is a generalised quadrangle of order (s, t) and check that S is a spread of GQ

INPUT:

- `GQ` – IncidenceStructure; the incidence structure that is supposed to be a generalised quadrangle
- `S` – iterable; the spread of `GQ` as an iterable of the blocks of `GQ`
- `s`, `t` – integers (optional); if (s, t) are given, then we check that `GQ` has order (s, t)

EXAMPLES:

```
sage: from sage.combinat.designs.gen_quadrangles_with_spread import *
sage: t = generalised_quadrangle_hermitian_with_ovoid(3)
sage: is_GQ_with_spread(*t)
Traceback (most recent call last):
...
TypeError: 'int' object is not iterable
sage: t = dual_GQ_ovoid(*t)
sage: is_GQ_with_spread(*t)
True
sage: is_GQ_with_spread(*t, s=3)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.gen_quadrangles_with_spread import *
>>> t = generalised_quadrangle_hermitian_with_ovoid(Integer(3))
>>> is_GQ_with_spread(*t)
Traceback (most recent call last):

>>> is_GQ_with_spread(*t, s=Integer(3))
True
```

Database of small combinatorial designs

This module implements combinatorial designs that cannot be obtained by more general constructions. Most of them come from the Handbook of Combinatorial Designs [DesignHandbook].

All this would only be a dream without the mathematical knowledge and help of Julian R. Abel.

These functions can all be obtained through the `designs.<tab>` functions.

This module implements:

- *CA(11,2,5,3)*, *CA(12,2,7,3)*, *CA(13,2,9,3)*, *CA(14,2,10,3)*, *CA(15,2,20,3)*, *CA(19,2,6,4)*, *CA(21,2,7,4)*, *CA(29,2,7,5)*, *CA(37,2,4,6)*, *CA(39,2,5,6)*, *CA(41,2,6,6)*

Functions

sage.combinat.designs.database.**BIBD_106_6_1**()

Return a (106,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_106_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(106, BIBD_106_6_1())
(106,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_106_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(106), BIBD_106_6_1())
(106,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_111_6_1**()

Return a (111,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_111_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(111, BIBD_111_6_1())
(111,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_111_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(111), BIBD_111_6_1())
(111,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_126_6_1**()

Return a (126,6,1)-BIBD.

This constructions appears in VI.16.92 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_126_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(126, BIBD_126_6_1())
(126,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_126_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(126), BIBD_126_6_1())
(126,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_136_6_1**()

Return a (136,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_136_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(136, BIBD_136_6_1())
(136,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_136_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(136), BIBD_136_6_1())
(136,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_141_6_1**()

Return a (141,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_141_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(141, BIBD_141_6_1())
(141,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_141_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(141), BIBD_141_6_1())
(141,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_171_6_1**()

Return a (171,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_171_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(171, BIBD_171_6_1())
(171,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_171_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(171), BIBD_171_6_1())
(171,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_196_6_1**()

Return a (196,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_196_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(196, BIBD_196_6_1())
(196,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_196_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(196), BIBD_196_6_1())
(196,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_201_6_1**()

Return a (201,6,1)-BIBD.

This constructions appears in II.3.32 from [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_201_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(201, BIBD_201_6_1())
(201,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_201_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(201), BIBD_201_6_1())
(201,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_45_9_8**(*from_code=False*)

Return a $(45, 9, 1)$-BIBD.

This BIBD is obtained from the codewords of minimal weight in the `ExtendedQuadraticResidueCode()` of length 48. This construction appears in VII.11.2 from [DesignHandbook], which cites [HT95].

INPUT:

- `from_code` – boolean; whether to build the design from hardcoded data (default) or from the code object (much longer)

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_45_9_8
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: B = BalancedIncompleteBlockDesign(45, BIBD_45_9_8(), lambd=8); B
(45,9,8)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_45_9_8
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> B = BalancedIncompleteBlockDesign(Integer(45), BIBD_45_9_8(),␣
↪lambd=Integer(8)); B
(45,9,8)-Balanced Incomplete Block Design
```

REFERENCE:

sage.combinat.designs.database.**BIBD_56_11_2**()

Return a symmetric $(56, 11, 2)$-BIBD.

The construction implemented is given in [Hall71].

Note

A symmetric (v, k, λ) BIBD is a (v, k, λ) BIBD with v blocks.

EXAMPLES:

sage: from sage.combinat.designs.database import BIBD_56_11_2 sage: D = IncidenceStructure(BIBD_56_11_2()) # needs sage.libs.gap sage: D.is_t_design(t=2, v=56, k=11, l=2) # needs sage.libs.gap True

sage.combinat.designs.database.**BIBD_66_6_1**()

Return a (66,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://dmgordon.org/cover) where it is attributed to Colin Barker.

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_66_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(66, BIBD_66_6_1())
(66,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_66_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(66), BIBD_66_6_1())
(66,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_76_6_1**()

Return a (76,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://dmgordon.org/cover) where it is attributed to Colin Barker.

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_76_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(76, BIBD_76_6_1())
(76,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_76_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(76), BIBD_76_6_1())
(76,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**BIBD_79_13_2**()

Return a symmetric $(79, 13, 2)$-BIBD.

The construction implemented is the one described in [Aschbacher71]. A typo in that paper was corrected in [Hall71].

Note

A symmetric (v, k, λ) BIBD is a (v, k, λ) BIBD with v blocks.

EXAMPLES:

sage: from sage.combinat.designs.database import BIBD_79_13_2 sage: D = IncidenceStructure(BIBD_79_13_2()) # needs sage.libs.gap sage: D.is_t_design(t=2, v=79, k=13, l=2) # needs sage.libs.gap True

sage.combinat.designs.database.**BIBD_96_6_1**()

Return a (96,6,1)-BIBD.

This BIBD was obtained from La Jolla covering repository (https://dmgordon.org/cover) where it is attributed to Colin Barker.

EXAMPLES:

```
sage: from sage.combinat.designs.database import BIBD_96_6_1
sage: from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
sage: BalancedIncompleteBlockDesign(96, BIBD_96_6_1())
(96,6,1)-Balanced Incomplete Block Design
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import BIBD_96_6_1
>>> from sage.combinat.designs.bibd import BalancedIncompleteBlockDesign
>>> BalancedIncompleteBlockDesign(Integer(96), BIBD_96_6_1())
(96,6,1)-Balanced Incomplete Block Design
```

sage.combinat.designs.database.**DM_12_6_1**()

Return a $(12, 6, 1)$-difference matrix as built in [Hanani75].

This design is Lemma 3.21 from [Hanani75].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_12_6_1
sage: G,M = DM_12_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_12_6_1
>>> G,M = DM_12_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(12,6)
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(12),Integer(6))
```

REFERENCES:

sage.combinat.designs.database.**DM_21_6_1**()

Return a $(21, 6, 1)$-difference matrix.

As explained in the Handbook III.3.50 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_21_6_1
sage: G,M = DM_21_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_21_6_1
>>> G,M = DM_21_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(21,6)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(21),Integer(6))                   ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_24_8_1**()

Return a $(24, 8, 1)$-difference matrix.

As explained in the Handbook III.3.52 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_24_8_1
sage: G,M = DM_24_8_1()
sage: is_difference_matrix(M,G,8,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_24_8_1
>>> G,M = DM_24_8_1()
>>> is_difference_matrix(M,G,Integer(8),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(24,8)
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(24),Integer(8))
```

sage.combinat.designs.database.**DM_273_17_1**()

Return a $(273, 17, 1)$-difference matrix.

Given by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_273_17_1
sage: G,M = DM_273_17_1()                                                   #␣
↪needs sage.schemes
sage: is_difference_matrix(M,G,17,1)                                        #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_273_17_1
```

(continues on next page)

(continued from previous page)

```
>>> G,M = DM_273_17_1()                                                    #␣
↪needs sage.schemes
>>> is_difference_matrix(M,G,Integer(17),Integer(1))                        ␣
↪              # needs sage.schemes
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(273,17)                                #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(273),Integer(17))                ␣
↪              # needs sage.schemes
```

sage.combinat.designs.database.**DM_28_6_1**()

Return a $(28, 6, 1)$-difference matrix.

As explained in the Handbook III.3.54 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_28_6_1
sage: G,M = DM_28_6_1()                                                    #␣
↪needs sage.modules
sage: is_difference_matrix(M,G,6,1)                                        #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_28_6_1
>>> G,M = DM_28_6_1()                                                      #␣
↪needs sage.modules
>>> is_difference_matrix(M,G,Integer(6),Integer(1))                         ␣
↪              # needs sage.modules
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(28,6)                                  #␣
↪needs sage.modules
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(28),Integer(6))                  ␣
↪              # needs sage.modules
```

sage.combinat.designs.database.**DM_33_6_1**()

Return a $(33, 6, 1)$-difference matrix.

As explained in the Handbook III.3.56 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_33_6_1
sage: G,M = DM_33_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_33_6_1
>>> G,M = DM_33_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(33,6)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(33),Integer(6))                   ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_35_6_1**()

Return a $(35, 6, 1)$-difference matrix.

As explained in the Handbook III.3.58 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_35_6_1
sage: G,M = DM_35_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_35_6_1
>>> G,M = DM_35_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(35,6)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(35),Integer(6))                   ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_36_9_1**()

Return a $(36, 9, 1)$-difference matrix.

As explained in the Handbook III.3.59 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_36_9_1
sage: G,M = DM_36_9_1()                                                    #␣
↪needs sage.modules
sage: is_difference_matrix(M,G,9,1)                                        #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_36_9_1
>>> G,M = DM_36_9_1()                                                    #␣
↪needs sage.modules
>>> is_difference_matrix(M,G,Integer(9),Integer(1))                        ␣
↪              # needs sage.modules
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(36,9)                                  #␣
↪needs sage.modules
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(36),Integer(9))                  ␣
↪              # needs sage.modules
```

sage.combinat.designs.database.**DM_39_6_1**()

Return a $(39, 6, 1)$-difference matrix.

As explained in the Handbook III.3.61 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_39_6_1
sage: G,M = DM_39_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_39_6_1
>>> G,M = DM_39_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

The design is available from the general constructor:

```
sage: designs.difference_matrix(39,6,existence=True)                       #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> designs.difference_matrix(Integer(39),Integer(6),existence=True)
↪              # needs sage.rings.finite_rings
True
```

sage.combinat.designs.database.**DM_44_6_1**()

Return a $(44, 6, 1)$-difference matrix.

As explained in the Handbook III.3.64 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_44_6_1
sage: G,M = DM_44_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_44_6_1
>>> G,M = DM_44_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(44,6)
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(44),Integer(6))
```

sage.combinat.designs.database.**DM_45_7_1**()

Return a $(45, 7, 1)$-difference matrix.

As explained in the Handbook III.3.65 [DesignHandbook].

… whose description contained a very deadly typo, kindly fixed by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_45_7_1
sage: G,M = DM_45_7_1()
sage: is_difference_matrix(M,G,7,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_45_7_1
>>> G,M = DM_45_7_1()
>>> is_difference_matrix(M,G,Integer(7),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(45,7)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(45),Integer(7))                   ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_48_9_1**()

Return a $(48, 9, 1)$-difference matrix.

As explained in the Handbook III.3.67 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_48_9_1
sage: G,M = DM_48_9_1()                                                     #␣
↪needs sage.rings.finite_rings
sage: is_difference_matrix(M,G,9,1)                                         #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_48_9_1
>>> G,M = DM_48_9_1()                                                       #␣
↪needs sage.rings.finite_rings
>>> is_difference_matrix(M,G,Integer(9),Integer(1))                         ␣
↪              # needs sage.rings.finite_rings
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(48,9)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(48),Integer(9))                   ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_51_6_1**()

Return a $(51, 6, 1)$-difference matrix.

As explained in the Handbook III.3.69 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_51_6_1
sage: G,M = DM_51_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_51_6_1
>>> G,M = DM_51_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(51,6)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(51),Integer(6))                   ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_52_6_1**()

Return a $(52, 6, 1)$-difference matrix.

As explained in the Handbook III.3.70 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_52_6_1
sage: G,M = DM_52_6_1()                                                     #␣
↪needs sage.rings.finite_rings
sage: is_difference_matrix(M,G,6,1)                                         #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_52_6_1
>>> G,M = DM_52_6_1()                                                       #␣
↪needs sage.rings.finite_rings
>>> is_difference_matrix(M,G,Integer(6),Integer(1))                         ␣
↪              # needs sage.rings.finite_rings
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(52,6)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(52),Integer(6))                   ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_55_7_1**()

Return a $(55, 7, 1)$-difference matrix.

As explained in the Handbook III.3.72 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_55_7_1
sage: G,M = DM_55_7_1()
sage: is_difference_matrix(M,G,7,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_55_7_1
>>> G,M = DM_55_7_1()
>>> is_difference_matrix(M,G,Integer(7),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(55,7)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(55),Integer(7))                    ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_56_8_1**()

Return a $(56, 8, 1)$-difference matrix.

As explained in the Handbook III.3.73 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_56_8_1
sage: G,M = DM_56_8_1()                                                     #␣
↪needs sage.rings.finite_rings
sage: is_difference_matrix(M,G,8,1)                                         #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_56_8_1
>>> G,M = DM_56_8_1()                                                     #␣
↪needs sage.rings.finite_rings
>>> is_difference_matrix(M,G,Integer(8),Integer(1))                          ␣
↪              # needs sage.rings.finite_rings
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(56,8)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(56),Integer(8))
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_57_8_1**()

Return a $(57, 8, 1)$-difference matrix.

Given by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_57_8_1
sage: G,M = DM_57_8_1()                                                    #␣
↪needs sage.rings.finite_rings sage.schemes
sage: is_difference_matrix(M,G,8,1)                                        #␣
↪needs sage.rings.finite_rings sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_57_8_1
>>> G,M = DM_57_8_1()                                                    #␣
↪needs sage.rings.finite_rings sage.schemes
>>> is_difference_matrix(M,G,Integer(8),Integer(1))
↪              # needs sage.rings.finite_rings sage.schemes
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(57,8)                                  #␣
↪needs sage.rings.finite_rings sage.schemes
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(57),Integer(8))
↪              # needs sage.rings.finite_rings sage.schemes
```

sage.combinat.designs.database.**DM_60_6_1**()

Return a $(60, 6, 1)$-difference matrix.

As explained in [JulianAbel13].

REFERENCES:

http://onlinelibrary.wiley.com/doi/10.1002/jcd.21384/abstract

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_60_6_1
sage: G,M = DM_60_6_1()
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_60_6_1
>>> G,M = DM_60_6_1()
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(60,6)
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(60),Integer(6))
```

sage.combinat.designs.database.**DM_75_8_1**()

Return a $(75, 8, 1)$-difference matrix.

As explained in the Handbook III.3.75 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_75_8_1
sage: G,M = DM_75_8_1()
sage: is_difference_matrix(M,G,8,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_75_8_1
>>> G,M = DM_75_8_1()
>>> is_difference_matrix(M,G,Integer(8),Integer(1))
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(75,8)                                   #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(75),Integer(8))                    ␣
↪              # needs sage.rings.finite_rings
```

sage.combinat.designs.database.**DM_993_32_1**()

Return a $(993, 32, 1)$-difference matrix.

Given by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_difference_matrix
sage: from sage.combinat.designs.database import DM_993_32_1
sage: G,M = DM_993_32_1()                                                   #␣
↪needs sage.schemes
```

(continues on next page)

(continued from previous page)

```
sage: is_difference_matrix(M,G,32,1)                                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_difference_matrix
>>> from sage.combinat.designs.database import DM_993_32_1
>>> G,M = DM_993_32_1()                                                       #␣
↪needs sage.schemes
>>> is_difference_matrix(M,G,Integer(32),Integer(1))                           ␣
↪              # needs sage.schemes
True
```

Can be obtained from the constructor:

```
sage: _ = designs.difference_matrix(993,32)                                   #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> _ = designs.difference_matrix(Integer(993),Integer(32))                   ␣
↪              # needs sage.schemes
```

sage.combinat.designs.database.**HigmanSimsDesign**()

Return the Higman-Sims designs, which is a $(176, 50, 14)$-BIBD.

This design is built from a from the *WittDesign* W on 24 points. We define two points a, b, and consider:

- The collection W_a of all blocks of W containing a but not containing b.
- The collection W_b of all blocks of W containing b but not containing a.

The design is then obtained from the incidence structure produced by the blocks $A \in W_a$ and $B \in W_b$ whose intersection has cardinality 2. This construction, due to M.Smith, can be found in [KY04] or in 10.A.(v) of [BL1984].

EXAMPLES:

```
sage: H = designs.HigmanSimsDesign(); H                    # optional - gap_
↪package_design
Incidence structure with 176 points and 176 blocks
sage: H.is_t_design(return_parameters=1)                   # optional - gap_
↪package_design
(True, (2, 176, 50, 14))
```

```
>>> from sage.all import *
>>> H = designs.HigmanSimsDesign(); H                   # optional - gap_
↪package_design
Incidence structure with 176 points and 176 blocks
>>> H.is_t_design(return_parameters=Integer(1))                  # optional -␣
↪gap_package_design
(True, (2, 176, 50, 14))
```

Make sure that the automorphism group of this designs is isomorphic to the automorphism group of the *HigmanSimsGraph()*. Note that the first of those permutation groups acts on 176 points, while the second acts on 100:

```
sage: gH = H.automorphism_group()                                    # optional - gap_
↪package_design
sage: gG = graphs.HigmanSimsGraph().automorphism_group()     # optional - gap_
↪package_design
sage: gG.is_isomorphic(gG)                          # long time, optional - gap_
↪package_design
True
```

```
>>> from sage.all import *
>>> gH = H.automorphism_group()                                    # optional - gap_
↪package_design
>>> gG = graphs.HigmanSimsGraph().automorphism_group()     # optional - gap_
↪package_design
>>> gG.is_isomorphic(gG)                          # long time, optional - gap_
↪package_design
True
```

REFERENCE:

sage.combinat.designs.database.**MOLS_10_2**()

Return a pair of MOLS of order 10.

Data obtained from http://www.cecm.sfu.ca/organics/papers/lam/paper/html/POLS10/POLS10.html

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_
↪latin_squares
sage: from sage.combinat.designs.database import MOLS_10_2
sage: MOLS = MOLS_10_2()                                                    #␣
↪needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))                    #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
↪squares
>>> from sage.combinat.designs.database import MOLS_10_2
>>> MOLS = MOLS_10_2()                                                    #␣
↪needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))                    #␣
↪needs sage.modules
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(2,10)
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(2),Integer(10))
True
```

sage.combinat.designs.database.**MOLS_12_5**()

Return 5 MOLS of order 12.

These MOLS have been found by Brendan McKay.

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_
↪latin_squares
sage: from sage.combinat.designs.database import MOLS_12_5
sage: MOLS = MOLS_12_5()                                                    #␣
↪needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))                    #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
↪squares
>>> from sage.combinat.designs.database import MOLS_12_5
>>> MOLS = MOLS_12_5()                                                      #␣
↪needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))                      #␣
↪needs sage.modules
True
```

sage.combinat.designs.database.**MOLS_14_4**()

Return four MOLS of order 14.

These MOLS were shared by Ian Wanless. The first proof of existence was given in [Todorov12].

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_
↪latin_squares
sage: from sage.combinat.designs.database import MOLS_14_4
sage: MOLS = MOLS_14_4()                                                    #␣
↪needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))                    #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
↪squares
>>> from sage.combinat.designs.database import MOLS_14_4
>>> MOLS = MOLS_14_4()                                                      #␣
↪needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))                      #␣
↪needs sage.modules
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(4,14)                              #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(4),Integer(14))              ␣
↪              # needs sage.schemes
True
```

REFERENCE:

sage.combinat.designs.database.**MOLS_15_4**()

Return 4 MOLS of order 15.

These MOLS were shared by Ian Wanless.

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_
↪latin_squares
sage: from sage.combinat.designs.database import MOLS_15_4
sage: MOLS = MOLS_15_4()                                                        #␣
↪needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))                        #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
↪squares
>>> from sage.combinat.designs.database import MOLS_15_4
>>> MOLS = MOLS_15_4()                                                          #␣
↪needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))                          #␣
↪needs sage.modules
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(4,15)                              #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(4),Integer(15))              ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**MOLS_18_3**()

Return 3 MOLS of order 18.

These MOLS were shared by Ian Wanless.

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_
↪latin_squares
sage: from sage.combinat.designs.database import MOLS_18_3
sage: MOLS = MOLS_18_3()                                                    #␣
↪needs sage.modules
sage: print(are_mutually_orthogonal_latin_squares(MOLS))                    #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
↪squares
>>> from sage.combinat.designs.database import MOLS_18_3
>>> MOLS = MOLS_18_3()                                                      #␣
↪needs sage.modules
>>> print(are_mutually_orthogonal_latin_squares(MOLS))                      #␣
↪needs sage.modules
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(3,18)
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(3),Integer(18))
True
```

sage.combinat.designs.database.**OA_10_1620**()

Return an OA(10,1620).

This is obtained through the generalized Brouwer-van Rees construction. Indeed, $1620 = 144.11 + (36 = 4.9)$ and there exists an $OA(10, 153) - OA(10, 9)$.

Note

This function should be removed once *find_brouwer_van_rees_with_one_truncated_column()* can handle all incomplete orthogonal arrays obtained through *incomplete_orthogonal_array()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_1620
sage: OA = OA_10_1620()                          # not tested -- ~7s
sage: is_orthogonal_array(OA,10,1620,2) # not tested -- ~7s
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_1620
>>> OA = OA_10_1620()                          # not tested -- ~7s
```

(continues on next page)

(continued from previous page)

```
>>> is_orthogonal_array(OA,Integer(10),Integer(1620),Integer(2)) # not tested -- ~
↪7s
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10,1620)                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(10),Integer(1620))          ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_10_205**()

Return an $OA(10, 205)$.

Julian R. Abel shared the following construction, which originally appeared in Theorem 8.7 of [Greig99], and can in Lemmas 5.14-5.16 of [ColDin01]:

> Consider a $PG(2, 4^2)$ containing a Baer subplane (i.e. a $PG(2, 4)$) B and a point $p \in B$. Among the $4^2 + 1 = 17$ lines of $PG(2, 4^2)$ containing p:
>
> - $4 + 1 = 5$ lines intersect B on 5 points
> - $4^2 - 4 = 12$ lines intersect B on 1 point
>
> As those lines are disjoint outside of B we can use them as groups to build a GDD on $16^2 + 16 + 1 - (4^4 + 4 + 1) = 252$ points. By keeping only 9 lines of the second kind, however, we obtain a $(204, \{9, 13, 17\})$-GDD of type 12^5.16^9.
>
> We complete it into a PBD by adding a block $g \cup \{204\}$ for each group g. We then build an OA from this PBD using the fact that all blocks of size 9 are disjoint.

See also

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_205
sage: OA = OA_10_205()                                                         #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,10,205,2)                                         #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_205
>>> OA = OA_10_205()                                                          #␣
↪needs sage.schemes
```

(continues on next page)

(continued from previous page)

```
>>> is_orthogonal_array(OA,Integer(10),Integer(205),Integer(2))
↪                        # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10,205)
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(10),Integer(205))
↪               # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_10_469**()

Return an OA(10,469).

This construction appears in [Brouwer80]. It is based on the same technique used in *brouwer_separable_design()*.

Julian R. Abel's instructions:

> Brouwer notes that a cyclic $PG(2,37)$ (or $(1407,38,1)$-BIBD) can be obtained with a base block containing $13, 9$, and 16 points in each residue class mod 3. Thus, by reducing the $PG(2,37)$ to its points congruent to $0 \pmod 3$ one obtains a $(469, \{9,13,16\})$-PBD which consists in 3 symmetric designs, i.e. 469 blocks of size 9, 469 blocks of size 13, and 469 blocks of size 16.
>
> For each block size s, one can build a matrix with size $s \times 469$ in which each block is a row, and such that each point of the PBD appears once per column. By multiplying a row of an $OA(9,s) - s.OA(9,1)$ with the rows of the matrix one obtains a parallel class of a resolvable $OA(9,469)$.
>
> Add to this the parallel class of all blocks $(0,0,...),(1,1,...),...$ to obtain a resolvable $OA(9,469)$ equivalent to an $OA(10,469)$.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_469
sage: OA = OA_10_469()                    # long time
↪needs sage.schemes
sage: is_orthogonal_array(OA,10,469,2)   # long time
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_469
>>> OA = OA_10_469()                    # long time
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(10),Integer(469),Integer(2))   # long time
↪                        # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10,469)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(10),Integer(469))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_10_520**()

Return an OA(10,520).

This design is built by the slightly more general construction *OA_520_plus_x()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_520
sage: OA = OA_10_520()                                                  #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,10,520,2)                                  #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_520
>>> OA = OA_10_520()                                                    #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(10),Integer(520),Integer(2))         ␣
↪                       # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10,520)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(10),Integer(520))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_10_796**()

Return an OA(10,796).

Construction shared by Julian R. Abel, from [AC07]:

> Truncate one block of a $TD(17, 47)$ to size 13, then add an extra point. Form a block on each group plus the extra point: we obtain a $(796, \{13, 16, 17, 47, 48\})$-PBD in which only the extra point lies in more than one block of size 48 (and each other point lies in exactly 1 such block).
>
> For each block B (of size k say) not containing the extra point, construct a $TD(10, k) - k.TD(k, 1)$ on $I(10)XB$. For each block B (of size $k = 47$ or 48) containing the extra point, construct a $TD(10, k) -$

$TD(k,1)$ on $I(10)XB$, the size 1 hole being on $I(10)XP$ where P is the extra point. Finally form 1 extra block of size 10 on $I(10)XP$.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_10_796
sage: OA = OA_10_796()                                                    #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,10,796,2)                                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_10_796
>>> OA = OA_10_796()                                                      #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(10),Integer(796),Integer(2))           ␣
↪                        # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(10,796)                      #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(10),Integer(796))      ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_11_160**()

Return an OA(11,160).

Published by Julian R. Abel in [Ab1995]. Uses the fact that $160 = 2^5 \times 5$ is a product of a power of 2 and a prime number.

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_160
sage: OA = OA_11_160()                                                    #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,11,160,2)                                    #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_11_160
>>> OA = OA_11_160()                                                    #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(11),Integer(160),Integer(2))          ␣
↪                      # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11,160)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11),Integer(160))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_11_185**()

Return an OA(11,185).

The construction is given in [Greig99]. In Julian R. Abel's words:

> Start with a $PG(2,16)$ with a 7 points Fano subplane; outside this plane there are $7(17-3)=98$ points on a line of the subplane and $273-98-7=168$ other points. Greig notes that the subdesign consisting of these 168 points is a $(168,\{10,12\})-PBD$. Now add the 17 points of a line disjoint from this subdesign (e.g. a line of the Fano subplane). This line will intersect every line of the 168 point subdesign in 1 point. Thus the new line sizes are 11 and 13, plus a unique line of size 17, giving a $(185,\{11,13,17\}$-PBD and an $OA(11,185)$.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_185
sage: OA = OA_11_185()                                                  #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,11,185,2)                                  #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_11_185
>>> OA = OA_11_185()                                                    #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(11),Integer(185),Integer(2))          ␣
↪                      # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11,185)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11),Integer(185))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_11_254**()

Return an OA(11,254).

This constructions appears in [Greig99].

From a cyclic $PG(2,19)$ whose base blocks contains 7,9, and 4 points in the congruence classes mod 3, build a $(254,11,13,16) - PBD$ by ignoring the points of a congruence class. There exist $OA(12,11), OA(12,13), OA(12,16)$, which gives the $OA(11,254)$.

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_254
sage: OA = OA_11_254()                                                  #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,11,254,2)                                  #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_11_254
>>> OA = OA_11_254()                                                    #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(11),Integer(254),Integer(2))         ␣
↪                      # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11,254)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11),Integer(254))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_11_640**()

Return an OA(11,640).

Published by Julian R. Abel in [Ab1995] (uses the fact that $640 = 2^7 \times 5$ is the product of a power of 2 and a prime number).

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_640
sage: OA = OA_11_640()                    # not tested (too long)                 #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,11,640,2)  # not tested (too long)                 #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_11_640
>>> OA = OA_11_640()                    # not tested (too long)                 #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(11),Integer(640),Integer(2))  # not tested␣
↪(too long)                 # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11,640)                            #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11),Integer(640))            ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_11_80**()

Return an OA(11,80).

As explained in the Handbook III.3.76 [DesignHandbook]. Uses the fact that $80 = 2^4 \times 5$ and that 5 is prime.

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_11_80
sage: OA = OA_11_80()                                                          #␣
↪needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA,11,80,2)                                          #␣
↪needs sage.rings.finite_rings sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_11_80
>>> OA = OA_11_80()                                                          #␣
↪needs sage.rings.finite_rings sage.schemes
>>> is_orthogonal_array(OA,Integer(11),Integer(80),Integer(2))                  ␣
↪                       # needs sage.rings.finite_rings sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(11,80)                            #␣
↪needs sage.rings.finite_rings sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(11),Integer(80))            ␣
↪              # needs sage.rings.finite_rings sage.schemes
True
```

sage.combinat.designs.database.**OA_12_522**()

Return an OA(12,522).

This design is built by the slightly more general construction *OA_520_plus_x()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_12_522
sage: OA = OA_12_522()                                                         #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,12,522,2)                                         #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_12_522
>>> OA = OA_12_522()                                                         #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(12),Integer(522),Integer(2))                 ␣
↪                       # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(12,522)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(12),Integer(522))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_14_524**()

Return an OA(14,524).

This design is built by the slightly more general construction *OA_520_plus_x()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_14_524
sage: OA = OA_14_524()                                                  #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,14,524,2)                                  #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_14_524
>>> OA = OA_14_524()                                                    #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(14),Integer(524),Integer(2))         ␣
↪                      # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(14,524)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(14),Integer(524))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_15_112**()

Return an OA(15,112).

Published by Julian R. Abel in [Ab1995]. Uses the fact that $112 = 2^4 \times 7$ and that 7 is prime.

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_112
sage: OA = OA_15_112()                                                          #␣
↪needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA,15,112,2)                                          #␣
↪needs sage.rings.finite_rings sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_15_112
>>> OA = OA_15_112()                                                          #␣
↪needs sage.rings.finite_rings sage.schemes
>>> is_orthogonal_array(OA,Integer(15),Integer(112),Integer(2))                ␣
↪                      # needs sage.rings.finite_rings sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(15,112)                            #␣
↪needs sage.rings.finite_rings sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(15),Integer(112))           ␣
↪              # needs sage.rings.finite_rings sage.schemes
True
```

sage.combinat.designs.database.**OA_15_224**()

Return an OA(15,224).

Published by Julian R. Abel in [Ab1995] (uses the fact that $224 = 2^5 \times 7$ is a product of a power of 2 and a prime number).

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_224
sage: OA = OA_15_224()                    # not tested (too long)               #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,15,224,2)  # not tested (too long)                 #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_15_224
>>> OA = OA_15_224()                    # not tested (too long)                #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(15),Integer(224),Integer(2))  # not tested␣
↪(too long)                  # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(15,224)                           #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(15),Integer(224))           ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_15_896**()

Return an OA(15,896).

Uses the fact that $896 = 2^7 \times 7$ is the product of a power of 2 and a prime number.

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_15_896
sage: OA = OA_15_896()                  # not tested (too long, ~2min)          #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,15,896,2)  # not tested (too long)                 #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_15_896
>>> OA = OA_15_896()                    # not tested (too long, ~2min)          #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(15),Integer(896),Integer(2))  # not tested␣
↪(too long)                  # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(15,896)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(15),Integer(896))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_16_176**()

Return an OA(16,176).

Published by Julian R. Abel in [Ab1995]. Uses the fact that $176 = 2^4 \times 11$ is a product of a power of 2 and a prime number.

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array

>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_16_176
>>> OA = OA_16_176()                                                    #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(16),Integer(176),Integer(2))         ␣
↪                      # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(16,176)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(16),Integer(176))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_16_208**()

Return an OA(16,208).

Published by Julian R. Abel in [Ab1995]. Uses the fact that $208 = 2^4 \times 13$ is a product of 2 and a prime number.

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_16_208
sage: OA = OA_16_208()                  # not tested (too long)                 #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,16,208,2)  # not tested (too long)                 #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_16_208
>>> OA = OA_16_208()                  # not tested (too long)                 #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(16),Integer(208),Integer(2))  # not tested␣
↪(too long)                 # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(16,208)                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(16),Integer(208))          ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_17_560**()

Return an OA(17,560).

This OA is built in Corollary 2.2 of [Thwarts].

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_17_560
sage: OA = OA_17_560()                                                        #␣
↪needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA,17,560,2)                                        #␣
↪needs sage.rings.finite_rings sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_17_560
>>> OA = OA_17_560()                                                          #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.rings.finite_rings sage.schemes
>>> is_orthogonal_array(OA,Integer(17),Integer(560),Integer(2))                ␣
↪                        # needs sage.rings.finite_rings sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(17,560)                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(17),Integer(560))          ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_20_352**()

Return an OA(20,352).

Published by Julian R. Abel in [Ab1995] (uses the fact that $352 = 2^5 \times 11$ is the product of a power of 2 and a prime number).

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_352
sage: OA = OA_20_352()                    # not tested (~25s)                  #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,20,352,2)  # not tested (~25s)                    #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_20_352
>>> OA = OA_20_352()                    # not tested (~25s)                    #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(20),Integer(352),Integer(2))  # not tested (~
↪25s)                      # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,352)                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(20),Integer(352))
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_20_416**()

Return an OA(20,416).

Published by Julian R. Abel in [Ab1995] (uses the fact that $416 = 2^5 \times 13$ is the product of a power of 2 and a prime number).

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_416
sage: OA = OA_20_416()                    # not tested (~35s)                    #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,20,416,2)  # not tested                             #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_20_416
>>> OA = OA_20_416()                    # not tested (~35s)                    #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(20),Integer(416),Integer(2))  # not tested
↪                        # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,416)                             #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(20),Integer(416))
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_20_544**()

Return an OA(20,544).

Published by Julian R. Abel in [Ab1995] (uses the fact that $544 = 2^5 \times 17$ is the product of a power of 2 and a prime number).

See also

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_20_544
sage: OA = OA_20_544()                  # not tested (too long ~1mn)            #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,20,544,2)  # not tested                            #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_20_544
>>> OA = OA_20_544()                  # not tested (too long ~1mn)            #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(20),Integer(544),Integer(2))  # not tested    ␣
↪                      # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(20,544)                            #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(20),Integer(544))            ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_25_1262**()

Return an OA(25,1262).

The construction is given in [Greig99]. In Julian R. Abel's words:

> Start with a cyclic $PG(2, 43)$ or $(1893, 44, 1)$-BIBD whose base block contains respectively $12, 13$ and 19 point in the residue classes mod 3. In the resulting BIBD, remove one of the three classes: the result is a $(1262, \{25, 31, 32\})$-PBD, from which the $OA(25, 1262)$ is obtained.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_25_1262
sage: OA = OA_25_1262()                          # not tested -- too long
sage: is_orthogonal_array(OA,25,1262,2) # not tested -- too long
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
```

(continues on next page)

(continued from previous page)

```
>>> from sage.combinat.designs.database import OA_25_1262
>>> OA = OA_25_1262()                          # not tested -- too long
>>> is_orthogonal_array(OA,Integer(25),Integer(1262),Integer(2)) # not tested --␣
↪too long
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(25,1262)                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(25),Integer(1262))          ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_520_plus_x**(x)

Return an $OA(10+x, 520+x)$.

The construction shared by Julian R. Abel works for *OA(10, 520)*, *OA(12, 522)*, and *OA(14, 524)*.

Let $n = 520 + x$ and $k = 10 + x$. Build a $TD(17, 31)$. Remove $8 - x$ points contained in a common block, add a new point p and create a block $g_i \cup \{p\}$ for every (possibly truncated) group g_i. The result is a $(520 + x, 9 + x, 16, 17, 31, 32) - PBD$. Note that all blocks of size ≥ 30 only intersect on p, and that the unique block B_9 of size 9 intersects all blocks of size 32 on one point. Now:

- Build an $OA(k, 16) - 16.OA(k, 16)$ for each block of size 16
- Build an $OA(k, 17) - 17.OA(k, 17)$ for each block of size 17
- Build an $OA(k, 31) - OA(k, 1)$ for each block of size 31 (with the hole on p).
- Build an $OA(k, 32) - 2.OA(k, 1)$ for each block B of size 32 (with the holes on p and $B \cap B_9$).
- Build an $OA(k, 9)$ on B_9.

Only a row $[p, p, ...]$ is missing from the $OA(10 + x, 520 + x)$

This construction is used in *OA(10, 520)*, *OA(12, 522)*, and *OA(14, 524)*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_520_plus_x
sage: OA = OA_520_plus_x(0)                    # not tested (already tested in OA_
↪10_520)
sage: is_orthogonal_array(OA,10,520,2)  # not tested (already tested in OA_10_520)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_520_plus_x
>>> OA = OA_520_plus_x(Integer(0))                    # not tested (already tested␣
↪in OA_10_520)
>>> is_orthogonal_array(OA,Integer(10),Integer(520),Integer(2))  # not tested␣
```

(continues on next page)

(continued from previous page)

```
↪(already tested in OA_10_520)
True
```

sage.combinat.designs.database.**OA_7_18**()

Return an OA(7,18).

Proved in [JulianAbel13].

See also

sage.combinat.designs.orthogonal_arrays.OA_from_quasi_difference_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_18
sage: OA = OA_7_18()
sage: is_orthogonal_array(OA,7,18,2)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_7_18
>>> OA = OA_7_18()
>>> is_orthogonal_array(OA,Integer(7),Integer(18),Integer(2))
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(7,18)                              #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(7),Integer(18))              ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_7_66**()

Return an OA(7,66).

Construction shared by Julian R. Abel.

See also

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_66
```

(continues on next page)

(continued from previous page)

```
sage: OA = OA_7_66()                                                        #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,7,66,2)                                        #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_7_66
>>> OA = OA_7_66()                                                          #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(7),Integer(66),Integer(2))               ␣
↪                       # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(7,66)                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(7),Integer(66))          ␣
↪               # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_7_68**()

Return an OA(7,68).

Construction shared by Julian R. Abel.

See also

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_68
sage: OA = OA_7_68()                                                        #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,7,68,2)                                        #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_7_68
>>> OA = OA_7_68()                                                          #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(7),Integer(68),Integer(2))               ␣
```

(continues on next page)

(continued from previous page)

```
↪                        # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(7,68)                              #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(7),Integer(68))              ␣
↪               # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_7_74**()

Return an OA(7,74).

Construction shared by Julian R. Abel.

See also

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_7_74
sage: OA = OA_7_74()                                                            #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,7,74,2)                                            #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_7_74
>>> OA = OA_7_74()                                                             #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(7),Integer(74),Integer(2))                   ␣
↪                        # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(7,74)                              #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(7),Integer(74))              ␣
↪               # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_8_69**()

Return an OA(8,69).

Construction shared by Julian R. Abel.

See also

sage.combinat.designs.orthogonal_arrays.OA_from_PBD()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_8_69
sage: OA = OA_8_69()                                                          #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,8,69,2)                                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_8_69
>>> OA = OA_8_69()                                                          #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(8),Integer(69),Integer(2))                ␣
↪                       # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(8,69)                            #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(8),Integer(69))           ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_8_76**()

Return an OA(8,76).

Construction shared by Julian R. Abel.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_8_76
```

(continues on next page)

(continued from previous page)

```
sage: OA = OA_8_76()                                                        #␣
↪needs sage.schemes
sage: is_orthogonal_array(OA,8,76,2)                                        #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_8_76
>>> OA = OA_8_76()                                                          #␣
↪needs sage.schemes
>>> is_orthogonal_array(OA,Integer(8),Integer(76),Integer(2))                ␣
↪                       # needs sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(8,76)                          #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(8),Integer(76))          ␣
↪               # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_9_1078**()

Return an OA(9,1078).

This is obtained through the generalized Brouwer-van Rees construction. Indeed, $1078 = 89.11 + (99 = 9.11)$ and there exists an $OA(9, 100) - OA(9, 11)$.

Note

This function should be removed once *find_brouwer_van_rees_with_one_truncated_column()* can handle all incomplete orthogonal arrays obtained through *incomplete_orthogonal_array()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_1078
sage: OA = OA_9_1078()                          # not tested -- ~3s
sage: is_orthogonal_array(OA,9,1078,2) # not tested -- ~3s
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_9_1078
>>> OA = OA_9_1078()                            # not tested -- ~3s
>>> is_orthogonal_array(OA,Integer(9),Integer(1078),Integer(2)) # not tested -- ~
```

(continues on next page)

(continued from previous page)

```
↪3s
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,1078)                    #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(1078))    ␣
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_9_120**()

Return an OA(9,120).

Construction shared by Julian R. Abel:

> From a resolvable $(120, 8, 1) - BIBD$, one can obtain 7 $MOLS(120)$ or a resolvable $TD(8, 120)$ by forming a resolvable $TD(8, 8) - 8.TD(8, 1)$ on $I_8 \times B$ for each block B in the BIBD. This gives a $TD(8, 120) - 120TD(8, 1)$ (which is resolvable as the BIBD is resolvable).

RBIBD_120_8_1()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_120
sage: OA = OA_9_120()                                                   #␣
↪needs sage.modules sage.schemes
sage: is_orthogonal_array(OA,9,120,2)                                   #␣
↪needs sage.modules sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_9_120
>>> OA = OA_9_120()                                                     #␣
↪needs sage.modules sage.schemes
>>> is_orthogonal_array(OA,Integer(9),Integer(120),Integer(2))          ␣
↪                      # needs sage.modules sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,120)                     #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(120))
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_9_135**()

Return an OA(9,135).

Construction shared by Julian R. Abel:

> This design can be built by Wilson's method ($135 = 8.16 + 7$) applied to an Orthogonal Array $OA(9 + 7, 16)$ with 7 groups truncated to size 1 in such a way that a block contain 0, 1 or 3 points of the truncated groups.
>
> This is possible, because $PG(2, 2)$ (the projective plane over $GF(2)$) is a subdesign in $PG(2, 16)$ (the projective plane over $GF(16)$); in a cyclic $PG(2, 16)$ or $BIBD(273, 17, 1)$ the points $\equiv 0 \pmod{39}$ form such a subdesign (note that $273 = 16^2 + 16 + 1$ and $273 = 39 \times 7$ and $7 = 2^2 + 2 + 1$).

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_135
sage: OA = OA_9_135()                                                          #␣
↪needs sage.rings.finite_rings sage.schemes
sage: is_orthogonal_array(OA,9,135,2)                                          #␣
↪needs sage.rings.finite_rings sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_9_135
>>> OA = OA_9_135()                                                          #␣
↪needs sage.rings.finite_rings sage.schemes
>>> is_orthogonal_array(OA,Integer(9),Integer(135),Integer(2))
↪                       # needs sage.rings.finite_rings sage.schemes
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,135)                            #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(135))
↪              # needs sage.schemes
True
```

As this orthogonal array requires a $(273, 17, 1)$ cyclic difference set, we check that it is available:

```
sage: G,D = designs.difference_family(273,17,1); G                             #␣
↪needs sage.libs.pari
Ring of integers modulo 273
```

```
>>> from sage.all import *
>>> G,D = designs.difference_family(Integer(273),Integer(17),Integer(1)); G
↪                        # needs sage.libs.pari
Ring of integers modulo 273
```

sage.combinat.designs.database.**OA_9_1612**()

Return an OA(9,1612).

This is obtained through the generalized Brouwer-van Rees construction. Indeed, $1612 = 89.17 + (99 = 9.11)$ and there exists an $OA(9, 100) - OA(9, 11)$.

Note

This function should be removed once *find_brouwer_van_rees_with_one_truncated_column()* can handle all incomplete orthogonal arrays obtained through *incomplete_orthogonal_array()*.

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_1612
sage: OA = OA_9_1612()                          # not tested -- ~6s
sage: is_orthogonal_array(OA,9,1612,2) # not tested -- ~6s
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_9_1612
>>> OA = OA_9_1612()                          # not tested -- ~6s
>>> is_orthogonal_array(OA,Integer(9),Integer(1612),Integer(2)) # not tested -- ~
↪6s
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,1612)                    #
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(1612))
↪              # needs sage.schemes
True
```

sage.combinat.designs.database.**OA_9_40**()

Return an OA(9,40).

As explained in the Handbook III.3.62 [DesignHandbook]. Uses the fact that $40 = 2^3 \times 5$ and that 5 is prime.

sage.combinat.designs.orthogonal_arrays.OA_n_times_2_pow_c_from_matrix()

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: from sage.combinat.designs.database import OA_9_40
sage: OA = OA_9_40()                                                    #␣
↪needs sage.rings.finite_rings
sage: is_orthogonal_array(OA,9,40,2)                                    #␣
↪needs sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> from sage.combinat.designs.database import OA_9_40
>>> OA = OA_9_40()                                                    #␣
↪needs sage.rings.finite_rings
>>> is_orthogonal_array(OA,Integer(9),Integer(40),Integer(2))          ␣
↪                       # needs sage.rings.finite_rings
True
```

The design is available from the general constructor:

```
sage: designs.orthogonal_arrays.is_available(9,40)                      #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(9),Integer(40))     ␣
↪               # needs sage.schemes
True
```

sage.combinat.designs.database.**QDM_19_6_1_1_1**()

Return a $(19, 6; 1, 1; 1)$-quasi-difference matrix.

Used to build an $OA(6, 20)$

Given in the Handbook III.3.49 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_19_6_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_19_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_19_6_1_1_1
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_19_6_1_1_1()
```

(continues on next page)

(continued from previous page)

```
>>> is_quasi_difference_matrix(M,G,Integer(6),Integer(1),Integer(1),Integer(1))
True
```

sage.combinat.designs.database.**QDM_21_5_1_1_1**()

Return a $(21, 5; 1, 1; 1)$-quasi-difference matrix.

Used to build an $OA(5, 22)$

Given in the Handbook III.3.51 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_21_5_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_21_5_1_1_1()
sage: is_quasi_difference_matrix(M,G,5,1,1,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_21_5_1_1_1
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_21_5_1_1_1()
>>> is_quasi_difference_matrix(M,G,Integer(5),Integer(1),Integer(1),Integer(1))
True
```

sage.combinat.designs.database.**QDM_21_6_1_1_5**()

Return a $(21, 6; 1, 1; 5)$-quasi-difference matrix.

Used to build an $OA(6, 26)$

Given in the Handbook III.3.53 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_21_6_1_1_5
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_21_6_1_1_5()
sage: is_quasi_difference_matrix(M,G,6,1,1,5)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_21_6_1_1_5
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_21_6_1_1_5()
>>> is_quasi_difference_matrix(M,G,Integer(6),Integer(1),Integer(1),Integer(5))
True
```

sage.combinat.designs.database.**QDM_25_6_1_1_5**()

Return a $(25, 6; 1, 1; 5)$-quasi-difference matrix.

Used to build an $OA(6, 30)$

Given in the Handbook III.3.55 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_25_6_1_1_5
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_25_6_1_1_5()                                                    #␣
↪needs sage.modules
sage: is_quasi_difference_matrix(M,G,6,1,1,5)                                   #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_25_6_1_1_5
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_25_6_1_1_5()                                                      #␣
↪needs sage.modules
>>> is_quasi_difference_matrix(M,G,Integer(6),Integer(1),Integer(1),Integer(5))  ␣
↪                                  # needs sage.modules
True
```

sage.combinat.designs.database.**QDM_33_6_1_1_1**()

Return a $(33, 6; 1, 1; 1)$-quasi-difference matrix.

Used to build an $OA(6, 34)$

Given in the Handbook III.3.57 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_33_6_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_33_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_33_6_1_1_1
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_33_6_1_1_1()
>>> is_quasi_difference_matrix(M,G,Integer(6),Integer(1),Integer(1),Integer(1))
True
```

sage.combinat.designs.database.**QDM_35_7_1_1_7**()

Return a $(35, 7; 1, 1; 7)$-quasi-difference matrix.

Used to build an $OA(7, 42)$

As explained in the Handbook III.3.63 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_35_7_1_1_7
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_35_7_1_1_7()
sage: is_quasi_difference_matrix(M,G,7,1,1,7)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_35_7_1_1_7
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_35_7_1_1_7()
>>> is_quasi_difference_matrix(M,G,Integer(7),Integer(1),Integer(1),Integer(7))
True
```

sage.combinat.designs.database.**QDM_37_6_1_1_1**()

Return a $(37, 6; 1, 1; 1)$-quasi-difference matrix.

Used to build an $OA(6, 38)$

Given in the Handbook III.3.60 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_37_6_1_1_1
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_37_6_1_1_1()
sage: is_quasi_difference_matrix(M,G,6,1,1,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_37_6_1_1_1
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_37_6_1_1_1()
>>> is_quasi_difference_matrix(M,G,Integer(6),Integer(1),Integer(1),Integer(1))
True
```

sage.combinat.designs.database.**QDM_45_7_1_1_9**()

Return a $(45, 7; 1, 1; 9)$-quasi-difference matrix.

Used to build an $OA(7, 54)$

As explained in the Handbook III.3.71 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_45_7_1_1_9
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_45_7_1_1_9()
sage: is_quasi_difference_matrix(M,G,7,1,1,9)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_45_7_1_1_9
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_45_7_1_1_9()
>>> is_quasi_difference_matrix(M,G,Integer(7),Integer(1),Integer(1),Integer(9))
True
```

sage.combinat.designs.database.**QDM_54_7_1_1_8**()

Return a $(54, 7; 1, 1; 8)$-quasi-difference matrix.

Used to build an $OA(7, 62)$

As explained in the Handbook III.3.74 [DesignHandbook].

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_54_7_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_54_7_1_1_8()
sage: is_quasi_difference_matrix(M,G,7,1,1,8)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_54_7_1_1_8
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_54_7_1_1_8()
>>> is_quasi_difference_matrix(M,G,Integer(7),Integer(1),Integer(1),Integer(8))
True
```

sage.combinat.designs.database.**QDM_57_9_1_1_8**()

Return a $(57, 9; 1, 1; 8)$-quasi-difference matrix.

Used to build an $OA(9, 65)$

Construction shared by Julian R. Abel

EXAMPLES:

```
sage: from sage.combinat.designs.database import QDM_57_9_1_1_8
sage: from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
sage: G,M = QDM_57_9_1_1_8()                                                #␣
↪needs sage.schemes
sage: is_quasi_difference_matrix(M,G,9,1,1,8)                               #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import QDM_57_9_1_1_8
>>> from sage.combinat.designs.designs_pyx import is_quasi_difference_matrix
>>> G,M = QDM_57_9_1_1_8()                                                  #␣
↪needs sage.schemes
>>> is_quasi_difference_matrix(M,G,Integer(9),Integer(1),Integer(1),Integer(8))  ␣
↪                                  # needs sage.schemes
True
```

sage.combinat.designs.database.**RBIBD_120_8_1**()

Return a resolvable $BIBD(120, 8, 1)$.

This function output a list `L` of 17×15 blocks such that `L[i*15:(i+1)*15]` is a partition of 120.

Construction shared by Julian R. Abel:

> Seiden's method: Start with a cyclic $(273, 17, 1) - BIBD$ and let B be an hyperoval, i.e. a set of 18 points which intersects any block of the BIBD in either 0 points (153 blocks) or 2 points (120 blocks). Dualise this design and take these last 120 blocks as points in the design; blocks in the design will correspond to the $273 - 18 = 255$ non-hyperoval points.
>
> The design is also resolvable. In the original $PG(2, 16)$ take any point T in the hyperoval and consider a block $B1$ containing T. The 15 points in $B1$ that do not belong to the hyperoval correspond to 15 blocks forming a parallel class in the dualised design. The other 16 parallel classes come in a similar way, by using point T and the other 16 blocks containing T.

OA_9_120()

EXAMPLES:

```
sage: from sage.combinat.designs.database import RBIBD_120_8_1
sage: from sage.combinat.designs.bibd import is_pairwise_balanced_design
sage: RBIBD = RBIBD_120_8_1()                                                  #␣
↪needs sage.modules
sage: is_pairwise_balanced_design(RBIBD,120,[8])                               #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.database import RBIBD_120_8_1
>>> from sage.combinat.designs.bibd import is_pairwise_balanced_design
>>> RBIBD = RBIBD_120_8_1()                                                  #␣
↪needs sage.modules
>>> is_pairwise_balanced_design(RBIBD,Integer(120),[Integer(8)])               ␣
↪              # needs sage.modules
True
```

It is indeed resolvable, and the parallel classes are given by 17 slices of consecutive 15 blocks:

```
sage: for i in range(17):                                                      #␣
↪needs sage.modules
....:     assert len(set(sum(RBIBD[i*15:(i+1)*15],[]))) == 120
```

```
>>> from sage.all import *
>>> for i in range(Integer(17)):                                               ␣
↪     # needs sage.modules
...     assert len(set(sum(RBIBD[i*Integer(15):(i+Integer(1))*Integer(15)],[])))␣
↪== Integer(120)
```

The BIBD is available from the constructor:

```
sage: _ = designs.balanced_incomplete_block_design(120,8)                      #␣
↪needs sage.modules
```

```
>>> from sage.all import *
>>> _ = designs.balanced_incomplete_block_design(Integer(120),Integer(8))      ␣
↪              # needs sage.modules
```

sage.combinat.designs.database.**ca_11_2_5_3**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_11_2_5_3
```

(continues on next page)

(continued from previous page)

```
sage: C = ca_11_2_5_3()
sage: is_covering_array(C,2,3)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_11_2_5_3
>>> C = ca_11_2_5_3()
>>> is_covering_array(C,Integer(2),Integer(3))
True
```

sage.combinat.designs.database.**ca_12_2_7_3**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_12_2_7_3
sage: C = ca_12_2_7_3()
sage: is_covering_array(C,2,3)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_12_2_7_3
>>> C = ca_12_2_7_3()
>>> is_covering_array(C,Integer(2),Integer(3))
True
```

sage.combinat.designs.database.**ca_13_2_9_3**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_13_2_9_3
sage: C = ca_13_2_9_3()
sage: is_covering_array(C,2,3)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_13_2_9_3
>>> C = ca_13_2_9_3()
>>> is_covering_array(C,Integer(2),Integer(3))
True
```

sage.combinat.designs.database.**ca_14_2_10_3**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_14_2_10_3
sage: C = ca_14_2_10_3()
sage: is_covering_array(C,2,3)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_14_2_10_3
>>> C = ca_14_2_10_3()
>>> is_covering_array(C,Integer(2),Integer(3))
True
```

sage.combinat.designs.database.**ca_15_2_20_3**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from [Nur2004]

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_15_2_20_3
sage: C = ca_15_2_20_3()
sage: is_covering_array(C,2,3)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_15_2_20_3
>>> C = ca_15_2_20_3()
>>> is_covering_array(C,Integer(2),Integer(3))
True
```

sage.combinat.designs.database.**ca_19_2_6_4**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_19_2_6_4
sage: C = ca_19_2_6_4()
sage: is_covering_array(C,2,4)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_19_2_6_4
>>> C = ca_19_2_6_4()
>>> is_covering_array(C,Integer(2),Integer(4))
True
```

sage.combinat.designs.database.**ca_21_2_7_4**()

Return a CA with the given parameters. This CA is proven to be optimal. This CA is also uniform.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_21_2_7_4
sage: C = ca_21_2_7_4()
sage: is_covering_array(C,2,4)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_21_2_7_4
>>> C = ca_21_2_7_4()
>>> is_covering_array(C,Integer(2),Integer(4))
True
```

sage.combinat.designs.database.**ca_29_2_7_5**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_29_2_7_5
sage: C = ca_29_2_7_5()
sage: is_covering_array(C,2,5)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_29_2_7_5
>>> C = ca_29_2_7_5()
>>> is_covering_array(C,Integer(2),Integer(5))
True
```

sage.combinat.designs.database.**ca_37_2_4_6**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_37_2_4_6
sage: C = ca_37_2_4_6()
sage: is_covering_array(C,2,6)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
```

(continues on next page)

(continued from previous page)

```
>>> from sage.combinat.designs.database import ca_37_2_4_6
>>> C = ca_37_2_4_6()
>>> is_covering_array(C,Integer(2),Integer(6))
True
```

sage.combinat.designs.database.**ca_39_2_5_6**()

Return a CA with the given parameters. This CA is proven to be optimal.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_39_2_5_6
sage: C = ca_39_2_5_6()
sage: is_covering_array(C,2,6)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_39_2_5_6
>>> C = ca_39_2_5_6()
>>> is_covering_array(C,Integer(2),Integer(6))
True
```

sage.combinat.designs.database.**ca_41_2_6_6**()

Return a CA with the given parameters. This CA is proven to be optimal. This CA is also uniform.

Data obtained from https://zenodo.org/records/1476059

EXAMPLES:

```
sage: from sage.combinat.designs.designs_pyx import is_covering_array
sage: from sage.combinat.designs.database import ca_41_2_6_6
sage: C = ca_41_2_6_6()
sage: is_covering_array(C,2,6)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.designs_pyx import is_covering_array
>>> from sage.combinat.designs.database import ca_41_2_6_6
>>> C = ca_41_2_6_6()
>>> is_covering_array(C,Integer(2),Integer(6))
True
```

sage.combinat.designs.database.**cyclic_shift**(l, i)

Difference families

This module gathers everything related to difference families. One can build a difference family (or check that it can be built) with *difference_family()*:

```
sage: G,F = designs.difference_family(13,4,1)                                 #␣
↪needs sage.libs.pari sage.modules
```

```
>>> from sage.all import *
>>> G,F = designs.difference_family(Integer(13),Integer(4),Integer(1))
↪                        # needs sage.libs.pari sage.modules
```

It defines the following functions:

are_complementary_difference_sets()	Check if A and B are complementary difference sets over the group G.
are_hadamard_difference_set_parameters()	Check whether (v,k,lmbda) is of the form (4N^2, 2N^2 - N, N^2 - N).
are_mcfarland_1973_parameters()	Test whether (v,k,lmbda) is a triple that can be obtained from the construction from [McF1973].
block_stabilizer()	Compute the left stabilizer of the block B under the action of G.
complementary_difference_sets()	Compute complementary difference sets over a group of order $n = 2m + 1$.
complementary_difference_setsI()	Construct complementary difference sets in a group of order $n \cong 3 \mod 4$, n a prime power.
complementary_difference_setsII()	Construct complementary difference sets in a group of order $n = p^t$, where $p \cong 5 \mod 8$ and $t \cong 1, 2, 3 \mod 4$.
complementary_difference_setsIII()	Construct complementary difference sets in a group of order $n = 2m + 1$, where $4m + 3$ is a prime power.
df_q_6_1()	Return a $(q, 6, 1)$-difference family over the finite field K.
difference_family()	Return a (k, l)-difference family on an Abelian group of cardinality v.
get_fixed_relative_difference_set()	Construct an equivalent relative difference set fixed by the size of the set.
group_law()	Return a triple (identity, operation, inverse) that define the operations on the group G.
hadamard_difference_set_product()	Make a product of two Hadamard difference sets.
is_difference_family()	Check whether D forms a difference family in the group G.
is_fixed_relative_difference_set()	Check if the relative difference set R is fixed by q.
is_relative_difference_set()	Check if R is a difference set of G relative to H, with the given parameters.
is_supplementary_difference_set()	Check that the sets in Ks are $n - \{v; k_1, ..., k_n; \lambda\}$ supplementary difference sets over group G of order v.
mcfarland_1973_construction()	Return a difference set.
one_cyclic_tiling()	Given a subset A of the cyclic additive group $G = Z/nZ$ return another subset B so that $A + B = G$ and $\|A\|\|B\| = n$ (i.e. any element of G is uniquely expressed as a sum $a + b$ with a in A and b in B).
one_radical_difference_family()	Search for a radical difference family on K using dancing links algorithm.
radical_difference_family()	Return a (v,k,l)-radical difference family.
radical_difference_set()	Return a difference set made of a cyclotomic coset in the finite field K and with parameters k and l.
relative_difference_set_from_homomorphism()	Construct $R((q^N - 1)/(q - 1), n, q^{N-1}, q^{N-2}d)$ where $nd = q - 1$.

continues on next page

Table 2 – continued from previous page

relative_difference_set_from_m_sequence()	Construct $R((q^N-1)/(q-1), q-1, q^{N-1}, q^{N-2})$ where `q` is a prime power and $N \geq 2$.
singer_difference_set()	Return a difference set associated to the set of hyperplanes in a projective space of dimension d over $GF(q)$.
skew_spin_goethals_seidel_difference_family()	Construct skew spin type Goethals-Seidel difference family with parameters $(n; k_1, k_2, k_3, k_4; \lambda)$.
skew_supplementary_difference_set()	Construct $4-\{n; n_1, n_2, n_3, n_4; \lambda\}$ supplementary difference sets, where S_1 is skew and $n_1+n_2+n_3+n_4 = n+\lambda$.
skew_supplementary_difference_set_over_polynomial_ring()	Construct skew supplementary difference sets over a polynomial ring of order `n`.
skew_supplementary_difference_set_with_paley_todd()	Construct $4-\{n; n_1, n_2, n_3, n_4; \lambda\}$ skew supplementary difference sets where S_1 is the Paley-Todd difference set.
spin_goethals_seidel_difference_family()	Construct a spin type Goethals-Seidel difference family with parameters $(n; k_1, k_2, k_3, k_4; \lambda)$.
supplementary_difference_set_from_rel_diff_se	Construct $4-\{2v; v, v+1, v, v; 2v\}$ supplementary difference sets where $q = 2v+1$.
supplementary_difference_set_hadamard()	Construct $4-\{n; n_1, n_2, n_3, n_4; \lambda\}$ supplementary difference sets, where $n_1+n_2+n_3+n_4 = n+\lambda$.
turyn_1965_3x3xK()	Return a difference set in either $C_3 \times C_3 \times C_4$ or $C_3 \times C_3 \times C_2 \times C_2$ with parameters $v=36$, $k=15$, $\lambda=6$.
twin_prime_powers_difference_set()	Return a difference set on $GF(p) \times GF(p+2)$.

Functions

sage.combinat.designs.difference_family.**_construct_gs_difference_family_from_full**(*S1*, *S2*, *mu*)

Construct a spin type Goethals-Seidel difference family given the first two sets.

This construction is described in [Djo2024]. Given the first two sets S_1, S_2, and the multiplier μ, the last two sets are computed as $S_3 = \mu S_2$, $S_4 = \mu S_3$.

The sets should contain elements of the additive group of integers modulo n.

INPUT:

- `S1` – list of integer modulo n; the first set
- `S2` – list of integer modulo n; the second set

OUTPUT:

The Goethals-Seidel difference family `(S_1, S_2, S_3, S_4)`.

sage.combinat.designs.difference_family.**_construct_gs_difference_family_from_compact**(*rep1*, *rep2*, *H*, *mu*)

Construct a spin type Goethals-Seidel difference family given a compact representation of the first two sets.

This construction is described in [Djo2024]. Given a subgroup H of a group G, and two sets of representatives rep_1, rep_2 we can construct the first two sets: $S_1 = \bigcup_{x \in rep_1} xH$ and $S_2 = \bigcup_{x \in rep_2} xH$. The list `H` should contain elements of the additive group of integers modulo n.

The other two sets are constructed using *`_construct_gs_difference_family_from_full()`*.

INPUT:

- `rep1` – list of integers; the first set of representatives
- `rep2` – list of integers; the second set of representatives
- `H` – list of integers modulo n; the subgroup used to generate the first two sets

OUTPUT:

The Goethals-Seidel difference family `(S_1, S_2, S_3, S_4)`.

sage.combinat.designs.difference_family.**are_complementary_difference_sets**(*G*, *A*, *B*, *verbose=False*)

Check if `A` and `B` are complementary difference sets over the group `G`.

According to [Sze1971], two sets A, B of size m are complementary difference sets over a group G of size $2m+1$ if:

1. they are $2 - \{2m+1; m, m; m-1\}$ supplementary difference sets
2. A is skew, i.e. $a \in A$ implies $-a \notin A$

INPUT:

- `G` – a group of odd order
- `A` – set of elements of `G`
- `B` – set of elements of `G`
- `verbose` – boolean (default: `False`); if `True` the function will be verbose when the sets do not satisfy the constraints

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import are_complementary_
↪difference_sets
sage: are_complementary_difference_sets(Zmod(7), [1, 2, 4], [1, 2, 4])
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import are_complementary_
↪difference_sets
>>> are_complementary_difference_sets(Zmod(Integer(7)), [Integer(1), Integer(2),␣
↪Integer(4)], [Integer(1), Integer(2), Integer(4)])
True
```

If `verbose=True`, the function will be verbose:

```
sage: are_complementary_difference_sets(Zmod(7), [1, 2, 5], [1, 2, 4],␣
↪verbose=True)
The sets are not supplementary difference sets with lambda = 2
False
```

```
>>> from sage.all import *
>>> are_complementary_difference_sets(Zmod(Integer(7)), [Integer(1), Integer(2),␣
↪Integer(5)], [Integer(1), Integer(2), Integer(4)], verbose=True)
The sets are not supplementary difference sets with lambda = 2
False
```

See also

is_supplementary_difference_set()

sage.combinat.designs.difference_family.**are_hadamard_difference_set_parameters**(*v*, *k*, *lmbda*)

Check whether `(v,k,lmbda)` is of the form `(4N^2, 2N^2 - N, N^2 - N)`.

INPUT:

- `(v, k, lmbda)` – parameters of a difference set

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import are_hadamard_difference_
↪set_parameters
sage: are_hadamard_difference_set_parameters(36, 15, 6)
True
sage: are_hadamard_difference_set_parameters(60, 13, 5)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import are_hadamard_difference_
↪set_parameters
>>> are_hadamard_difference_set_parameters(Integer(36), Integer(15), Integer(6))
True
>>> are_hadamard_difference_set_parameters(Integer(60), Integer(13), Integer(5))
False
```

sage.combinat.designs.difference_family.**are_mcfarland_1973_parameters**(*v*, *k*, *lmbda*, *return_parameters=False*)

Test whether `(v,k,lmbda)` is a triple that can be obtained from the construction from [McF1973].

See *mcfarland_1973_construction()*.

INPUT:

- `v`, `k`, `lmbda` – integers; parameters of the difference family
- `return_parameters` – boolean (default: `False`); if `True`, return a pair `(True, (q, s))` so that `(q,s)` can be used in the function *mcfarland_1973_construction()* to actually build a `(v,k, lmbda)`-difference family. Or `(False, None)` if the construction is not possible

EXAMPLES:

```
sage: # needs sage.rings.finite_rings
sage: from sage.combinat.designs.difference_family import are_mcfarland_1973_
↪parameters
sage: are_mcfarland_1973_parameters(64, 28, 12)
```

sage.combinat.designs.difference_family.**block_stabilizer**(G, B)

Compute the left stabilizer of the block `B` under the action of `G`.

This function return the list of all $x \in G$ such that $x \cdot B = B$ (as a set).

INPUT:

- `G` – a group (additive or multiplicative)
- `B` – a subset of `G`

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import block_stabilizer

sage: Z8 = Zmod(8)
sage: block_stabilizer(Z8, [Z8(0),Z8(2),Z8(4),Z8(6)])
[0, 2, 4, 6]
sage: block_stabilizer(Z8, [Z8(0),Z8(2)])
[0]

sage: C = cartesian_product([Zmod(4),Zmod(3)])
sage: block_stabilizer(C, [C((0,0)),C((2,0)),C((0,1)),C((2,1))])
[(0, 0), (2, 0)]

sage: b = list(map(Zmod(45),[1, 3, 7, 10, 22, 25, 30, 35, 37, 38, 44]))
sage: block_stabilizer(Zmod(45),b)
[0]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import block_stabilizer

>>> Z8 = Zmod(Integer(8))
>>> block_stabilizer(Z8, [Z8(Integer(0)),Z8(Integer(2)),Z8(Integer(4)),
↪Z8(Integer(6))])
[0, 2, 4, 6]
>>> block_stabilizer(Z8, [Z8(Integer(0)),Z8(Integer(2))])
[0]

>>> C = cartesian_product([Zmod(Integer(4)),Zmod(Integer(3))])
>>> block_stabilizer(C, [C((Integer(0),Integer(0))),C((Integer(2),Integer(0))),
↪C((Integer(0),Integer(1))),C((Integer(2),Integer(1)))])
```

(continues on next page)

(continued from previous page)

```
[(0, 0), (2, 0)]

>>> b = list(map(Zmod(Integer(45)),[Integer(1), Integer(3), Integer(7),␣
↪Integer(10), Integer(22), Integer(25), Integer(30), Integer(35), Integer(37),␣
↪Integer(38), Integer(44)]))
>>> block_stabilizer(Zmod(Integer(45)),b)
[0]
```

sage.combinat.designs.difference_family.**complementary_difference_sets**(*n*, *existence=False*, *check=True*)

Compute complementary difference sets over a group of order $n = 2m + 1$.

According to [Sze1971], two sets A, B of size m are complementary difference sets over a group G of size $n = 2m + 1$ if:

1. they are $2 - \{2m + 1; m, m; m - 1\}$ supplementary difference sets
2. A is skew, i.e. $a \in A$ implies $-a \notin A$

This method tries to call *complementary_difference_setsI()*, *complementary_difference_setsII()* or *complementary_difference_setsIII()* if the parameter n satisfies the requirements of one of these functions.

INPUT:

- `n` – integer; the order of the group over which the sets are constructed
- `existence` – boolean (default: `False`); if `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are complementary difference sets before returning them; setting this to `False` might speed up the computation for large values of `n`

OUTPUT:

If `existence=False`, the function returns group `G` and two complementary difference sets, or raises an error if data for the given `n` is not available. If `existence=True`, the function returns a boolean representing whether complementary difference sets can be constructed for the given `n`.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import complementary_
↪difference_sets
sage: complementary_difference_sets(15)                                    #␣
↪needs sage.libs.pari
(Ring of integers modulo 15, [1, 2, 4, 6, 7, 10, 12], [0, 1, 2, 6, 9, 13, 14])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import complementary_difference_
↪sets
>>> complementary_difference_sets(Integer(15))                              ␣
↪     # needs sage.libs.pari
(Ring of integers modulo 15, [1, 2, 4, 6, 7, 10, 12], [0, 1, 2, 6, 9, 13, 14])
```

If `existence=True`, the function returns a boolean:

```
sage: complementary_difference_sets(15, existence=True)                    #␣
↪needs sage.libs.pari
True
sage: complementary_difference_sets(16, existence=True)
False
```

```
>>> from sage.all import *
>>> complementary_difference_sets(Integer(15), existence=True)              ␣
↪     # needs sage.libs.pari
True
>>> complementary_difference_sets(Integer(16), existence=True)
False
```

See also

are_complementary_difference_sets()

sage.combinat.designs.difference_family.**complementary_difference_setsI**(*n*, *check=True*)

Construct complementary difference sets in a group of order $n \cong 3 \mod 4$, n a prime power.

Let G be a Galois Field of order n, where n satisfies the requirements above. Let A be the set of nonzero quadratic elements in G, and $B = A$. Then A and B are complementary difference sets over a group of order n. This construction is described in [Sze1971].

INPUT:

- `n` – integer; the order of the group G
- `check` – boolean (default: `True`); if `True`, check that the sets are complementary difference sets before returning them

OUTPUT:

The function returns the Galois field of order `n` and the two sets, or raises an error if `n` does not satisfy the requirements of this construction.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import complementary_
↪difference_setsI
sage: complementary_difference_setsI(19)
(Finite Field of size 19,
 [1, 4, 5, 6, 7, 9, 11, 16, 17],
 [1, 4, 5, 6, 7, 9, 11, 16, 17])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import complementary_difference_
↪setsI
>>> complementary_difference_setsI(Integer(19))
(Finite Field of size 19,
 [1, 4, 5, 6, 7, 9, 11, 16, 17],
 [1, 4, 5, 6, 7, 9, 11, 16, 17])
```

are_complementary_difference_sets() complementary_difference_sets()

sage.combinat.designs.difference_family.**complementary_difference_setsII**(*n*, *check=True*)

Construct complementary difference sets in a group of order $n = p^t$, where $p \cong 5 \mod 8$ and $t \cong 1, 2, 3 \mod 4$.

Consider a finite field G of order n and let ρ be the generator of the corresponding multiplicative group. Then, there are two different constructions, depending on whether t is even or odd.

If $t \cong 2 \mod 4$, let C_0 be the set of nonzero octic residues in G, and let $C_i = \rho^i C_0$ for $1 \leq i \leq 7$. Then, $A = C_0 \cup C_1 \cup C_2 \cup C_3$ and $B = C_0 \cup C_1 \cup C_6 \cup C_7$.

If t is odd, let C_0 be the set of nonzero fourth powers in G, and let $C_i = \rho^i C_0$ for $1 \leq i \leq 3$. Then, $A = C_0 \cup C_1$ and $B = C_0 \cup C_3$.

For more details on this construction, see [Sze1971].

INPUT:

- `n` – integer; the order of the group G
- `check` – boolean (default: `True`); if `True`, check that the sets are complementary difference sets before returning them; setting this to `False` might speed up the computation for large values of `n`

OUTPUT:

The function returns the Galois field of order `n` and the two sets, or raises an error if `n` does not satisfy the requirements of this construction.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import complementary_
↪difference_setsII
sage: complementary_difference_setsII(5)                                    #␣
↪needs sage.libs.pari
(Finite Field of size 5, [1, 2], [1, 3])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import complementary_difference_
↪setsII
>>> complementary_difference_setsII(Integer(5))                              ␣
↪     # needs sage.libs.pari
(Finite Field of size 5, [1, 2], [1, 3])
```

are_complementary_difference_sets() complementary_difference_sets()

sage.combinat.designs.difference_family.**complementary_difference_setsIII**(*n*, *check=True*)

Construct complementary difference sets in a group of order $n = 2m + 1$, where $4m + 3$ is a prime power.

Consider a finite field G of order n and let ρ be a primitive element of this group. Now let Q be the set of nonzero quadratic residues in G, and let $A = \{a | \rho^{2a} - 1 \in Q\}$, $B' = \{b | -(\rho^{2b} + 1) \in Q\}$. Then A and $B = Q \setminus B'$ are complementary difference sets over the ring of integers modulo n. For more details, see [Sz1969].

INPUT:

- `n` – integer; the order of the group over which the sets are constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are complementary difference sets before returning them; setting this to `False` might speed up the computation for large values of `n`

OUTPUT:

The function returns the Galois field of order `n` and the two sets, or raises an error if `n` does not satisfy the requirements of this construction.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import complementary_
↪difference_setsIII
sage: complementary_difference_setsIII(11)                                  #␣
↪needs sage.libs.pari
(Ring of integers modulo 11, [1, 2, 5, 7, 8], [0, 1, 3, 8, 10])
```

```

are_complementary_difference_sets() complementary_difference_sets()

`sage.combinat.designs.difference_family.`**`df_q_6_1`**(*K*, *existence=False*, *check=True*)

Return a $(q, 6, 1)$-difference family over the finite field K.

The construction uses Theorem 11 of [Wi72].

EXAMPLES:

```
sage: # needs sage.rings.finite_rings
sage: from sage.combinat.designs.difference_family import is_difference_family,␣
↪df_q_6_1
sage: prime_powers = [v for v in range(31,500,30) if is_prime_power(v)]
sage: parameters = [v for v in prime_powers
....:               if df_q_6_1(GF(v,'a'), existence=True) is True]
sage: parameters
[31, 151, 181, 211, 241, 271, 331, 361, 421]
sage: for v in parameters:
....:     K = GF(v, 'a')
....:     df = df_q_6_1(K, check=True)
....:     assert is_difference_family(K, df, v, 6, 1)
```

```
>>> from sage.all import *
>>> # needs sage.rings.finite_rings
>>> from sage.combinat.designs.difference_family import is_difference_family, df_
↪q_6_1
>>> prime_powers = [v for v in range(Integer(31),Integer(500),Integer(30)) if is_
```

(continues on next page)

(continued from previous page)

```
↪prime_power(v)]
>>> parameters = [v for v in prime_powers
...               if df_q_6_1(GF(v,'a'), existence=True) is True]
>>> parameters
[31, 151, 181, 211, 241, 271, 331, 361, 421]
>>> for v in parameters:
...     K = GF(v, 'a')
...     df = df_q_6_1(K, check=True)
...     assert is_difference_family(K, df, v, Integer(6), Integer(1))
```

Todo

Do improvements due to Zhen and Wu 1999.

sage.combinat.designs.difference_family.**difference_family**(*v*, *k*, *l=1*, *existence=False*, *explain_construction=False*, *check=True*)

Return a (`k`, `l`)-difference family on an Abelian group of cardinality `v`.

Let G be a finite Abelian group. For a given subset D of G, we define ΔD to be the multi-set of differences $\Delta D = \{x - y; x \in D, y \in D, x \neq y\}$. A (G, k, λ)-*difference family* is a collection of k-subsets of G, $D = \{D_1, D_2, \ldots, D_b\}$ such that the union of the difference sets ΔD_i for $i = 1, ...b$, seen as a multi-set, contains each element of $G \backslash \{0\}$ exactly λ-times.

When there is only one block, i.e. $\lambda(v-1) = k(k-1)$, then a (G, k, λ)-difference family is also called a *difference set*.

See also Wikipedia article Difference_set.

If there is no such difference family, an `EmptySetError` is raised and if there is no construction at the moment `NotImplementedError` is raised.

INPUT:

- `v`, `k`, `l` – parameters of the difference family. If `l` is not provided it is assumed to be `1`
- `existence` – if `True`, then return either `True` if Sage knows how to build such design, `Unknown` if it does not and `False` if it knows that the design does not exist
- `explain_construction` – instead of returning a difference family, returns a string that explains the construction used
- `check` – boolean (default: `True`); if `True`, then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

OUTPUT:

A pair `(G,D)` made of a group G and a difference family D on that group. Or, if `existence=True` a troolean or if `explain_construction=True` a string.

EXAMPLES:

```
sage: G,D = designs.difference_family(73,4)                                #␣
↪needs sage.libs.pari

Todo

Implement recursive constructions from Buratti "Recursive for difference matrices and relative difference families" (1998) and Jungnickel "Composition theorems for difference families and regular planes" (1978)

sage.combinat.designs.difference_family.**get_fixed_relative_difference_set**(*G*, *rel_diff_set*, *as_elements=False*)

Construct an equivalent relative difference set fixed by the size of the set.

Given a relative difference set $R(q+1, q-1, q, 1)$, it is possible to find a translation of this set fixed by q (see Section 3 of [Spe1975]). We say that a set is fixed by t if $\{td|d \in R\} = R$.

In addition, the set returned by this function will contain the element 0. This is needed in the construction of supplementary difference sets (see *supplementary_difference_set_from_rel_diff_set()*).

INPUT:

- `G` – a group, of which `rel_diff_set` is a subset
- `rel_diff_set` – the relative difference set
- `as_elements` – boolean (default: `False`); if `True`, the list returned will contain elements of the abelian group (this may slow down the computation considerably)

OUTPUT:

By default, this function returns the set as a list of integers. However, if `as_elements=True` it will return the set as a list containing elements of the abelian group. If no such set can be found, the function will raise an error.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import relative_difference_set_
↪from_m_sequence, get_fixed_relative_difference_set
sage: G, s1 = relative_difference_set_from_m_sequence(5, 2, return_group=True)  #␣
↪needs sage.libs.pari sage.modules
sage: get_fixed_relative_difference_set(G, s1)  # random                          #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.libs.pari sage.modules
[2, 10, 19, 23, 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import relative_difference_set_
↪from_m_sequence, get_fixed_relative_difference_set
>>> G, s1 = relative_difference_set_from_m_sequence(Integer(5), Integer(2),␣
↪return_group=True)  # needs sage.libs.pari sage.modules
>>> get_fixed_relative_difference_set(G, s1)  # random                          #␣
↪needs sage.libs.pari sage.modules
[2, 10, 19, 23, 0]
```

If `as_elements=True`, the result will contain elements of the group:

```
sage: get_fixed_relative_difference_set(G, s1, as_elements=True)  # random      #␣
↪needs sage.libs.pari sage.modules
[(2), (10), (19), (23), (0)]
```

```
>>> from sage.all import *
>>> get_fixed_relative_difference_set(G, s1, as_elements=True)  # random      #␣
↪needs sage.libs.pari sage.modules
[(2), (10), (19), (23), (0)]
```

sage.combinat.designs.difference_family.**group_law**(*G*)

Return a triple `(identity, operation, inverse)` that define the operations on the group `G`.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import group_law
sage: group_law(Zmod(3))
(0, <built-in function add>, <built-in function neg>)
sage: group_law(SymmetricGroup(5))                                              #␣
↪needs sage.groups
((), <built-in function mul>, <built-in function inv>)
sage: group_law(VectorSpace(QQ, 3))                                             #␣
↪needs sage.modules
((0, 0, 0), <built-in function add>, <built-in function neg>)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import group_law
>>> group_law(Zmod(Integer(3)))
(0, <built-in function add>, <built-in function neg>)
>>> group_law(SymmetricGroup(Integer(5)))                                        ␣
↪     # needs sage.groups
((), <built-in function mul>, <built-in function inv>)
>>> group_law(VectorSpace(QQ, Integer(3)))                                       ␣
↪     # needs sage.modules
((0, 0, 0), <built-in function add>, <built-in function neg>)
```

sage.combinat.designs.difference_family.**hadamard_difference_set_product**(*G1*, *D1*, *G2*, *D2*)

Make a product of two Hadamard difference sets.

This product construction appears in [Tu1984].

INPUT:

- `G1, D1, G2, D2` – two Hadamard difference sets

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import hadamard_difference_set_
↪product
sage: from sage.combinat.designs.difference_family import is_difference_family

sage: G1,D1 = designs.difference_family(16,6,2)                                    #␣
↪needs sage.rings.finite_rings
sage: G2,D2 = designs.difference_family(36,15,6)                                   #␣
↪needs sage.rings.finite_rings

sage: G11,D11 = hadamard_difference_set_product(G1,D1,G1,D1)                       #␣
↪needs sage.rings.finite_rings
sage: assert is_difference_family(G11, D11, 256, 120, 56)                          #␣
↪needs sage.rings.finite_rings
sage: assert designs.difference_family(256, 120, 56, existence=True) is True      #␣
↪needs sage.rings.finite_rings

sage: G12,D12 = hadamard_difference_set_product(G1,D1,G2,D2)                       #␣
↪needs sage.rings.finite_rings
sage: assert is_difference_family(G12, D12, 576, 276, 132)                         #␣
↪needs sage.rings.finite_rings
sage: assert designs.difference_family(576, 276, 132, existence=True) is True     #␣
↪needs sage.rings.finite_rings
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import hadamard_difference_set_
↪product
>>> from sage.combinat.designs.difference_family import is_difference_family

>>> G1,D1 = designs.difference_family(Integer(16),Integer(6),Integer(2))          ␣
↪                        # needs sage.rings.finite_rings
>>> G2,D2 = designs.difference_family(Integer(36),Integer(15),Integer(6))         ␣
↪                        # needs sage.rings.finite_rings

>>> G11,D11 = hadamard_difference_set_product(G1,D1,G1,D1)                        #␣
↪needs sage.rings.finite_rings
>>> assert is_difference_family(G11, D11, Integer(256), Integer(120),␣
↪Integer(56))                          # needs sage.rings.finite_rings
>>> assert designs.difference_family(Integer(256), Integer(120), Integer(56),␣
↪existence=True) is True     # needs sage.rings.finite_rings

>>> G12,D12 = hadamard_difference_set_product(G1,D1,G2,D2)                        #␣
↪needs sage.rings.finite_rings
>>> assert is_difference_family(G12, D12, Integer(576), Integer(276),␣
↪Integer(132))                         # needs sage.rings.finite_rings
>>> assert designs.difference_family(Integer(576), Integer(276), Integer(132),␣
↪existence=True) is True    # needs sage.rings.finite_rings
```

sage.combinat.designs.difference_family.**hadamard_difference_set_product_parameters**()

Check whether a product construction is available for Hadamard difference set with parameter `N`.

This function looks for two integers N_1 and N_2 greater than 1 and so that $N = 2N_1N_2$ and there exists Hadamard difference set with parameters $(4N_i^2, 2N_i^2 - N_i, N_i^2 - N_i)$. If such pair exists, the output is the pair `(N_1, N_2)` otherwise it is `None`.

INPUT:

- `N` – positive integer

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import hadamard_difference_set_
↪product_parameters
sage: hadamard_difference_set_product_parameters(8)                             #␣
↪needs sage.rings.finite_rings
(2, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import hadamard_difference_set_
↪product_parameters
>>> hadamard_difference_set_product_parameters(Integer(8))                      ␣
↪     # needs sage.rings.finite_rings
(2, 2)
```

sage.combinat.designs.difference_family.**is_difference_family**(*G*, *D*, *v=None*, *k=None*, *l=None*, *verbose=False*)

Check whether `D` forms a difference family in the group `G`.

INPUT:

- `G` – group of cardinality `v`
- `D` – set of `k`-subsets of `G`
- `v`, `k`, `l` – (optional) parameters of the difference family
- `verbose` – boolean (default: `False`); whether to print additional information

See also

difference_family()

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import is_difference_family
sage: G = Zmod(21)
sage: D = [[0,1,4,14,16]]
sage: is_difference_family(G, D, 21, 5)
True

sage: G = Zmod(41)
sage: D = [[0,1,4,11,29],[0,2,8,17,21]]
sage: is_difference_family(G, D, verbose=True)

...      [-b-d, a+b+d, a-b+c-d, a-b+c, -b+c+d]]
>>> is_difference_family(G, D)
True
```

The following example has a third block with a non-trivial stabilizer:

```
sage: G = Zmod(15)
sage: D = [[0,1,4],[0,2,9],[0,5,10]]
sage: is_difference_family(G,D,verbose=True)
It is a (15,3,1)-difference family
True
```

```
>>> from sage.all import *
>>> G = Zmod(Integer(15))
>>> D = [[Integer(0),Integer(1),Integer(4)],[Integer(0),Integer(2),Integer(9)],
↪[Integer(0),Integer(5),Integer(10)]]
>>> is_difference_family(G,D,verbose=True)
It is a (15,3,1)-difference family
True
```

The function also supports multiplicative groups (non necessarily Abelian):

```
sage: # needs sage.groups
sage: G = DihedralGroup(8)
sage: x,y = G.gens()
sage: i = G.one()
sage: D1 = [[i,x,x^4], [i,x^2, y*x], [i,x^5,y], [i,x^6,y*x^2], [i,x^7,y*x^5]]
sage: is_difference_family(G, D1, 16, 3, 2)
True
sage: from sage.combinat.designs.bibd import BIBD_from_difference_family
sage: bibd = BIBD_from_difference_family(G, D1, lambd=2)
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> G = DihedralGroup(Integer(8))
>>> x,y = G.gens()
>>> i = G.one()
>>> D1 = [[i,x,x**Integer(4)], [i,x**Integer(2), y*x], [i,x**Integer(5),y], [i,
```

(continues on next page)

(continued from previous page)

```
↪x**Integer(6),y*x**Integer(2)], [i,x**Integer(7),y*x**Integer(5)]]
>>> is_difference_family(G, D1, Integer(16), Integer(3), Integer(2))
True
>>> from sage.combinat.designs.bibd import BIBD_from_difference_family
>>> bibd = BIBD_from_difference_family(G, D1, lambd=Integer(2))
```

sage.combinat.designs.difference_family.**is_fixed_relative_difference_set**(R, q)

Check if the relative difference set `R` is fixed by `q`.

A relative difference set R is fixed by q if $\{qd|d \in R\} = R$ (see Section 3 of [Spe1975]).

INPUT:

- `R` – list containing elements of an abelian group; the relative difference set
- `q` – integer

EXAMPLES:

```
sage: # needs sage.modules
sage: from sage.combinat.designs.difference_family import relative_difference_set_
↪from_m_sequence, get_fixed_relative_difference_set, is_fixed_relative_
↪difference_set
sage: G, s1 = relative_difference_set_from_m_sequence(7, 2, return_group=True)  #␣
↪needs sage.libs.pari
sage: s2 = get_fixed_relative_difference_set(G, s1, as_elements=True)           #␣
↪needs sage.libs.pari
sage: is_fixed_relative_difference_set(s2, len(s2))                             #␣
↪needs sage.libs.pari
True
sage: G = AdditiveAbelianGroup([15])
sage: s3 = [G[1], G[2], G[3], G[4]]
sage: is_fixed_relative_difference_set(s3, len(s3))
False
```

```
>>> from sage.all import *
>>> # needs sage.modules

↪from_m_sequence, get_fixed_relative_difference_set, is_fixed_relative_
↪difference_set
>>> G, s1 = relative_difference_set_from_m_sequence(Integer(7), Integer(2),␣
↪return_group=True)  # needs sage.libs.pari
>>> s2 = get_fixed_relative_difference_set(G, s1, as_elements=True)           #␣
↪needs sage.libs.pari
>>> is_fixed_relative_difference_set(s2, len(s2))                             #␣
↪needs sage.libs.pari
True
>>> G = AdditiveAbelianGroup([Integer(15)])
>>> s3 = [G[Integer(1)], G[Integer(2)], G[Integer(3)], G[Integer(4)]]
>>> is_fixed_relative_difference_set(s3, len(s3))
False
```

If the relative difference set does not contain elements of the group, the method returns false:

```
sage: G, s1 = relative_difference_set_from_m_sequence(7, 2, return_group=True)  #␣
↪needs sage.libs.pari sage.modules
sage: s2 = get_fixed_relative_difference_set(G, s1, as_elements=False)          #␣
↪needs sage.libs.pari sage.modules
sage: is_fixed_relative_difference_set(s2, len(s2))                             #␣
↪needs sage.libs.pari sage.modules
False
```

```
>>> from sage.all import *
>>> G, s1 = relative_difference_set_from_m_sequence(Integer(7), Integer(2),␣
↪return_group=True)  # needs sage.libs.pari sage.modules
>>> s2 = get_fixed_relative_difference_set(G, s1, as_elements=False)          #␣
↪needs sage.libs.pari sage.modules
>>> is_fixed_relative_difference_set(s2, len(s2))                             #␣
↪needs sage.libs.pari sage.modules
False
```

sage.combinat.designs.difference_family.**is_relative_difference_set**(*R*, *G*, *H*, *params*, *verbose=False*)

Check if `R` is a difference set of `G` relative to `H`, with the given parameters.

This function checks that G, H and R have the orders specified in the parameters, and that R satisfies the definition of relative difference set (from [EB1966]): the collection of differences $r - s$, $r, s \in R$, $r \neq s$ contains only elements of G which are not in H, and contains every such element exactly d times.

INPUT:

- `R` – list; the relative difference set of length k
- `G` – an additive abelian group of order mn
- `H` – list; a submodule of `G` of order n
- `params` – tuple in the form (m, n, k, d)
- `verbose` – boolean (default: `False`); if `True`, the function will be verbose when the sequences do not satisfy the constraints

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import _get_submodule_of_order,
↪ relative_difference_set_from_m_sequence, is_relative_difference_set
sage: q, N = 5, 2
sage: params = ((q^N-1) // (q-1), q - 1, q^(N-1), q^(N-2))
sage: G, R = relative_difference_set_from_m_sequence(q, N, return_group=True)   #␣
↪needs sage.libs.pari sage.modules
sage: H = _get_submodule_of_order(G, q - 1)                                     #␣
↪needs sage.libs.pari sage.modules
sage: is_relative_difference_set(R, G, H, params)                               #␣
↪needs sage.libs.pari sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import _get_submodule_of_order,␣
↪relative_difference_set_from_m_sequence, is_relative_difference_set
>>> q, N = Integer(5), Integer(2)
```

(continues on next page)

(continued from previous page)

```
>>> params = ((q**N-Integer(1)) // (q-Integer(1)), q - Integer(1), q**(N-
↪Integer(1)), q**(N-Integer(2)))
>>> G, R = relative_difference_set_from_m_sequence(q, N, return_group=True)    #␣
↪needs sage.libs.pari sage.modules
>>> H = _get_submodule_of_order(G, q - Integer(1))                              ␣
↪     # needs sage.libs.pari sage.modules
>>> is_relative_difference_set(R, G, H, params)                                 #␣
↪needs sage.libs.pari sage.modules
True
```

If we pass the `verbose` argument, the function will explain why it failed:

```
sage: R2 = [G[1], G[2], G[3], G[5], G[6]]                                       #␣
↪needs sage.libs.pari sage.modules
sage: is_relative_difference_set(R2, G, H, params, verbose=True)                #␣
↪needs sage.libs.pari sage.modules
There is a value in the difference set which is not repeated d times
False
```

```
>>> from sage.all import *
>>> R2 = [G[Integer(1)], G[Integer(2)], G[Integer(3)], G[Integer(5)],␣
↪G[Integer(6)]]                                          # needs sage.libs.pari␣
↪sage.modules
>>> is_relative_difference_set(R2, G, H, params, verbose=True)                  #␣
↪needs sage.libs.pari sage.modules
There is a value in the difference set which is not repeated d times
False
```

sage.combinat.designs.difference_family.**is_supplementary_difference_set**(*Ks*, *v=None*, *lmbda=None*, *G=None*, *verbose=False*)

Check that the sets in `Ks` are $n - \{v; k_1, ..., k_n; \lambda\}$ supplementary difference sets over group `G` of order `v`.

From the definition in [Spe1975]: let $S_1, S_2, ..., S_n$ be n subsets of a group G of order v such that $|S_i| = k_i$. If, for each $g \in G$, $g \neq 0$, the total number of solutions of $a_i - a'_i = g$, with $a_i, a'_i \in S_i$ is λ, then $S_1, S_2, ..., S_n$ are $n - \{v; k_1, ..., k_n; \lambda\}$ supplementary difference sets.

One of the parameters `v` or `G` must always be specified. If `G` is not given, the function will use an `AdditiveAbelianGroup` of order `v`.

INPUT:

- `Ks` – list of sets to be checked
- `v` – integer; the parameter v of the supplementary difference sets
- `lmbda` – integer; the parameter λ of the supplementary difference sets
- `G` – a group of order v
- `verbose` – boolean (default: `False`); if `True`, the function will be verbose when the sets do not satisfy the constraints

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import supplementary_
↪difference_set_from_rel_diff_set, is_supplementary_difference_set
sage: G, [S1, S2, S3, S4] = supplementary_difference_set_from_rel_diff_set(17)  #␣
↪needs sage.modules sage.rings.finite_rings
sage: is_supplementary_difference_set([S1, S2, S3, S4], lmbda=16, G=G)          #␣
↪needs sage.modules sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import supplementary_difference_
↪set_from_rel_diff_set, is_supplementary_difference_set
>>> G, [S1, S2, S3, S4] = supplementary_difference_set_from_rel_diff_
↪set(Integer(17))  # needs sage.modules sage.rings.finite_rings
>>> is_supplementary_difference_set([S1, S2, S3, S4], lmbda=Integer(16), G=G)    ␣
↪     # needs sage.modules sage.rings.finite_rings
True
```

The parameter `v` can be given instead of `G`:

```
sage: is_supplementary_difference_set([S1, S2, S3, S4], v=16, lmbda=16)         #␣
↪needs sage.modules sage.rings.finite_rings
True
sage: is_supplementary_difference_set([S1, S2, S3, S4], v=20, lmbda=16)         #␣
↪needs sage.modules sage.rings.finite_rings
False
```

```
>>> from sage.all import *
>>> is_supplementary_difference_set([S1, S2, S3, S4], v=Integer(16),␣
↪lmbda=Integer(16))          # needs sage.modules sage.rings.finite_rings
True
>>> is_supplementary_difference_set([S1, S2, S3, S4], v=Integer(20),␣
↪lmbda=Integer(16))          # needs sage.modules sage.rings.finite_rings
False
```

If `verbose=True`, the function will be verbose:

```
sage: is_supplementary_difference_set([S1, S2, S3, S4], lmbda=14, G=G,          #␣
↪needs sage.modules sage.rings.finite_rings
....:                                 verbose=True)
Number of pairs with difference (1) is 16, but lambda is 14
False
```

```
>>> from sage.all import *
>>> is_supplementary_difference_set([S1, S2, S3, S4], lmbda=Integer(14), G=G,    ␣
↪     # needs sage.modules sage.rings.finite_rings
...                                 verbose=True)
Number of pairs with difference (1) is 16, but lambda is 14
False
```

See also

supplementary_difference_set_from_rel_diff_set()

sage.combinat.designs.difference_family.**mcfarland_1973_construction**(q, s)

Return a difference set.

The difference set returned has the following parameters

$$v = \frac{q^{s+1}(q^{s+1}+q-2)}{q-1}, k = \frac{q^s(q^{s+1}-1)}{q-1}, \lambda = \frac{q^s(q^s-1)}{q-1}$$

This construction is due to [McF1973].

INPUT:

- q, s – integers; parameters for the difference set (see the above formulas for the expression of v, k, l in terms of q and s)

See also

The function *are_mcfarland_1973_parameters()* makes the translation between the parameters (q, s) corresponding to a given triple (v, k, λ).

ALGORITHM:

Uses dancing links *sage.combinat.dlx*

sage.combinat.designs.difference_family.**one_radical_difference_family**(K, k)

Search for a radical difference family on `K` using dancing links algorithm.

For the definition of radical difference family, see *radical_difference_family()*. Here, we consider only radical difference family with $\lambda = 1$.

INPUT:

- `K` – a finite field of cardinality q
- `k` – positive integer so that $k(k-1)$ divides $q-1$

OUTPUT: either a difference family or `None` if it does not exist

ALGORITHM:

The existence of a radical difference family is equivalent to a one dimensional tiling (or packing) problem in a cyclic group. This subsequent problem is solved by a call to the function *one_cyclic_tiling()*.

Let K^* be the multiplicative group of the finite field K. A radical family has the form $\mathcal{B} = \{x_1 B, \ldots, x_k B\}$, where $B = \{x : x^k = 1\}$ (for k odd) or $B = \{x : x^{k-1} = 1\} \cup \{0\}$ (for k even). Equivalently, K^* decomposes as:

$$K^* = \Delta(x_1 B) \cup \cdots \cup \Delta(x_k B) = x_1 \Delta B \cup \cdots \cup x_k \Delta B.$$

We observe that $C = B \backslash 0$ is a subgroup of the (cyclic) group K^*, that can thus be generated by some element r. Furthermore, we observe that ΔB is always a union of cosets of $\pm C$ (which is twice larger than C).

$$\begin{array}{lll} (k \text{ odd}) & \Delta B & = \{r^i - r^j : r^i \neq r^j\} \qquad = \pm C \cdot \{r^i - 1 : 0 < i \leq m\} \\ (k \text{ even}) & \Delta B & = \{r^i - r^j : r^i \neq r^j\} \cup C \quad = \pm C \cdot \{r^i - 1 : 0 < i < m\} \cup \pm C \end{array}$$

where

$$(k \text{ odd})\ m = (k-1)/2 \quad \text{and} \quad (k \text{ even})\ m = k/2.$$

Consequently, $\mathcal{B} = \{x_1 B, \ldots, x_k B\}$ is a radical difference family if and only if $\{x_1(\Delta B/(\pm C)), \ldots, x_k(\Delta B/(\pm C))\}$ is a partition of the cyclic group $K^*/(\pm C)$.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import (
....:     one_radical_difference_family,
....:     is_difference_family)

>>> is_difference_family(GF(Integer(449)), df, Integer(449), Integer(8),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(1))                                    # needs sage.rings.finite_rings
True
```

sage.combinat.designs.difference_family.**radical_difference_family**(*K*, *k*, *l=1*, *existence=False*, *check=True*)

Return a `(v,k,1)`-radical difference family.

Let fix an integer k and a prime power $q = tk(k-1)+1$. Let K be a field of cardinality q. A $(q,k,1)$-difference family is *radical* if its base blocks are either: a coset of the k-th root of unity for k odd or a coset of $k-1$-th root of unity and 0 if k is even (the number t is the number of blocks of that difference family).

The terminology comes from M. Buratti article [Bu95] but the first constructions go back to R. Wilson [Wi72].

INPUT:

- `K` – a finite field
- `k` – positive integer; the size of the blocks
- `l` – integer (default: 1); the λ parameter
- `existence` – if `True`, then return either `True` if Sage knows how to build such design, `Unknown` if it does not and `False` if it knows that the design does not exist
- `check` – boolean (default: `True`); if `True` then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import radical_difference_
↪family

sage: radical_difference_family(GF(73), 9)                                    #␣
↪needs sage.rings.finite_rings
[[1, 2, 4, 8, 16, 32, 37, 55, 64]]

sage: radical_difference_family(GF(281), 5)                                   #␣
↪needs sage.rings.finite_rings
[[1, 86, 90, 153, 232],

sage.combinat.designs.difference_family.**radical_difference_set**(*K*, *k*, *l=1*, *existence=False*, *check=True*)

Return a difference set made of a cyclotomic coset in the finite field `K` and with parameters `k` and `l`.

Most of these difference sets appear in chapter VI.18.48 of the Handbook of combinatorial designs.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import radical_difference_set

sage: D = radical_difference_set(GF(7), 3, 1); D                                #␣
↪needs sage.rings.finite_rings
[[1, 2, 4]]
sage: sorted(x-y for x in D[0] for y in D[0] if x != y)                          #␣
↪needs sage.rings.finite_rings
[1, 2, 3, 4, 5, 6]

sage.combinat.designs.difference_family.**relative_difference_set_from_homomorphism**(*q*, *N*, *d*, *check=True*, *return_group=False*)

Construct $R((q^N-1)/(q-1), n, q^{N-1}, q^{N-2}d)$ where $nd = q-1$.

Given a prime power q, a number $N \geq 2$ and integers d such that $d|q-1$ we create the relative difference set using the construction from Corollary 5.1.1 of [EB1966].

INPUT:

- `q` – a prime power
- `N` – integer greater than 1
- `d` – integer which divides $q-1$
- `check` – boolean (default: `True`); if `True`, check that the result is a relative difference set before returning it
- `return_group` – boolean (default: `False`); if `True`, the function will also return the group from which the set is created

OUTPUT:

If `return_group=False`, the function return only the relative difference set. Otherwise, it returns a tuple containing the group and the set.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import relative_difference_set_

sage.combinat.designs.difference_family.**relative_difference_set_from_m_sequence**(*q*, *N*, *check=True*, *return_group=False*)

Construct $R((q^N-1)/(q-1), q-1, q^{N-1}, q^{N-2})$ where `q` is a prime power and $N \geq 2$.

The relative difference set is constructed over the set of additive integers modulo $q^N - 1$, as described in Theorem 5.1 of [EB1966]. Given an m-sequence (a_i) of period $q^N - 1$, the set is: $R = \{i | 0 \leq i \leq q^{N-1}, a_i = 1\}$.

INPUT:

- `q` – a prime power
- `N` – a nonnegative number
- `check` – boolean (default: `True`); if `True`, check that the result is a relative difference set before returning it
- `return_group` – boolean (default: `False`); if `True`, the function will also return the group from which the set is created

OUTPUT:

If `return_group=False`, the function return only the relative difference set. Otherwise, it returns a tuple containing the group and the set.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import relative_difference_set_
↪from_m_sequence
sage: relative_difference_set_from_m_sequence(2, 4,                # random      #␣
↪needs sage.modules sage.rings.finite_rings
....:                                              return_group=True)
(Additive abelian group isomorphic to Z/15,
 [(0), (4), (5), (6), (7), (9), (11), (12)])

sage.combinat.designs.difference_family.**singer_difference_set**(*q*, *d*)

Return a difference set associated to the set of hyperplanes in a projective space of dimension d over $GF(q)$.

A Singer difference set has parameters:

$$v = \frac{q^{d+1}-1}{q-1}, \quad k = \frac{q^d-1}{q-1}, \quad \lambda = \frac{q^{d-1}-1}{q-1}.$$

The idea of the construction is as follows. One consider the finite field $GF(q^{d+1})$ as a vector space of dimension $d+1$ over $GF(q)$. The set of $GF(q)$-lines in $GF(q^{d+1})$ is a projective plane and its set of hyperplanes form a balanced incomplete block design.

Now, considering a multiplicative generator z of $GF(q^{d+1})$, we get a transitive action of a cyclic group on our projective plane from which it is possible to build a difference set.

The construction is given in details in [Stinson2004], section 3.3.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import singer_difference_set,␣
↪is_difference_family
sage: G,D = singer_difference_set(3,2)                                          #␣

It is a (820,91,10)-difference family
True
```

sage.combinat.designs.difference_family.**skew_spin_goethals_seidel_difference_family**(*n*, *existence=False*, *check=True*)

Construct skew spin type Goethals-Seidel difference family with parameters $(n; k_1, k_2, k_3, k_4; \lambda)$.

The construction is described in [Djo2024]. This function contains, for each value of n, either a full representation of S_1, S_2 together with the multiplier μ, or a subgroup H, two sets of representatives, and the multiplier.

This data is used to construct the difference family using the helper functions *_construct_gs_difference_family_from_full()* and *_construct_gs_difference_family_from_compact()*.

INPUT:

- `n` – integer; the parameter of the GS difference family
- `existence` – boolean (default: `False`); if `True`, only check whether the skew difference family can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are a skew difference family before returning them; setting this parameter to `False` may speed up the computation considerably

OUTPUT:

If `existence=False`, the function returns the group G of integers modulo `n` and a list containing 4 sets, or raises an error if data for the given `n` is not available. If `existence=True`, the function returns a boolean representing whether the skew difference family can be constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import skew_spin_goethals_
↪seidel_difference_family
sage: G, [S1, S2, S3, S4] = skew_spin_goethals_seidel_difference_family(61)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import skew_spin_goethals_seidel_
↪difference_family
>>> G, [S1, S2, S3, S4] = skew_spin_goethals_seidel_difference_family(Integer(61))
```

If existence is `True`, the function returns a boolean:

```
sage: skew_spin_goethals_seidel_difference_family(61, existence=True)
True
sage: skew_spin_goethals_seidel_difference_family(5, existence=True)
False
```

```
>>> from sage.all import *
>>> skew_spin_goethals_seidel_difference_family(Integer(61), existence=True)
True
>>> skew_spin_goethals_seidel_difference_family(Integer(5), existence=True)
False
```

sage.combinat.designs.difference_family.**skew_supplementary_difference_set**(*n*, *existence=False*, *check=True*, *return_group=False*)

Construct $4-\{n; n_1, n_2, n_3, n_4; \lambda\}$ supplementary difference sets, where S_1 is skew and $n_1+n_2+n_3+n_4 = n+\lambda$.

These sets are constructed from available data, as described in [Djo1994a]. The set $S_1 \subset G$ is always skew, i.e. $S_1 \cap (-S_1) = \emptyset$ and $S_1 \cup (-S_1) = G \setminus \{0\}$.

The data is taken from:

- $n = 103, 151$: [Djo1994a]
- $n = 67, 113, 127, 157, 163, 181, 241$: [Djo1992a]
- $n = 37, 43$: [Djo1992b]
- $n = 39, 49, 65, 93, 121, 129, 133, 217, 219, 267$: [Djo1992c]
- $n = 97$: [Djo2008a]
- $n = 109, 145, 247$: [Djo2008b]

- $n = 73$: [Djo2023b]
- $n = 213,631$: [DGK2014]
- $n = 331$: [DK2016]

Additional skew Supplementary difference sets are built using the function *skew_supplementary_difference_set_over_polynomial_ring()*, and *skew_supplementary_difference_set_with_paley_todd()*.

INPUT:

- `n` – integer; the parameter of the supplementary difference set
- `existence` – boolean (default: `False`); if `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are supplementary difference sets with S_1 skew before returning them; setting this parameter to `False` may speed up the computation considerably
- `return_group` – boolean (default: `False`); if `True`, the function will also return the group from which the sets are created

OUTPUT:

If `existence=False`, the function returns a list containing 4 sets, or raises an error if data for the given `n` is not available. If `return_group=True` the function will additionally return the group from which the sets are created. If `existence=True`, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import skew_supplementary_
↪difference_set
sage: [S1, S2, S3, S4] = skew_supplementary_difference_set(39)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import skew_supplementary_
↪difference_set
>>> [S1, S2, S3, S4] = skew_supplementary_difference_set(Integer(39))
```

If `return_group=True`, the function will also return the group:

```
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set(103, return_
↪group=True)
```

```
>>> from sage.all import *
>>> G, [S1, S2, S3, S4] = skew_supplementary_difference_set(Integer(103), return_
↪group=True)
```

If `existence=True`, the function returns a boolean:

```
sage: skew_supplementary_difference_set(103, existence=True)
True
sage: skew_supplementary_difference_set(17, existence=True)
False
```

```
>>> from sage.all import *
>>> skew_supplementary_difference_set(Integer(103), existence=True)
True
>>> skew_supplementary_difference_set(Integer(17), existence=True)
False
```

Note

The data for $n = 247$ in [Djo2008b] contains a typo: the set α_2 should contain 223 instead of 233. This can be verified by checking the resulting sets, which are given explicitly in the paper.

sage.combinat.designs.difference_family.**skew_supplementary_difference_set_over_polynomial_ring**(*n*, *existence=False*, *check=*

Construct skew supplementary difference sets over a polynomial ring of order `n`.

The skew supplementary difference sets for $n = 81, 169$ are taken from [Djo1994a].

INPUT:

- `n` – integer; the parameter of the supplementary difference sets
- `existence` – boolean (default: `False`); if `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are supplementary difference sets with S_1 skew before returning them; setting this parameter to `False` may speed up the computation considerably

OUTPUT:

If `existence=False`, the function returns a Polynomial Ring of order `n` and a list containing 4 sets, or raises an error if data for the given `n` is not available. If `existence=True`, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import skew_supplementary_
↪difference_set_over_polynomial_ring
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set_over_polynomial_
↪ring(81)      # needs sage.libs.pari
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import skew_supplementary_
↪difference_set_over_polynomial_ring
>>> G, [S1, S2, S3, S4] = skew_supplementary_difference_set_over_polynomial_
↪ring(Integer(81))      # needs sage.libs.pari
```

If `existence=True`, the function returns a boolean:

```
sage: skew_supplementary_difference_set_over_polynomial_ring(81, existence=True)
True
sage: skew_supplementary_difference_set_over_polynomial_ring(17, existence=True)
False
```

```
>>> from sage.all import *
>>> skew_supplementary_difference_set_over_polynomial_ring(Integer(81),␣
↪existence=True)
True
>>> skew_supplementary_difference_set_over_polynomial_ring(Integer(17),␣
↪existence=True)
False
```

sage.combinat.designs.difference_family.**skew_supplementary_difference_set_with_paley_todd**(*n*, *existence=False*, *check=True*)

Construct $4-\{n; n_1, n_2, n_3, n_4; \lambda\}$ skew supplementary difference sets where S_1 is the Paley-Todd difference set.

The skew SDS returned have the property that $n_1 + n_2 + n_3 + n_4 = n + \lambda$.

This construction is described in [DK2016]. The function contains, for each value of n, a set H containing integers modulo n, and four sets J, K, L. Then, these are used to construct $(n; k_2, k_3, k_4; \lambda_2)$ difference family, with $\lambda_2 = k_2 + k_3 + k_4 + (3n-1)/4$. Finally, these sets together with the Paley-Todd difference set form a skew supplementary difference set.

INPUT:

- `n` – integer; the parameter of the supplementary difference set
- `existence` – boolean (default: `False`); if `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are supplementary difference sets with S_1 skew before returning them; setting this parameter to `False` may speed up the computation considerably

OUTPUT:

If `existence=False`, the function returns the group G of integers modulo `n` and a list containing 4 sets, or raises an error if data for the given `n` is not available. If `existence=True`, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import skew_supplementary_
↪difference_set_with_paley_todd
sage: G, [S1, S2, S3, S4] = skew_supplementary_difference_set_with_paley_todd(239)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import skew_supplementary_
↪difference_set_with_paley_todd
>>> G, [S1, S2, S3, S4] = skew_supplementary_difference_set_with_paley_
↪todd(Integer(239))
```

If existence is `True`, the function returns a boolean:

```
sage: skew_supplementary_difference_set_with_paley_todd(239, existence=True)
True
sage: skew_supplementary_difference_set_with_paley_todd(17, existence=True)
False
```

```
>>> from sage.all import *
>>> skew_supplementary_difference_set_with_paley_todd(Integer(239),␣
↪existence=True)
True
>>> skew_supplementary_difference_set_with_paley_todd(Integer(17), existence=True)
False
```

sage.combinat.designs.difference_family.**spin_goethals_seidel_difference_family**(*n*, *existence=False*, *check=True*)

Construct a spin type Goethals-Seidel difference family with parameters $(n; k_1, k_2, k_3, k_4; \lambda)$.

The construction is described in [Djo2024]. This function contains, for each value of n, either a full representation of S_1, S_2 together with the multiplier μ, or a subgroup H, two sets of representatives, and the multiplier. This data is used to construct the difference family using the helper functions *_construct_gs_difference_family_from_full()* and *_construct_gs_difference_family_from_compact()*.

Additionally, this function also checks if a (skew) difference family can be constructed using *skew_spin_goethals_seidel_difference_family()*.

INPUT:

- `n` – integer; the parameter of the GS difference family
- `existence` – boolean (default: `False`); if `True`, only check whether the difference family can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are a difference family before returning them; setting this parameter to `False` may speed up the computation considerably

OUTPUT:

If `existence=False`, the function returns the group G of integers modulo `n` and a list containing 4 sets, or raises an error if data for the given `n` is not available. If `existence=True`, the function returns a boolean representing whether the difference family can be constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import spin_goethals_seidel_
↪difference_family
sage: G, [S1, S2, S3, S4] = spin_goethals_seidel_difference_family(73)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import spin_goethals_seidel_
↪difference_family
>>> G, [S1, S2, S3, S4] = spin_goethals_seidel_difference_family(Integer(73))
```

If existence is `True`, the function returns a boolean:

```
sage: spin_goethals_seidel_difference_family(73, existence=True)
True
sage: spin_goethals_seidel_difference_family(5, existence=True)
False
```

```
>>> from sage.all import *
>>> spin_goethals_seidel_difference_family(Integer(73), existence=True)
True
```

(continues on next page)

(continued from previous page)

```
>>> spin_goethals_seidel_difference_family(Integer(5), existence=True)
False
```

sage.combinat.designs.difference_family.**supplementary_difference_set_from_rel_diff_set**(*q*, *existence=False*, *check=True*)

Construct $4-\{2v; v, v+1, v, v; 2v\}$ supplementary difference sets where $q = 2v + 1$.

The sets are created from relative difference sets as detailed in Theorem 3.3 of [Spe1975]. this construction requires that q is an odd prime power and that there exists $s \geq 0$ such that $(q - (2^{s+1} + 1))/2^{s+1}$ is an odd prime power.

Note that the construction from [Spe1975] states that the resulting sets are $4-\{2v; v+1, v, v, v; 2v\}$ supplementary difference sets. However, the implementation of that construction returns $4-\{2v; v, v+1, v, v; 2v\}$ supplementary difference sets. This is not important, since the supplementary difference sets are not ordered.

INPUT:

- `q` – an odd prime power
- `existence` – boolean (default: `False`); if `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are supplementary difference sets before returning them

OUTPUT:

If `existence=False`, the function returns the 4 sets (containing integers), or raises an error if `q` does not satisfy the constraints. If `existence=True`, the function returns a boolean representing whether supplementary difference sets can be constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import supplementary_
↪difference_set_from_rel_diff_set
sage: supplementary_difference_set_from_rel_diff_set(17)  #random                #␣
↪needs sage.libs.pari
(Additive abelian group isomorphic to Z/16,
 [[(1), (5), (6), (7), (9), (13), (14), (15)],
  [(0), (2), (3), (5), (6), (10), (11), (13), (14)],
  [(0), (1), (2), (3), (5), (6), (7), (12)],
  [(0), (2), (3), (5), (6), (7), (9), (12)]])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import supplementary_difference_
↪set_from_rel_diff_set
>>> supplementary_difference_set_from_rel_diff_set(Integer(17))  #random          ␣
↪     # needs sage.libs.pari
(Additive abelian group isomorphic to Z/16,
 [[(1), (5), (6), (7), (9), (13), (14), (15)],
  [(0), (2), (3), (5), (6), (10), (11), (13), (14)],
  [(0), (1), (2), (3), (5), (6), (7), (12)],
  [(0), (2), (3), (5), (6), (7), (9), (12)]])
```

If `existence=True`, the function returns a boolean:

```
sage: supplementary_difference_set_from_rel_diff_set(7, existence=True)
False
sage: supplementary_difference_set_from_rel_diff_set(17, existence=True)
True
```

```
>>> from sage.all import *
>>> supplementary_difference_set_from_rel_diff_set(Integer(7), existence=True)
False
>>> supplementary_difference_set_from_rel_diff_set(Integer(17), existence=True)
True
```

See also

is_supplementary_difference_set()

sage.combinat.designs.difference_family.**supplementary_difference_set_hadamard**(*n*, *existence=False*, *check=True*)

Construct $4-\{n;n_1,n_2,n_3,n_4;\lambda\}$ supplementary difference sets, where $n_1+n_2+n_3+n_4=n+\lambda$.

These sets are constructed from available data, as described in [Djo1994a]. The data is taken from:

- $n=191$: [Djo2008c]
- $n=239$: [Djo1994b]
- $n=251$: [DGK2014]

Additional SDS are constructed using *skew_supplementary_difference_set()*.

INPUT:

- `n` – integer; the parameter of the supplementary difference set
- `existence` – boolean (default: `False`); if `True`, only check whether the supplementary difference sets can be constructed
- `check` – boolean (default: `True`); if `True`, check that the sets are supplementary difference sets before returning them; Setting this parameter to `False` may speed up the computation considerably

OUTPUT:

If `existence=False`, the function returns the ring of integers modulo `n` and a list containing the 4 sets, or raises an error if data for the given `n` is not available. If `existence=True`, the function returns a boolean representing whether skew supplementary difference sets can be constructed.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import supplementary_
↪difference_set_hadamard
sage: G, [S1, S2, S3, S4] = supplementary_difference_set_hadamard(191)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import supplementary_difference_
↪set_hadamard
>>> G, [S1, S2, S3, S4] = supplementary_difference_set_hadamard(Integer(191))
```

If `existence=True`, the function returns a boolean:

```
sage: supplementary_difference_set_hadamard(191, existence=True)
True
sage: supplementary_difference_set_hadamard(17, existence=True)
False
```

```
>>> from sage.all import *
>>> supplementary_difference_set_hadamard(Integer(191), existence=True)
True
>>> supplementary_difference_set_hadamard(Integer(17), existence=True)
False
```

sage.combinat.designs.difference_family.**turyn_1965_3x3xK**(*k=4*)

Return a difference set in either $C_3 \times C_3 \times C_4$ or $C_3 \times C_3 \times C_2 \times C_2$ with parameters $v = 36$, $k = 15$, $\lambda = 6$.

This example appears in [Tu1965].

INPUT:

- `k` – either `2` (to get a difference set in $C_3 \times C_3 \times C_2 \times C_2$) or `4` (to get a difference set in $C_3 \times C_3 \times C_3 \times C_4$)

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import turyn_1965_3x3xK
sage: from sage.combinat.designs.difference_family import is_difference_family
sage: G,D = turyn_1965_3x3xK(4)
sage: assert is_difference_family(G, D, 36, 15, 6)
sage: G,D = turyn_1965_3x3xK(2)
sage: assert is_difference_family(G, D, 36, 15, 6)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import turyn_1965_3x3xK
>>> from sage.combinat.designs.difference_family import is_difference_family
>>> G,D = turyn_1965_3x3xK(Integer(4))
>>> assert is_difference_family(G, D, Integer(36), Integer(15), Integer(6))
>>> G,D = turyn_1965_3x3xK(Integer(2))
>>> assert is_difference_family(G, D, Integer(36), Integer(15), Integer(6))
```

sage.combinat.designs.difference_family.**twin_prime_powers_difference_set**(*p*, *check=True*)

Return a difference set on $GF(p) \times GF(p+2)$.

The difference set is built from the following element of the Cartesian product of finite fields $GF(p) \times GF(p+2)$:

- $(x, 0)$ with any x
- (x, y) with x and y squares
- (x, y) with x and y non-squares

For more information see Wikipedia article Difference_set.

INPUT:

- `check` – boolean (default: `True`); if `True`, then the result of the computation is checked before being returned. This should not be needed but ensures that the output is correct

EXAMPLES:

```
sage: from sage.combinat.designs.difference_family import twin_prime_powers_
↪difference_set
sage: G, D = twin_prime_powers_difference_set(3)
sage: G
The Cartesian product of (Finite Field of size 3, Finite Field of size 5)
sage: D
[[(1, 1), (1, 4), (2, 2), (2, 3), (0, 0), (1, 0), (2, 0)]]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_family import twin_prime_powers_
↪difference_set
>>> G, D = twin_prime_powers_difference_set(Integer(3))
>>> G
The Cartesian product of (Finite Field of size 3, Finite Field of size 5)
>>> D
[[(1, 1), (1, 4), (2, 2), (2, 3), (0, 0), (1, 0), (2, 0)]]
```

Difference matrices

This module gathers code related to difference matrices. One can build those objects (or know if they can be built) with *difference_matrix()*:

```
sage: G,DM = designs.difference_matrix(9,5,1)
```

```
>>> from sage.all import *
>>> G,DM = designs.difference_matrix(Integer(9),Integer(5),Integer(1))
```

Functions

sage.combinat.designs.difference_matrices.**difference_matrix**(*g*, *k*, *lmbda=1*, *existence=False*, *check=True*)

Return a (g, k, λ)-difference matrix.

A matrix M is a (g, k, λ)-difference matrix if it has size $\lambda g \times k$, its entries belong to the group G of cardinality g, and for any two rows R, R' of M and $x \in G$ there are exactly λ values i such that $R_i - R'_i = x$.

INPUT:

- `k` – integer; number of columns. If `k` is `None` it is set to the largest value available
- `g` – integer; cardinality of the group G
- `lmbda` – integer (default: 1); number of times each element of G appears as a difference
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

> **Note**
>
> When `k=None` and `existence=True` the function returns an integer, i.e. the largest k such that we can build a (g, k, λ)-DM.

EXAMPLES:

```
sage: G,M = designs.difference_matrix(25,10); G
Finite Field in x of size 5^2
sage: designs.difference_matrix(993,None,existence=1)
32
```

```
>>> from sage.all import *
>>> G,M = designs.difference_matrix(Integer(25),Integer(10)); G
Finite Field in x of size 5^2
>>> designs.difference_matrix(Integer(993),None,existence=Integer(1))
32
```

Here we print for each g the maximum possible k for which Sage knows how to build a $(g, k, 1)$-difference matrix:

```
sage: for g in range(2,30):
....:     k_max = designs.difference_matrix(g=g,k=None,existence=True)
....:     print("{:2} {}".format(g, k_max))

sage.combinat.designs.difference_matrices.**difference_matrix_product**(*k*, *M1*, *G1*, *lmbda1*, *M2*, *G2*, *lmbda2*, *check=True*)

Return the product of the `(G1, k, lmbda1)` and `(G2, k, lmbda2)` difference matrices `M1` and `M2`.

The result is a $(G1 \times G2, k, \lambda_1\lambda_2)$-difference matrix.

INPUT:

- `k`, `lmbda1`, `lmbda2` – positive integers
- `G1`, `G2` – groups
- `M1`, `M2` – `(G1, k, lmbda1)` and `(G, k, lmbda2)` difference matrices
- `check` – boolean (default: `True`); whether to check the output before it is returned

EXAMPLES:

```
sage: from sage.combinat.designs.difference_matrices import (
....:     difference_matrix_product,
....:     is_difference_matrix)
```

(continues on next page)

(continued from previous page)

```
sage: G1,M1 = designs.difference_matrix(11,6)
sage: G2,M2 = designs.difference_matrix(7,6)
sage: G,M = difference_matrix_product(6,M1,G1,1,M2,G2,1)
sage: G1
Finite Field of size 11
sage: G2
Finite Field of size 7
sage: G
The Cartesian product of (Finite Field of size 11, Finite Field of size 7)
sage: is_difference_matrix(M,G,6,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_matrices import (
...     difference_matrix_product,
...     is_difference_matrix)
>>> G1,M1 = designs.difference_matrix(Integer(11),Integer(6))
>>> G2,M2 = designs.difference_matrix(Integer(7),Integer(6))
>>> G,M = difference_matrix_product(Integer(6),M1,G1,Integer(1),M2,G2,Integer(1))
>>> G1
Finite Field of size 11
>>> G2
Finite Field of size 7
>>> G
The Cartesian product of (Finite Field of size 11, Finite Field of size 7)
>>> is_difference_matrix(M,G,Integer(6),Integer(1))
True
```

sage.combinat.designs.difference_matrices.**find_product_decomposition**(*k*, *lmbda=1*)

Try to find a product decomposition construction for difference matrices.

INPUT:

- `g`, `k`, `lmbda` – integers, parameters of the difference matrix

OUTPUT:

A pair of pairs `(g1,lmbda),(g2,lmbda2)` if Sage knows how to build $(g1, k, lmbda1)$ and $(g2, k, lmbda2)$ difference matrices and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.designs.difference_matrices import find_product_
↪decomposition
sage: find_product_decomposition(77,6)
((7, 1), (11, 1))
sage: find_product_decomposition(616,7)
((7, 1), (88, 1))
sage: find_product_decomposition(24,10)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.difference_matrices import find_product_
↪decomposition
```

(continues on next page)

(continued from previous page)

```
>>> find_product_decomposition(Integer(77),Integer(6))
((7, 1), (11, 1))
>>> find_product_decomposition(Integer(616),Integer(7))
((7, 1), (88, 1))
>>> find_product_decomposition(Integer(24),Integer(10))
False
```

Evenly distributed sets in finite fields

This module consists of a simple class *EvenlyDistributedSetsBacktracker*. Its main purpose is to iterate through the evenly distributed sets of a given finite field.

The naive backtracker implemented here is not directly used to generate difference family as even for small parameters it already takes time to run. Instead, its output has been stored into a database *sage.combinat.designs.database*. If the backtracker is improved, then one might want to update this database with more values.

Classes and methods

class sage.combinat.designs.evenly_distributed_sets.**EvenlyDistributedSetsBacktracker**

Bases: object

Set of evenly distributed subsets in finite fields.

> **Definition:** Let K be a finite field of cardinality q and k an integer so that $k(k-1)$ divides $q-1$. Let $H = K^*$ be the multiplicative group of invertible elements in K. A *k-evenly distributed set* in K is a set $B = \{b_1, b_2, \ldots, b_k\}$ of k elements of K so that the $k(k-1)$ differences $\Delta B = \{b_i - b_j; i \neq j\}$ hit each coset modulo $H^{2(q-1)/(k(k-1))}$ exactly twice.

Evenly distributed sets were introduced by Wilson [Wi72] (see also [BJL99-1], Chapter VII.6). He proved that for any k, and for any prime power q large enough such that $k(k-1)$ divides k there exists a k-evenly distributed set in the field of cardinality q. This existence result based on a counting argument (using Dirichlet theorem) does not provide a simple method to generate them.

From a k-evenly distributed set, it is straightforward to build a $(q, k, 1)$-difference family (see *to_difference_family()*). Another approach to generate a difference family, somehow dual to this one, is via radical difference family (see in particular *radical_difference_family()* from the module *difference_family*).

By default, this backtracker only considers evenly distributed sets up to affine automorphisms, i.e. B is considered equivalent to $sB + t$ for any invertible element s and any element t in the field K. Note that the set of differences is just multiplicatively translated by s as $\Delta(sB + t) = s(\Delta B)$, and so that B is an evenly distributed set if and only if sB is one too. This behaviour can be modified via the argument `up_to_isomorphism` (see the input section and the examples below).

INPUT:

- `K` – a finite field of cardinality q
- `k` – positive integer such that $k(k-1)$ divides $q-1$
- `up_to_isomorphism` – boolean (default: `True`); whether only consider evenly distributed sets up to automorphisms of the field of the form $x \mapsto ax+b$. If set to `False` then the iteration is over all evenly distributed sets that contain `0` and `1`.
- `check` – boolean (default: `False`); whether you want to check intermediate steps of the iterator. This is mainly intended for debugging purpose. Setting it to `True` will considerably slow the iteration.

EXAMPLES:

The main part of the code is contained in the iterator. To get one evenly distributed set just do:

```
sage: from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(151),6)
sage: B = E.an_element()
sage: B
[0, 1, 69, 36, 57, 89]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(151)),Integer(6))
>>> B = E.an_element()
>>> B
[0, 1, 69, 36, 57, 89]
```

The class has a method to convert it to a difference family:

```
sage: E.to_difference_family(B)
[[0, 1, 69, 36, 57, 89],
 [0, 132, 48, 71, 125, 121],
 [0, 59, 145, 10, 41, 117],
 [0, 87, 114, 112, 127, 42],
 [0, 8, 99, 137, 3, 108]]
```

```
>>> from sage.all import *
>>> E.to_difference_family(B)
[[0, 1, 69, 36, 57, 89],
 [0, 132, 48, 71, 125, 121],
 [0, 59, 145, 10, 41, 117],
 [0, 87, 114, 112, 127, 42],
 [0, 8, 99, 137, 3, 108]]
```

It is also possible to run over all evenly distributed sets:

```
sage: E = EvenlyDistributedSetsBacktracker(Zmod(13), 4, up_to_isomorphism=False)
sage: for B in E: print(B)
[0, 1, 11, 5]
[0, 1, 4, 6]
[0, 1, 9, 3]
[0, 1, 8, 10]

sage: E = EvenlyDistributedSetsBacktracker(Zmod(13), 4, up_to_isomorphism=True)
sage: for B in E: print(B)
[0, 1, 11, 5]
```

```
>>> from sage.all import *
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(13)), Integer(4), up_to_
↪isomorphism=False)
>>> for B in E: print(B)
```

(continues on next page)

(continued from previous page)

```
[0, 1, 11, 5]
[0, 1, 4, 6]
[0, 1, 9, 3]
[0, 1, 8, 10]

>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(13)), Integer(4), up_to_
↪isomorphism=True)
>>> for B in E: print(B)
[0, 1, 11, 5]
```

Or only count them:

```
sage: for k in range(13, 200, 12):
....:     if is_prime_power(k):
....:         K = GF(k,'a')
....:         E1 = EvenlyDistributedSetsBacktracker(K, 4, False)
....:         E2 = EvenlyDistributedSetsBacktracker(K, 4, True)
....:         print("{:3} {:3} {:3}".format(k, E1.cardinality(), E2.
↪cardinality()))
 13   4   1
 25  40   4
 37  12   1
 49  24   2
 61  12   1
 73  48   4
 97  64   6
109  72   6
121 240  20
157  96   8
169 240  20
181 204  17
193 336  28
```

```
>>> from sage.all import *
>>> for k in range(Integer(13), Integer(200), Integer(12)):
...     if is_prime_power(k):
...         K = GF(k,'a')
...         E1 = EvenlyDistributedSetsBacktracker(K, Integer(4), False)
...         E2 = EvenlyDistributedSetsBacktracker(K, Integer(4), True)
...         print("{:3} {:3} {:3}".format(k, E1.cardinality(), E2.cardinality()))
 13   4   1
 25  40   4
 37  12   1
 49  24   2
 61  12   1
 73  48   4
 97  64   6
109  72   6
121 240  20
157  96   8
169 240  20
181 204  17
```

(continues on next page)

(continued from previous page)

```
193 336  28
```

Note that by definition, the number of evenly distributed sets up to isomorphisms is at most $k(k-1)$ times smaller than without isomorphisms. But it might not be exactly $k(k-1)$ as some of them might have symmetries:

```
sage: B = EvenlyDistributedSetsBacktracker(Zmod(13), 4).an_element()
sage: B
[0, 1, 11, 5]
sage: [9*x + 5 for x in B]
[5, 1, 0, 11]
sage: [3*x + 11 for x in B]
[11, 1, 5, 0]
```

```
>>> from sage.all import *
>>> B = EvenlyDistributedSetsBacktracker(Zmod(Integer(13)), Integer(4)).an_
↪element()
>>> B
[0, 1, 11, 5]
>>> [Integer(9)*x + Integer(5) for x in B]
[5, 1, 0, 11]
>>> [Integer(3)*x + Integer(11) for x in B]
[11, 1, 5, 0]
```

an_element()

Return an evenly distributed set.

If there is no such subset raise an `EmptySetError`.

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker

sage: E = EvenlyDistributedSetsBacktracker(Zmod(41),5)
sage: E.an_element()
[0, 1, 13, 38, 31]

sage: E = EvenlyDistributedSetsBacktracker(Zmod(61),6)
sage: E.an_element()
Traceback (most recent call last):
...
EmptySetError: no 6-evenly distributed set in Ring of integers modulo 61
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker

>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(41)),Integer(5))
>>> E.an_element()
[0, 1, 13, 38, 31]

>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(61)),Integer(6))
>>> E.an_element()
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
EmptySetError: no 6-evenly distributed set in Ring of integers modulo 61
```

cardinality()

Return the number of evenly distributed sets.

Use with precaution as there can be a lot of such sets and this method might be very long to answer!

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker

sage: E = EvenlyDistributedSetsBacktracker(GF(25,'a'), 4); E
4-evenly distributed sets (up to isomorphism)
 in Finite Field in a of size 5^2
sage: E.cardinality()
4

sage: E = EvenlyDistributedSetsBacktracker(GF(25,'a'), 4,
....:                                      up_to_isomorphism=False)
sage: E.cardinality()
40
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker

>>> E = EvenlyDistributedSetsBacktracker(GF(Integer(25),'a'), Integer(4)); E
4-evenly distributed sets (up to isomorphism)
 in Finite Field in a of size 5^2
>>> E.cardinality()
4

>>> E = EvenlyDistributedSetsBacktracker(GF(Integer(25),'a'), Integer(4),
...                                      up_to_isomorphism=False)
>>> E.cardinality()
40
```

to_difference_family(*B*, *check=True*)

Given an evenly distributed set `B` convert it to a difference family.

As for any $x \in K^* = H$ we have $|\Delta B \cap xH^{2(q-1)/(k(k-1))}| = 2$ (see *EvenlyDistributedSetsBacktracker*), the difference family is produced as $\{xB : x \in H^{2(q-1)/(k(k-1))}\}$

This method is useful if you want to obtain the difference family from the output of the iterator.

INPUT:

- `B` – an evenly distributed set
- `check` – boolean (default: `True`); whether to check the result

EXAMPLES:

```
sage: from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker
sage: E = EvenlyDistributedSetsBacktracker(Zmod(41),5)
sage: B = E.an_element(); B
[0, 1, 13, 38, 31]
sage: D = E.to_difference_family(B); D
[[0, 1, 13, 38, 31], [0, 32, 6, 27, 8]]

sage: from sage.combinat.designs.difference_family import is_difference_family
sage: is_difference_family(Zmod(41),D,41,5,1)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.evenly_distributed_sets import␣
↪EvenlyDistributedSetsBacktracker
>>> E = EvenlyDistributedSetsBacktracker(Zmod(Integer(41)),Integer(5))
>>> B = E.an_element(); B
[0, 1, 13, 38, 31]
>>> D = E.to_difference_family(B); D
[[0, 1, 13, 38, 31], [0, 32, 6, 27, 8]]

>>> from sage.combinat.designs.difference_family import is_difference_family
>>> is_difference_family(Zmod(Integer(41)),D,Integer(41),Integer(5),
↪Integer(1))
True
```

Setting `check` to `False` is much faster:

```
sage: timeit("df = E.to_difference_family(B, check=True)") # random
625 loops, best of 3: 117 µs per loop

sage: timeit("df = E.to_difference_family(B, check=False)")  # random
625 loops, best of 3: 1.83 µs per loop
```

```
>>> from sage.all import *
>>> timeit("df = E.to_difference_family(B, check=True)") # random
625 loops, best of 3: 117 µs per loop

>>> timeit("df = E.to_difference_family(B, check=False)")  # random
625 loops, best of 3: 1.83 µs per loop
```

External representations of block designs

This module is an API to the abstract tree represented by an XML document containing the External Representation of a list of block designs. The module also provides the related I/O operations for reading/writing `ext-rep` files or data. The parsing is based on expat.

This is a modified form of the module `ext_rep.py` (version 0.8) written by Peter Dobcsanyi [Do2009] peter@design-theory.org.

Todo

The XML data from the designtheory.org database contains a wealth of information about things like automorphism groups, transitivity, cycle type representatives, etc, but none of this data is made available through the current implementation.

class sage.combinat.designs.ext_rep.**XTree**(*node*)

Bases: object

A lazy class to wrap a rooted tree representing an XML document. The tree's nodes are tuples of the structure: (name, {dictionary of attributes}, [list of children])

Methods and services of an XTree object `t`:

- `t.attribute` – attribute named
- `t.child` – first child named
- `t[i]` – i-th child
- `for child in t:` – iterate over `t`'s children
- `len(t)` – number of `t`'s children

If child is not an empty subtree, return the subtree as an `XTree` object. If child is an empty subtree, return `_name` of the subtree. Otherwise return the child itself.

The lazy tree idea originated from a utility class of the pyRXP 0.9 package by Robin Becker at ReportLab.

class sage.combinat.designs.ext_rep.**XTreeProcessor**

Bases: object

An incremental event-driven parser for ext-rep documents. The processing stages:

- `<list_of_designs ...>` opening element. call-back: `list_of_designs_proc`
- `<list_definition>` subtree. call-back: `list_definition_proc`
- `<info>` subtree. call-back: `info_proc`
- iterating over `<designs>` processing each `<block_design>` separately. call-back: `block_design_proc`
- finishing with closing `</designs>` and `</list_of_designs>`.

parse(*xml_source*)

The main parsing function. Given an XML source (either a file handle or a string), parse the entire XML source.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: proc.save_designs = True
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)
sage: proc.list_of_designs[0]
(2, [[0, 1], [0, 1]])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> proc = ext_rep.XTreeProcessor()
>>> proc.save_designs = True
>>> f = ext_rep.open_extrep_file(file_loc)
>>> proc.parse(f)
>>> f.close()
>>> os.remove(file_loc)
>>> proc.list_of_designs[Integer(0)]
(2, [[0, 1], [0, 1]])
```

sage.combinat.designs.ext_rep.**check_dtrs_protocols**(*input_name*, *input_pv*)

Check that the XML data is in a valid format. We can currently handle version 2.0. For more information see http://designtheory.org/library/extrep/

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: ext_rep.check_dtrs_protocols('source', '2.0')
sage: ext_rep.check_dtrs_protocols('source', '3.0')
Traceback (most recent call last):
...
RuntimeError: Incompatible dtrs_protocols: program: 2.0 source: 3.0
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> ext_rep.check_dtrs_protocols('source', '2.0')
>>> ext_rep.check_dtrs_protocols('source', '3.0')
Traceback (most recent call last):
...
RuntimeError: Incompatible dtrs_protocols: program: 2.0 source: 3.0
```

sage.combinat.designs.ext_rep.**designs_from_XML**(*fname*)

Return a list of designs contained in an XML file fname. The list contains tuples of the form (v, bs) where v is the number of points of the design and bs is the list of blocks.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: ext_rep.designs_from_XML(file_loc)[0]
(2, [[0, 1], [0, 1]])
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: from sage.combinat.designs.block_design import BlockDesign
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: v, blocks = ext_rep.designs_from_XML(file_loc)[0]
sage: d = BlockDesign(v, blocks)
sage: d.blocks()
[[0, 1], [0, 1]]
sage: d.is_t_design(t=2)
```

(continues on next page)

(continued from previous page)

```
True
sage: d.is_t_design(return_parameters=True)
(True, (2, 2, 2, 2))
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> ext_rep.designs_from_XML(file_loc)[Integer(0)]
(2, [[0, 1], [0, 1]])
>>> os.remove(file_loc)

>>> from sage.combinat.designs import ext_rep
>>> from sage.combinat.designs.block_design import BlockDesign
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> v, blocks = ext_rep.designs_from_XML(file_loc)[Integer(0)]
>>> d = BlockDesign(v, blocks)
>>> d.blocks()
[[0, 1], [0, 1]]
>>> d.is_t_design(t=Integer(2))
True
>>> d.is_t_design(return_parameters=True)
(True, (2, 2, 2, 2))
```

sage.combinat.designs.ext_rep.**designs_from_XML_url**(*url*)

Return a list of designs contained in an XML file named by a URL. The list contains tuples of the form (v, bs) where v is the number of points of the design and bs is the list of blocks.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: ext_rep.designs_from_XML_url("file://" + file_loc)[0]
(2, [[0, 1], [0, 1]])
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-
↪k2.icgsa.txt.bz2") # optional - internet
[(3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 1], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]])]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> ext_rep.designs_from_XML_url("file://" + file_loc)[Integer(0)]
(2, [[0, 1], [0, 1]])
>>> os.remove(file_loc)
```

(continues on next page)

(continued from previous page)

```
>>> from sage.combinat.designs import ext_rep
>>> ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-b6-k2.
↪icgsa.txt.bz2") # optional - internet
[(3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 1], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 1], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [0, 2]]),
 (3, [[0, 1], [0, 1], [0, 1], [0, 2], [0, 2], [1, 2]]),
 (3, [[0, 1], [0, 1], [0, 2], [0, 2], [1, 2], [1, 2]])]
```

sage.combinat.designs.ext_rep.**dump_to_tmpfile**(*s*)

Utility function to dump a string to a temporary file.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile("boo")
sage: os.remove(file_loc)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile("boo")
>>> os.remove(file_loc)
```

sage.combinat.designs.ext_rep.**open_extrep_file**(*fname*)

Try to guess the compression type from extension and open the extrep file.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: f = ext_rep.open_extrep_file(file_loc)
sage: proc.parse(f)
sage: f.close()
sage: os.remove(file_loc)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> proc = ext_rep.XTreeProcessor()
>>> f = ext_rep.open_extrep_file(file_loc)
>>> proc.parse(f)
>>> f.close()
>>> os.remove(file_loc)
```

sage.combinat.designs.ext_rep.**open_extrep_url**(*url*)

Try to guess the compression type from extension and open the extrep file pointed to by the url. This function (unlike open_extrep_file) returns the uncompressed text contained in the file.

EXAMPLES:

```
sage: from sage.combinat.designs import ext_rep
sage: file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
sage: proc = ext_rep.XTreeProcessor()
sage: s = ext_rep.open_extrep_url("file://" + file_loc)
sage: proc.parse(s)
sage: os.remove(file_loc)

sage: from sage.combinat.designs import ext_rep
sage: s = ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-
↪b6-k2.icgsa.txt.bz2") # optional - internet
```

```
>>> from sage.all import *
>>> from sage.combinat.designs import ext_rep
>>> file_loc = ext_rep.dump_to_tmpfile(ext_rep.v2_b2_k2_icgsa)
>>> proc = ext_rep.XTreeProcessor()
>>> s = ext_rep.open_extrep_url("file://" + file_loc)
>>> proc.parse(s)
>>> os.remove(file_loc)

>>> from sage.combinat.designs import ext_rep
>>> s = ext_rep.designs_from_XML_url("http://designtheory.org/database/v-b-k/v3-
↪b6-k2.icgsa.txt.bz2") # optional - internet
```

Group-divisible designs (GDD)

This module gathers everything related to Group-Divisible Designs. The constructions defined here can be accessed through `designs.<tab>`:

```
sage: designs.group_divisible_design(14,{4},{2})
Group Divisible Design on 14 points of type 2^7
```

```
>>> from sage.all import *
>>> designs.group_divisible_design(Integer(14),{Integer(4)},{Integer(2)})
Group Divisible Design on 14 points of type 2^7
```

The main function implemented here is *group_divisible_design()* (which calls all others) and the main class is *GroupDivisibleDesign*. The following functions are available:

group_divisible_design()	Return a (v, K, G)-Group Divisible Design.
GDD_4_2()	Return a $(2q, \{4\}, \{2\})$-GDD for q a prime power with $q \equiv 1 \pmod 6$.

Functions

sage.combinat.designs.group_divisible_designs.**GDD_4_2**(q, *existence=False*, *check=True*)

Return a $(2q, \{4\}, \{2\})$-GDD for q a prime power with $q \equiv 1 \pmod 6$.

This method implements Lemma VII.5.17 from [BJL99] (p.495).

INPUT:

- `q` – integer
- `existence` – boolean; instead of building the design, return:

  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

EXAMPLES:

```
sage: from sage.combinat.designs.group_divisible_designs import GDD_4_2
sage: GDD_4_2(7,existence=True)
True
sage: GDD_4_2(7)
Group Divisible Design on 14 points of type 2^7
sage: GDD_4_2(8,existence=True)
Unknown
sage: GDD_4_2(8)
Traceback (most recent call last):
...
NotImplementedError
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.group_divisible_designs import GDD_4_2
>>> GDD_4_2(Integer(7),existence=True)
True
>>> GDD_4_2(Integer(7))
Group Divisible Design on 14 points of type 2^7
>>> GDD_4_2(Integer(8),existence=True)
Unknown
>>> GDD_4_2(Integer(8))
Traceback (most recent call last):
...
NotImplementedError
```

class sage.combinat.designs.group_divisible_designs.**GroupDivisibleDesign**(*points*, *groups*, *blocks*, *G=None*, *K=None*, *lambd=1*, *check=True*, *copy=True*, ***kwds*)

Bases: *IncidenceStructure*

Group Divisible Design (GDD).

Let K and G be sets of positive integers and let λ be a positive integer. A Group Divisible Design of index λ and order v is a triple $(V, \mathcal{G}, \mathcal{B})$ where:

- V is a set of cardinality v
- $\mathcal{G}$ is a partition of V into groups whose size belongs to G
- $\mathcal{B}$ is a family of subsets of V whose size belongs to K such that any two points $p_1, p_2 \in V$ from different groups appear simultaneously in exactly λ elements of $\mathcal{B}$. Besides, a group and a block intersect on at most one point.

If $K = \{k_1, ..., k_l\}$ and G has exactly m_i groups of cardinality k_i then G is said to have type $k_1^{m_1}...k_l^{m_l}$.

INPUT:

- `points` – the underlying set. If `points` is an integer v, then the set is considered to be $\{0, ..., v-1\}$
- `groups` – the groups of the design. Set to `None` for an automatic guess (this triggers `check=True` and can thus cost some time)
- `blocks` – collection of blocks
- `G` – list of integers of which the sizes of the groups must be elements. Set to `None` (automatic guess) by default
- `K` – list of integers of which the sizes of the blocks must be elements. Set to `None` (automatic guess) by default
- `lambd` – integer (default: 1); value of λ
- `check` – boolean (default: `True`); whether to check that the design is indeed a GDD with the right parameters
- `copy` – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the instance's internal data.

EXAMPLES:

```
sage: from sage.combinat.designs.group_divisible_designs import␣
↪GroupDivisibleDesign
sage: TD = designs.transversal_design(4,10)
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: GDD = GroupDivisibleDesign(40,groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.group_divisible_designs import GroupDivisibleDesign
>>> TD = designs.transversal_design(Integer(4),Integer(10))
>>> groups = [list(range(i*Integer(10),(i+Integer(1))*Integer(10))) for i in␣
↪range(Integer(4))]
>>> GDD = GroupDivisibleDesign(Integer(40),groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
```

With unspecified groups:

```
sage: # needs sage.schemes
sage: D = designs.transversal_design(4,3).relabel(list('abcdefghiklm'),
↪inplace=False).blocks()
sage: GDD = GroupDivisibleDesign('abcdefghiklm',None,D)
sage: sorted(GDD.groups())
[['a', 'b', 'c'], ['d', 'e', 'f'], ['g', 'h', 'i'], ['k', 'l', 'm']]
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> D = designs.transversal_design(Integer(4),Integer(3)).relabel(list(
↪'abcdefghiklm'),inplace=False).blocks()
>>> GDD = GroupDivisibleDesign('abcdefghiklm',None,D)
>>> sorted(GDD.groups())
[['a', 'b', 'c'], ['d', 'e', 'f'], ['g', 'h', 'i'], ['k', 'l', 'm']]
```

groups()

Return the groups of the Group-Divisible Design.

EXAMPLES:

```
sage: from sage.combinat.designs.group_divisible_designs import␣
↪GroupDivisibleDesign
sage: TD = designs.transversal_design(4,10)
sage: groups = [list(range(i*10,(i+1)*10)) for i in range(4)]
sage: GDD = GroupDivisibleDesign(40,groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
sage: GDD.groups()
[[0, 1, 2, 3, 4, 5, 6, 7, 8, 9],
 [10, 11, 12, 13, 14, 15, 16, 17, 18, 19],
 [20, 21, 22, 23, 24, 25, 26, 27, 28, 29],
 [30, 31, 32, 33, 34, 35, 36, 37, 38, 39]]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.group_divisible_designs import␣
↪GroupDivisibleDesign
>>> TD = designs.transversal_design(Integer(4),Integer(10))
>>> groups = [list(range(i*Integer(10),(i+Integer(1))*Integer(10))) for i in␣
↪range(Integer(4))]
>>> GDD = GroupDivisibleDesign(Integer(40),groups,TD); GDD
Group Divisible Design on 40 points of type 10^4
>>> GDD.groups()
[[0, 1, 2, 3, 4, 5, 6, 7, 8, 9],
 [10, 11, 12, 13, 14, 15, 16, 17, 18, 19],
 [20, 21, 22, 23, 24, 25, 26, 27, 28, 29],
 [30, 31, 32, 33, 34, 35, 36, 37, 38, 39]]
```

sage.combinat.designs.group_divisible_designs.**group_divisible_design**(*v*, *K*, *G*, *existence=False*, *check=False*)

Return a (v, K, G)-Group Divisible Design.

A (v, K, G)-GDD is a pair $(\mathcal{G}, \mathcal{B})$ where:

- $\mathcal{G}$ is a partition of $X = \bigcup \mathcal{G}$ where $|X| = v$
- $\forall S \in \mathcal{G}, |S| \in G$
- $\forall S \in \mathcal{B}, |S| \in K$
- $\mathcal{G} \cup \mathcal{B}$ is a $(v, K \cup G)$-PBD

For more information, see the documentation of *GroupDivisibleDesign* or *PairwiseBalancedDesign*.

INPUT:

- `v` – integer
- `K`, `G` – sets of integers
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)

  - `False` – meaning that the design does not exist

- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

> **Note**
>
> The GDD returned by this function are defined on `range(v)`, and its groups are sets of consecutive integers.

EXAMPLES:

```
sage: designs.group_divisible_design(14,{4},{2})
Group Divisible Design on 14 points of type 2^7
```

```
>>> from sage.all import *
>>> designs.group_divisible_design(Integer(14),{Integer(4)},{Integer(2)})
Group Divisible Design on 14 points of type 2^7
```

Hypergraph isomorphic copy search

This module implements a code for the following problem:

INPUT: two hypergraphs H_1, H_2

OUTPUT: a copy of H_2 in H_1

It is also possible to enumerate all such copies, and to require that such copies be induced copies. More formally:

A copy of H_2 in H_1 is an injection $f : V(H_2) \mapsto V(H_1)$ such that for any set $S_2 \in E(H_2)$ we have $f(S_2) \in E(H_1)$.

It is an *induced* copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{S : S \in E(H_1)$ and $S \subseteq f(V(H_2))\}$.

The functions implemented here lists all such injections. In particular, the number of copies of H in itself is equal to $|Aut(H)|$.

The feature is available through *`IncidenceStructure.isomorphic_substructures_iterator()`*.

Implementation

A hypergraph is stored as a list of edges, each of which is a "dense" bitset over $|V(H_1)|$ points. In particular, two sets of distinct cardinalities require the same memory space. A hypergraph is a C struct with the following fields:

- `n`, `m` – (`int`) number of points and edges
- `limbs` – (`int`) number of 64-bits blocks per set
- `set_space` – (`uint64_t *`) address of the memory used to store the sets
- `sets` – (`uint64_t **`) `sets[i]` points toward the `limbs` blocks encoding set i. Note also that `sets[i][limbs]` is equal to the cardinality of `set[i]`, so that `sets` has length `m*(limbs+1)*sizeof(uint64_t)`.
- `names` – (`int *`) associates an integer 'name' to each of the `n` points

The operations used on this data structure are:

- `void permute(hypergraph * h, int n1, int n2)` – exchanges points $n1$ and $n2$ in the data structure. Note that their names are also exchanged so that we still know which is which.

- `int induced_hypergraph(hypergraph * h1, int n, hypergraph * tmp1)` – stores in `tmp1` the hypergraph induced by the first n points, i.e. all sets S such that $S \subseteq \{0, ..., n-1\}$. The function returns the number of such sets.
- `void trace_hypergraph64(hypergraph * h, int n, hypergraph * tmp)` – stores in `tmp1` the trace of h on the first n points, i.e. all sets of the form $S \cap \{0, \ldots, n-1\}$.

Algorithm

We try all possible assignments of a representant $r_i \in H_1$ for every $i \in H_2$. When we have picked a representant for the first $n <$ points $\{0, \ldots, n-1\} \subsetneq V(H_2)$, we check that:

- The hypergraph induced by the (ordered) list $0, \ldots, n-1$ in H_2 is equal to the one induced by $r_0, \ldots, r_{n-1}$ in H_1.
- If $S \subseteq \{0, ..., n-1\}$ is contained in c sets of size k in H_2, then $\{r_i : i \in S\}$ is contained in $\geq c$ sets of size k in H_1. This is done by comparing the trace of the hypergraphs while remembering the original size of each set.

As we very often need to build the hypergraph obtained by the trace of the first n points (for all possible n), those hypergraphs are cached. The hypergraphs induced by the same points are handled similarly.

Limitations

Number of points For efficiency reason the implementation assumes that H_2 has ≤ 64 points. Making this work for larger values means that calls to `qsort` have to be replaced by calls to `qsort_r` (i.e. to sort the edges you need to know the number of limbs per edge) and that induces a big slowdown for small cases (~50% when this code was implemented). Also, 64 points for H_2 is already very very big considering the problem at hand. Even $|V(H_1)| > 64$ seems too much.

Vertex ordering The order of vertices in H_2 has a huge influence on the performance of the algorithm. If no set of H_2 contains more that one of the first $k < n$ points, then almost all partial assignments of representants are possible for the first k points (though the degree of the vertices is taken into account). For this reason it is best to pick an ordering such that the first vertices are contained in as many sets as possible together. A heuristic is implemented at *relabel_heuristic()*.

AUTHORS:

- Nathann Cohen (November 2014, written in various airports between Nice and Chennai).

Methods

class sage.combinat.designs.subhypergraph_search.**SubHypergraphSearch**

Bases: object

relabel_heuristic()

Relabel H_2 in order to make the algorithm faster.

Objective: we try to pick an ordering $p_1, ..., p_k$ of the points of H_2 that maximizes the number of sets involving the first points in the ordering. One way to formalize the problems indicates that it may be NP-Hard (generalizes the max clique problem for graphs) so we do not try to solve it exactly: we just need a sufficiently good heuristic.

Assuming that the first points are $p_1, ..., p_k$, we determine p_{k+1} as the point x such that the number of sets S with $x \in S$ and $S \cap \{p_1, ..., p_k\} \neq \emptyset$ is maximal. In case of ties, we take a point with maximum degree.

This function is called when an instance of *SubHypergraphSearch* is created.

EXAMPLES:

```
sage: d = designs.projective_plane(3)                                    #␣
↪needs sage.schemes
sage: d.isomorphic_substructures_iterator(d).relabel_heuristic()         #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> d = designs.projective_plane(Integer(3))                                ␣
↪     # needs sage.schemes
>>> d.isomorphic_substructures_iterator(d).relabel_heuristic()            #␣
↪needs sage.schemes
```

Incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure is specified by a list of points, blocks, or an incidence matrix ([1],[2]). *IncidenceStructure* instances have the following methods:

automorphism_group()	Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.
block_sizes()	Return the set of block sizes.
blocks()	Return the list of blocks.
canonical_label()	Return a canonical label for the incidence structure.
coloring()	Compute a (weak) k-coloring of the hypergraph.
complement()	Return the complement of the incidence structure.
copy()	Return a copy of the incidence structure.
degree()	Return the degree of a point `p` (or a set of points).
degrees()	Return the degree of all sets of given size, or the degree of all points.
dual()	Return the dual of the incidence structure.
edge_coloring()	Compute a proper edge-coloring.
ground_set()	Return the ground set (i.e the list of points).
incidence_graph()	Return the incidence graph of the incidence structure.
incidence_matrix()	Return the incidence matrix A of the design. A is a $(v \times b)$ matrix defined by: `A[i,j] = 1` if `i` is in block `B_j` and 0 otherwise.
induced_substructure()	Return the substructure induced by a set of points.
intersection_graph()	Return the intersection graph of the incidence structure.
is_berge_cyclic()	Check whether `self` is a Berge-Cyclic uniform hypergraph.
is_connected()	Test whether the design is connected.
is_generalized_quadrangle()	Test if the incidence structure is a generalized quadrangle.
is_isomorphic()	Return whether the two incidence structures are isomorphic.
is_regular()	Test whether the incidence structure is r-regular.
is_resolvable()	Test whether the hypergraph is resolvable.
is_simple()	Test whether this design is simple (i.e. no repeated block).
is_spread()	Check whether the input is a spread for `self`.
is_t_design()	Test whether `self` is a $t-(v,k,l)$ design.
is_uniform()	Test whether the incidence structure is k-uniform
isomorphic_substructures_iterator()	Iterate over all copies of `H2` contained in `self`.
num_blocks()	Return the number of blocks.

[1] Block designs and incidence structures from wikipedia, Wikipedia article Block_design Wikipedia article Incidence_structure
[2] E. Assmus, J. Key, Designs and their codes, CUP, 1992.

Table 3 – continued from previous page

num_points()	Return the size of the ground set.
packing()	Return a maximum packing.
rank()	Return the rank of the hypergraph (the maximum size of a block).
relabel()	Relabel the ground set.
trace()	Return the trace of a set of points.

Methods

class sage.combinat.designs.incidence_structures.**IncidenceStructure**(*points=None*, *blocks=None*, *incidence_matrix=None*, *name=None*, *check=True*, *copy=True*)

Bases: SageObject

A base class for incidence structures (i.e. hypergraphs, i.e. set systems)

An incidence structure (i.e. hypergraph, i.e. set system) can be defined from a collection of blocks (i.e. sets, i.e. edges), optionally with an explicit ground set (i.e. point set, i.e. vertex set). Alternatively they can be defined from a binary incidence matrix.

INPUT:

- `points` – (i.e. ground set, i.e. vertex set) the underlying set. If `points` is an integer v, then the set is considered to be $\{0, ..., v-1\}$.

  Note

  The following syntax, where `points` is omitted, automatically defines the ground set as the union of the blocks:

  ```
  sage: H = IncidenceStructure([['a','b','c'],['c','d','e']])
  sage: sorted(H.ground_set())
  ['a', 'b', 'c', 'd', 'e']
  ```

  ```
  >>> from sage.all import *
  >>> H = IncidenceStructure([['a','b','c'],['c','d','e']])
  >>> sorted(H.ground_set())
  ['a', 'b', 'c', 'd', 'e']
  ```

- `blocks` – (i.e. edges, i.e. sets) the blocks defining the incidence structure; can be any iterable
- `incidence_matrix` – a binary incidence matrix; each column represents a set
- `name` – string (such as "Fano plane")

- `check` – whether to check the input
- `copy` – (use with caution) if set to `False` then `blocks` must be a list of lists of integers. The list will not be copied but will be modified in place (each block is sorted, and the whole list is sorted). Your `blocks` object will become the *IncidenceStructure* instance's internal data.

EXAMPLES:

An incidence structure can be constructed by giving the number of points and the list of blocks:

```
sage: IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,
↪5]])
Incidence structure with 7 points and 7 blocks
```

```
>>> from sage.all import *
>>> IncidenceStructure(Integer(7), [[Integer(0),Integer(1),Integer(2)],
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
Incidence structure with 7 points and 7 blocks
```

Only providing the set of blocks is sufficient. In this case, the ground set is defined as the union of the blocks:

```
sage: IncidenceStructure([[1,2,3],[2,3,4]])
Incidence structure with 4 points and 2 blocks
```

```
>>> from sage.all import *
>>> IncidenceStructure([[Integer(1),Integer(2),Integer(3)],[Integer(2),Integer(3),
↪Integer(4)]])
Incidence structure with 4 points and 2 blocks
```

Or by its adjacency matrix (a $\{0,1\}$-matrix in which rows are indexed by points and columns by blocks):

```
sage: m = matrix([[0,1,0],[0,0,1],[1,0,1],[1,1,1]])                              #␣
↪needs sage.modules
sage: IncidenceStructure(m)                                                      #␣
↪needs sage.modules
Incidence structure with 4 points and 3 blocks
```

```
>>> from sage.all import *
>>> m = matrix([[Integer(0),Integer(1),Integer(0)],[Integer(0),Integer(0),
↪Integer(1)],[Integer(1),Integer(0),Integer(1)],[Integer(1),Integer(1),
↪Integer(1)]])                                  # needs sage.modules
>>> IncidenceStructure(m)                                                        #␣
↪needs sage.modules
Incidence structure with 4 points and 3 blocks
```

The points can be any (hashable) object:

```
sage: V = [(0,'a'),(0,'b'),(1,'a'),(1,'b')]
sage: B = [(V[0],V[1],V[2]), (V[1],V[2]), (V[0],V[2])]
sage: I = IncidenceStructure(V, B)
sage: I.ground_set()
[(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]
```

(continues on next page)

(continued from previous page)

```
sage: I.blocks()
[[(0, 'a'), (0, 'b'), (1, 'a')], [(0, 'a'), (1, 'a')], [(0, 'b'), (1, 'a')]]
```

```
>>> from sage.all import *
>>> V = [(Integer(0),'a'),(Integer(0),'b'),(Integer(1),'a'),(Integer(1),'b')]
>>> B = [(V[Integer(0)],V[Integer(1)],V[Integer(2)]), (V[Integer(1)],
↪V[Integer(2)]), (V[Integer(0)],V[Integer(2)])]
>>> I = IncidenceStructure(V, B)
>>> I.ground_set()
[(0, 'a'), (0, 'b'), (1, 'a'), (1, 'b')]
>>> I.blocks()
[[(0, 'a'), (0, 'b'), (1, 'a')], [(0, 'a'), (1, 'a')], [(0, 'b'), (1, 'a')]]
```

The order of the points and blocks does not matter as they are sorted on input (see Issue #11333):

```
sage: A = IncidenceStructure([0,1,2], [[0],[0,2]])
sage: B = IncidenceStructure([1,0,2], [[0],[2,0]])
sage: B == A
True

sage: C = BlockDesign(2, [[0], [1,0]])
sage: D = BlockDesign(2, [[0,1], [0]])
sage: C == D
True
```

```
>>> from sage.all import *
>>> A = IncidenceStructure([Integer(0),Integer(1),Integer(2)], [[Integer(0)],
↪[Integer(0),Integer(2)]])
>>> B = IncidenceStructure([Integer(1),Integer(0),Integer(2)], [[Integer(0)],
↪[Integer(2),Integer(0)]])
>>> B == A
True

>>> C = BlockDesign(Integer(2), [[Integer(0)], [Integer(1),Integer(0)]])
>>> D = BlockDesign(Integer(2), [[Integer(0),Integer(1)], [Integer(0)]])
>>> C == D
True
```

If you care for speed, you can set `copy` to `False`, but in that case, your input must be a list of lists and the ground set must be $0, ..., v-1$:

```
sage: blocks = [[0,1],[2,0],[1,2]]  # a list of lists of integers
sage: I = IncidenceStructure(3, blocks, copy=False)
sage: I._blocks is blocks
True
```

```
>>> from sage.all import *
>>> blocks = [[Integer(0),Integer(1)],[Integer(2),Integer(0)],[Integer(1),
↪Integer(2)]]  # a list of lists of integers
>>> I = IncidenceStructure(Integer(3), blocks, copy=False)
>>> I._blocks is blocks
True
```

automorphism_group()

Return the subgroup of the automorphism group of the incidence graph which respects the P B partition. It is (isomorphic to) the automorphism group of the block design, although the degrees differ.

EXAMPLES:

```
sage: # needs sage.groups sage.rings.finite_rings
sage: P = designs.DesarguesianProjectivePlaneDesign(2); P
(7,3,1)-Balanced Incomplete Block Design
sage: G = P.automorphism_group()
sage: G.is_isomorphic(PGL(3,2))
True
sage: G
Permutation Group with generators [...]
sage: G.cardinality()
168
```

```
>>> from sage.all import *
>>> # needs sage.groups sage.rings.finite_rings
>>> P = designs.DesarguesianProjectivePlaneDesign(Integer(2)); P
(7,3,1)-Balanced Incomplete Block Design
>>> G = P.automorphism_group()
>>> G.is_isomorphic(PGL(Integer(3),Integer(2)))
True
>>> G
Permutation Group with generators [...]
>>> G.cardinality()
168
```

A non self-dual example:

```
sage: IS = IncidenceStructure(list(range(4)), [[0,1,2,3],[1,2,3]])
sage: IS.automorphism_group().cardinality()                                  #␣
↪needs sage.groups
6
sage: IS.dual().automorphism_group().cardinality()                          #␣
↪needs sage.groups sage.modules
1
```

```
>>> from sage.all import *
>>> IS = IncidenceStructure(list(range(Integer(4))), [[Integer(0),Integer(1),
↪Integer(2),Integer(3)],[Integer(1),Integer(2),Integer(3)]])
>>> IS.automorphism_group().cardinality()                                   #␣
↪needs sage.groups
6
>>> IS.dual().automorphism_group().cardinality()                            #␣
↪needs sage.groups sage.modules
1
```

Examples with non-integer points:

```
sage: I = IncidenceStructure('abc', ('ab','ac','bc'))
sage: I.automorphism_group()                                                #␣
↪needs sage.groups
```

(continues on next page)

(continued from previous page)

```
Permutation Group with generators [('b','c'), ('a','b')]
sage: IncidenceStructure([[(1,2),(3,4)]]).automorphism_group()              #␣
↪needs sage.groups
Permutation Group with generators [((1,2),(3,4))]
```

```
>>> from sage.all import *
>>> I = IncidenceStructure('abc', ('ab','ac','bc'))
>>> I.automorphism_group()                                                  #␣
↪needs sage.groups
Permutation Group with generators [('b','c'), ('a','b')]
>>> IncidenceStructure([[(Integer(1),Integer(2)),(Integer(3),Integer(4))]]).
↪automorphism_group()              # needs sage.groups
Permutation Group with generators [((1,2),(3,4))]
```

block_sizes()

Return the set of block sizes.

EXAMPLES:

```
sage: BD = IncidenceStructure(8, [[0,1,3],[1,4,5,6],[1,2],[5,6,7]])
sage: BD.block_sizes()
[3, 2, 4, 3]
sage: BD = IncidenceStructure(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,
↪6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
```

```
>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(8), [[Integer(0),Integer(1),Integer(3)],
↪[Integer(1),Integer(4),Integer(5),Integer(6)],[Integer(1),Integer(2)],
↪[Integer(5),Integer(6),Integer(7)]])
>>> BD.block_sizes()
[3, 2, 4, 3]
>>> BD = IncidenceStructure(Integer(7),[[Integer(0),Integer(1),Integer(2)],
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
```

blocks()

Return the list of blocks.

EXAMPLES:

```
sage: BD = IncidenceStructure(7,[[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,
↪6],[2,4,5]])
sage: BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

```
>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(7),[[Integer(0),Integer(1),Integer(2)],
```

(continues on next page)

(continued from previous page)

```
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],[Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.blocks()
[[0, 1, 2], [0, 3, 4], [0, 5, 6], [1, 3, 5], [1, 4, 6], [2, 3, 6], [2, 4, 5]]
```

canonical_label()

Return a canonical label for the incidence structure.

A canonical label is relabeling of the points into integers $\{0, ..., n-1\}$ such that isomorphic incidence structures are relabelled to equal objects.

EXAMPLES:

```
sage: # needs sage.schemes
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
sage: fano1 == fano2
False
sage: fano1.relabel(fano1.canonical_label())
sage: fano2.relabel(fano2.canonical_label())
sage: fano1 == fano2
True
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> fano1 = designs.balanced_incomplete_block_design(Integer(7),Integer(3))
>>> fano2 = designs.projective_plane(Integer(2))
>>> fano1 == fano2
False
>>> fano1.relabel(fano1.canonical_label())
>>> fano2.relabel(fano2.canonical_label())
>>> fano1 == fano2
True
```

coloring(*k*, *solver=None*, *verbose=None*, *integrality_tolerance=0*)

Compute a (weak) k-coloring of the hypergraph.

A weak coloring of a hypergraph $\mathcal{H}$ is an assignment of colors to its vertices such that no set is monochromatic.

INPUT:

- `k` – integer; compute a coloring with k colors if an integer is provided, otherwise returns an optimal coloring (i.e. with the minimum possible number of colors).
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – nonnegative integer (default: 0); set the level of verbosity you want from the linear program solver. Since the problem is NP-complete, its solving may take some time depending on the graph. A value of 0 means that there will be no message printed by the solver.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

EXAMPLES:

The Fano plane has chromatic number 3:

```
sage: len(designs.steiner_triple_system(7).coloring())                          #␣
↪needs sage.numerical.mip
3
```

```
>>> from sage.all import *
>>> len(designs.steiner_triple_system(Integer(7)).coloring())                   ␣
↪     # needs sage.numerical.mip
3
```

One admissible 3-coloring:

```
sage: designs.steiner_triple_system(7).coloring()    # not tested              #␣
↪needs sage.numerical.mip
[[0, 2, 5, 1], [4, 3], [6]]
```

```
>>> from sage.all import *
>>> designs.steiner_triple_system(Integer(7)).coloring()    # not tested      ␣
↪     # needs sage.numerical.mip
[[0, 2, 5, 1], [4, 3], [6]]
```

The chromatic number of a graph is equal to the chromatic number of its 2-uniform corresponding hypergraph:

```
sage: g = graphs.PetersenGraph()
sage: H = IncidenceStructure(g.edges(sort=True, labels=False))
sage: len(g.coloring())
3
sage: len(H.coloring())                                                         #␣
↪needs sage.numerical.mip
3
```

```
>>> from sage.all import *
>>> g = graphs.PetersenGraph()
>>> H = IncidenceStructure(g.edges(sort=True, labels=False))
>>> len(g.coloring())
3
>>> len(H.coloring())                                                          #␣
↪needs sage.numerical.mip
3
```

complement(*uniform=False*)

Return the complement of the incidence structure.

Two different definitions of "complement" are made available, according to the value of `uniform`.

INPUT:

- `uniform` – boolean
  - if set to `False` (default), returns the incidence structure whose blocks are the complements of all blocks of the incidence structure.

– If set to `True` and the incidence structure is k-uniform, returns the incidence structure whose blocks are all k-sets of the ground set that do not appear in `self`.

EXAMPLES:

The complement of a *BalancedIncompleteBlockDesign* is also a 2-design:

```
sage: bibd = designs.balanced_incomplete_block_design(13,4)                    #␣
↪needs sage.schemes
sage: bibd.is_t_design(return_parameters=True)                                 #␣
↪needs sage.schemes
(True, (2, 13, 4, 1))
sage: bibd.complement().is_t_design(return_parameters=True)                    #␣
↪needs sage.schemes
(True, (2, 13, 9, 6))
```

```
>>> from sage.all import *
>>> bibd = designs.balanced_incomplete_block_design(Integer(13),Integer(4))  ␣
↪              # needs sage.schemes
>>> bibd.is_t_design(return_parameters=True)                                  #␣
↪needs sage.schemes
(True, (2, 13, 4, 1))
>>> bibd.complement().is_t_design(return_parameters=True)                     #␣
↪needs sage.schemes
(True, (2, 13, 9, 6))
```

The "uniform" complement of a graph is a graph:

```
sage: g = graphs.PetersenGraph()
sage: G = IncidenceStructure(g.edges(sort=True, labels=False))
sage: H = G.complement(uniform=True)
sage: h = Graph(H.blocks())
sage: g == h
False
sage: g == h.complement()
True
```

```
>>> from sage.all import *
>>> g = graphs.PetersenGraph()
>>> G = IncidenceStructure(g.edges(sort=True, labels=False))
>>> H = G.complement(uniform=True)
>>> h = Graph(H.blocks())
>>> g == h
False
>>> g == h.complement()
True
```

copy()

Return a copy of the incidence structure.

EXAMPLES:

```
sage: IS = IncidenceStructure([[1,2,3,"e"]], name='Test')
sage: IS
Incidence structure with 4 points and 1 blocks
```

(continues on next page)

(continued from previous page)

```
sage: copy(IS)
Incidence structure with 4 points and 1 blocks
sage: [1, 2, 3, 'e'] in copy(IS)
True
sage: copy(IS)._name
'Test'
```

```
>>> from sage.all import *
>>> IS = IncidenceStructure([[Integer(1),Integer(2),Integer(3),"e"]], name=
↪'Test')
>>> IS
Incidence structure with 4 points and 1 blocks
>>> copy(IS)
Incidence structure with 4 points and 1 blocks
>>> [Integer(1), Integer(2), Integer(3), 'e'] in copy(IS)
True
>>> copy(IS)._name
'Test'
```

degree(*p=None*, *subset=False*)

Return the degree of a point `p` (or a set of points).

The degree of a point (or set of points) is the number of blocks that contain it.

INPUT:

- `p` – a point (or a set of points) of the incidence structure
- `subset` – boolean (default: `False`); whether to interpret the argument as a set of point or as a point (default)

EXAMPLES:

```
sage: designs.steiner_triple_system(9).degree(3)
4
sage: designs.steiner_triple_system(9).degree({1,2},subset=True)
1
```

```
>>> from sage.all import *
>>> designs.steiner_triple_system(Integer(9)).degree(Integer(3))
4
>>> designs.steiner_triple_system(Integer(9)).degree({Integer(1),Integer(2)},
↪subset=True)
1
```

degrees(*size=None*)

Return the degree of all sets of given size, or the degree of all points.

The degree of a point (or set of point) is the number of blocks that contain it.

INPUT:

- `size` – integer; return the degree of all subsets of points of cardinality `size`. When `size=None`, the function outputs the degree of all points.

> **Note**
>
> When `size=None` the output is indexed by the points. When `size=1` it is indexed by tuples of size 1. This is the same information, stored slightly differently.

OUTPUT: a dictionary whose values are degrees and keys are either:

- the points of the incidence structure if `size=None` (default)
- the subsets of size `size` of the points stored as tuples

EXAMPLES:

```
sage: IncidenceStructure([[1,2,3],[1,4]]).degrees(2)
{(1, 2): 1, (1, 3): 1, (1, 4): 1, (2, 3): 1, (2, 4): 0, (3, 4): 0}
```

```
>>> from sage.all import *
>>> IncidenceStructure([[Integer(1),Integer(2),Integer(3)],[Integer(1),
↪Integer(4)]]).degrees(Integer(2))
{(1, 2): 1, (1, 3): 1, (1, 4): 1, (2, 3): 1, (2, 4): 0, (3, 4): 0}
```

In a Steiner triple system, all pairs have degree 1:

```
sage: S13 = designs.steiner_triple_system(13)
sage: all(v == 1 for v in S13.degrees(2).values())
True
```

```
>>> from sage.all import *
>>> S13 = designs.steiner_triple_system(Integer(13))
>>> all(v == Integer(1) for v in S13.degrees(Integer(2)).values())
True
```

dual(*algorithm=None*)

Return the dual of the incidence structure.

INPUT:

- `algorithm` – whether to use Sage's implementation (`algorithm=None`, default) or use GAP's (`algorithm='gap'`)

> **Note**
>
> The `algorithm='gap'` option requires GAP's Design package (included in the `gap_packages` Sage spkg).

EXAMPLES:

The dual of a projective plane is a projective plane:

```
sage: PP = designs.DesarguesianProjectivePlaneDesign(4)                    #␣
↪needs sage.rings.finite_rings
sage: PP.dual().is_t_design(return_parameters=True)                        #␣
↪needs sage.modules sage.rings.finite_rings
(True, (2, 21, 5, 1))
```

```
>>> from sage.all import *
>>> PP = designs.DesarguesianProjectivePlaneDesign(Integer(4))
↪     # needs sage.rings.finite_rings
>>> PP.dual().is_t_design(return_parameters=True)
↪needs sage.modules sage.rings.finite_rings
(True, (2, 21, 5, 1))
```

REFERENCE:

- Leonard Soicher, Design package manual

edge_coloring()

Compute a proper edge-coloring.

A proper edge-coloring is an assignment of colors to the sets of the incidence structure such that two sets with non-empty intersection receive different colors. The coloring returned minimizes the number of colors.

OUTPUT: a partition of the sets into color classes

EXAMPLES:

```
sage: H = Hypergraph([{1,2,3},{2,3,4},{3,4,5},{4,5,6}]); H
Incidence structure with 6 points and 4 blocks
sage: C = H.edge_coloring()
sage: C # random
[[[3, 4, 5]], [[2, 3, 4]], [[4, 5, 6], [1, 2, 3]]]
sage: Set(map(Set,sum(C,[]))) == Set(map(Set,H.blocks()))
True
```

```
>>> from sage.all import *
>>> H = Hypergraph([{Integer(1),Integer(2),Integer(3)},{Integer(2),Integer(3),
↪Integer(4)},{Integer(3),Integer(4),Integer(5)},{Integer(4),Integer(5),
↪Integer(6)}]); H
Incidence structure with 6 points and 4 blocks
>>> C = H.edge_coloring()
>>> C # random
[[[3, 4, 5]], [[2, 3, 4]], [[4, 5, 6], [1, 2, 3]]]
>>> Set(map(Set,sum(C,[]))) == Set(map(Set,H.blocks()))
True
```

ground_set()

Return the ground set (i.e the list of points).

EXAMPLES:

```
sage: IncidenceStructure(3, [[0,1],[0,2]]).ground_set()
[0, 1, 2]
```

```
>>> from sage.all import *
>>> IncidenceStructure(Integer(3), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)]]).ground_set()
[0, 1, 2]
```

incidence_graph(*labels=False*)

Return the incidence graph of the incidence structure.

A point and a block are adjacent in this graph whenever they are incident.

INPUT:

- `labels` – boolean; whether to return a graph whose vertices are integers, or labelled elements
  - `labels is False` – default; in this case the first vertices of the graphs are the elements of *`ground_set()`*, and appear in the same order. Similarly, the following vertices represent the elements of *`blocks()`*, and appear in the same order.
  - `labels is True`, the points keep their original labels, and the blocks are `Set` objects.

    Note that the labelled incidence graph can be incorrect when blocks are repeated, and on some (rare) occasions when the elements of *`ground_set()`* mix `Set()` and non-`Set` objects.

EXAMPLES:

```
sage: BD = IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],
....:                             [1,4,6],[2,3,6],[2,4,5]])
sage: BD.incidence_graph()                                                  #␣
↪needs sage.modules
Bipartite graph on 14 vertices
sage: A = BD.incidence_matrix()                                             #␣
↪needs sage.modules
sage: Graph(block_matrix([[A*0, A],                                         #␣
↪needs sage.modules
....:                     [A.transpose(),A*0]])) == BD.incidence_graph()
True
```

```
>>> from sage.all import *
>>> BD = IncidenceStructure(Integer(7), [[Integer(0),Integer(1),Integer(2)],
↪[Integer(0),Integer(3),Integer(4)],[Integer(0),Integer(5),Integer(6)],
↪[Integer(1),Integer(3),Integer(5)],
...                               [Integer(1),Integer(4),Integer(6)],
↪[Integer(2),Integer(3),Integer(6)],[Integer(2),Integer(4),Integer(5)]])
>>> BD.incidence_graph()                                                    #␣
↪needs sage.modules
Bipartite graph on 14 vertices
>>> A = BD.incidence_matrix()                                               #␣
↪needs sage.modules
>>> Graph(block_matrix([[A*Integer(0), A],                                      ␣
↪     # needs sage.modules
...                     [A.transpose(),A*Integer(0)]])) == BD.incidence_
↪graph()
True
```

incidence_matrix()

Return the incidence matrix A of the design. A is a $(v \times b)$ matrix defined by: `A[i,j] = 1` if `i` is in block `B_j` and 0 otherwise.

EXAMPLES:

```
sage: BD = IncidenceStructure(7, [[0,1,2],[0,3,4],[0,5,6],[1,3,5],
....:                             [1,4,6],[2,3,6],[2,4,5]])
sage: BD.block_sizes()
[3, 3, 3, 3, 3, 3, 3]
sage: BD.incidence_matrix()                                                 #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.modules
[1 1 1 0 0 0 0]
[1 0 0 1 1 0 0]

↪needs sage.modules
[1 1 1 0]
[1 1 0 0]
[0 1 1 1]
```

induced_substructure(*points*)

Return the substructure induced by a set of points.

The substructure induced in $\mathcal{H}$ by a set $X \subseteq V(\mathcal{H})$ of points is the incidence structure $\mathcal{H}_X$ defined on X whose sets are all $S \in \mathcal{H}$ such that $S \subseteq X$.

INPUT:

- `points` – set of points

> **Note**
>
> This method goes over all sets of `self` before building a new *IncidenceStructure* (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:

A Fano plane with one point removed:

```
sage: F = designs.steiner_triple_system(7)
sage: F.induced_substructure([0..5])
Incidence structure with 6 points and 4 blocks
```

```
>>> from sage.all import *
>>> F = designs.steiner_triple_system(Integer(7))
>>> F.induced_substructure((ellipsis_range(Integer(0),Ellipsis,Integer(5))))
Incidence structure with 6 points and 4 blocks
```

intersection_graph(*sizes=None*, *immutable=False*)

Return the intersection graph of the incidence structure.

The vertices of this graph are the *blocks()* of the incidence structure. Two of them are adjacent if the size of their intersection belongs to the set `sizes`.

INPUT:

- `sizes` – list/set of integers; for convenience, setting `sizes` to `5` has the same effect as `sizes=[5]`. When set to `None` (default), behaves as `sizes=PositiveIntegers()`.
- `immutable` – boolean (default: `False`); whether to return an immutable or a mutable graph

EXAMPLES:

The intersection graph of a *balanced_incomplete_block_design()* is a `strongly regular graph` (when it is not trivial):

```
sage: BIBD =  designs.balanced_incomplete_block_design(19,3)
sage: G = BIBD.intersection_graph(1)
sage: G.is_strongly_regular(parameters=True)
(57, 24, 11, 9)
```

```
>>> from sage.all import *
>>> BIBD =  designs.balanced_incomplete_block_design(Integer(19),Integer(3))
>>> G = BIBD.intersection_graph(Integer(1))
>>> G.is_strongly_regular(parameters=True)
(57, 24, 11, 9)
```

is_berge_cyclic()

Check whether `self` is a Berge-Cyclic uniform hypergraph.

A k-uniform Berge cycle (named after Claude Berge) of length ℓ is a cyclic list of distinct k-sets $F_1, \ldots, F_\ell$, $\ell > 1$, and distinct vertices $C = \{v_1, \ldots, v_\ell\}$ such that for each $1 \leq i \leq \ell$, F_i contains v_i and v_{i+1} (where $v_{l+1} = v_1$).

A uniform hypergraph is Berge-cyclic if its incidence graph is cyclic. It is called "Berge-acyclic" otherwise.

For more information, see [Fag1983] and Wikipedia article Hypergraph.

EXAMPLES:

```
sage: Hypergraph(5, [[1, 2, 3], [2, 3, 4]]).is_berge_cyclic()                #␣
↪needs sage.modules
True
sage: Hypergraph(6, [[1, 2, 3], [3, 4, 5]]).is_berge_cyclic()                #␣
↪needs sage.modules
False
```

```
>>> from sage.all import *
>>> Hypergraph(Integer(5), [[Integer(1), Integer(2), Integer(3)], [Integer(2),
↪ Integer(3), Integer(4)]]).is_berge_cyclic()                # needs sage.
↪modules
True
>>> Hypergraph(Integer(6), [[Integer(1), Integer(2), Integer(3)], [Integer(3),
↪ Integer(4), Integer(5)]]).is_berge_cyclic()                # needs sage.
↪modules
False
```

is_connected()

Test whether the design is connected.

EXAMPLES:

```
sage: IncidenceStructure(3, [[0,1],[0,2]]).is_connected()
True
sage: IncidenceStructure(4, [[0,1],[2,3]]).is_connected()
False
```

```
>>> from sage.all import *
>>> IncidenceStructure(Integer(3), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)]]).is_connected()
True
>>> IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(2),
↪Integer(3)]]).is_connected()
False
```

is_generalized_quadrangle(*verbose=False*, *parameters=False*)

Test if the incidence structure is a generalized quadrangle.

An incidence structure is a generalized quadrangle iff (see [BH2012], section 9.6):

- two blocks intersect on at most one point.
- For every point p not in a block B, there is a unique block B' intersecting both $\{p\}$ and B

It is a *regular* generalized quadrangle if furthermore:

- it is $s+1$-*uniform* for some positive integer s.
- it is $t+1$-*regular* for some positive integer t.

For more information, see the Wikipedia article Generalized_quadrangle.

> **Note**
>
> Some references (e.g. [PT2009] or Wikipedia article Generalized_quadrangle) only allow *regular* generalized quadrangles. To use such a definition, see the `parameters` optional argument described below, or the methods *is_regular()* and *is_uniform()*.

INPUT:

- `verbose` – boolean; whether to print an explanation when the instance is not a generalized quadrangle
- `parameters` – boolean (default: `False`); if set to `True`, the function returns a pair `(s,t)` instead of `True` answers. In this case, s and t are the integers defined above if they exist (each can be set to `False` otherwise).

EXAMPLES:

```
sage: h = designs.CremonaRichmondConfiguration()                    #␣
↪needs networkx
sage: h.is_generalized_quadrangle()                                 #␣
↪needs networkx
True
```

```
>>> from sage.all import *
>>> h = designs.CremonaRichmondConfiguration()                      #␣
↪needs networkx
>>> h.is_generalized_quadrangle()                                   #␣
↪needs networkx
True
```

This is actually a *regular* generalized quadrangle:

```
sage: h.is_generalized_quadrangle(parameters=True)                  #␣
↪needs networkx
(2, 2)
```

```
>>> from sage.all import *
>>> h.is_generalized_quadrangle(parameters=True)                    #␣
↪needs networkx
(2, 2)
```

is_isomorphic(*other*, *certificate=False*)

Return whether the two incidence structures are isomorphic.

INPUT:

- `other` – an incidence structure
- `certificate` – boolean (default: `False`); whether to return an isomorphism from `self` to `other` instead of a boolean answer

EXAMPLES:

```
sage: # needs sage.schemes
sage: fano1 = designs.balanced_incomplete_block_design(7,3)
sage: fano2 = designs.projective_plane(2)
```

(continues on next page)

(continued from previous page)

```
sage: fano1.is_isomorphic(fano2)
True
sage: fano1.is_isomorphic(fano2,certificate=True)
{0: 0, 1: 1, 2: 2, 3: 6, 4: 4, 5: 3, 6: 5}
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> fano1 = designs.balanced_incomplete_block_design(Integer(7),Integer(3))
>>> fano2 = designs.projective_plane(Integer(2))
>>> fano1.is_isomorphic(fano2)
True
>>> fano1.is_isomorphic(fano2,certificate=True)
{0: 0, 1: 1, 2: 2, 3: 6, 4: 4, 5: 3, 6: 5}
```

is_regular(*r=None*)

Test whether the incidence structure is r-regular.

An incidence structure is said to be r-regular if all its points are incident with exactly r blocks.

INPUT:

- `r` – integer

OUTPUT:

If `r` is defined, a boolean is returned. If `r` is set to `None` (default), the method returns either `False` or the integer `r` such that the incidence structure is r-regular.

Warning

In case of 0-regular incidence structure, beware that `if not H.is_regular()` is a satisfied condition.

EXAMPLES:

```
sage: designs.balanced_incomplete_block_design(7,3).is_regular()              #␣
↪needs sage.schemes
3
sage: designs.balanced_incomplete_block_design(7,3).is_regular(r=3)           #␣
↪needs sage.schemes
True
sage: designs.balanced_incomplete_block_design(7,3).is_regular(r=4)           #␣
↪needs sage.schemes
False
```

```
>>> from sage.all import *
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪regular()             # needs sage.schemes
3
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪regular(r=Integer(3))          # needs sage.schemes
True
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
```

(continues on next page)

(continued from previous page)

```
↪regular(r=Integer(4))          # needs sage.schemes
False
```

is_resolvable(*certificate*, *solver=False*, *verbose=None*, *check=0*, *integrality_tolerance=True*)

Test whether the hypergraph is resolvable.

A hypergraph is said to be resolvable if its sets can be partitionned into classes, each of which is a partition of the ground set.

Note

This problem is solved using an Integer Linear Program, and GLPK (the default LP solver) has been reported to be very slow on some instances. If you hit this wall, consider installing a more powerful MILP solver (CPLEX, Gurobi, …).

INPUT:

- `certificate` – boolean; whether to return the classes along with the binary answer (see examples below)
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – integer (default: 0); sets the level of verbosity. Set to 0 by default, which means quiet.
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

EXAMPLES:

Some resolvable designs:

```
sage: TD = designs.transversal_design(2,2,resolvable=True)
sage: TD.is_resolvable()
True

sage: AG = designs.AffineGeometryDesign(3,1,GF(2))                    #␣
↪needs sage.combinat
sage: AG.is_resolvable()                                              #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(2),Integer(2),resolvable=True)
>>> TD.is_resolvable()
True

>>> AG = designs.AffineGeometryDesign(Integer(3),Integer(1),GF(Integer(2)))  ␣
↪                        # needs sage.combinat
>>> AG.is_resolvable()                                                 #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat
True
```

Their classes:

```
sage: b, cls = TD.is_resolvable(True)
sage: b
True
sage: cls # random
[[[0, 3], [1, 2]], [[1, 3], [0, 2]]]

sage: # needs sage.combinat
sage: b, cls = AG.is_resolvable(True)
sage: b
True
sage: cls  # random
[[[6, 7], [4, 5], [0, 1], [2, 3]],
 [[5, 7], [0, 4], [3, 6], [1, 2]],
 [[0, 2], [4, 7], [1, 3], [5, 6]],
 [[3, 4], [0, 7], [1, 5], [2, 6]],
 [[3, 7], [1, 6], [0, 5], [2, 4]],
 [[0, 6], [2, 7], [1, 4], [3, 5]],
 [[4, 6], [0, 3], [2, 5], [1, 7]]]
```

```
>>> from sage.all import *
>>> b, cls = TD.is_resolvable(True)
>>> b
True
>>> cls # random
[[[0, 3], [1, 2]], [[1, 3], [0, 2]]]

>>> # needs sage.combinat
>>> b, cls = AG.is_resolvable(True)
>>> b
True
>>> cls  # random
[[[6, 7], [4, 5], [0, 1], [2, 3]],
 [[5, 7], [0, 4], [3, 6], [1, 2]],
 [[0, 2], [4, 7], [1, 3], [5, 6]],
 [[3, 4], [0, 7], [1, 5], [2, 6]],
 [[3, 7], [1, 6], [0, 5], [2, 4]],
 [[0, 6], [2, 7], [1, 4], [3, 5]],
 [[4, 6], [0, 3], [2, 5], [1, 7]]]
```

A non-resolvable design:

```
sage: Fano = designs.balanced_incomplete_block_design(7,3)                    #␣
↪needs sage.schemes
sage: Fano.is_resolvable()                                                    #␣
↪needs sage.schemes
False
sage: Fano.is_resolvable(True)                                                #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.schemes
(False, [])
```

```
>>> from sage.all import *
>>> Fano = designs.balanced_incomplete_block_design(Integer(7),Integer(3))    ␣
↪              # needs sage.schemes
>>> Fano.is_resolvable()                                                      #␣
↪needs sage.schemes
False
>>> Fano.is_resolvable(True)                                                  #␣
↪needs sage.schemes
(False, [])
```

is_simple()

Test whether this design is simple (i.e. no repeated block).

EXAMPLES:

```
sage: IncidenceStructure(3, [[0,1],[1,2],[0,2]]).is_simple()
True
sage: IncidenceStructure(3, [[0],[0]]).is_simple()
False

sage: V = [(0,'a'),(0,'b'),(1,'a'),(1,'b')]
sage: B = [[V[0],V[1]], [V[1],V[2]]]
sage: I = IncidenceStructure(V, B)
sage: I.is_simple()
True
sage: I2 = IncidenceStructure(V, B*2)
sage: I2.is_simple()
False
```

```
>>> from sage.all import *
>>> IncidenceStructure(Integer(3), [[Integer(0),Integer(1)],[Integer(1),
↪Integer(2)],[Integer(0),Integer(2)]]).is_simple()
True
>>> IncidenceStructure(Integer(3), [[Integer(0)],[Integer(0)]]).is_simple()
False

>>> V = [(Integer(0),'a'),(Integer(0),'b'),(Integer(1),'a'),(Integer(1),'b')]
>>> B = [[V[Integer(0)],V[Integer(1)]], [V[Integer(1)],V[Integer(2)]]]
>>> I = IncidenceStructure(V, B)
>>> I.is_simple()
True
>>> I2 = IncidenceStructure(V, B*Integer(2))
>>> I2.is_simple()
False
```

is_spread(*spread*)

Check whether the input is a spread for `self`.

A spread of an incidence structure (P, B) is a subset of B which forms a partition of P.

INPUT:

- `spread` – iterable; defines the spread

EXAMPLES:

```
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[1, 2, 3], [4, 5, 6]])
True
sage: E.is_spread([1, 2, 3, 4, 5, 6])
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
sage: E.is_spread([[1, 2, 3, 4], [5, 6]])
False
```

```
>>> from sage.all import *
>>> E = IncidenceStructure([[Integer(1), Integer(2), Integer(3)], [Integer(4),
 ↪ Integer(5), Integer(6)], [Integer(1), Integer(5), Integer(6)]])
>>> E.is_spread([[Integer(1), Integer(2), Integer(3)], [Integer(4),␣
 ↪Integer(5), Integer(6)]])
True
>>> E.is_spread([Integer(1), Integer(2), Integer(3), Integer(4), Integer(5),␣
 ↪Integer(6)])
Traceback (most recent call last):
...
TypeError: 'sage.rings.integer.Integer' object is not iterable
>>> E.is_spread([[Integer(1), Integer(2), Integer(3), Integer(4)],␣
 ↪[Integer(5), Integer(6)]])
False
```

Order of blocks or of points within each block doesn't matter:

```
sage: E = IncidenceStructure([[1, 2, 3], [4, 5, 6], [1, 5, 6]])
sage: E.is_spread([[5, 6, 4], [3, 1, 2]])
True
```

```
>>> from sage.all import *
>>> E = IncidenceStructure([[Integer(1), Integer(2), Integer(3)], [Integer(4),
 ↪ Integer(5), Integer(6)], [Integer(1), Integer(5), Integer(6)]])
>>> E.is_spread([[Integer(5), Integer(6), Integer(4)], [Integer(3),␣
 ↪Integer(1), Integer(2)]])
True
```

is_t_design(*t=None*, *v=None*, *k=None*, *l=None*, *return_parameters=False*)

Test whether `self` is a $t-(v,k,l)$ design.

A $t-(v,k,\lambda)$ (sometimes called t-design for short) is a block design in which:

- the underlying set has cardinality v
- the blocks have size k
- each t-subset of points is covered by λ blocks

INPUT:

- `t`, `v`, `k`, `l` – integers; their value is set to `None` by default. The function tests whether the design is a $t-(v,k,l)$ design using the provided values and guesses the others. Note that `l` cannot be specified if

`t` is not.

- `return_parameters` – boolean; whether to return the parameters of the t-design. If set to `True`, the function returns a pair `(boolean_answer, (t,v,k,l))`.

EXAMPLES:

```
sage: fano_blocks = [[0,1,2],[0,3,4],[0,5,6],[1,3,5],[1,4,6],[2,3,6],[2,4,5]]
sage: BD = IncidenceStructure(7, fano_blocks)
sage: BD.is_t_design()
True
sage: BD.is_t_design(return_parameters=True)
(True, (2, 7, 3, 1))
sage: BD.is_t_design(2, 7, 3, 1)
True
sage: BD.is_t_design(1, 7, 3, 3)
True
sage: BD.is_t_design(0, 7, 3, 7)
True

sage: BD.is_t_design(0,6,3,7) or BD.is_t_design(0,7,4,7) or BD.is_t_design(0,
↪7,3,8)
False

sage: BD = designs.AffineGeometryDesign(3, 1, GF(2))                    #␣
↪needs sage.combinat
sage: BD.is_t_design(1)                                                 #␣
↪needs sage.combinat
True
sage: BD.is_t_design(2)                                                 #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> fano_blocks = [[Integer(0),Integer(1),Integer(2)],[Integer(0),Integer(3),
↪Integer(4)],[Integer(0),Integer(5),Integer(6)],[Integer(1),Integer(3),
↪Integer(5)],[Integer(1),Integer(4),Integer(6)],[Integer(2),Integer(3),
↪Integer(6)],[Integer(2),Integer(4),Integer(5)]]
>>> BD = IncidenceStructure(Integer(7), fano_blocks)
>>> BD.is_t_design()
True
>>> BD.is_t_design(return_parameters=True)
(True, (2, 7, 3, 1))
>>> BD.is_t_design(Integer(2), Integer(7), Integer(3), Integer(1))
True
>>> BD.is_t_design(Integer(1), Integer(7), Integer(3), Integer(3))
True
>>> BD.is_t_design(Integer(0), Integer(7), Integer(3), Integer(7))
True

>>> BD.is_t_design(Integer(0),Integer(6),Integer(3),Integer(7)) or BD.is_t_
↪design(Integer(0),Integer(7),Integer(4),Integer(7)) or BD.is_t_
↪design(Integer(0),Integer(7),Integer(3),Integer(8))
False
```

(continues on next page)

(continued from previous page)

```
>>> BD = designs.AffineGeometryDesign(Integer(3), Integer(1), GF(Integer(2)))␣
↪                        # needs sage.combinat
>>> BD.is_t_design(Integer(1))                                                ␣
↪     # needs sage.combinat
True
>>> BD.is_t_design(Integer(2))                                                ␣
↪     # needs sage.combinat
True
```

Steiner triple and quadruple systems are other names for $2-(v,3,1)$ and $3-(v,4,1)$ designs:

```
sage: S3_9 = designs.steiner_triple_system(9)
sage: S3_9.is_t_design(2,9,3,1)
True

sage: blocks = designs.steiner_quadruple_system(8)
sage: S4_8 = IncidenceStructure(8, blocks)
sage: S4_8.is_t_design(3,8,4,1)
True

sage: blocks = designs.steiner_quadruple_system(14)
sage: S4_14 = IncidenceStructure(14, blocks)
sage: S4_14.is_t_design(3,14,4,1)
True
```

```
>>> from sage.all import *
>>> S3_9 = designs.steiner_triple_system(Integer(9))
>>> S3_9.is_t_design(Integer(2),Integer(9),Integer(3),Integer(1))
True

>>> blocks = designs.steiner_quadruple_system(Integer(8))
>>> S4_8 = IncidenceStructure(Integer(8), blocks)
>>> S4_8.is_t_design(Integer(3),Integer(8),Integer(4),Integer(1))
True

>>> blocks = designs.steiner_quadruple_system(Integer(14))
>>> S4_14 = IncidenceStructure(Integer(14), blocks)
>>> S4_14.is_t_design(Integer(3),Integer(14),Integer(4),Integer(1))
True
```

Some examples of Witt designs that need the gap database:

```
sage: # optional - gap_package_design
sage: BD = designs.WittDesign(9)
sage: BD.is_t_design(2,9,3,1)
True
sage: W12 = designs.WittDesign(12)
sage: W12.is_t_design(5,12,6,1)
True
sage: W12.is_t_design(4)
True
```

```
>>> from sage.all import *
>>> # optional - gap_package_design
>>> BD = designs.WittDesign(Integer(9))
>>> BD.is_t_design(Integer(2),Integer(9),Integer(3),Integer(1))
True
>>> W12 = designs.WittDesign(Integer(12))
>>> W12.is_t_design(Integer(5),Integer(12),Integer(6),Integer(1))
True
>>> W12.is_t_design(Integer(4))
True
```

Further examples:

```
sage: D = IncidenceStructure(4,[[],[]])
sage: D.is_t_design(return_parameters=True)
(True,  (0, 4, 0, 2))

sage: D = IncidenceStructure(4, [[0,1],[0,2],[0,3]])
sage: D.is_t_design(return_parameters=True)
(True, (0, 4, 2, 3))

sage: D = IncidenceStructure(4, [[0],[1],[2],[3]])
sage: D.is_t_design(return_parameters=True)
(True, (1, 4, 1, 1))

sage: D = IncidenceStructure(4,[[0,1],[2,3]])
sage: D.is_t_design(return_parameters=True)
(True, (1, 4, 2, 1))

sage: D = IncidenceStructure(4, [list(range(4))])
sage: D.is_t_design(return_parameters=True)
(True, (4, 4, 4, 1))
```

```
>>> from sage.all import *
>>> D = IncidenceStructure(Integer(4),[[],[]])
>>> D.is_t_design(return_parameters=True)
(True,  (0, 4, 0, 2))

>>> D = IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)],[Integer(0),Integer(3)]])
>>> D.is_t_design(return_parameters=True)
(True, (0, 4, 2, 3))

>>> D = IncidenceStructure(Integer(4), [[Integer(0)],[Integer(1)],
↪[Integer(2)],[Integer(3)]])
>>> D.is_t_design(return_parameters=True)
(True, (1, 4, 1, 1))

>>> D = IncidenceStructure(Integer(4),[[Integer(0),Integer(1)],[Integer(2),
↪Integer(3)]])
>>> D.is_t_design(return_parameters=True)
(True, (1, 4, 2, 1))
```

(continues on next page)

(continued from previous page)

```
>>> D = IncidenceStructure(Integer(4), [list(range(Integer(4)))])
>>> D.is_t_design(return_parameters=True)
(True, (4, 4, 4, 1))
```

is_uniform(*k=None*)

Test whether the incidence structure is k-uniform

An incidence structure is said to be k-uniform if all its blocks have size k.

INPUT:

- `k` – integer

OUTPUT:

If `k` is defined, a boolean is returned. If `k` is set to `None` (default), the method returns either `False` or the integer `k` such that the incidence structure is k-uniform.

Warning

In case of 0-uniform incidence structure, beware that `if not H.is_uniform()` is a satisfied condition.

EXAMPLES:

```
sage: designs.balanced_incomplete_block_design(7,3).is_uniform()            #␣
↪needs sage.schemes
3
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=3)         #␣
↪needs sage.schemes
True
sage: designs.balanced_incomplete_block_design(7,3).is_uniform(k=4)         #␣
↪needs sage.schemes
False
```

```
>>> from sage.all import *
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪uniform()            # needs sage.schemes
3
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪uniform(k=Integer(3))          # needs sage.schemes
True
>>> designs.balanced_incomplete_block_design(Integer(7),Integer(3)).is_
↪uniform(k=Integer(4))          # needs sage.schemes
False
```

isomorphic_substructures_iterator(*H2*, *induced=False*)

Iterate over all copies of `H2` contained in `self`.

A hypergraph H_1 contains an isomorphic copy of a hypergraph H_2 if there exists an injection $f : V(H_2) \mapsto V(H_1)$ such that for any set $S_2 \in E(H_2)$ the set $S_1 = f(S2)$ belongs to $E(H_1)$.

It is an *induced* copy if no other set of $E(H_1)$ is contained in $f(V(H_2))$, i.e. $|E(H_2)| = \{S : S \in E(H_1)$ and $f(V(H_2))\}$.

This function lists all such injections. In particular, the number of copies of H in itself is equal to *the size of its automorphism group*.

See *subhypergraph_search* for more information.

INPUT:

- `H2` – an *IncidenceStructure* object
- `induced` – boolean (default: `False`); whether to require the copies to be induced

EXAMPLES:

How many distinct C_5 in Petersen's graph ?

```
sage: P = graphs.PetersenGraph()
sage: C = graphs.CycleGraph(5)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
120
```

```
>>> from sage.all import *
>>> P = graphs.PetersenGraph()
>>> C = graphs.CycleGraph(Integer(5))
>>> IP = IncidenceStructure(P.edges(sort=True, labels=False))
>>> IC = IncidenceStructure(C.edges(sort=True, labels=False))
>>> sum(Integer(1) for _ in IP.isomorphic_substructures_iterator(IC))
120
```

As the automorphism group of C_5 has size 10, the number of distinct unlabelled copies is 12. Let us check that all functions returned correspond to an actual C_5 subgraph:

```
sage: for f in IP.isomorphic_substructures_iterator(IC):
....:     assert all(P.has_edge(f[x],f[y]) for x,y in C.edges(sort=True,␣
↪labels=False))
```

```
>>> from sage.all import *
>>> for f in IP.isomorphic_substructures_iterator(IC):
...     assert all(P.has_edge(f[x],f[y]) for x,y in C.edges(sort=True,␣
↪labels=False))
```

The number of induced copies, in this case, is the same:

```
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC,induced=True))
120
```

```
>>> from sage.all import *
>>> sum(Integer(1) for _ in IP.isomorphic_substructures_iterator(IC,
↪induced=True))
120
```

They begin to differ if we make one vertex universal:

```
sage: P.add_edges([(0,x) for x in P], loops=False)
sage: IP = IncidenceStructure(P.edges(sort=True, labels=False))
```

(continues on next page)

(continued from previous page)

```
sage: IC = IncidenceStructure(C.edges(sort=True, labels=False))
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC))
420
sage: sum(1 for _ in IP.isomorphic_substructures_iterator(IC,induced=True))
60
```

```
>>> from sage.all import *
>>> P.add_edges([(Integer(0),x) for x in P], loops=False)
>>> IP = IncidenceStructure(P.edges(sort=True, labels=False))
>>> IC = IncidenceStructure(C.edges(sort=True, labels=False))
>>> sum(Integer(1) for _ in IP.isomorphic_substructures_iterator(IC))
420
>>> sum(Integer(1) for _ in IP.isomorphic_substructures_iterator(IC,
↪induced=True))
60
```

The number of copies of H in itself is the size of its automorphism group:

```
sage: H = designs.projective_plane(3)                                    #␣
↪needs sage.schemes
sage: sum(1 for _ in H.isomorphic_substructures_iterator(H))             #␣
↪needs sage.schemes
5616
sage: H.automorphism_group().cardinality()                               #␣
↪needs sage.groups sage.schemes
5616
```

```
>>> from sage.all import *
>>> H = designs.projective_plane(Integer(3))                                ␣
↪     # needs sage.schemes
>>> sum(Integer(1) for _ in H.isomorphic_substructures_iterator(H))         ␣
↪     # needs sage.schemes
5616
>>> H.automorphism_group().cardinality()                                 #␣
↪needs sage.groups sage.schemes
5616
```

n_blocks()

Return the number of blocks.

EXAMPLES:

```
sage: designs.DesarguesianProjectivePlaneDesign(2).n_blocks()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2], [1,2,3]])
sage: B.n_blocks()
5
```

```
>>> from sage.all import *
>>> designs.DesarguesianProjectivePlaneDesign(Integer(2)).n_blocks()
7
>>> B = IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(0),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2)],[Integer(0),Integer(3)],[Integer(1),Integer(2)], [Integer(1),
↪Integer(2),Integer(3)]])
>>> B.n_blocks()
5
```

n_points()

Return the size of the ground set.

EXAMPLES:

```
sage: designs.DesarguesianProjectivePlaneDesign(2).n_points()
7
sage: B = IncidenceStructure(4, [[0,1],[0,2],[0,3],[1,2], [1,2,3]])
sage: B.n_points()
4
```

```
>>> from sage.all import *
>>> designs.DesarguesianProjectivePlaneDesign(Integer(2)).n_points()
7
>>> B = IncidenceStructure(Integer(4), [[Integer(0),Integer(1)],[Integer(0),
↪Integer(2)],[Integer(0),Integer(3)],[Integer(1),Integer(2)], [Integer(1),
↪Integer(2),Integer(3)]])
>>> B.n_points()
4
```

num_blocks()

alias of *n_blocks()*.

num_points()

alias of *n_points()*.

packing(*solver*, *verbose=None*, *integrality_tolerance=0*)

Return a maximum packing.

A maximum packing in a hypergraph is collection of disjoint sets/blocks of maximal cardinality. This problem is NP-complete in general, and in particular on 3-uniform hypergraphs. It is solved here with an Integer Linear Program.

For more information, see the Wikipedia article Packing_in_a_hypergraph.

INPUT:

- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on LP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – integer (default: 0); sets the level of verbosity. Set to 0 by default, which means quiet.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

EXAMPLES:

```
sage: P = IncidenceStructure([[1,2],[3,4],[2,3]]).packing()                 #␣
↪needs sage.numerical.mip
sage: sorted(sorted(b) for b in P)                                          #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.numerical.mip
[[1, 2], [3, 4]]
sage: len(designs.steiner_triple_system(9).packing())                    #␣
↪needs sage.numerical.mip
3
```

```
>>> from sage.all import *
>>> P = IncidenceStructure([[Integer(1),Integer(2)],[Integer(3),Integer(4)],
↪[Integer(2),Integer(3)]]).packing()                  # needs sage.numerical.
↪mip
>>> sorted(sorted(b) for b in P)                                          #␣
↪needs sage.numerical.mip
[[1, 2], [3, 4]]
>>> len(designs.steiner_triple_system(Integer(9)).packing())                ␣
↪     # needs sage.numerical.mip
3
```

rank()

Return the rank of the hypergraph (the maximum size of a block).

EXAMPLES:

```
sage: h = Hypergraph(8, [[0,1,3],[1,4,5,6],[1,2]])
sage: h.rank()
4
```

```
>>> from sage.all import *
>>> h = Hypergraph(Integer(8), [[Integer(0),Integer(1),Integer(3)],
↪[Integer(1),Integer(4),Integer(5),Integer(6)],[Integer(1),Integer(2)]])
>>> h.rank()
4
```

relabel(*perm=None*, *inplace=True*)

Relabel the ground set.

INPUT:

- `perm` – can be one of
  - a dictionary – then each point `p` (which should be a key of `perm`) is relabeled to `perm[p]`
  - an iterable of length `n` – the first point returned by *ground_set()* is relabeled to `perm[0]`, the second to `perm[1]`, ...
  - a callable – then each point `p` is relabeled to `perm(p)`
  - `None` – the incidence structure is relabeled to be on $\{0, 1, ..., n-1\}$ in the ordering given by *ground_set()*
- `inplace` – boolean (default: `False`); if `True` then return a relabeled graph and does not touch `self`

EXAMPLES:

```
sage: # needs sage.schemes
sage: TD = designs.transversal_design(5,5)
sage: TD.relabel({i: chr(97+i) for i in range(25)})
```

(continues on next page)

(continued from previous page)

```
sage: TD.ground_set()
['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm',
 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y']
sage: TD.blocks()[:3]
[['a', 'f', 'k', 'p', 'u'], ['a', 'g', 'm', 's', 'y'], ['a', 'h', 'o', 'q', 'x
↪']]
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> TD = designs.transversal_design(Integer(5),Integer(5))
>>> TD.relabel({i: chr(Integer(97)+i) for i in range(Integer(25))})
>>> TD.ground_set()
['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h', 'i', 'j', 'k', 'l', 'm',
 'n', 'o', 'p', 'q', 'r', 's', 't', 'u', 'v', 'w', 'x', 'y']
>>> TD.blocks()[:Integer(3)]
[['a', 'f', 'k', 'p', 'u'], ['a', 'g', 'm', 's', 'y'], ['a', 'h', 'o', 'q', 'x
↪']]
```

Relabel to integer points:

```
sage: TD.relabel()                                                          #␣
↪needs sage.schemes
sage: TD.blocks()[:3]                                                       #␣
↪needs sage.schemes
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23]]
```

```
>>> from sage.all import *
>>> TD.relabel()                                                          #␣
↪needs sage.schemes
>>> TD.blocks()[:Integer(3)]                                                 ␣
↪     # needs sage.schemes
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23]]
```

trace(*points*, *min_size=1*, *multiset=True*)

Return the trace of a set of points.

Given an hypergraph $\mathcal{H}$, the *trace* of a set X of points in $\mathcal{H}$ is the hypergraph whose blocks are all non-empty $S \cap X$ where $S \in \mathcal{H}$.

INPUT:

- `points` – set of points
- `min_size` – integer (default: 1); minimum size of the sets to keep. By default all empty sets are discarded, i.e. `min_size=1`
- `multiset` – boolean (default: `True`); whether to keep multiple copies of the same set

Note

This method goes over all sets of `self` before building a new *IncidenceStructure* (which involves some relabelling and sorting). It probably should not be called in a performance-critical code.

EXAMPLES:

A Baer subplane of order 2 (i.e. a Fano plane) in a projective plane of order 4:

```
sage: # needs sage.schemes
sage: P4 = designs.projective_plane(4)
sage: F = designs.projective_plane(2)
sage: for x in Subsets(P4.ground_set(),7):
....:     if P4.trace(x,min_size=2).is_isomorphic(F):
....:         break
sage: subplane = P4.trace(x,min_size=2); subplane
Incidence structure with 7 points and 7 blocks
sage: subplane.is_isomorphic(F)
True
```

```
>>> from sage.all import *
>>> # needs sage.schemes
>>> P4 = designs.projective_plane(Integer(4))
>>> F = designs.projective_plane(Integer(2))
>>> for x in Subsets(P4.ground_set(),Integer(7)):
...     if P4.trace(x,min_size=Integer(2)).is_isomorphic(F):
...         break
>>> subplane = P4.trace(x,min_size=Integer(2)); subplane
Incidence structure with 7 points and 7 blocks
>>> subplane.is_isomorphic(F)
True
```

Mutually orthogonal Latin squares (MOLS)

The main function of this module is *mutually_orthogonal_latin_squares()* and can be can be used to generate MOLS (or check that they exist):

```
sage: MOLS = designs.mutually_orthogonal_latin_squares(4,8)                    #␣
↪needs sage.schemes
```

```
>>> from sage.all import *
>>> MOLS = designs.mutually_orthogonal_latin_squares(Integer(4),Integer(8))          ␣
↪              # needs sage.schemes
```

For more information on MOLS, see the Wikipedia entry on MOLS. If you are only interested by latin squares, see *latin*.

The functions defined here are

mutually_orthogonal_latin_squares()	Return k Mutually Orthogonal $n \times n$ Latin Squares.
are_mutually_orthogonal_latin_squares()	Check that the list `l` of matrices in are MOLS.
latin_square_product()	Return the product of two (or more) latin squares.
MOLS_table()	Print the MOLS table.

Table of MOLS

Sage can produce a table of MOLS similar to the one from the Handbook of Combinatorial Designs [DesignHandbook] (available here).

```
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(600) # long time
      0   1   2   3   4   5   6   7   8   9  10  11  12  13  14  15  16  17  18  19
   ------------------------------------------------------------------------------
  0| +oo +oo   1   2   3   4   1   6   7   8   2  10   5  12   4   4  15  16   5  18
 20|   4   5   3  22   7  24   4  26   5  28   4  30  31   5   4   5   8  36   4   5
 40|   7  40   5  42   5   6   4  46   8  48   6   5   5  52   5   6   7   7   5  58
 60|   5  60   5   6  63   7   5  66   5   6   6  70   7  72   5   7   6   6   6  78
 80|   9  80   8  82   6   6   6   6   7  88   6   7   6   6   6   6   7  96   6   8
100|   8 100   6 102   7   7   6 106   6 108   6   6  13 112   6   7   6   8   6   6
120|   7 120   6   6   6 124   6 126 127   7   6 130   6   7   6   7   7 136   6 138
140|   6   7   6  10  10   7   6   7   6 148   6 150   7   8   8   7   6 156   7   6

Functions

sage.combinat.designs.latin_squares.**MOLS_table**(*start*, *stop=None*, *compare=False*, *width=None*)

Print the MOLS table that Sage can produce.

INPUT:

- `start`, `stop` – integers; print the table of MOLS for value of n such that `start<=n<stop`. If only one integer is given as input, it is interpreted as the value of `stop` with `start=0` (same behaviour as `range`).
- `compare` – boolean; if sets to `True` the MOLS displays with $+$ and $-$ entries its difference with the table from the Handbook of Combinatorial Designs (2ed).
- `width` – integer; the width of each column of the table. By default, it is computed from range of values determined by the parameters `start` and `stop`.

EXAMPLES:

```
sage: # needs sage.schemes
sage: from sage.combinat.designs.latin_squares import MOLS_table
sage: MOLS_table(100)
       0   1   2   3   4   5   6   7   8   9  10  11  12  13  14  15  16  17  18 ␣

sage.combinat.designs.latin_squares.**are_mutually_orthogonal_latin_squares**(*l*, *verbose=False*)

Check whether the list of matrices in `l` form mutually orthogonal latin squares.

INPUT:

- `verbose` – if `True` then print why the list of matrices provided are not mutually orthogonal latin squares

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import are_mutually_orthogonal_
↪latin_squares
sage: m1 = matrix([[0,1,2],[2,0,1],[1,2,0]])
sage: m2 = matrix([[0,1,2],[1,2,0],[2,0,1]])
sage: m3 = matrix([[0,1,2],[2,0,1],[1,2,0]])
sage: are_mutually_orthogonal_latin_squares([m1,m2])
True
sage: are_mutually_orthogonal_latin_squares([m1,m3])
False
sage: are_mutually_orthogonal_latin_squares([m2,m3])
True
sage: are_mutually_orthogonal_latin_squares([m1,m2,m3], verbose=True)
Squares 0 and 2 are not orthogonal
False

sage: m = designs.mutually_orthogonal_latin_squares(7,8)                    #␣
↪needs sage.schemes
sage: are_mutually_orthogonal_latin_squares(m)                              #␣
↪needs sage.schemes
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import are_mutually_orthogonal_latin_
↪squares
>>> m1 = matrix([[Integer(0),Integer(1),Integer(2)],[Integer(2),Integer(0),
↪Integer(1)],[Integer(1),Integer(2),Integer(0)]])
>>> m2 = matrix([[Integer(0),Integer(1),Integer(2)],[Integer(1),Integer(2),
↪Integer(0)],[Integer(2),Integer(0),Integer(1)]])
>>> m3 = matrix([[Integer(0),Integer(1),Integer(2)],[Integer(2),Integer(0),
↪Integer(1)],[Integer(1),Integer(2),Integer(0)]])
>>> are_mutually_orthogonal_latin_squares([m1,m2])
True
>>> are_mutually_orthogonal_latin_squares([m1,m3])
False
>>> are_mutually_orthogonal_latin_squares([m2,m3])
True
>>> are_mutually_orthogonal_latin_squares([m1,m2,m3], verbose=True)
```

(continues on next page)

(continued from previous page)

```
Squares 0 and 2 are not orthogonal
False

>>> m = designs.mutually_orthogonal_latin_squares(Integer(7),Integer(8))          ␣
↪               # needs sage.schemes
>>> are_mutually_orthogonal_latin_squares(m)                                      #␣
↪needs sage.schemes
True
```

sage.combinat.designs.latin_squares.**latin_square_product**(*M*, *N*, **others*)

Return the product of two (or more) latin squares.

Given two Latin Squares M, N of respective sizes m, n, the direct product $M \times N$ of size mn is defined by $(M \times N)((i_1, i_2), (j_1, j_2)) = (M(i_1, j_1), N(i_2, j_2))$ where $i_1, j_1 \in [m], i_2, j_2 \in [n]$

Each pair of values $(i, j) \in [m] \times [n]$ is then relabeled to $in + j$.

This is Lemma 6.25 of [Stinson2004].

INPUT:

- `M`, `N`, `*others` – an arbitrary number of latin squares (greater than or equal to 2)

EXAMPLES:

```
sage: from sage.combinat.designs.latin_squares import latin_square_product
sage: m=designs.mutually_orthogonal_latin_squares(3,4)[0]                       #␣
↪needs sage.schemes
sage: latin_square_product(m,m,m)                                               #␣
↪needs sage.schemes
64 x 64 sparse matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.latin_squares import latin_square_product

```

sage.combinat.designs.latin_squares.**mutually_orthogonal_latin_squares**(*k*, *n*, *partitions=False*, *check=True*)

Return k Mutually Orthogonal $n \times n$ Latin Squares (MOLS).

For more information on Mutually Orthogonal Latin Squares, see *latin_squares*.

INPUT:

- `k` – integer; number of MOLS. If `k` is `None` it is set to the largest value available
- `n` – integer; size of the latin square
- `partitions` – boolean; a Latin Square can be seen as 3 partitions of the n^2 cells of the array into n sets of size n, respectively:
  - The partition of rows

- The partition of columns
- The partition of number (cells numbered with 0, cells numbered with 1, ...)

These partitions have the additional property that any two sets from different partitions intersect on exactly one element.

When `partitions` is set to `True`, this function returns a list of $k+2$ partitions satisfying this intersection property instead of the $k+2$ MOLS (though the data is exactly the same in both cases).

- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

EXAMPLES:

```
sage: designs.mutually_orthogonal_latin_squares(4,5)                    #␣
↪needs sage.schemes
[
[0 1 2 3 4]  [0 1 2 3 4]  [0 1 2 3 4]  [0 1 2 3 4]
[1 2 3 4 0]  [2 3 4 0 1]  [3 4 0 1 2]  [4 0 1 2 3]
[2 3 4 0 1]  [4 0 1 2 3]  [1 2 3 4 0]  [3 4 0 1 2]
[3 4 0 1 2]  [1 2 3 4 0]  [4 0 1 2 3]  [2 3 4 0 1]
[4 0 1 2 3], [3 4 0 1 2], [2 3 4 0 1], [1 2 3 4 0]
]

```

What is the maximum number of MOLS of size 8 that Sage knows how to build?:

```
sage: designs.orthogonal_arrays.largest_available_k(8)-2                    #␣
↪needs sage.schemes
7
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(8))-Integer(2)      ␣
↪              # needs sage.schemes
7
```

If you only want to know if Sage is able to build a given set of MOLS, query the `orthogonal_arrays.*` functions:

```
sage: designs.orthogonal_arrays.is_available(5+2, 5) # 5 MOLS of order 5
False
sage: designs.orthogonal_arrays.is_available(4+2,6)  # 4 MOLS of order 6      #␣
↪needs sage.schemes
False
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(5)+Integer(2), Integer(5)) # 5␣
↪MOLS of order 5
False
>>> designs.orthogonal_arrays.is_available(Integer(4)+Integer(2),Integer(6))  # 4␣
↪MOLS of order 6        # needs sage.schemes
False
```

Sage, however, is not able to prove that the second MOLS do not exist:

```
sage: designs.orthogonal_arrays.exists(4+2,6)  # 4 MOLS of order 6            #␣
↪needs sage.schemes
Unknown
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.exists(Integer(4)+Integer(2),Integer(6))  # 4 MOLS␣
↪of order 6              # needs sage.schemes
Unknown
```

If you ask for such a MOLS then you will respectively get an informative `EmptySetError` or `NotImplementedError`:

```
sage: designs.mutually_orthogonal_latin_squares(5, 5)
Traceback (most recent call last):
...
EmptySetError: there exist at most n-1 MOLS of size n if n>=2
sage: designs.mutually_orthogonal_latin_squares(4,6)                        #␣
↪needs sage.schemes
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build 4 MOLS of order 6
```

```
>>> from sage.all import *
>>> designs.mutually_orthogonal_latin_squares(Integer(5), Integer(5))
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
EmptySetError: there exist at most n-1 MOLS of size n if n>=2
>>> designs.mutually_orthogonal_latin_squares(Integer(4),Integer(6))
↪              # needs sage.schemes
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build 4 MOLS of order 6
```

Orthogonal arrays (OA)

This module gathers some construction related to orthogonal arrays (or transversal designs). One can build an $OA(k,n)$ (or check that it can be built) from the Sage console with `designs.orthogonal_arrays.build`:

```
sage: OA = designs.orthogonal_arrays.build(4,8)
```

```
>>> from sage.all import *
>>> OA = designs.orthogonal_arrays.build(Integer(4),Integer(8))
```

See also the modules *orthogonal_arrays_build_recursive* or *orthogonal_arrays_find_recursive* for recursive constructions.

This module defines the following functions:

orthogonal_array()	Return an orthogonal array of parameters k, n, t.
transversal_design()	Return a transversal design of parameters k, n.
incomplete_orthogonal_array()	Return an $OA(k,n) - \sum_{1\leq i\leq x} OA(k,s_i)$.

is_transversal_design()	Check that a given set of blocks `B` is a transversal design.
is_orthogonal_array()	Check that the integer matrix OA is an $OA(k,n,t)$.
wilson_construction()	Return a $OA(k, rm+u)$ from a truncated $OA(k+s, r)$ by Wilson's construction.
TD_product()	Return the product of two transversal designs.
OA_find_disjoint_blocks()	Return x disjoint blocks contained in a given $OA(k,n)$.
OA_relabel()	Return a relabelled version of the OA.
OA_standard_label()	Return a version of the OA relabelled to symbols $(0,\ldots,n-1)$.
OA_from_quasi_difference_matrix()	Return an Orthogonal Array from a Quasi-Difference matrix
OA_from_Vmt()	Return an Orthogonal Array from a $V(m,t)$
OA_from_PBD()	Return an $OA(k,n)$ from a PBD
OA_n_times_2_pow_c_from_matrix()	Return an $OA(k, \lvert G\rvert \cdot 2^c)$ from a constrained $(G, k-1, 2)$-difference matrix.
OA_from_wider_OA()	Return the first k columns of OA.
QDM_from_Vmt()	Return a QDM a $V(m,t)$

Functions

class sage.combinat.designs.orthogonal_arrays.**OAMainFunctions**(**args*, ***kwds*)

Bases: object

Functions related to orthogonal arrays.

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

From here you have access to:

- *build(k,n,t=2)*: return an orthogonal array with the given parameters.
- *is_available(k,n,t=2)*: answer whether there is a construction available in Sage for a given set of parameters.
- *exists(k,n,t=2)*: answer whether an orthogonal array with these parameters exist.
- *largest_available_k(n,t=2)*: return the largest integer k such that Sage knows how to build an $OA(k, n)$.
- *explain_construction(k,n,t=2)*: return a string that explains the construction that Sage uses to build an $OA(k, n)$.

EXAMPLES:

```
sage: designs.orthogonal_arrays.build(3,2)
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]

sage: designs.orthogonal_arrays.build(5,5)
[[0, 0, 0, 0, 0], [0, 1, 2, 3, 4], [0, 2, 4, 1, 3],
 [0, 3, 1, 4, 2], [0, 4, 3, 2, 1], [1, 0, 4, 3, 2],
 [1, 1, 1, 1, 1], [1, 2, 3, 4, 0], [1, 3, 0, 2, 4],
 [1, 4, 2, 0, 3], [2, 0, 3, 1, 4], [2, 1, 0, 4, 3],
 [2, 2, 2, 2, 2], [2, 3, 4, 0, 1], [2, 4, 1, 3, 0],
 [3, 0, 2, 4, 1], [3, 1, 4, 2, 0], [3, 2, 1, 0, 4],
 [3, 3, 3, 3, 3], [3, 4, 0, 1, 2], [4, 0, 1, 2, 3],
 [4, 1, 3, 0, 2], [4, 2, 0, 3, 1], [4, 3, 2, 1, 0],
 [4, 4, 4, 4, 4]]
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.build(Integer(3),Integer(2))
[[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 0]]

>>> designs.orthogonal_arrays.build(Integer(5),Integer(5))
[[0, 0, 0, 0, 0], [0, 1, 2, 3, 4], [0, 2, 4, 1, 3],
 [0, 3, 1, 4, 2], [0, 4, 3, 2, 1], [1, 0, 4, 3, 2],
 [1, 1, 1, 1, 1], [1, 2, 3, 4, 0], [1, 3, 0, 2, 4],
 [1, 4, 2, 0, 3], [2, 0, 3, 1, 4], [2, 1, 0, 4, 3],
 [2, 2, 2, 2, 2], [2, 3, 4, 0, 1], [2, 4, 1, 3, 0],
 [3, 0, 2, 4, 1], [3, 1, 4, 2, 0], [3, 2, 1, 0, 4],
 [3, 3, 3, 3, 3], [3, 4, 0, 1, 2], [4, 0, 1, 2, 3],
 [4, 1, 3, 0, 2], [4, 2, 0, 3, 1], [4, 3, 2, 1, 0],
 [4, 4, 4, 4, 4]]
```

What is the largest value of k for which Sage knows how to compute a $OA(k, 14, 2)$?:

```
sage: designs.orthogonal_arrays.largest_available_k(14)
6
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(14))
6
```

If you ask for an orthogonal array that does not exist, then you will either obtain an `EmptySetError` (if it knows that such an orthogonal array does not exist) or a `NotImplementedError`:

```
sage: designs.orthogonal_arrays.build(4,2)
Traceback (most recent call last):
...
EmptySetError: There exists no OA(4,2) as k(=4)>n+t-1=3
sage: designs.orthogonal_arrays.build(12,20)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build an OA(12,20)!
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.build(Integer(4),Integer(2))
Traceback (most recent call last):
...
EmptySetError: There exists no OA(4,2) as k(=4)>n+t-1=3
>>> designs.orthogonal_arrays.build(Integer(12),Integer(20))
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build an OA(12,20)!
```

static build(*k*, *n*, *t=2*, *resolvable=False*)

Return an $OA(k, n)$ of strength t.

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

INPUT:

- `k`, `n`, `t` – integers; parameters of the orthogonal array
- `resolvable` – boolean (default: `False`); set to `True` if you want the design to be resolvable. The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc.

EXAMPLES:

```
sage: designs.orthogonal_arrays.build(3,3,resolvable=True) # indirect doctest
[[0, 0, 0],
 [1, 2, 1],
 [2, 1, 2],
 [0, 2, 2],
 [1, 1, 0],
 [2, 0, 1],
```

(continues on next page)

(continued from previous page)

```
 [0, 1, 1],
 [1, 0, 2],
 [2, 2, 0]]
sage: OA_7_50 = designs.orthogonal_arrays.build(7,50)      # indirect doctest
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.build(Integer(3),Integer(3),resolvable=True) #␣
↪indirect doctest
[[0, 0, 0],
 [1, 2, 1],
 [2, 1, 2],
 [0, 2, 2],
 [1, 1, 0],
 [2, 0, 1],
 [0, 1, 1],
 [1, 0, 2],
 [2, 2, 0]]
>>> OA_7_50 = designs.orthogonal_arrays.build(Integer(7),Integer(50))      #␣
↪indirect doctest
```

static exists(*k*, *n*, *t=2*)

Return the existence status of an $OA(k,n)$.

INPUT:

- `k`, `n`, `t` – integers; parameters of the orthogonal array

Warning

The function does not only return booleans, but `True`, `False`, or `Unknown`.

See also

is_available()

EXAMPLES:

```
sage: designs.orthogonal_arrays.exists(3,6) # indirect doctest
True
sage: designs.orthogonal_arrays.exists(4,6) # indirect doctest
Unknown
sage: designs.orthogonal_arrays.exists(7,6) # indirect doctest
False
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.exists(Integer(3),Integer(6)) # indirect doctest
True
>>> designs.orthogonal_arrays.exists(Integer(4),Integer(6)) # indirect doctest
Unknown
```

(continues on next page)

(continued from previous page)

```
>>> designs.orthogonal_arrays.exists(Integer(7),Integer(6)) # indirect doctest
False
```

static explain_construction(*k*, *n*, *t=2*)

Return a string describing how to builds an $OA(k,n)$.

INPUT:

- k, n, t – integers; parameters of the orthogonal array

EXAMPLES:

```
sage: designs.orthogonal_arrays.explain_construction(9,565)
"Wilson's construction n=23.24+13 with master design OA(9+1,23)"
sage: designs.orthogonal_arrays.explain_construction(10,154)
'the database contains a (137,10;1,0;17)-quasi difference matrix'
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.explain_construction(Integer(9),Integer(565))
"Wilson's construction n=23.24+13 with master design OA(9+1,23)"
>>> designs.orthogonal_arrays.explain_construction(Integer(10),Integer(154))
'the database contains a (137,10;1,0;17)-quasi difference matrix'
```

static is_available(*k*, *n*, *t=2*)

Return whether Sage can build an $OA(k,n)$.

INPUT:

- k, n, t – integers; parameters of the orthogonal array

See also

exists()

EXAMPLES:

```
sage: designs.orthogonal_arrays.is_available(3,6) # indirect doctest
True
sage: designs.orthogonal_arrays.is_available(4,6) # indirect doctest
False
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.is_available(Integer(3),Integer(6)) # indirect␣
↪doctest
True
>>> designs.orthogonal_arrays.is_available(Integer(4),Integer(6)) # indirect␣
↪doctest
False
```

static largest_available_k(*n*, *t=2*)

Return the largest k such that Sage can build an $OA(k,n)$.

INPUT:

- n – integer

- `t` – integer (default: 2); strength of the array

EXAMPLES:

```
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(0))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(1))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(10))
4
>>> designs.orthogonal_arrays.largest_available_k(Integer(27))
28
>>> designs.orthogonal_arrays.largest_available_k(Integer(100))
10
>>> designs.orthogonal_arrays.largest_available_k(-Integer(1))
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

sage.combinat.designs.orthogonal_arrays.**OA_find_disjoint_blocks**(*OA*, *k*, *n*, *x*, *solver*, *integrality_tolerance*)

Return x disjoint blocks contained in a given $OA(k, n)$.

x blocks of an OA are said to be disjoint if they all have different values for a every given index, i.e. if they correspond to disjoint blocks in the TD associated with the OA.

INPUT:

- `OA` – an orthogonal array
- `k`, `n`, `x` – integers
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

See also

incomplete_orthogonal_array()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_find_disjoint_blocks
sage: k=3;n=4;x=3
sage: Bs = OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,x)
sage: assert len(Bs) == x
sage: for i in range(k):
....:     assert len(set([B[i] for B in Bs])) == x
sage: OA_find_disjoint_blocks(designs.orthogonal_arrays.build(k,n),k,n,5)

```

sage.combinat.designs.orthogonal_arrays.**OA_from_PBD**(*k*, *n*, *PBD*, *check=True*)

Return an $OA(k,n)$ from a PBD.

Construction

Let $\mathcal{B}$ be a $(n,K,1)$-PBD. If there exists for every $i \in K$ a $TD(k,i) - i \times TD(k,1)$ (i.e. if there exist k idempotent MOLS), then one can obtain a $OA(k,n)$ by concatenating:

- A $TD(k,i) - i \times TD(k,1)$ defined over the elements of B for every $B \in \mathcal{B}$.
- The rows $(i,...,i)$ of length k for every $i \in [n]$.

Note

This function raises an exception when Sage is unable to build the necessary designs.

INPUT:

- `k`, `n` – integers
- `PBD` – a PBD on $0,\dots,n-1$

EXAMPLES:

We start from the example VI.1.2 from the [DesignHandbook] to build an $OA(3,10)$:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_from_PBD
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array
sage: pbd = [[0,1,2,3],[0,4,5,6],[0,7,8,9],[1,4,7],[1,5,8],
....: [1,6,9],[2,4,9],[2,5,7],[2,6,8],[3,4,8],[3,5,9],[3,6,7]]
sage: oa = OA_from_PBD(3,10,pbd)
sage: is_orthogonal_array(oa, 3, 10)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_from_PBD
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array
>>> pbd = [[Integer(0),Integer(1),Integer(2),Integer(3)],[Integer(0),Integer(4),
↪Integer(5),Integer(6)],[Integer(0),Integer(7),Integer(8),Integer(9)],
↪[Integer(1),Integer(4),Integer(7)],[Integer(1),Integer(5),Integer(8)],
... [Integer(1),Integer(6),Integer(9)],[Integer(2),Integer(4),Integer(9)],
↪[Integer(2),Integer(5),Integer(7)],[Integer(2),Integer(6),Integer(8)],
↪[Integer(3),Integer(4),Integer(8)],[Integer(3),Integer(5),Integer(9)],
↪[Integer(3),Integer(6),Integer(7)]]
>>> oa = OA_from_PBD(Integer(3),Integer(10),pbd)
>>> is_orthogonal_array(oa, Integer(3), Integer(10))
True
```

But we cannot build an $OA(4,10)$ for this PBD (although there exists an $OA(4,10)$:

```
sage: OA_from_PBD(4,10,pbd)
Traceback (most recent call last):
...
EmptySetError: There is no OA(n+1,n) - 3.OA(n+1,1)
as all blocks intersect in a projective plane.
```

```
>>> from sage.all import *
>>> OA_from_PBD(Integer(4),Integer(10),pbd)
Traceback (most recent call last):
...
EmptySetError: There is no OA(n+1,n) - 3.OA(n+1,1)
as all blocks intersect in a projective plane.
```

Or an $OA(3,6)$ (as the PBD has 10 points):

```
sage: _ = OA_from_PBD(3,6,pbd)
Traceback (most recent call last):
...
RuntimeError: PBD is not a valid Pairwise Balanced Design on [0,...,5]
```

```
>>> from sage.all import *
>>> _ = OA_from_PBD(Integer(3),Integer(6),pbd)
Traceback (most recent call last):
...
RuntimeError: PBD is not a valid Pairwise Balanced Design on [0,...,5]
```

sage.combinat.designs.orthogonal_arrays.**OA_from_Vmt**(m, t, V)

Return an Orthogonal Array from a $V(m,t)$.

INPUT:

- m, t – integers
- V – the vector $V(m,t)$

See also

- *QDM_from_Vmt()*
- *OA_from_quasi_difference_matrix()*

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest
```

```
>>> from sage.all import *
>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(46)) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.**OA_from_quasi_difference_matrix**(*M*, *G*, *add_col=True*, *fill_hole=True*)

Return an Orthogonal Array from a Quasi-Difference matrix.

Difference Matrices

Let G be a group of order g. A *difference matrix* M is a $g \times k$ matrix with entries from G such that for any $1 \leq i < j < k$ the set $\{d_{li} - d_{lj} : 1 \leq l \leq g\}$ is equal to G.

By concatenating the g matrices $M + x$ (where $x \in G$), one obtains a matrix of size $g^2 \times x$ which is also an $OA(k, g)$.

Quasi-difference Matrices

A quasi-difference matrix is a difference matrix with missing entries. The construction above can be applied again in this case, where the missing entries in each column of M are replaced by unique values on which G has a trivial action.

This produces an incomplete orthogonal array with a "hole" (i.e. missing rows) of size 'u' (i.e. the number of missing values per column of M). If there exists an $OA(k, u)$, then adding the rows of this $OA(k, u)$ to the incomplete orthogonal array should lead to an OA…

Formal definition (from the Handbook of Combinatorial Designs [DesignHandbook])

Let G be an abelian group of order n. A $(n, k; \lambda, \mu; u)$-quasi-difference matrix (QDM) is a matrix $Q = (q_{ij})$ with $\lambda(n-1+2u)+\mu$ rows and k columns, with each entry either empty or containing an element of G. Each column contains exactly λu entries, and each row contains at most one empty entry. Furthermore, for each $1 \leq i < j \leq k$ the multiset

$$\{q_{li} - q_{lj} : 1 \leq l \leq \lambda(n-1+2u)+\mu, \text{ with } q_{li} \text{ and } q_{lj} \text{ not empty}\}$$

contains every nonzero element of G exactly λ times, and contains 0 exactly μ times.

Construction

If a $(n, k; \lambda, \mu; u)$-QDM exists and $\mu \leq \lambda$, then an $ITD_\lambda(k, n+u; u)$ exists. Start with a $(n, k; \lambda, \mu; u)$-QDM A over the group G. Append $\lambda - \mu$ rows of zeroes. Then select u elements $\infty_1, \ldots, \infty_u$ not in G, and replace the empty entries, each by one of these infinite symbols, so that ∞_i appears exactly once in each column. Develop the

resulting matrix over the group G (leaving infinite symbols fixed), to obtain a $\lambda(n^2+2nu)\times k$ matrix T. Then T is an orthogonal array with k columns and index λ, having $n+u$ symbols and one hole of size u.

Adding to T an $OA(k,u)$ with elements $\infty_1,\dots,\infty_u$ yields the $ITD_\lambda(k,n+u;u)$.

For more information, see the Handbook of Combinatorial Designs [DesignHandbook] or http://web.cs.du.edu/~petr/milehigh/2013/Colbourn.pdf.

INPUT:

- `M` – the difference matrix whose entries belong to `G`
- `G` – a group
- `add_col` – boolean; whether to add a column to the final OA equal to $(x_1,\dots,x_g,x_1,\dots,x_g,\dots)$ where $G=\{x_1,\dots,x_g\}$
- `fill_hole` – boolean; whether to return the incomplete orthogonal array, or complete it with the $OA(k,u)$ (default). When `fill_hole is None`, no block of the incomplete OA contains more than one value $\geq |G|$.

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,20) # indirect doctest
```

```
>>> from sage.all import *
>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(20)) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.**OA_from_wider_OA**(*OA*, *k*)

Return the first k columns of OA.

If OA has k columns, this function returns OA immediately.

INPUT:

- `OA` – an orthogonal array
- `k` – integer

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_from_wider_OA
sage: OA_from_wider_OA(designs.orthogonal_arrays.build(6,20,2),1)[:5]
[(19,), (19,), (19,), (19,), (19,)]
sage: _ = designs.orthogonal_arrays.build(5,46) # indirect doctest
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_from_wider_OA
>>> OA_from_wider_OA(designs.orthogonal_arrays.build(Integer(6),Integer(20),
↪Integer(2)),Integer(1))[:Integer(5)]
[(19,), (19,), (19,), (19,), (19,)]
>>> _ = designs.orthogonal_arrays.build(Integer(5),Integer(46)) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.**OA_n_times_2_pow_c_from_matrix**(*k*, *c*, *G*, *A*, *Y*, *check=True*)

Return an $OA(k,|G|\cdot 2^c)$ from a constrained $(G,k-1,2)$-difference matrix.

This construction appears in [AC1994] and [Ab1995].

Let G be an additive Abelian group. We denote by H a $GF(2)$-hyperplane in $GF(2^c)$.

Let A be a $(k-1) \times 2|G|$ array with entries in $G \times GF(2^c)$ and Y be a vector with $k-1$ entries in $GF(2^c)$. Let B and C be respectively the part of the array that belong to G and $GF(2^c)$.

The input A and Y must satisfy the following conditions. For any $i \neq j$ and $g \in G$:

- there are exactly two values of s such that $B_{i,s} - B_{j,s} = g$ (i.e. B is a $(G, k-1, 2)$-difference matrix),
- let s_1 and s_2 denote the two values of s given above, then exactly one of $C_{i,s_1} - C_{j,s_1}$ and $C_{i,s_2} - C_{j,s_2}$ belongs to the $GF(2)$-hyperplane $(Y_i - Y_j) \cdot H$ (we implicitly assumed that $Y_i \neq Y_j$).

Under these conditions, it is easy to check that the array whose $k-1$ rows of length $|G| \cdot 2^c$ indexed by $1 \leq i \leq k-1$ given by $A_{i,s} + (0, Y_i \cdot v)$ where $1 \leq s \leq 2|G|, v \in H$ is a $(G \times GF(2^c), k-1, 1)$-difference matrix.

INPUT:

- `k`, `c` – integers
- `G` – an additive Abelian group
- `A` – a matrix with entries in $G \times GF(2^c)$
- `Y` – a vector with entries in $GF(2^c)$
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

Note

By convention, a multiplicative generator w of $GF(2^c)^*$ is fixed (inside the function). The hyperplane H is the one spanned by $w^0, w^1, \ldots, w^{c-1}$. The $GF(2^c)$ part of the input matrix A and vector Y are given in the following form: the integer i corresponds to the element w^i and `None` corresponds to 0.

```

sage.combinat.designs.orthogonal_arrays.**OA_relabel**(*OA*, *k*, *n*, *blocks=()*, *matrix=None*, *symbol_list=None*)

Return a relabelled version of the OA.

INPUT:

- `OA` – an OA, or rather a list of blocks of length k, each of which contains integers from 0 to $n-1$
- `k`, `n` – integers
- `blocks` – list of blocks; relabels the integers of the OA from $[0..n-1]$ into $[0..n-1]$ in such a way that the i blocks from `block` are respectively relabeled as `[n-i,...,n-i]`, ..., `[n-1,...,n-1]`. Thus, the blocks from this list are expected to have disjoint values for each coordinate.

  If set to the empty list (default) no such relabelling is performed.
- `matrix` – a matrix of dimensions k, n such that if the i th coordinate of a block is x, this x will be relabelled with `matrix[i][x]`. This is not necessarily an integer between 0 and $n-1$, and it is not necessarily an integer either. This is performed *after* the previous relabelling.

  If set to `None` (default) no such relabelling is performed.
- `symbol_list` – list of the desired symbols for the relabelled OA. If this is not `None`, the same relabelling is done on all blocks such that the index of an element in symbol_list is its preimage in the relabelling map.

> **Note**
>
> A `None` coordinate in one block remains a `None` coordinate in the final block.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_relabel
sage: OA = designs.orthogonal_arrays.build(3,2)
sage: OA_relabel(OA,3,2,matrix=[["A","B"],["C","D"],["E","F"]])
[['A', 'C', 'E'], ['A', 'D', 'F'], ['B', 'C', 'F'], ['B', 'D', 'E']]
```

(continues on next page)

(continued from previous page)

```
sage: TD = OA_relabel(OA,3,2,matrix=[[0,1],[2,3],[4,5]]); TD
[[0, 2, 4], [0, 3, 5], [1, 2, 5], [1, 3, 4]]
sage: from sage.combinat.designs.orthogonal_arrays import is_transversal_design
sage: is_transversal_design(TD,3,2)
True

sage: OA = designs.orthogonal_arrays.build(3,2)
sage: OA_relabel(OA, 3, 2, symbol_list=['A', 'B'])
[['A', 'A', 'A'], ['A', 'B', 'B'], ['B', 'A', 'B'], ['B', 'B', 'A']]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_relabel
>>> OA = designs.orthogonal_arrays.build(Integer(3),Integer(2))
>>> OA_relabel(OA,Integer(3),Integer(2),matrix=[["A","B"],["C","D"],["E","F"]])
[['A', 'C', 'E'], ['A', 'D', 'F'], ['B', 'C', 'F'], ['B', 'D', 'E']]

>>> TD = OA_relabel(OA,Integer(3),Integer(2),matrix=[[Integer(0),Integer(1)],
↪[Integer(2),Integer(3)],[Integer(4),Integer(5)]]); TD
[[0, 2, 4], [0, 3, 5], [1, 2, 5], [1, 3, 4]]
>>> from sage.combinat.designs.orthogonal_arrays import is_transversal_design
>>> is_transversal_design(TD,Integer(3),Integer(2))
True

>>> OA = designs.orthogonal_arrays.build(Integer(3),Integer(2))
>>> OA_relabel(OA, Integer(3), Integer(2), symbol_list=['A', 'B'])
[['A', 'A', 'A'], ['A', 'B', 'B'], ['B', 'A', 'B'], ['B', 'B', 'A']]
```

Making sure that `[2,2,2,2]` is a block of $OA(4,3)$. We do this by relabelling block `[0,0,0,0]` which belongs to the design:

```
sage: designs.orthogonal_arrays.build(4,3)
[[0, 0, 0, 0], [0, 1, 2, 1], [0, 2, 1, 2], [1, 0, 2, 2], [1, 1, 1, 0], [1, 2, 0,␣
↪1], [2, 0, 1, 1], [2, 1, 0, 2], [2, 2, 2, 0]]
sage: OA_relabel(designs.orthogonal_arrays.build(4,3),4,3,blocks=[[0,0,0,0]])
[[2, 2, 2, 2], [2, 0, 1, 0], [2, 1, 0, 1], [0, 2, 1, 1], [0, 0, 0, 2], [0, 1, 2,␣
↪0], [1, 2, 0, 0], [1, 0, 2, 1], [1, 1, 1, 2]]
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.build(Integer(4),Integer(3))
[[0, 0, 0, 0], [0, 1, 2, 1], [0, 2, 1, 2], [1, 0, 2, 2], [1, 1, 1, 0], [1, 2, 0,␣
↪1], [2, 0, 1, 1], [2, 1, 0, 2], [2, 2, 2, 0]]
>>> OA_relabel(designs.orthogonal_arrays.build(Integer(4),Integer(3)),Integer(4),
↪Integer(3),blocks=[[Integer(0),Integer(0),Integer(0),Integer(0)]])
[[2, 2, 2, 2], [2, 0, 1, 0], [2, 1, 0, 1], [0, 2, 1, 1], [0, 0, 0, 2], [0, 1, 2,␣
↪0], [1, 2, 0, 0], [1, 0, 2, 1], [1, 1, 1, 2]]
```

`sage.combinat.designs.orthogonal_arrays.`**`OA_standard_label`**`(`OA`)`

Return the inputted OA with entries relabelled as integers [0,…,n-1].

INPUT:

- `OA` – list of lists with symbols as entries that are not necessarily integers

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import OA_standard_label
sage: C = [['a', 'a', 'a', 'b'],
....:      ['a', 'a', 'b', 'a'],
....:      ['a', 'b', 'a', 'a'],
....:      ['b', 'a', 'a', 'a'],
....:      ['b', 'b', 'b', 'b']]
sage: OA_standard_label(C)
[[0, 0, 0, 1], [0, 0, 1, 0], [0, 1, 0, 0], [1, 0, 0, 0], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import OA_standard_label
>>> C = [['a', 'a', 'a', 'b'],
...      ['a', 'a', 'b', 'a'],
...      ['a', 'b', 'a', 'a'],
...      ['b', 'a', 'a', 'a'],
...      ['b', 'b', 'b', 'b']]
>>> OA_standard_label(C)
[[0, 0, 0, 1], [0, 0, 1, 0], [0, 1, 0, 0], [1, 0, 0, 0], [1, 1, 1, 1]]
```

sage.combinat.designs.orthogonal_arrays.**QDM_from_Vmt**(*m*, *t*, *V*)

Return a QDM from a $V(m,t)$.

Definition

Let q be a prime power and let $q = mt + 1$ for m, t integers. Let ω be a primitive element of $\mathbf{F}_q$. A $V(m,t)$ vector is a vector $(a_1, \ldots, a_{m+1}$ for which, for each $1 \leq k < m$, the differences

$$\{a_{i+k} - a_i : 1 \leq i \leq m+1, i+k \neq m+2\}$$

represent the m cyclotomic classes of $\mathbf{F}_{mt+1}$ (compute subscripts modulo $m+2$). In other words, for fixed k, is $a_{i+k} - a_i = \omega^{mx+\alpha}$ and $a_{j+k} - a_j = \omega^{my+\beta}$ then $\alpha \not\equiv \beta \mod m$

Construction of a quasi-difference matrix from a `V(m,t)` vector

Starting with a $V(m,t)$ vector $(a_1, \ldots, a_{m+1})$, form a single row of length $m+2$ whose first entry is empty, and whose remaining entries are $(a_1, \ldots, a_{m+1})$. Form t rows by multiplying this row by the t th roots, i.e. the powers of ω^m. From each of these t rows, form $m+2$ rows by taking the $m+2$ cyclic shifts of the row. The result is a $(a, m+2; 1, 0; t) - QDM$.

For more information, refer to the Handbook of Combinatorial Designs [DesignHandbook].

INPUT:

- `m`, `t` – integers
- `V` – the vector $V(m,t)$

See also

OA_from_quasi_difference_matrix()

EXAMPLES:

```
sage: _ = designs.orthogonal_arrays.build(6,46) # indirect doctest
```

```
>>> from sage.all import *
>>> _ = designs.orthogonal_arrays.build(Integer(6),Integer(46)) # indirect doctest
```

sage.combinat.designs.orthogonal_arrays.**TD_product**(*k*, *TD1*, *n1*, *TD2*, *n2*, *check=True*)

Return the product of two transversal designs.

From a transversal design TD_1 of parameters k, n_1 and a transversal design TD_2 of parameters k, n_2, this function returns a transversal design of parameters k, n where $n = n_1 \times n_2$.

Formally, if the groups of TD_1 are $V_1^1, \ldots, V_k^1$ and the groups of TD_2 are $V_1^2, \ldots, V_k^2$, the groups of the product design are $V_1^1 \times V_1^2, \ldots, V_k^1 \times V_k^2$ and its blocks are the $\{(x_1^1, x_1^2), \ldots, (x_k^1, x_k^2)\}$ where $\{x_1^1, \ldots, x_k^1\}$ is a block of TD_1 and $\{x_1^2, \ldots, x_k^2\}$ is a block of TD_2.

INPUT:

- `TD1`, `TD2` – transversal designs
- `k`, `n1`, `n2` – integers
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

Note

This function uses transversal designs with $V_1 = \{0, \ldots, n-1\}, \ldots, V_k = \{(k-1)n, \ldots, kn-1\}$ both as input and output.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays import TD_product
sage: TD1 = designs.transversal_design(6,7)
sage: TD2 = designs.transversal_design(6,12)
sage: TD6_84 = TD_product(6,TD1,7,TD2,12)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays import TD_product
>>> TD1 = designs.transversal_design(Integer(6),Integer(7))
>>> TD2 = designs.transversal_design(Integer(6),Integer(12))
>>> TD6_84 = TD_product(Integer(6),TD1,Integer(7),TD2,Integer(12))
```

class sage.combinat.designs.orthogonal_arrays.**TransversalDesign**(*blocks*, *k=None*, *n=None*, *check=True*, ***kwds*)

Bases: *GroupDivisibleDesign*

Class for Transversal Designs.

INPUT:

- `blocks` – collection of blocks
- `k`, `n` – integers; parameters of the transversal design. They can be set to `None` (default) in which case their value is determined by the blocks.
- `check` – boolean (default: `True`); whether to check that the design is indeed a transversal design with the right parameters

EXAMPLES:

```
sage: designs.transversal_design(None,5)
Transversal Design TD(6,5)
sage: designs.transversal_design(None,30)
Transversal Design TD(6,30)
sage: designs.transversal_design(None,36)
Transversal Design TD(10,36)
```

```
>>> from sage.all import *
>>> designs.transversal_design(None,Integer(5))
Transversal Design TD(6,5)
>>> designs.transversal_design(None,Integer(30))
Transversal Design TD(6,30)
>>> designs.transversal_design(None,Integer(36))
Transversal Design TD(10,36)
```

sage.combinat.designs.orthogonal_arrays.**incomplete_orthogonal_array**(*k*, *n*, *holes*, *resolvable=False*, *existence=False*)

Return an $OA(k,n) - \sum_{1\leq i\leq x} OA(k,s_i)$.

An $OA(k,n) - \sum_{1\leq i\leq x} OA(k,s_i)$ is an orthogonal array from which have been removed disjoint $OA(k,s_1),...,OA(k,s_x)$. If there exist $OA(k,s_1),...,OA(k,s_x)$ they can be used to fill the holes and give rise to an $OA(k,n)$.

A very useful particular case (see e.g. the Wilson construction in `wilson_construction()`) is when all $s_i = 1$. In that case the incomplete design is a $OA(k,n) - x.OA(k,1)$. Such design is equivalent to transversal design $TD(k,n)$ from which has been removed x disjoint blocks.

INPUT:

- `k`, `n` – integers
- `holes` – list of integers respective sizes of the holes to be found
- `resolvable` – boolean (default: `False`); set to `True` if you want the design to be resolvable. The classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc.
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

Note

By convention, the ground set is always $V = \{0,...,n-1\}$.

If all holes have size 1, in the incomplete orthogonal array returned by this function the holes are $\{n-1,...,n-s_1\}^k$, $\{n-s_1-1,...,n-s_1-s_2\}^k$, etc.

More generally, if `holes` is equal to $u1,...,uk$, the i-th hole is the set of points $\{n - \sum_{j\geq i} u_j, ..., n - \sum_{j\geq i+1} u_j\}^k$.

OA_find_disjoint_blocks()

EXAMPLES:

```
sage: IOA = designs.incomplete_orthogonal_array(3,3,[1,1,1])
sage: IOA
[[0, 1, 2], [0, 2, 1], [1, 0, 2], [1, 2, 0], [2, 0, 1], [2, 1, 0]]
sage: missing_blocks = [[0,0,0],[1,1,1],[2,2,2]]
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: is_orthogonal_array(IOA + missing_blocks,3,3,2)
True
```

```
>>> from sage.all import *
>>> IOA = designs.incomplete_orthogonal_array(Integer(3),Integer(3),[Integer(1),
↪Integer(1),Integer(1)])
>>> IOA
[[0, 1, 2], [0, 2, 1], [1, 0, 2], [1, 2, 0], [2, 0, 1], [2, 1, 0]]
>>> missing_blocks = [[Integer(0),Integer(0),Integer(0)],[Integer(1),Integer(1),
↪Integer(1)],[Integer(2),Integer(2),Integer(2)]]
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> is_orthogonal_array(IOA + missing_blocks,Integer(3),Integer(3),Integer(2))
True
```

sage.combinat.designs.orthogonal_arrays.**is_transversal_design**(*B*, *k*, *n*, *verbose=False*)

Check that a given set of blocks `B` is a transversal design.

See *transversal_design()* for a definition.

INPUT:

- `B` – the list of blocks
- `k`, `n` – integers
- `verbose` – boolean; whether to display information about what is going wrong

Note

The transversal design must have $\{0,\dots,kn-1\}$ as a ground set, partitioned as k sets of size n: $\{0,\dots,k-1\} \sqcup \{k,\dots,2k-1\} \sqcup \cdots \sqcup \{k(n-1),\dots,kn-1\}$.

EXAMPLES:

```
sage: TD = designs.transversal_design(5, 5, check=True) # indirect doctest
sage: from sage.combinat.designs.orthogonal_arrays import is_transversal_design
sage: is_transversal_design(TD, 5, 5)
True
sage: is_transversal_design(TD, 4, 4)
False
```

```
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(5), Integer(5), check=True) #␣
↪indirect doctest
>>> from sage.combinat.designs.orthogonal_arrays import is_transversal_design
>>> is_transversal_design(TD, Integer(5), Integer(5))
True
>>> is_transversal_design(TD, Integer(4), Integer(4))
False
```

sage.combinat.designs.orthogonal_arrays.**largest_available_k**(*n*, *t=2*)

Return the largest k such that Sage can build an $OA(k, n)$.

INPUT:

- n – integer
- t – integer (default: 2); strength of the array

EXAMPLES:

```
sage: designs.orthogonal_arrays.largest_available_k(0)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(1)
+Infinity
sage: designs.orthogonal_arrays.largest_available_k(10)
4
sage: designs.orthogonal_arrays.largest_available_k(27)
28
sage: designs.orthogonal_arrays.largest_available_k(100)
10
sage: designs.orthogonal_arrays.largest_available_k(-1)
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

```
>>> from sage.all import *
>>> designs.orthogonal_arrays.largest_available_k(Integer(0))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(1))
+Infinity
>>> designs.orthogonal_arrays.largest_available_k(Integer(10))
4
>>> designs.orthogonal_arrays.largest_available_k(Integer(27))
28
>>> designs.orthogonal_arrays.largest_available_k(Integer(100))
10
>>> designs.orthogonal_arrays.largest_available_k(-Integer(1))
Traceback (most recent call last):
...
ValueError: n(=-1) was expected to be >=0
```

sage.combinat.designs.orthogonal_arrays.**orthogonal_array**(*k*, *n*, *t=2*, *resolvable=False*, *check=True*, *existence=False*, *explain_construction=False*)

Return an orthogonal array of parameters k, n, t.

An orthogonal array of parameters k, n, t is a matrix with k columns filled with integers from $[n]$ in such a way that for any t columns, each of the n^t possible rows occurs exactly once. In particular, the matrix has n^t rows.

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

An orthogonal array is said to be *resolvable* if it corresponds to a resolvable transversal design (see `sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable()`).

For more information on orthogonal arrays, see Wikipedia article Orthogonal_array.

INPUT:

- `k` – integer; number of columns. If `k` is `None` it is set to the largest value available.
- `n` – integer; number of symbols
- `t` – integer (default: 2); strength of the array
- `resolvable` – boolean (default: `False`); set to `True` if you want the design to be resolvable. The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc.
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

  Note

  When `k=None` and `existence=True` the function returns an integer, i.e. the largest k such that we can build a $OA(k, n)$.

- `explain_construction` – boolean; return a string describing the construction

OUTPUT: the kind of output depends on the input:

- if `existence=False` (the default) then the output is a list of lists that represent an orthogonal array with parameters `k` and `n`
- if `existence=True` and `k` is an integer, then the function returns a troolean: either `True`, `Unknown` or `False`
- if `existence=True` and `k=None` then the output is the largest value of `k` for which Sage knows how to compute a $TD(k, n)$.

Note

This method implements theorems from [Stinson2004]. See the code's documentation for details.

See also

When $t = 2$ an orthogonal array is also a transversal design (see *transversal_design()*) and a family of mutually orthogonal latin squares (see *mutually_orthogonal_latin_squares()*).

sage.combinat.designs.orthogonal_arrays.**transversal_design**(*k*, *n*, *resolvable=False*, *check=True*, *existence=False*)

Return a transversal design of parameters k, n.

A transversal design of parameters k, n is a collection $\mathcal{S}$ of subsets of $V = V_1 \cup \cdots \cup V_k$ (where the *groups* V_i are disjoint and have cardinality n) such that:

- Any $S \in \mathcal{S}$ has cardinality k and intersects each group on exactly one element.
- Any two elements from distincts groups are contained in exactly one element of $\mathcal{S}$.

More general definitions sometimes involve a λ parameter, and we assume here that $\lambda = 1$.

For more information on transversal designs, see http://mathworld.wolfram.com/TransversalDesign.html.

INPUT:

- `n`, `k` – integers; if `k is None` it is set to the largest value available
- `resolvable` – boolean; set to `True` if you want the design to be resolvable (see *sage.combinat.designs.incidence_structures.IncidenceStructure.is_resolvable()*). The n classes of the resolvable design are obtained as the first n blocks, then the next n blocks, etc ... Set to `False` by default.
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

Note

When `k=None` and `existence=True` the function returns an integer, i.e. the largest k such that we can build a $TD(k, n)$.

OUTPUT: the kind of output depends on the input:

- if `existence=False` (the default) then the output is a list of lists that represent a $TD(k, n)$ with $V_1 = \{0, \ldots, n-1\}, \ldots, V_k = \{(k-1)n, \ldots, kn-1\}$
- if `existence=True` and `k` is an integer, then the function returns a troolean: either `True`, `Unknown` or `False`
- if `existence=True` and `k=None` then the output is the largest value of `k` for which Sage knows how to compute a $TD(k, n)$.

See also

orthogonal_array() – a transversal design $TD(k,n)$ is equivalent to an orthogonal array $OA(k,n,2)$.

EXAMPLES:

```
sage: TD = designs.transversal_design(5,5); TD
Transversal Design TD(5,5)
sage: TD.blocks()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23],
 [0, 8, 11, 19, 22], [0, 9, 13, 17, 21], [1, 5, 14, 18, 22],
 [1, 6, 11, 16, 21], [1, 7, 13, 19, 20], [1, 8, 10, 17, 24],
 [1, 9, 12, 15, 23], [2, 5, 13, 16, 24], [2, 6, 10, 19, 23],
 [2, 7, 12, 17, 22], [2, 8, 14, 15, 21], [2, 9, 11, 18, 20],
 [3, 5, 12, 19, 21], [3, 6, 14, 17, 20], [3, 7, 11, 15, 24],
 [3, 8, 13, 18, 23], [3, 9, 10, 16, 22], [4, 5, 11, 17, 23],
 [4, 6, 13, 15, 22], [4, 7, 10, 18, 21], [4, 8, 12, 16, 20],
 [4, 9, 14, 19, 24]]
```

```
>>> from sage.all import *
>>> TD = designs.transversal_design(Integer(5),Integer(5)); TD
Transversal Design TD(5,5)
>>> TD.blocks()
[[0, 5, 10, 15, 20], [0, 6, 12, 18, 24], [0, 7, 14, 16, 23],
 [0, 8, 11, 19, 22], [0, 9, 13, 17, 21], [1, 5, 14, 18, 22],
 [1, 6, 11, 16, 21], [1, 7, 13, 19, 20], [1, 8, 10, 17, 24],
 [1, 9, 12, 15, 23], [2, 5, 13, 16, 24], [2, 6, 10, 19, 23],
 [2, 7, 12, 17, 22], [2, 8, 14, 15, 21], [2, 9, 11, 18, 20],
 [3, 5, 12, 19, 21], [3, 6, 14, 17, 20], [3, 7, 11, 15, 24],
 [3, 8, 13, 18, 23], [3, 9, 10, 16, 22], [4, 5, 11, 17, 23],
 [4, 6, 13, 15, 22], [4, 7, 10, 18, 21], [4, 8, 12, 16, 20],
 [4, 9, 14, 19, 24]]
```

Some examples of the maximal number of transversal Sage is able to build:

```
sage: TD_4_10 = designs.transversal_design(4,10)
sage: designs.transversal_design(5,10,existence=True)
Unknown
```

```
>>> from sage.all import *
>>> TD_4_10 = designs.transversal_design(Integer(4),Integer(10))
>>> designs.transversal_design(Integer(5),Integer(10),existence=True)
Unknown
```

For prime powers, there is an explicit construction which gives a $TD(n+1,n)$:

```
sage: designs.transversal_design(4, 3, existence=True)
True
sage: designs.transversal_design(674, 673, existence=True)
True
```

```
>>> from sage.all import *
>>> designs.transversal_design(Integer(4), Integer(3), existence=True)
True
>>> designs.transversal_design(Integer(674), Integer(673), existence=True)
True
```

For other values of `n` it depends:

```
sage: designs.transversal_design(7, 6, existence=True)
False
sage: designs.transversal_design(4, 6, existence=True)
Unknown
sage: designs.transversal_design(3, 6, existence=True)
True

sage: designs.transversal_design(11, 10, existence=True)
False
sage: designs.transversal_design(4, 10, existence=True)
True
sage: designs.transversal_design(5, 10, existence=True)
Unknown

sage: designs.transversal_design(7, 20, existence=True)
Unknown
sage: designs.transversal_design(6, 12, existence=True)
True
sage: designs.transversal_design(7, 12, existence=True)
True
sage: designs.transversal_design(8, 12, existence=True)
Unknown

sage: designs.transversal_design(6, 20, existence = True)
True
sage: designs.transversal_design(7, 20, existence = True)
Unknown
```

```
>>> from sage.all import *
>>> designs.transversal_design(Integer(7), Integer(6), existence=True)
False
>>> designs.transversal_design(Integer(4), Integer(6), existence=True)
Unknown
>>> designs.transversal_design(Integer(3), Integer(6), existence=True)
True

>>> designs.transversal_design(Integer(11), Integer(10), existence=True)
False
>>> designs.transversal_design(Integer(4), Integer(10), existence=True)
True
>>> designs.transversal_design(Integer(5), Integer(10), existence=True)
Unknown

>>> designs.transversal_design(Integer(7), Integer(20), existence=True)
Unknown
```

(continues on next page)

(continued from previous page)

```
>>> designs.transversal_design(Integer(6), Integer(12), existence=True)
True
>>> designs.transversal_design(Integer(7), Integer(12), existence=True)
True
>>> designs.transversal_design(Integer(8), Integer(12), existence=True)
Unknown

>>> designs.transversal_design(Integer(6), Integer(20), existence = True)
True
>>> designs.transversal_design(Integer(7), Integer(20), existence = True)
Unknown
```

If you ask for a transversal design that Sage is not able to build then an `EmptySetError` or a `NotImplementedError` is raised:

```
sage: designs.transversal_design(47, 100)
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build a TD(47,100)!
sage: designs.transversal_design(55, 54)
Traceback (most recent call last):
...
EmptySetError: There exists no TD(55,54)!
```

```
>>> from sage.all import *
>>> designs.transversal_design(Integer(47), Integer(100))
Traceback (most recent call last):
...
NotImplementedError: I don't know how to build a TD(47,100)!
>>> designs.transversal_design(Integer(55), Integer(54))
Traceback (most recent call last):
...
EmptySetError: There exists no TD(55,54)!
```

Those two errors correspond respectively to the cases where Sage answer `Unknown` or `False` when the parameter `existence` is set to `True`:

```
sage: designs.transversal_design(47, 100, existence=True)
Unknown
sage: designs.transversal_design(55, 54, existence=True)
False
```

```
>>> from sage.all import *
>>> designs.transversal_design(Integer(47), Integer(100), existence=True)
Unknown
>>> designs.transversal_design(Integer(55), Integer(54), existence=True)
False
```

If for a given n you want to know the largest k for which Sage is able to build a $TD(k,n)$ just call the function with k set to `None` and `existence` set to `True` as follows:

```
sage: designs.transversal_design(None, 6, existence=True)
3
sage: designs.transversal_design(None, 20, existence=True)
6
sage: designs.transversal_design(None, 30, existence=True)
6
sage: designs.transversal_design(None, 120, existence=True)
9
```

```
>>> from sage.all import *
>>> designs.transversal_design(None, Integer(6), existence=True)
3
>>> designs.transversal_design(None, Integer(20), existence=True)
6
>>> designs.transversal_design(None, Integer(30), existence=True)
6
>>> designs.transversal_design(None, Integer(120), existence=True)
9
```

sage.combinat.designs.orthogonal_arrays.**wilson_construction**(*OA*, *k*, *r*, *m*, *u*, *check=True*, *explain_construction=False*)

Return a $OA(k, rm + \sum_i u_i)$ from a truncated $OA(k + s, r)$ by Wilson's construction.

Simple form:

Let OA be a truncated $OA(k + s, r)$ with s truncated columns of sizes $u_1, ..., u_s$, whose blocks have sizes in $\{k + b_1, ..., k + b_t\}$. If there exist:

- An $OA(k, m + b_i) - b_i.OA(k, 1)$ for every $1 \leq i \leq t$
- An $OA(k, u_i)$ for every $1 \leq i \leq s$

Then there exists an $OA(k, rm + \sum u_i)$. The construction is a generalization of Lemma 3.16 in [HananiBIBD].

Brouwer-Van Rees form:

Let OA be a truncated $OA(k + s, r)$ with s truncated columns of sizes $u_1, ..., u_s$. Let the set H_i of the u_i points of column $k + i$ be partitionned into $\sum_j H_{ij}$. Let m_{ij} be integers such that:

- For $0 \leq i < l$ there exists an $OA(k, \sum_j m_{ij}|H_{ij}|)$
- For any block $B \in OA$ intersecting the sets $H_{ij(i)}$ there exists an $OA(k, m+\sum_i m_{ij}) - \sum_i OA(k, m_{ij(j)})$.

Then there exists an $OA(k, rm + \sum_{i,j} m_{ij})$. This construction appears in [BvR1982].

INPUT:

- `OA` – an incomplete orthogonal array with $k + s$ columns. The elements of a column of size c must belong to $\{0, ..., c\}$. The missing entries of a block are represented by `None` values. If `OA=None`, it is defined as a truncated orthogonal arrays with $k + s$ columns.
- `k`, `r`, `m` – integers
- `u` – list; two cases depending on the form to use:
  - Simple form: a list of length s such that column `k+i` has size `u[i]`. The untruncated points of column `k+i` are assumed to be `[0,...,u[i]-1]`.
  - Brouwer-Van Rees form: a list of length s such that `u[i]` is the list of pairs $(m_{i0}, |H_{i0}|), ..., (m_{ip_i}, |H_{ip_i}|)$. The untruncated points of column `k+i` are assumed to be $[0, ..., u_i - 1]$

where $u_i = \sum_j |H_{ip_i}|$. Besides, the first $|H_{i0}|$ points represent H_{i0}, the next $|H_{i1}|$ points represent H_{i1}, etc…

- `explain_construction` – boolean; return a string describing the construction
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

↪Integer(5))]])
>>> is_orthogonal_array(OAb,Integer(5),Integer(256))
True
```

Orthogonal arrays (build recursive constructions)

This module implements several constructions of *Orthogonal Arrays*. As their input can be complex, they all have a counterpart in the *orthogonal_arrays_find_recursive* module that automatically computes it.

All these constructions are automatically queried when the *orthogonal_array()* function is called.

construction_3_3()	Return an $OA(k, nm+i)$.
construction_3_4()	Return a $OA(k, nm+rs)$.
construction_3_5()	Return an $OA(k, nm+r+s+t)$.
construction_3_6()	Return a $OA(k, nm+i)$.
construction_q_x()	Return an $OA(k, (q-1)*(q-x)+x+2)$ using the $q-x$ construction.
OA_and_oval()	Return a $OA(q+1, q)$ whose blocks contains ≤ 2 zeroes in the last q columns.
thwart_lemma_3_5()	Return an $OA(k, nm+a+b+c+d)$.
thwart_lemma_4_1()	Return an $OA(k, nm+4(n-2))$.
three_factor_product()	Return an $OA(k+1, n_1n_2n_3)$.
brouwer_separable_design()	Return a $OA(k, t(q^2+q+1)+x)$ using Brouwer's result on separable designs.

Functions

sage.combinat.designs.orthogonal_arrays_build_recursive.**OA_and_oval**(*q*, *solver*, *integrality_tolerance*)

Return a $OA(q+1,q)$ whose blocks contains ≤ 2 zeroes in the last q columns.

This OA is build from a projective plane of order q, in which there exists an oval O of size $q+1$ (i.e. a set of $q+1$ points no three of which are [colinear/contained in a common set of the projective plane]).

Removing an element $x \in O$ and all sets that contain it, we obtain a $TD(q+1,q)$ in which O intersects all columns except one. As O is an oval, no block of the TD intersects it more than twice.

INPUT:

- `q` – a prime power
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

Note

This function is called by *`construction_3_6()`*, an implementation of Construction 3.6 from [AC07].

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_build_recursive import OA_and_
↪oval
sage: _ = OA_and_oval
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_build_recursive import OA_and_
↪oval
>>> _ = OA_and_oval
```

sage.combinat.designs.orthogonal_arrays_build_recursive.**brouwer_separable_design**(*k*, *t*, *q*, *x*, *check=False*, *verbose=False*, *explain_construction=False*)

Return a $OA(k, t(q^2+q+1)+x)$ using Brouwer's result on separable designs.

This method is an implementation of Brouwer's construction presented in [Brouwer80]. It consists in a systematic application of the usual transformation from PBD to OA, applied to a specific PBD.

Baer subplanes

When q is a prime power, the projective plane $PG(2,q^2)$ can be partitionned into subplanes $PG(2,q)$ (called Baer subplanes), giving $PG(2,q^2) = B_1 \cup \cdots \cup B_{q^2-q+1}$. As a result, every line of the $PG(2,q^2)$ intersects one of the subplane on $q+1$ points and all others on 1 point.

The OA are built by considering $B_1 \cup \cdots \cup B_t$, for a total of $t(q^2+q+1)$ points (to which x new points are then added). The blocks of this subdesign belong to two categories:

- The blocks of size t: they come from the lines which intersect a B_i on $q+1$ points for some $i > t$. The blocks of size t can be partitionned into $q^2-q+t-1$ parallel classes according to their associated subplane B_i with $i > t$.
- The blocks of size $q+t$: those blocks form a symmetric design, as every point is incident with $q+t$ of them.

Constructions

In the following, we write $N = t(q^2+q+1)+x$. The code is also heavily commented, and will clear any doubt.

- i) $x = 0$: in that case we build a resolvable $OA(k-1, N)$ that will then be completed into an $OA(k, N)$.
  - *Sets of size t*)

    We take the product of each parallel class with the parallel classes of a resolvable $OA(k-1,t) - t.OA(k-1,t)$, yielding new parallel classes.
  - *Sets of size $q+t$*)

    A $N \times (q+t)$ array is built whose rows are the sets of size $q+t$ such that every value appears once per column. For each block of a $OA(k-1, q+t) - (q+t).OA(k-1,t)$, the product with the rows of the matrix yields a parallel class.
- ii) $x = q+t$
  - *Sets of size t*)

    Each set of size t gives a $OA(k,t) - t.OA(k,1)$, except if there is only one parallel class in which case a $OA(k,t)$ is sufficient.
  - *Sets of size $q+t$*)

    A $(N-x) \times (q+t)$ array M is built whose $N-x$ rows are the sets of size $q+t$ such that every value appears once per column. For each of the new $x = q+t$ points $p_1, \ldots, p_{q+t}$ we build a matrix M_i obtained from M by adding a column equal to $(p_i, p_i, p_i \ldots)$. We add to the OA the product of all rows of the M_i with the block of the $x = q+t$ parallel classes of a resolvable $OA(k, t+q+1) - (t+q+1).OA(k,1)$.
  - *Set of size x*) An $OA(k,x)$
- iii) $x = q^2 - q + 1 - t$
  - *Sets of size t*)

    All blocks of the i-th parallel class are extended with the i-th new point. The blocks are then replaced by a $OA(k, t+1) - (t+1).OA(k,1)$ or, if there is only one parallel class (i.e. $x = 1$) by a $OA(k, t+1) - OA(k,1)$.
  - *Set of size $q+t$*)

    They are replaced by $OA(k, q+t) - (q+t).OA(k,1)$.
  - *Set of size x*) An $OA(k,x)$
- iv) $x = q^2 + 1$
  - *Sets of size t*)

All blocks of the i-th parallel class are extended with the i-th new point (the other $x-q-t$ new points are not touched at this step). The blocks are then replaced by a $OA(k,t+1)-(t+1).OA(k,1)$ or, if there is only one parallel class (i.e. $x=1$) by a $OA(k,t+1)-OA(k,1)$.

  - *Sets of size* $q+t$) Same as for ii)
  - *Set of size* x) An $OA(k,x)$

- v) $0<x<q^2-q+1-t$
  - *Sets of size* t)

    The blocks of the first x parallel class are extended with the x new points, and replaced with $OA(k.t+1)-(t+1).OA(k,1)$ or, if $x=1$, by $OA(k.t+1)-.OA(k,1)$

    The blocks of the other parallel classes are replaced by $OA(k,t)-t.OA(k,t)$ or, if there is only one class left, by $OA(k,t)-OA(k,t)$
  - *Sets of size* $q+t$)

    They are replaced with $OA(k,q+t)-(q+t).OA(k,1)$.
  - *Set of size* x) An $OA(k,x)$

- vi) $t+q<x<q^2+1$
  - *Sets of size* t) Same as in v) with an x equal to $x-q+t$.
  - *Sets of size* t) Same as in vii)
  - *Set of size* x) An $OA(k,x)$

INPUT:

- `k`, `t`, `q`, `x` – integers
- `check` – boolean (default: `False`); whether to check that output is correct before returning it
- `verbose` – boolean; whether to print some information on the construction and parameters being used
- `explain_construction` – boolean; return a string describing the construction

```

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_3_3**(*k*, *n*, *m*, *i*, *explain_construction=False*)

Return an $OA(k, nm + i)$.

This is Wilson's construction with i truncated columns of size 1 and such that a block B_0 of the incomplete OA intersects all truncated columns. As a consequence, all other blocks intersect only 0 or 1 of the last i columns. This allow to consider the block B_0 only up to its first k coordinates and then use a $OA(k, i)$ instead of a $OA(k, m + i) - i.OA(k, 1)$.

This is construction 3.3 from [AC07].

INPUT:

- `k`, `n`, `m`, `i` – integers such that the following designs are available: $OA(k, n)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, r)$
- `explain_construction` – boolean; return a string describing the construction

   Journal of Combinatorial Designs, 2007
```

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_3_4**(*k*, *n*, *m*, *r*, *s*, *explain_construction=False*)

Return a $OA(k, nm + rs)$.

This is Wilson's construction applied to a truncated $OA(k + r + 1, n)$ with r columns of size 1 and one column of size s.

The unique elements of the r truncated columns are picked so that a block B_0 contains them all.

- If there exists an $OA(k, m + r + 1)$ the column of size s is truncated in order to intersect B_0.
- Otherwise, if there exists an $OA(k, m + r)$, the last column must not intersect B_0

This is construction 3.4 from [AC07].

INPUT:

- `k`, `n`, `m`, `r`, `s` – integers; we assume that $s < n$ and $1 \leq r, s$

  The following designs must be available: $OA(k, n)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, s)$. Additionally, it requires either a $OA(k, m + r)$ or a $OA(k, m + r + 1)$.

- `explain_construction` – boolean; return a string describing the construction

```

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_3_5**(*k*, *n*, *m*, *r*, *s*, *t*, *explain_construction=False*)

Return an $OA(k, nm + r + s + t)$.

This is exactly Wilson's construction with three truncated groups except we make sure that all blocks have size $> k$, so we don't need a $OA(k, m + 0)$ but only $OA(k, m + 1)$, $OA(k, m + 2)$,`OA(k,m+3)`.

This is construction 3.5 from [AC07].

INPUT:

- `k`, `n`, `m` – integers
- `r`, `s`, `t` – integers; sizes of the three truncated groups, such that $r \leq s$ and $(q - r - 1)(q - s) \geq (q - s - 1) * (q - r)$
- `explain_construction` – boolean; return a string describing the construction

The following designs must be available : $OA(k, n)$, $OA(k, r)$, $OA(k, s)$, $OA(k, t)$, $OA(k, m+1)$, $OA(k, m+2)$, $OA(k, m + 3)$.

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_3_6**(*k*, *n*, *m*, *i*, *explain_construction=False*)

Return a $OA(k, nm + i)$.

This is Wilson's construction with r columns of order 1, in which each block intersects at most two truncated columns. Such a design exists when n is a prime power and is returned by *OA_and_oval()*.

INPUT:

- `k`, `n`, `m`, `i` – integers; n must be a prime power. The following designs must be available: $OA(k + r, q)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, m + 2)$
- `explain_construction` – boolean; return a string describing the construction

This is construction 3.6 from [AC07].

sage.combinat.designs.orthogonal_arrays_build_recursive.**construction_q_x**(*k*, *q*, *x*, *check=True*, *explain_construction=False*)

Return an $OA(k,(q-1)*(q-x)+x+2)$ using the $q-x$ construction.

Let $v=(q-1)*(q-x)+x+2$. If there exists a projective plane of order q (e.g. when q is a prime power) and $0<x<q$ then there exists a $(v-1,\{q-x-1,q-x+1\})$-GDD of type $(q-1)^{q-x}(x+1)^1$ (see [Greig99] or Theorem 2.50, section IV.2.3 of [DesignHandbook]). By adding to the ground set one point contained in all groups of the GDD, one obtains a $(v,\{q-x-1,q-x+1,q,x+2\})$-PBD with exactly one set of size $x+2$.

Thus, assuming that we have the following:

- $OA(k,q-x-1)-(q-x-1).OA(k,1)$
- $OA(k,q-x+1)-(q-x+1).OA(k,1)$
- $OA(k,q)-q.OA(k,1)$
- $OA(k,x+2)$

Then we can build from the PBD an $OA(k,v)$.

Construction of the PBD (shared by Julian R. Abel):

> Start with a resolvable $(q^2,q,1)$-BIBD and put the points into a $q\times q$ array so that rows form a parallel class and columns form another.
>
> Now delete:
>
> - All $x(q-1)$ points from the first x columns and not in the first row
> - All $q-x$ points in the last $q-x$ columns AND the first row.
>
> Then add a point p_1 to the blocks that are rows. Add a second point p_2 to the $q-x$ blocks that are columns of size $q-1$, plus the first row of size $x+1$.

INPUT:

- `k`, `q`, `x` – integers such that $0<x<q$ and such that Sage can build:
  - A projective plane of order q
  - $OA(k,q-x-1)-(q-x-1).OA(k,1)$
  - $OA(k,q-x+1)-(q-x+1).OA(k,1)$
  - $OA(k,q)-q.OA(k,1)$

– $OA(k, x+2)$

- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `explain_construction` – boolean; return a string describing the construction

REFERENCES:

`sage.combinat.designs.orthogonal_arrays_build_recursive.`**`three_factor_product`**(*k*, *n1*, *n2*, *n3*, *check=False*, *explain_construction=False*)

Return an $OA(k+1, n_1 n_2 n_3)$.

The three factor product construction from [DukesLing14] does the following:

If $n_1 \leq n_2 \leq n_3$ are such that there exists an $OA(k, n_1)$, $OA(k+1, n_2)$ and $OA(k+1, n_3)$, then there exists a $OA(k+1, n_1 n_2 n_3)$.

It works with a modified product of orthogonal arrays ([Rees93], [Rees00]) which keeps track of parallel classes in the OA (the definition is given for transversal designs).

A subset of blocks in an $TD(k, n)$ is called a c-parallel class if every point is covered exactly c times. A 1-parallel class is a parallel class.

The modified product:

If there exists an $OA(k, n_1)$, and if there exists an $OA(k, n_2)$ whose blocks are partitionned into s n_1-parallel classes and $n_2 - sn_1$ parallel classes, then there exists an $OA(k, n_1 n_2)$ whose blocks can be partitionned into sn_1^2 parallel classes and $(n_1 n_2 - sn_1^2)/n_1 = n_2 - sn_1$ n_1-parallel classes.

Proof:

- The product of the blocks of a parallel class with an $OA(k, n_1)$ yields an n_1-parallel class of an $OA(k, n_1 n_2)$.
- The product of the blocks of a n_1-parallel class of $OA(k, n_2)$ with an $OA(k, n_1)$ can be done in such a way that it yields $n_1 n_2$ parallel classes of $OA(k, n_1 n_2)$. Those classes cover exactly the pairs that would have been covered with the usual product.

  This can be achieved by simple cyclic permutations. Let us build the product of the n_1-parallel class $\mathcal{P} \subseteq OA(k, n_2)$ with $OA(k, n_1)$: when computing the product of $P \in \mathcal{P}$ with $B^1 \in OA(k, n_1)$ the i-th coordinate should not be (B_i^1, P_i) but $(B_i^1 + r, P_i)$ (the sum is mod n_1) where r is the number of blocks of $\mathcal{P}$ we have already processed whose i-th coordinate is equal to P_i (note that $r < n_1$ as $\mathcal{P}$ is n_1-parallel).

With these tools, one can obtain the designs promised by the three factors construction applied to k, n_1, n_2, n_3 (thanks to Julian R. Abel's help):

1) Let s be the largest integer $\leq n_3/n_1$. Apply the product construction to $OA(k, n_1)$ and a resolvable $OA(k, n_3)$ whose blocks are partitionned into s n_1-parallel classes and $n_3 - sn_1$ parallel classes. It results in a $OA(k, n_1 n_3)$ partitionned into sn_1^2 parallel classes plus $(n_1 n_3 - sn_1^2)/n_1 = n_3 - sn_1$ n_1-parallel classes.
2) Add $n_3 - n_1$ parallel classes to every n_1-parallel class to turn them into n_3-parallel classes. Apply the product construction to this partitionned $OA(k, n_1 n_3)$ with a resolvable $OA(k, n_2)$.
3) As $OA(k, n_2)$ is resolvable, the n_2-parallel classes of $OA(k, n_1 n_2 n_3)$ are actually the union of n_2 parallel classes, thus the $OA(k, n_1 n_2 n_3)$ is resolvable and can be turned into an $OA(k+1, n_1 n_2 n_3)$

INPUT:

- `k`, `n1`, `n2`, `n3` – integers
- `check` – boolean; whether to check that everything is going smoothly while the design is being built. It is disabled by default, as the constructor of orthogonal arrays checks the final design anyway.
- `explain_construction` – boolean; return a string describing the construction

sage.combinat.designs.orthogonal_arrays_build_recursive.**thwart_lemma_3_5**(*k*, *n*, *m*, *a*, *b*, *c*, *d=0*, *complement=False*, *explain_construction=False*)

Return an $OA(k, nm + a + b + c + d)$.

(When `d=0`)

According to [Thwarts] when n is a prime power and $a + b + c \leq n + 1$, one can build an $OA(k + 3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $\leq k + 2$.

(in order to build a $OA(k, nm + a + b + c)$ the following designs must also exist: $OA(k, a)$, $OA(k, b)$, $OA(k, c)$, $OA(k, m + 0)$, $OA(k, m + 1)$, $OA(k, m + 2)$)

Considering the complement of each truncated column, it is also possible to build an $OA(k + 3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $> k$ whenever $(n-a)+(n-b)+(n-c) \leq n + 1$.

(in order to build a $OA(k, nm + a + b + c)$ the following designs must also exist: $OA(k, a)$, $OA(k, b)$, $OA(k, c)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$)

Here is the proof of Lemma 3.5 from [Thwarts] enriched with explanations from Julian R. Abel:

> For any prime power n one can build $k - 1$ MOLS by associating to every nonzero $x \in \mathbb{F}_n$ the latin square:
>
> $$M_x(i, j) = i + x * j \text{ where } i, j \in \mathbb{F}_n$$
>
> In particular $M_1(i, j) = i + j$, whose n columns and lines are indexed by the elements of $\mathbb{F}_n$. If we order the elements of $\mathbb{F}_n$ as $0, 1, ..., n - 1, x + 0, ..., x + n - 1, x^2 + 0, ...$ and reorder the columns and lines of M_1 accordingly, the top-left $a \times b$ squares contains at most $a + b - 1$ distinct symbols.

(When $d \neq 0$)

If there exists an $OA(k + 3, n)$ with three truncated columns of sizes a, b, c in such a way that all blocks have size $\leq k + 2$, by truncating arbitrarily another column to size d one obtains an OA with 4 truncated columns whose blocks miss at least one value. Thus, following the proof again one can build an $OA(k + 4)$ with four truncated columns of sizes a, b, c, d with blocks of size $\leq k + 3$.

(in order to build a $OA(k, nm + a + b + c + d)$ the following designs must also exist: $OA(k, a)$, $OA(k, b)$, $OA(k, c)$, $OA(k, d)$, $OA(k, m + 0)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$)

As before, this also shows that one can build an $OA(k + 4, n)$ with four truncated columns of sizes a, b, c, d in such a way that all blocks have size $> k$ whenever $(n - a) + (n - b) + (n - c) \leq n + 1$

(in order to build a $OA(k, nm+a+b+c+d)$ the following designs must also exist: $OA(k, n-a)$, $OA(k, n-b)$, $OA(k, n - c)$, $OA(k, d)$, $OA(k, m + 1)$, $OA(k, m + 2)$, $OA(k, m + 3)$, $OA(k, m + 4)$)

INPUT:

- `k`, `n`, `m`, `a`, `b`, `c`, `d` – integers which must satisfy the constraints above. In particular, $a + b + c \leq n + 1$ must hold By default, $d = 0$.
- `complement` – boolean; whether to complement the sets, i.e. follow the $n-a, n-b, n-c$ variant described above
- `explain_construction` – boolean; return a string describing the construction

Orthogonal arrays (find recursive constructions)

This module implements several functions to find recursive constructions of *Orthogonal Arrays*.

The main function of this module, i.e. *find_recursive_construction()*, queries all implemented recursive constructions of designs implemented in *orthogonal_arrays_build_recursive* in order to obtain an $OA(k, n)$.

find_recursive_construction() is called by the *orthogonal_array()* function.

find_recursive_construction()	Find a recursive construction of an $OA(k,n)$ (calls all others `find_*` functions)
find_product_decomposition()	Find $n_1n_2 = n$ to obtain an $OA(k,n)$ by the product construction
find_wilson_decomposition_with_one_truncated_group()	Find $rm + u = n$ to obtain an $OA(k,n)$ by Wilson's construction with one truncated column.
find_wilson_decomposition_with_two_truncated_groups()	Find $rm + r_1 + r_2 = n$ to obtain an $OA(k,n)$ by Wilson's construction with two truncated columns.
find_construction_3_3()	Find a decomposition for construction 3.3 from [AC07].
find_construction_3_4()	Find a decomposition for construction 3.4 from [AC07].
find_construction_3_5()	Find a decomposition for construction 3.5 from [AC07].
find_construction_3_6()	Find a decomposition for construction 3.6 from [AC07].
find_q_x()	Find integers q, x such that the $q - x$ construction yields an $OA(k,n)$.
find_thwart_lemma_3_5()	Find the values on which Lemma 3.5 from [Thwarts] applies.
find_thwart_lemma_4_1()	Find a decomposition for Lemma 4.1 from [Thwarts].
find_three_factor_product()	Find $n_1n_2n_3 = n$ to obtain an $OA(k,n)$ by the three-factor product from [DukesLing14]
find_brouwer_separable_design()	Find $t(q^2+q+1)+x = n$ to obtain an $OA(k,n)$ by Brouwer's separable design construction.
find_brouwer_van_rees_with_cated_column()	Find $rm + x_1 + ... + x_c = n$ such that the Brouwer-van Rees constructions yields a $OA(k,n)$.

REFERENCES:

Functions

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_brouwer_separable_design**(k, n)

Find $t(q^2+q+1)+x = n$ to obtain an $OA(k,n)$ by Brouwer's separable design construction.

INPUT:

- `k`, `n` – integers

The assumptions made on the parameters t, q, x are explained in the documentation of *brouwer_separable_design()*.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪brouwer_separable_design
sage: find_brouwer_separable_design(5,13)[1]
(5, 1, 3, 0)
sage: find_brouwer_separable_design(5,14)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪brouwer_separable_design
>>> find_brouwer_separable_design(Integer(5),Integer(13))[Integer(1)]
(5, 1, 3, 0)
```

(continues on next page)

(continued from previous page)

```
>>> find_brouwer_separable_design(Integer(5),Integer(14))
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_brouwer_van_rees_with_one_truncated_colu**

Find $rm + x_1 + ... + x_c = n$ such that the Brouwer-van Rees constructions yields a $OA(k, n)$.

Let $n = rm + \sum_{1 \leq i \leq c}$ such that $c \leq r$. The generalization of Wilson's construction found by Brouwer and van Rees (with one truncated column) ensures that an $OA(k, n)$ exists if the following designs exist: $OA(k + 1, r)$, $OA(k, m)$, $OA(k, \sum_{1 \leq i \leq c} u_i)$, $OA(k, m + x_1) - OA(k, x_1)$, ..., $OA(k, m + x_c) - OA(k, x_c)$.

For more information, see the documentation of *wilson_construction()*.

INPUT:

- k, n – integers

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪brouwer_van_rees_with_one_truncated_column
sage: find_brouwer_van_rees_with_one_truncated_column(5,53)[1]
(None, 5, 7, 7, [[(2, 1), (2, 1)]])
sage: find_brouwer_van_rees_with_one_truncated_column(6,96)[1]
(None, 6, 7, 13, [[(3, 1), (1, 1), (1, 1)]])
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪brouwer_van_rees_with_one_truncated_column
>>> find_brouwer_van_rees_with_one_truncated_column(Integer(5),
↪Integer(53))[Integer(1)]
(None, 5, 7, 7, [[(2, 1), (2, 1)]])
>>> find_brouwer_van_rees_with_one_truncated_column(Integer(6),
↪Integer(96))[Integer(1)]
(None, 6, 7, 13, [[(3, 1), (1, 1), (1, 1)]])
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_construction_3_3**(k, n)

Find a decomposition for construction 3.3 from [AC07].

INPUT:

- k, n – integers

See also

construction_3_3()

OUTPUT:

A pair f, args such that f(*args) returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_3
```

(continues on next page)

(continued from previous page)

```
sage: find_construction_3_3(11,177)[1]
(11, 11, 16, 1)
sage: find_construction_3_3(12,11)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_3
>>> find_construction_3_3(Integer(11),Integer(177))[Integer(1)]
(11, 11, 16, 1)
>>> find_construction_3_3(Integer(12),Integer(11))
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_construction_3_4**(k, n)

Find a decomposition for construction 3.4 from [AC07].

INPUT:

- k, n – integers

See also

construction_3_4()

OUTPUT:

A pair f,args such that f(*args) returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_4
sage: find_construction_3_4(8,196)[1]
(8, 25, 7, 12, 9)
sage: find_construction_3_4(9,24)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_4
>>> find_construction_3_4(Integer(8),Integer(196))[Integer(1)]
(8, 25, 7, 12, 9)
>>> find_construction_3_4(Integer(9),Integer(24))
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_construction_3_5**(k, n)

Find a decomposition for construction 3.5 from [AC07].

INPUT:

- k, n – integers

See also

construction_3_5()

OUTPUT:

A pair `f,args` such that `f(*args)` returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_5
sage: find_construction_3_5(8,111)[1]
(8, 13, 6, 9, 11, 13)
sage: find_construction_3_5(9,24)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_5
>>> find_construction_3_5(Integer(8),Integer(111))[Integer(1)]
(8, 13, 6, 9, 11, 13)
>>> find_construction_3_5(Integer(9),Integer(24))
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_construction_3_6**(k, n)

Find a decomposition for construction 3.6 from [AC07].

INPUT:

- `k`, `n` – integers

See also

construction_3_6()

OUTPUT:

A pair `f,args` such that `f(*args)` returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_6
sage: find_construction_3_6(8,95)[1]
(8, 13, 7, 4)
sage: find_construction_3_6(8,98)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪construction_3_6
>>> find_construction_3_6(Integer(8),Integer(95))[Integer(1)]
(8, 13, 7, 4)
>>> find_construction_3_6(Integer(8),Integer(98))
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_product_decomposition**(k, n)

Find $n_1 n_2 = n$ to obtain an $OA(k, n)$ by the product construction.

If Sage can build a $OA(k, n_1)$ and a $OA(k, n_2)$ such that $n = n_1 \times n_2$ then a $OA(k, n)$ can be built by a product construction (which correspond to Wilson's construction with no truncated column). This function look for a pair of integers (n_1, n_2) with $n1 \leq n_2$, $n_1 \times n_2 = n$ and such that both an $OA(k, n_1)$ and an $OA(k, n_2)$ are available.

INPUT:

- `k`, `n` – integers

OUTPUT:

A pair `f,args` such that `f(*args)` is an $OA(k,n)$ or `False` if no product decomposition was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪product_decomposition
sage: f,args = find_product_decomposition(6, 84)
sage: args
(None, 6, 7, 12, (), False)
sage: _ = f(*args)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪product_decomposition
>>> f,args = find_product_decomposition(Integer(6), Integer(84))
>>> args
(None, 6, 7, 12, (), False)
>>> _ = f(*args)
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_q_x**(k, n)

Find integers q, x such that the $q-x$ construction yields an $OA(k,n)$.

See the documentation of *construction_q_x()* to find out what hypotheses the integers q, x must satisfy.

Warning

For efficiency reasons, this function checks that Sage can build an $OA(k+1, q-x-1)$ and an $OA(k+1, q-x+1)$, which is stronger than checking that Sage can build a $OA(k, q-x-1)-(q-x-1).OA(k,1)$ and a $OA(k, q-x+1)-(q-x+1).OA(k,1)$. The latter would trigger a lot of independent set computations in *sage.combinat.designs.orthogonal_arrays.incomplete_orthogonal_array()*.

INPUT:

- `k`, `n` – integers

See also

construction_q_x()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_q_x
sage: find_q_x(10,9)
False
sage: find_q_x(9,158)[1]
(9, 16, 6)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_q_x
>>> find_q_x(Integer(10),Integer(9))
False
```

(continues on next page)

(continued from previous page)

```
>>> find_q_x(Integer(9),Integer(158))[Integer(1)]
(9, 16, 6)
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_recursive_construction**(n)

Find a recursive construction of an $OA(k,n)$ (calls all others `find_*` functions).

This determines whether an $OA(k,n)$ can be built through the following constructions:

- *wilson_construction()*
- *construction_3_3()*
- *construction_3_4()*
- *construction_3_5()*
- *construction_3_6()*
- *construction_q_x()*
- *thwart_lemma_3_5()*
- *thwart_lemma_4_1()*
- *three_factor_product()*
- *brouwer_separable_design()*

INPUT:

- `k`, `n` – integers

OUTPUT:

Return a pair `f,args` such that `f(*args)` returns the requested OA if possible, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪recursive_construction
sage: from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
sage: count = 0
sage: for n in range(10,150):
....:     k = designs.orthogonal_arrays.largest_available_k(n)
....:     if find_recursive_construction(k,n):
....:         count = count + 1
....:         f,args = find_recursive_construction(k,n)
....:         OA = f(*args)
....:         assert is_orthogonal_array(OA,k,n,2,verbose=True)
sage: count
56
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪recursive_construction
>>> from sage.combinat.designs.orthogonal_arrays import is_orthogonal_array
>>> count = Integer(0)
>>> for n in range(Integer(10),Integer(150)):
...     k = designs.orthogonal_arrays.largest_available_k(n)
...     if find_recursive_construction(k,n):
```

(continues on next page)

(continued from previous page)

```
...           count = count + Integer(1)
...           f,args = find_recursive_construction(k,n)
...           OA = f(*args)
...           assert is_orthogonal_array(OA,k,n,Integer(2),verbose=True)
>>> count
56
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_three_factor_product**(k, n)

Find $n_1n_2n_3 = n$ to obtain an $OA(k, n)$ by the three-factor product from [DukesLing14].

INPUT:

- k, n – integers

See also

three_factor_product()

OUTPUT:

A pair f,args such that f(*args) returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪three_factor_product
sage: find_three_factor_product(10,648)[1]
(9, 8, 9, 9)
sage: find_three_factor_product(10,50)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_three_
↪factor_product
>>> find_three_factor_product(Integer(10),Integer(648))[Integer(1)]
(9, 8, 9, 9)
>>> find_three_factor_product(Integer(10),Integer(50))
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_thwart_lemma_3_5**(k, N)

Find the values on which Lemma 3.5 from [Thwarts] applies.

OUTPUT:

A pair (f,args) such that f(*args) returns an $OA(k, n)$ or False if the construction is not available.

See also

thwart_lemma_3_5()

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪thwart_lemma_3_5
sage: from sage.combinat.designs.designs_pyx import is_orthogonal_array

sage: f,args = find_thwart_lemma_3_5(7,66)
sage: args
(7, 9, 7, 1, 1, 1, 0, False)
sage: OA = f(*args)
sage: is_orthogonal_array(OA,7,66,2)
True

sage: f,args = find_thwart_lemma_3_5(6,100)
sage: args
(6, 8, 10, 8, 7, 5, 0, True)
sage: OA = f(*args)
sage: is_orthogonal_array(OA,6,100,2)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪thwart_lemma_3_5
>>> from sage.combinat.designs.designs_pyx import is_orthogonal_array

>>> f,args = find_thwart_lemma_3_5(Integer(7),Integer(66))
>>> args
(7, 9, 7, 1, 1, 1, 0, False)
>>> OA = f(*args)
>>> is_orthogonal_array(OA,Integer(7),Integer(66),Integer(2))
True

>>> f,args = find_thwart_lemma_3_5(Integer(6),Integer(100))
>>> args
(6, 8, 10, 8, 7, 5, 0, True)
>>> OA = f(*args)
>>> is_orthogonal_array(OA,Integer(6),Integer(100),Integer(2))
True
```

Some values from [Thwarts]:

```
sage: kn = ((10,1046), (10,1048), (10,1059), (11,1524),
....:       (11,2164), (12,3362), (12,3992),  (12,3994))
sage: for k,n in kn:

...     assert designs.orthogonal_array(k,n,existence=True) is True
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_thwart_lemma_4_1**(k, n)

Find a decomposition for Lemma 4.1 from [Thwarts].

INPUT:

- k, n – integers

See also

thwart_lemma_4_1()

OUTPUT:

A pair `f,args` such that `f(*args)` returns the requested OA.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪thwart_lemma_4_1
sage: find_thwart_lemma_4_1(10,408)[1]
(10, 13, 28)
sage: find_thwart_lemma_4_1(10,50)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪thwart_lemma_4_1
>>> find_thwart_lemma_4_1(Integer(10),Integer(408))[Integer(1)]
(10, 13, 28)
```

(continues on next page)

(continued from previous page)

```
>>> find_thwart_lemma_4_1(Integer(10),Integer(50))
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_wilson_decomposition_with_one_truncated_**

Find $rm + u = n$ to obtain an $OA(k, n)$ by Wilson's construction with one truncated column.

This function looks for possible integers m, t, u satisfying that $mt + u = n$ and such that Sage knows how to build a $OA(k, m)$, $OA(k, m + 1)$, $OA(k + 1, t)$ and a $OA(k, u)$.

INPUT:

- `k`, `n` – integers

OUTPUT:

A pair `f,args` such that `f(*args)` is an $OA(k, n)$ or `False` if no decomposition with one truncated block was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪wilson_decomposition_with_one_truncated_group
sage: f,args = find_wilson_decomposition_with_one_truncated_group(4,38)
sage: args
(None, 4, 5, 7, (3,), False)
sage: _ = f(*args)

sage: find_wilson_decomposition_with_one_truncated_group(4,20)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪wilson_decomposition_with_one_truncated_group
>>> f,args = find_wilson_decomposition_with_one_truncated_group(Integer(4),
↪Integer(38))
>>> args
(None, 4, 5, 7, (3,), False)
>>> _ = f(*args)

>>> find_wilson_decomposition_with_one_truncated_group(Integer(4),Integer(20))
False
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**find_wilson_decomposition_with_two_truncated_**

Find $rm + r_1 + r_2 = n$ to obtain an $OA(k, n)$ by Wilson's construction with two truncated columns.

Look for integers r, m, r_1, r_2 satisfying $n = rm + r_1 + r_2$ and $1 \leq r_1, r_2 < r$ and such that the following designs exist : $OA(k + 2, r)$, $OA(k, r1)$, $OA(k, r2)$, $OA(k, m)$, $OA(k, m + 1)$, $OA(k, m + 2)$.

INPUT:

- `k`, `n` – integers

OUTPUT:

A pair `f,args` such that `f(*args)` is an $OA(k, n)$ or `False` if no decomposition with two truncated blocks was found.

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪wilson_decomposition_with_two_truncated_groups
sage: f,args = find_wilson_decomposition_with_two_truncated_groups(5,58)
sage: args
(None, 5, 7, 7, (4, 5), False)
sage: _ = f(*args)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.orthogonal_arrays_find_recursive import find_
↪wilson_decomposition_with_two_truncated_groups
>>> f,args = find_wilson_decomposition_with_two_truncated_groups(Integer(5),
↪Integer(58))
>>> args
(None, 5, 7, 7, (4, 5), False)
>>> _ = f(*args)
```

sage.combinat.designs.orthogonal_arrays_find_recursive.**int_as_sum**(*value*, *S*, *k_max*)

Return a tuple $(s_1, s_2, \ldots, s_k)$ of less then k_max elements of S such that $value = s_1 + s_2 + \ldots + s_k$. If there is no such tuples then the function returns `None`.

INPUT:

- `value` – integer
- `S` – list of integers
- `k_max` – integer

EXAMPLES:

```
sage: from sage.combinat.designs.orthogonal_arrays_find_recursive import int_as_
↪sum
sage: D = int_as_sum(21,[5,12],100)
sage: for k in range(20,40):
....:     print("{} {}".format(k, int_as_sum(k,[5,12],100)))
20 (5, 5, 5, 5)
21 None
22 (12, 5, 5)
23 None
24 (12, 12)
25 (5, 5, 5, 5, 5)
26 None
27 (12, 5, 5, 5)
28 None
29 (12, 12, 5)
30 (5, 5, 5, 5, 5, 5)
31 None
32 (12, 5, 5, 5, 5)
33 None
34 (12, 12, 5, 5)
35 (5, 5, 5, 5, 5, 5, 5)
36 (12, 12, 12)
37 (12, 5, 5, 5, 5, 5)

Resolvable balanced incomplete block design (RBIBD)

This module contains everything related to resolvable Balanced Incomplete Block Designs. The constructions implemented here can be obtained through the `designs.<tab>` object:

```
designs.resolvable_balanced_incomplete_block_design(15,3)
```

For Balanced Incomplete Block Design (BIBD) see the module *bibd*. A BIBD is said to be *resolvable* if its blocks can be partitionned into parallel classes, i.e. partitions of its ground set.

The main function of this module is *resolvable_balanced_incomplete_block_design()*, which calls all others.

resolvable_balanced_incomplete_block_design()	Return a resolvable BIBD of parameters v, k.
kirkman_triple_system()	Return a Kirkman Triple System on v points.
v_4_1_rbibd()	Return a $(v, 4, 1)$-RBIBD
PBD_4_7()	Return a $(v, \{4, 7\})$-PBD
PBD_4_7_from_Y()	Return a $(3v + 1, \{4, 7\})$-PBD from a $(v, \{4, 5, 7\}, \mathbf{N} - \{3, 6, 10\})$-GDD.

References:

Functions

sage.combinat.designs.resolvable_bibd.**PBD_4_7**(*v*, *check=True*, *existence=False*)

Return a $(v, \{4, 7\})$-PBD.

For all v such that $n \equiv 1 \pmod 3$ and $n \neq 10, 19, 31$ there exists a $(v, \{4, 7\})$-PBD. This is proved in Proposition IX.4.5 from [BJL99], which this method implements.

This construction of PBD is used by the construction of Kirkman Triple Systems.

EXAMPLES:

```
sage: from sage.combinat.designs.resolvable_bibd import PBD_4_7
sage: PBD_4_7(22)
Pairwise Balanced Design on 22 points with sets of sizes in [4, 7]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.resolvable_bibd import PBD_4_7
>>> PBD_4_7(Integer(22))
Pairwise Balanced Design on 22 points with sets of sizes in [4, 7]
```

sage.combinat.designs.resolvable_bibd.**PBD_4_7_from_Y**(*gdd*, *check=True*)

Return a $(3v + 1, \{4, 7\})$-PBD from a $(v, \{4, 5, 7\}, \mathbf{N} - \{3, 6, 10\})$-GDD.

This implements Lemma IX.3.11 from [BJL99] (p.625). All points of the GDD are tripled, and a $+\infty$ point is added to the design.

- A group of size $s \in Y = \mathbf{N} - \{3, 6, 10\}$ becomes a set of size $3s$. Adding ∞ to it gives it size $3s + 1$, and this set is then replaced by a $(3s + 1, \{4, 7\})$-PBD.
- A block of size $s \in \{4, 5, 7\}$ becomes a $(3s, \{4, 7\}, \{3\})$-GDD.

This lemma is part of the existence proof of $(v, \{4, 7\})$-PBD as explained in IX.4.5 from [BJL99]).

INPUT:

- `gdd` – a $(v, \{4, 5, 7\}, Y)$-GDD where $Y = \mathbf{N} - \{3, 6, 10\}$
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.

EXAMPLES:

```
sage: from sage.combinat.designs.resolvable_bibd import PBD_4_7_from_Y
sage: PBD_4_7_from_Y(designs.transversal_design(7,8))                    #␣
↪needs sage.schemes
Pairwise Balanced Design on 169 points with sets of sizes in [4, 7]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.resolvable_bibd import PBD_4_7_from_Y
>>> PBD_4_7_from_Y(designs.transversal_design(Integer(7),Integer(8)))      ␣
↪              # needs sage.schemes
Pairwise Balanced Design on 169 points with sets of sizes in [4, 7]
```

sage.combinat.designs.resolvable_bibd.**kirkman_triple_system**(*v*, *existence=False*)

Return a Kirkman Triple System on v points.

A Kirkman Triple System $KTS(v)$ is a resolvable Steiner Triple System. It exists if and only if $v \equiv 3 \pmod 6$.

INPUT:

- `n` – integer
- `existence` – boolean (default: `False`); whether to build the $KTS(n)$ or only answer whether it exists

IncidenceStructure.is_resolvable()

EXAMPLES:

A solution to Kirkmman's original problem:

```
sage: kts = designs.kirkman_triple_system(15)
sage: classes = kts.is_resolvable(1)[1]
sage: names = '0123456789abcde'
sage: def to_name(r_s_t):
....:     r, s, t = r_s_t
....:     return ' ' + names[r] + names[s] + names[t] + ' '
sage: rows = ['   '.join(('Day {}'.format(i) for i in range(1,8)))]
sage: rows.extend('   '.join(map(to_name,row)) for row in zip(*classes))
sage: print('\n'.join(rows))
Day 1   Day 2   Day 3   Day 4   Day 5   Day 6   Day 7
 07e     18e     29e     3ae     4be     5ce     6de
 139     24a     35b     46c     05d     167     028
 26b     03c     14d     257     368     049     15a
 458     569     06a     01b     12c     23d     347
 acd     7bd     78c     89d     79a     8ab     9bc
```

```
>>> from sage.all import *
>>> kts = designs.kirkman_triple_system(Integer(15))
>>> classes = kts.is_resolvable(Integer(1))[Integer(1)]
>>> names = '0123456789abcde'
>>> def to_name(r_s_t):
...     r, s, t = r_s_t
...     return ' ' + names[r] + names[s] + names[t] + ' '
>>> rows = ['   '.join(('Day {}'.format(i) for i in range(Integer(1),
↪Integer(8))))]
>>> rows.extend('   '.join(map(to_name,row)) for row in zip(*classes))
>>> print('\n'.join(rows))
Day 1   Day 2   Day 3   Day 4   Day 5   Day 6   Day 7
 07e     18e     29e     3ae     4be     5ce     6de
 139     24a     35b     46c     05d     167     028
 26b     03c     14d     257     368     049     15a
 458     569     06a     01b     12c     23d     347
 acd     7bd     78c     89d     79a     8ab     9bc
```

`sage.combinat.designs.resolvable_bibd.`**`resolvable_balanced_incomplete_block_design`**`(`*v*, *k*, *existence=False*`)`

Return a resolvable BIBD of parameters v, k.

A BIBD is said to be *resolvable* if its blocks can be partitionned into parallel classes, i.e. partitions of the ground set.

INPUT:

- `v`, `k` – integers
- `existence` – boolean; instead of building the design, return:
  - `True` – meaning that Sage knows how to build the design
  - `Unknown` – meaning that Sage does not know how to build the design, but that the design may exist (see `sage.misc.unknown`)
  - `False` – meaning that the design does not exist

See also

- *IncidenceStructure.is_resolvable()*
- *balanced_incomplete_block_design()*

EXAMPLES:

```
sage: KTS15 = designs.resolvable_balanced_incomplete_block_design(15,3)
sage: KTS15
(15,3,1)-Balanced Incomplete Block Design
sage: KTS15.is_resolvable()
True
```

```
>>> from sage.all import *
>>> KTS15 = designs.resolvable_balanced_incomplete_block_design(Integer(15),
↪Integer(3))
>>> KTS15
(15,3,1)-Balanced Incomplete Block Design
>>> KTS15.is_resolvable()
True
```

`sage.combinat.designs.resolvable_bibd.`**`v_4_1_rbibd`**(*v*, *existence=False*)

Return a $(v, 4, 1)$-RBIBD.

INPUT:

- `n` – integer
- `existence` – boolean (default: `False`); whether to build the design or only answer whether it exists

See also

- *IncidenceStructure.is_resolvable()*
- *resolvable_balanced_incomplete_block_design()*

Note

A resolvable $(v, 4, 1)$-BIBD exists whenever $1 \equiv 4 \pmod{()12}$. This function, however, only implements a construction of $(v, 4, 1)$-BIBD such that $v = 3q + 1 \equiv 1 \pmod 3$ where q is a prime power (see VII.7.5.a from [BJL99]).

EXAMPLES:

```
sage: rBIBD = designs.resolvable_balanced_incomplete_block_design(28,4)
sage: rBIBD.is_resolvable()
True
sage: rBIBD.is_t_design(return_parameters=True)
(True, (2, 28, 4, 1))
```

```
>>> from sage.all import *
>>> rBIBD = designs.resolvable_balanced_incomplete_block_design(Integer(28),
↪Integer(4))
>>> rBIBD.is_resolvable()
True
>>> rBIBD.is_t_design(return_parameters=True)
(True, (2, 28, 4, 1))
```

Steiner quadruple systems

A Steiner Quadruple System on n points is a family $SQS_n \subset \binom{[n]}{4}$ of 4-sets, such that any set $S \subset [n]$ of size three is a subset of exactly one member of SQS_n.

This module implements Haim Hanani's constructive proof that a Steiner Quadruple System exists if and only if $n \equiv 2, 4 \pmod 6$. Hanani's proof consists in 6 different constructions that build a large Steiner Quadruple System from a smaller one, and though it does not give a very clear understanding of why it works (to say the least)... it does !

The constructions have been implemented while reading two papers simultaneously, for one of them sometimes provides the informations that the other one does not. The first one is Haim Hanani's original paper [Han1960], and the other one is a paper from Horan and Hurlbert which goes through all constructions [HH2012].

It can be used through the `designs` object:

```
sage: designs.steiner_quadruple_system(8)
Incidence structure with 8 points and 14 blocks
```

```
>>> from sage.all import *
>>> designs.steiner_quadruple_system(Integer(8))
Incidence structure with 8 points and 14 blocks
```

AUTHORS:

- Nathann Cohen (May 2013, while listening to "*Le Blues Du Pauvre Delahaye*")

Index

This module's main function is the following:

steiner_quadruple_system()	Return a Steiner Quadruple System on n points

This function redistributes its work among 6 constructions:

Construction 1	*two_n()*	Return a Steiner Quadruple System on $2n$ points
Construction 2	*three_n_minus_two()*	Return a Steiner Quadruple System on $3n-2$ points
Construction 3	*three_n_minus_eight()*	Return a Steiner Quadruple System on $3n-8$ points
Construction 4	*three_n_minus_four()*	Return a Steiner Quadruple System on $3n-4$ points
Construction 5	*four_n_minus_six()*	Return a Steiner Quadruple System on $4n-6$ points
Construction 6	*twelve_n_minus_ten()*	Return a Steiner Quadruple System on $12n-10$ points

It also defines two specific Steiner Quadruple Systems that the constructions require, i.e. SQS_{14} and SQS_{38} as well as the systems of pairs $P_\alpha(m)$ and $\overline{P}_\alpha(m)$ (see [Han1960]).

Functions

sage.combinat.designs.steiner_quadruple_systems.**P**(*alpha*, *m*)

Return the collection of pairs $P_\alpha(m)$.

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import P
sage: P(3,4)
[(0, 5), (2, 7), (4, 1), (6, 3)]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import P
>>> P(Integer(3),Integer(4))
[(0, 5), (2, 7), (4, 1), (6, 3)]
```

sage.combinat.designs.steiner_quadruple_systems.**barP**(*eps*, *m*)

Return the collection of pairs $\overline{P}_\alpha(m)$.

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP
sage: barP(3,4)
[(0, 4), (3, 5), (1, 2)]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import barP
>>> barP(Integer(3),Integer(4))
[(0, 4), (3, 5), (1, 2)]
```

sage.combinat.designs.steiner_quadruple_systems.**barP_system**()

Return the 1-factorization of K_{2m} $\overline{P}(m)$.

For more information on this system, see [Han1960].

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import barP_system
sage: barP_system(3)
[[(4, 3), (2, 5)],
[(0, 5), (4, 1)],
[(0, 2), (1, 3)],
[(1, 5), (4, 2), (0, 3)],
[(0, 4), (3, 5), (1, 2)],
[(0, 1), (2, 3), (4, 5)]]
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import barP_system
>>> barP_system(Integer(3))
[[(4, 3), (2, 5)],
[(0, 5), (4, 1)],
[(0, 2), (1, 3)],
[(1, 5), (4, 2), (0, 3)],
[(0, 4), (3, 5), (1, 2)],
[(0, 1), (2, 3), (4, 5)]]
```

sage.combinat.designs.steiner_quadruple_systems.**four_n_minus_six**(B)

Return a Steiner Quadruple System on $4n-6$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import four_n_minus_six
sage: for n in range(4, 20):
....:     if (n%6) in [2,4]:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not four_n_minus_six(sqs).is_t_design(3,4*n-6,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import four_n_minus_six
>>> for n in range(Integer(4), Integer(20)):
...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
...         sqs = designs.steiner_quadruple_system(n)
...         if not four_n_minus_six(sqs).is_t_design(Integer(3),Integer(4)*n-
↪Integer(6),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**relabel_system**(B)

Relabel the set so that $\{n-4, n-3, n-2, n-1\}$ is in B.

INPUT:

- B – list of 4-uples on $0, ..., n-1$

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import relabel_system
sage: SQS8 = designs.steiner_quadruple_system(8)
```

(continues on next page)

(continued from previous page)

```
sage: relabel_system(SQS8)
Incidence structure with 8 points and 14 blocks
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import relabel_system
>>> SQS8 = designs.steiner_quadruple_system(Integer(8))
>>> relabel_system(SQS8)
Incidence structure with 8 points and 14 blocks
```

sage.combinat.designs.steiner_quadruple_systems.**steiner_quadruple_system**(*check=False*)

Return a Steiner Quadruple System on n points.

INPUT:

- `n` – integer such that $n \equiv 2, 4 \pmod 6$
- `check` – boolean (default: `False`); whether to check that the system is a Steiner Quadruple System before returning it

EXAMPLES:

```
sage: sqs4 = designs.steiner_quadruple_system(4)
sage: sqs4
Incidence structure with 4 points and 1 blocks
sage: sqs4.is_t_design(3,4,4,1)
True

sage: sqs8 = designs.steiner_quadruple_system(8)
sage: sqs8
Incidence structure with 8 points and 14 blocks
sage: sqs8.is_t_design(3,8,4,1)
True
```

```
>>> from sage.all import *
>>> sqs4 = designs.steiner_quadruple_system(Integer(4))
>>> sqs4
Incidence structure with 4 points and 1 blocks
>>> sqs4.is_t_design(Integer(3),Integer(4),Integer(4),Integer(1))
True

>>> sqs8 = designs.steiner_quadruple_system(Integer(8))
>>> sqs8
Incidence structure with 8 points and 14 blocks
>>> sqs8.is_t_design(Integer(3),Integer(8),Integer(4),Integer(1))
True
```

sage.combinat.designs.steiner_quadruple_systems.**three_n_minus_eight**(B)

Return a Steiner Quadruple System on $3n - 8$ points.

INPUT:

- `B` – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪eight
sage: for n in range(4, 30):
....:     if (n%12) == 2:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not three_n_minus_eight(sqs).is_t_design(3,3*n-8,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪eight
>>> for n in range(Integer(4), Integer(30)):
...     if (n%Integer(12)) == Integer(2):
...         sqs = designs.steiner_quadruple_system(n)
...         if not three_n_minus_eight(sqs).is_t_design(Integer(3),Integer(3)*n-
↪Integer(8),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**three_n_minus_four**(B)

Return a Steiner Quadruple System on $3n-4$ points.

INPUT:

- B – a Steiner Quadruple System on n points where $n \equiv 10 \pmod{12}$

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪four
sage: for n in range(4, 30):
....:     if n%12 == 10:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not three_n_minus_four(sqs).is_t_design(3,3*n-4,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_four
>>> for n in range(Integer(4), Integer(30)):
...     if n%Integer(12) == Integer(10):
...         sqs = designs.steiner_quadruple_system(n)
...         if not three_n_minus_four(sqs).is_t_design(Integer(3),Integer(3)*n-
↪Integer(4),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**three_n_minus_two**(B)

Return a Steiner Quadruple System on $3n-2$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_
↪two
```

(continues on next page)

(continued from previous page)

```
sage: for n in range(4, 30):
....:     if (n%6) in [2,4]:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not three_n_minus_two(sqs).is_t_design(3,3*n-2,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import three_n_minus_two
>>> for n in range(Integer(4), Integer(30)):
...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
...         sqs = designs.steiner_quadruple_system(n)
...         if not three_n_minus_two(sqs).is_t_design(Integer(3),Integer(3)*n-
↪Integer(2),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**twelve_n_minus_ten**(B)

Return a Steiner Quadruple System on $12n - 6$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import twelve_n_minus_
↪ten
sage: for n in range(4, 15):
....:     if (n%6) in [2,4]:
....:         sqs = designs.steiner_quadruple_system(n)
....:         if not twelve_n_minus_ten(sqs).is_t_design(3,12*n-10,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import twelve_n_minus_ten
>>> for n in range(Integer(4), Integer(15)):
...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
...         sqs = designs.steiner_quadruple_system(n)
...         if not twelve_n_minus_ten(sqs).is_t_design(Integer(3),Integer(12)*n-
↪Integer(10),Integer(4),Integer(1)):
...             print("Something is wrong !")
```

sage.combinat.designs.steiner_quadruple_systems.**two_n**(B)

Return a Steiner Quadruple System on $2n$ points.

INPUT:

- B – a Steiner Quadruple System on n points

EXAMPLES:

```
sage: from sage.combinat.designs.steiner_quadruple_systems import two_n
sage: for n in range(4, 30):
....:     if (n%6) in [2,4]:
....:         sqs = designs.steiner_quadruple_system(n)
```

(continues on next page)

(continued from previous page)

```
....:         if not two_n(sqs).is_t_design(3,2*n,4,1):
....:             print("Something is wrong !")
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.steiner_quadruple_systems import two_n
>>> for n in range(Integer(4), Integer(30)):
...     if (n%Integer(6)) in [Integer(2),Integer(4)]:
...         sqs = designs.steiner_quadruple_system(n)
...         if not two_n(sqs).is_t_design(Integer(3),Integer(2)*n,Integer(4),
↪Integer(1)):
...             print("Something is wrong !")
```

Two-graphs

A two-graph on n points is a family $T \subset \binom{[n]}{3}$ of 3-sets, such that any 4-set $S \subset [n]$ of size four contains an even number of elements of T. Any graph $([n], E)$ gives rise to a two-graph $T(E) = \{t \in \binom{[n]}{3} : \left|\binom{t}{2} \cap E\right| \ odd\}$, and any two graphs with the same two-graph can be obtained one from the other by `Seidel switching`. This defines an equivalence relation on the graphs on $[n]$, called Seidel switching equivalence. Conversely, given a two-graph T, one can construct a graph Γ in the corresponding Seidel switching class with an isolated vertex w. The graph $\Gamma \setminus w$ is called the *descendant* of T w.r.t. v.

T is called regular if each two-subset of $[n]$ is contained in the same number alpha of triples of T.

This module implements a direct construction of a two-graph from a list of triples, construction of descendant graphs, regularity checking, and other things such as constructing the complement two-graph, cf. [BH2012].

AUTHORS:

- Dima Pasechnik (Aug 2015)

Index

This module's methods are the following:

is_regular_twograph()	Test if `self` is a regular two-graph, i.e. a 2-design
complement()	Return the complement of `self`
descendant()	Return the descendant graph at w

This module's functions are the following:

taylor_twograph()	Construct Taylor's two-graph for $U_3(q)$
is_twograph()	Check that the incidence system is a two-graph
twograph_descendant()	Return the descendant graph w.r.t. a given vertex of the two-graph of a given graph

Methods

class sage.combinat.designs.twographs.**TwoGraph**(*points=None*, *blocks=None*, *incidence_matrix=None*, *name=None*, *check=False*, *copy=True*)

Bases: *IncidenceStructure*

Two-graphs class.

A two-graph on n points is a 3-uniform hypergraph, i.e. a family $T \subset \binom{[n]}{3}$ of 3-sets, such that any 4-set $S \subset [n]$ of size four contains an even number of elements of T. For more information, see the documentation of the *twographs* module.

complement()

The two-graph which is the complement of `self`.

That is, the two-graph consisting exactly of triples not in `self`. Note that this is different from *complement* of the *parent class*.

EXAMPLES:

```
sage: p = graphs.CompleteGraph(8).line_graph().twograph()                    #␣
↪needs sage.modules
sage: pc = p.complement(); pc                                                #␣
↪needs sage.modules
Incidence structure with 28 points and 1260 blocks
```

```
>>> from sage.all import *
>>> p = graphs.CompleteGraph(Integer(8)).line_graph().twograph()             ␣
↪     # needs sage.modules
>>> pc = p.complement(); pc                                                 #␣
↪needs sage.modules
Incidence structure with 28 points and 1260 blocks
```

descendant(*v*, *immutable=False*)

The descendant `graph` at `v`.

The *switching class of graphs* corresponding to `self` contains a graph `D` with `v` its own connected component; removing `v` from `D`, one obtains the descendant graph of `self` at `v`, which is constructed by this method.

INPUT:

- `v` – an element of *ground_set()*
- `immutable` – boolean (default: `False`); whether to return an immutable or a mutable graph

EXAMPLES:

```
sage: p = graphs.PetersenGraph().twograph().descendant(0)                    #␣
↪needs sage.modules
sage: p.is_strongly_regular(parameters=True)                                 #␣
↪needs sage.modules
(9, 4, 1, 2)
```

```
>>> from sage.all import *
>>> p = graphs.PetersenGraph().twograph().descendant(Integer(0))             ␣
↪     # needs sage.modules
>>> p.is_strongly_regular(parameters=True)                                   #␣
↪needs sage.modules
(9, 4, 1, 2)
```

is_regular_twograph(*alpha=False*)

Test if the *TwoGraph* is regular, i.e. is a 2-design.

Namely, each pair of elements of *ground_set()* is contained in exactly `alpha` triples.

INPUT:

- `alpha` – boolean (default: `False`); return the value of `alpha`, if possible

EXAMPLES:

```
sage: # needs sage.modules
sage: p = graphs.PetersenGraph().twograph()
sage: p.is_regular_twograph(alpha=True)
4
sage: p.is_regular_twograph()
True
sage: p = graphs.PathGraph(5).twograph()
sage: p.is_regular_twograph(alpha=True)
False
sage: p.is_regular_twograph()
False
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> p = graphs.PetersenGraph().twograph()
>>> p.is_regular_twograph(alpha=True)
4
>>> p.is_regular_twograph()
True
>>> p = graphs.PathGraph(Integer(5)).twograph()
>>> p.is_regular_twograph(alpha=True)
False
>>> p.is_regular_twograph()
False
```

`sage.combinat.designs.twographs.`**`is_twograph`**`(`T`)`

Check whether the incidence system T is a two-graph.

INPUT:

- `T` – an *incidence structure*

EXAMPLES:

a two-graph from a graph:

```
sage: from sage.combinat.designs.twographs import (is_twograph, TwoGraph)
sage: p = graphs.PetersenGraph().twograph()                                 #␣
↪needs sage.modules
sage: is_twograph(p)                                                        #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.twographs import (is_twograph, TwoGraph)
>>> p = graphs.PetersenGraph().twograph()                                   #␣
↪needs sage.modules
>>> is_twograph(p)                                                          #␣
↪needs sage.modules
True
```

a non-regular 2-uniform hypergraph which is a two-graph:

```
sage: is_twograph(TwoGraph([[1,2,3],[1,2,4]]))
True
```

```
>>> from sage.all import *
>>> is_twograph(TwoGraph([[Integer(1),Integer(2),Integer(3)],[Integer(1),
↪Integer(2),Integer(4)]]))
True
```

sage.combinat.designs.twographs.**taylor_twograph**(*q*)

Constructing Taylor's two-graph for $U_3(q)$, q odd prime power.

The Taylor's two-graph T has the q^3+1 points of the projective plane over F_{q^2} singular w.r.t. the non-degenerate Hermitean form S preserved by $U_3(q)$ as its ground set; the triples are $\{x,y,z\}$ satisfying the condition that $S(x,y)S(y,z)S(z,x)$ is square (respectively non-square) if $q \cong 1 \mod 4$ (respectively if $q \cong 3 \mod 4$). See §7E of [BL1984].

There is also a $2-(q^3+1,q+1,1)$-design on these q^3+1 points, known as the unital of order q, also invariant under $U_3(q)$.

INPUT:

- `q` – a power of an odd prime

EXAMPLES:

```
sage: from sage.combinat.designs.twographs import taylor_twograph
sage: T = taylor_twograph(3); T                                                 #␣
↪needs sage.rings.finite_rings
Incidence structure with 28 points and 1260 blocks
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.twographs import taylor_twograph
>>> T = taylor_twograph(Integer(3)); T                                          ␣
↪     # needs sage.rings.finite_rings
Incidence structure with 28 points and 1260 blocks
```

sage.combinat.designs.twographs.**twograph_descendant**(*G*, *v*, *name=None*, *immutable=None*)

Return the descendant graph w.r.t. vertex v of the two-graph of G.

In the *switching class* of G, construct a graph Δ with v an isolated vertex, and return the subgraph $\Delta \setminus v$. It is equivalent to, although much faster than, computing the *TwoGraph.descendant()* of two-graph of G, as the intermediate two-graph is not constructed.

INPUT:

- `G` – a graph
- `v` – a vertex of `G`
- `name` – (default: `None`) no name, otherwise derive from the construction
- `immutable` – boolean (default: `None`); whether to create a mutable/immutable graph. `immutable=None` (default) means that the graph and its descendant will behave the same way.

EXAMPLES:

one of s.r.g.'s from the database:

```
sage: from sage.combinat.designs.twographs import twograph_descendant
sage: A = graphs.strongly_regular_graph(280,135,70)                    # optional -
↪ gap_package_design internet
sage: twograph_descendant(A, 0).is_strongly_regular(parameters=True)   # optional -
↪ gap_package_design internet
(279, 150, 85, 75)
```

```
>>> from sage.all import *
>>> from sage.combinat.designs.twographs import twograph_descendant
>>> A = graphs.strongly_regular_graph(Integer(280),Integer(135),Integer(70))     ␣
↪             # optional - gap_package_design internet
>>> twograph_descendant(A, Integer(0)).is_strongly_regular(parameters=True)   #␣
↪optional - gap_package_design internet
(279, 150, 85, 75)
```

4.1.6 sage.combinat.integer_lists

Enumerated set of lists of integers with constraints, in inverse lexicographic order

- *IntegerListsLex*: the enumerated set of lists of nonnegative integers with specified constraints, in inverse lexicographic order.
- *IntegerListsBackend_invlex*: Cython back-end for *IntegerListsLex*.

HISTORY:

This generic tool was originally written by Hivert and Thiery in MuPAD-Combinat in 2000 and ported over to Sage by Mike Hansen in 2007. It was then completely rewritten in 2015 by Gillespie, Schilling, and Thiery, with the help of many, to deal with limitations and lack of robustness w.r.t. input.

class sage.combinat.integer_lists.invlex.**IntegerListsBackend_invlex**

Bases: *IntegerListsBackend*

Cython back-end of a set of lists of integers with specified constraints enumerated in inverse lexicographic order.

check

class sage.combinat.integer_lists.invlex.**IntegerListsLex**(**args*, ***kwds*)

Bases: *IntegerLists*

Lists of nonnegative integers with constraints, in inverse lexicographic order.

An *integer list* is a list l of nonnegative integers, its *parts*. The slope (at position i) is the difference `l[i+1]-l[i]` between two consecutive parts.

This class allows to construct the set S of all integer lists l satisfying specified bounds on the sum, the length, the slope, and the individual parts, enumerated in *inverse* lexicographic order, that is from largest to smallest in lexicographic order. Note that, to admit such an enumeration, S is almost necessarily finite (see *On finiteness and inverse lexicographic enumeration*).

The main purpose is to provide a generic iteration engine for all the enumerated sets like *Partitions*, *Compositions*, *IntegerVectors*. It can also be used to generate many other combinatorial objects like Dyck paths, Motzkin paths, etc. Mathematically speaking, this is a special case of set of integral points of a polytope (or union thereof, when the length is not fixed).

INPUT:

- `min_sum` – nonnegative integer (default: 0); a lower bound on `sum(l)`

- `max_sum` – nonnegative integer or ∞ (default: ∞); an upper bound on `sum(l)`
- `n` – nonnegative integer (optional); if specified, this overrides `min_sum` and `max_sum`
- `min_length` – nonnegative integer (default: 0); a lower bound on `len(l)`
- `max_length` – nonnegative integer or ∞ (default: ∞); an upper bound on `len(l)`
- `length` – integer (optional); overrides `min_length` and `max_length` if specified
- `min_part` – nonnegative integer; a lower bounds on all parts: `min_part <= l[i]` for `0 <= i < len(l)`
- `floor` – list of nonnegative integers or a function; lower bounds on the individual parts $l[i]$

  If `floor` is a list of integers, then `floor<=l[i]` for `0 <= i < min(len(l), len(floor)`. Similarly, if `floor` is a function, then `floor(i) <= l[i]` for `0 <= i < len(l)`.
- `max_part` – nonnegative integer or ∞; an upper bound on all parts: `l[i] <= max_part` for `0 <= i < len(l)`
- `ceiling` – upper bounds on the individual parts `l[i]`; this takes the same type of input as `floor`, except that ∞ is allowed in addition to integers, and the default value is ∞.
- `min_slope` – integer or $-\infty$ (default: $-\infty$); a lower bound on the slope between consecutive parts: `min_slope <= l[i+1]-l[i]` for `0 <= i < len(l)-1`
- `max_slope` – integer or $+\infty$ (defaults: $+\infty$); an upper bound on the slope between consecutive parts: `l[i+1]-l[i] <= max_slope` for `0 <= i < len(l)-1`
- `category` – a category (default: `FiniteEnumeratedSets`)
- `check` – boolean (default: `True`); whether to display the warnings raised when functions are given as input to `floor` or `ceiling` and the errors raised when there is no proper enumeration.
- `name` – string or `None` (default: `None`); if set, this will be passed down to `rename()` to specify the name of `self`. It is recommended to use rename method directly because this feature may become deprecated.
- `element_constructor` – a function (or callable) that creates elements of `self` from a list. See also `Parent`
- `element_class` – a class for the elements of `self` (default: $ClonableArray$). This merely sets the attribute `self.Element`. See the examples for details.

Note

When several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is enumerated (and therefore counted). The others are still considered valid. See the examples below.

This feature is questionable. It is recommended not to rely on it, as it may eventually be discontinued.

EXAMPLES:

We create the enumerated set of all lists of nonnegative integers of length 3 and sum 2:

```
sage: C = IntegerListsLex(2, length=3)
sage: C
Integer lists of sum 2 satisfying certain constraints
sage: C.cardinality()
6
sage: [p for p in C]
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

(continues on next page)

(continued from previous page)

```
sage: [2, 0, 0] in C
True
sage: [2, 0, 1] in C
False
sage: "a" in C
False
sage: ["a"] in C
False
sage: C.first()
[2, 0, 0]
```

```
>>> from sage.all import *
>>> C = IntegerListsLex(Integer(2), length=Integer(3))
>>> C
Integer lists of sum 2 satisfying certain constraints
>>> C.cardinality()
6
>>> [p for p in C]
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]

>>> [Integer(2), Integer(0), Integer(0)] in C
True
>>> [Integer(2), Integer(0), Integer(1)] in C
False
>>> "a" in C
False
>>> ["a"] in C
False
>>> C.first()
[2, 0, 0]
```

One can specify lower and upper bounds on each part:

```
sage: list(IntegerListsLex(5, length=3, floor=[1,2,0], ceiling=[3,2,3]))
[[3, 2, 0], [2, 2, 1], [1, 2, 2]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(5), length=Integer(3), floor=[Integer(1),
↪Integer(2),Integer(0)], ceiling=[Integer(3),Integer(2),Integer(3)]))
[[3, 2, 0], [2, 2, 1], [1, 2, 2]]
```

When the length is fixed as above, one can also use *IntegerVectors*:

```
sage: IntegerVectors(2,3).list()
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(2),Integer(3)).list()
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

Using the slope condition, one can generate integer partitions (but see *Partitions*):

```
sage: list(IntegerListsLex(4, max_slope=0))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), max_slope=Integer(0)))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The following is the list of all partitions of 7 with parts at least 2:

```
sage: list(IntegerListsLex(7, max_slope=0, min_part=2))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(7), max_slope=Integer(0), min_part=Integer(2)))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

floor and ceiling conditions

Next we list all partitions of 5 of length at most 3 which are bounded below by `[2,1,1]`:

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, floor=[2,1,1]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), max_length=Integer(3),␣
↪floor=[Integer(2),Integer(1),Integer(1)]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

Note that `[5]` is considered valid, because the floor constraints only apply to existing positions in the list. To obtain instead the partitions containing `[2,1,1]`, one needs to use `min_length` or `length`:

```
sage: list(IntegerListsLex(5, max_slope=0, length=3, floor=[2,1,1]))
[[3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), length=Integer(3),␣
↪floor=[Integer(2),Integer(1),Integer(1)]))
[[3, 1, 1], [2, 2, 1]]
```

Here is the list of all partitions of 5 which are contained in `[3,2,2]`:

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, ceiling=[3,2,2]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), max_length=Integer(3),␣
↪ceiling=[Integer(3),Integer(2),Integer(2)]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

This is the list of all compositions of 4 (but see *Compositions*):

```
sage: list(IntegerListsLex(4, min_part=1))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), min_part=Integer(1)))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

This is the list of all integer vectors of sum 4 and length 3:

```
sage: list(IntegerListsLex(4, length=3))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1],
 [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
 [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), length=Integer(3)))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1],
 [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
 [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

For whatever it is worth, the `floor` and `min_part` constraints can be combined:

```
sage: L = IntegerListsLex(5, floor=[2,0,2], min_part=1)
sage: L.list()
[[5], [4, 1], [3, 2], [2, 3], [2, 1, 2]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(5), floor=[Integer(2),Integer(0),Integer(2)], min_
↪part=Integer(1))
>>> L.list()
[[5], [4, 1], [3, 2], [2, 3], [2, 1, 2]]
```

This is achieved by updating the floor upon constructing `L`:

```
sage: [L.floor(i) for i in range(5)]
[2, 1, 2, 1, 1]
```

```
>>> from sage.all import *
>>> [L.floor(i) for i in range(Integer(5))]
[2, 1, 2, 1, 1]
```

Similarly, the `ceiling` and `max_part` constraints can be combined:

```
sage: L = IntegerListsLex(4, ceiling=[2,3,1], max_part=2, length=3)
sage: L.list()
[[2, 2, 0], [2, 1, 1], [1, 2, 1]]
sage: [L.ceiling(i) for i in range(5)]
[2, 2, 1, 2, 2]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(4), ceiling=[Integer(2),Integer(3),Integer(1)],␣
↪max_part=Integer(2), length=Integer(3))
```

(continues on next page)

(continued from previous page)

```
>>> L.list()
[[2, 2, 0], [2, 1, 1], [1, 2, 1]]
>>> [L.ceiling(i) for i in range(Integer(5))]
[2, 2, 1, 2, 2]
```

This can be used to generate Motzkin words (see Wikipedia article Motzkin_number):

```
sage: def motzkin_words(n):
....:     return IntegerListsLex(length=n+1, min_slope=-1, max_slope=1,
....:                 ceiling=[0]+[+oo for i in range(n-1)]+[0])
sage: motzkin_words(4).list()
[[0, 1, 2, 1, 0],
 [0, 1, 1, 1, 0],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 0],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 0],
 [0, 0, 0, 1, 0],
 [0, 0, 0, 0, 0]]
sage: [motzkin_words(n).cardinality() for n in range(8)]
[1, 1, 2, 4, 9, 21, 51, 127]
sage: oeis(_)                  # optional -- internet
0: A001006: Motzkin numbers: number of ways of drawing any number
of nonintersecting chords joining n (labeled) points on a circle.
1: ...
2: ...
```

```
>>> from sage.all import *
>>> def motzkin_words(n):
...     return IntegerListsLex(length=n+Integer(1), min_slope=-Integer(1), max_
↪slope=Integer(1),
...                 ceiling=[Integer(0)]+[+oo for i in range(n-
↪Integer(1))]+[Integer(0)])
>>> motzkin_words(Integer(4)).list()
[[0, 1, 2, 1, 0],
 [0, 1, 1, 1, 0],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 0],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 0],
 [0, 0, 0, 1, 0],
 [0, 0, 0, 0, 0]]
>>> [motzkin_words(n).cardinality() for n in range(Integer(8))]
[1, 1, 2, 4, 9, 21, 51, 127]
>>> oeis(_)                  # optional -- internet
0: A001006: Motzkin numbers: number of ways of drawing any number
of nonintersecting chords joining n (labeled) points on a circle.
1: ...
2: ...
```

or Dyck words (see also *DyckWords*), through the bijection with paths from $(0, 0)$ to (n, n) with left and up steps

that remain below the diagonal:

```
sage: def dyck_words(n):
....:     return IntegerListsLex(length=n, ceiling=list(range(n+1)), min_slope=0)
sage: [dyck_words(n).cardinality() for n in range(8)]
[1, 1, 2, 5, 14, 42, 132, 429]
sage: dyck_words(3).list()
[[0, 1, 2], [0, 1, 1], [0, 0, 2], [0, 0, 1], [0, 0, 0]]
```

```
>>> from sage.all import *
>>> def dyck_words(n):
...     return IntegerListsLex(length=n, ceiling=list(range(n+Integer(1))), min_
↪slope=Integer(0))
>>> [dyck_words(n).cardinality() for n in range(Integer(8))]
[1, 1, 2, 5, 14, 42, 132, 429]
>>> dyck_words(Integer(3)).list()
[[0, 1, 2], [0, 1, 1], [0, 0, 2], [0, 0, 1], [0, 0, 0]]
```

On finiteness and inverse lexicographic enumeration

The set of all lists of integers cannot be enumerated in inverse lexicographic order, since there is no largest list (take $[n]$ for n as large as desired):

```
sage: IntegerListsLex().first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

```
>>> from sage.all import *
>>> IntegerListsLex().first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

Here is a variant which could be enumerated in lexicographic order but not in inverse lexicographic order:

```
sage: L = IntegerListsLex(length=2, ceiling=[Infinity, 0], floor=[0,1])
sage: for l in L: print(l)
Traceback (most recent call last):
...
ValueError: infinite upper bound for values of m
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(length=Integer(2), ceiling=[Infinity, Integer(0)],␣
↪floor=[Integer(0),Integer(1)])
>>> for l in L: print(l)
Traceback (most recent call last):
...
ValueError: infinite upper bound for values of m
```

Even when the sum is specified, it is not necessarily possible to enumerate *all* elements in inverse lexicographic order. In the following example, the list `[1, 1, 1]` will never appear in the enumeration:

```
sage: IntegerListsLex(3).first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

```
>>> from sage.all import *
>>> IntegerListsLex(Integer(3)).first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

If one wants to proceed anyway, one can sign a waiver by setting `check=False` (again, be warned that some valid lists may never appear):

```
sage: L = IntegerListsLex(3, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), check=False)
>>> it = iter(L)
>>> [next(it) for i in range(Integer(6))]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

In fact, being inverse lexicographically enumerable is almost equivalent to being finite. The only infinity that can occur would be from a tail of numbers $0, 1$ as in the previous example, where the 1 moves further and further to the right. If there is any list that is inverse lexicographically smaller than such a configuration, the iterator would not reach it and hence would not be considered iterable. Given that the infinite cases are very specific, at this point only the finite cases are supported (without signing the waiver).

The finiteness detection is not complete yet, so some finite cases may not be supported either, at least not without disabling the checks. Practical examples of such are welcome.

On trailing zeroes, and their caveats

As mentioned above, when several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is listed:

```
sage: L = IntegerListsLex(max_length=4, max_part=1)
sage: L.list()
[[1, 1, 1, 1],
 [1, 1, 1],
 [1, 1, 0, 1],
 [1, 1],
 [1, 0, 1, 1],
 [1, 0, 1],
 [1, 0, 0, 1],
 [1],
 [0, 1, 1, 1],
 [0, 1, 1],
 [0, 1, 0, 1],
 [0, 1],
```

(continues on next page)

(continued from previous page)

```
 [0, 0, 1, 1],
 [0, 0, 1],
 [0, 0, 0, 1],
 []]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(max_length=Integer(4), max_part=Integer(1))
>>> L.list()
[[1, 1, 1, 1],
 [1, 1, 1],
 [1, 1, 0, 1],
 [1, 1],
 [1, 0, 1, 1],
 [1, 0, 1],
 [1, 0, 0, 1],
 [1],
 [0, 1, 1, 1],
 [0, 1, 1],
 [0, 1, 0, 1],
 [0, 1],
 [0, 0, 1, 1],
 [0, 0, 1],
 [0, 0, 0, 1],
 []]
```

and counted:

```
sage: L.cardinality()
16
```

```
>>> from sage.all import *
>>> L.cardinality()
16
```

Still, the others are considered as elements of L:

```
sage: L = IntegerListsLex(4,min_length=3,max_length=4)
sage: L.list()
[..., [2, 2, 0], ...]

sage: [2, 2, 0] in L        # in L.list()
True
sage: [2, 2, 0, 0] in L     # not in L.list() !
True
sage: [2, 2, 0, 0, 0] in L
False
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(4),min_length=Integer(3),max_length=Integer(4))
>>> L.list()
[..., [2, 2, 0], ...]
```

(continues on next page)

(continued from previous page)

```
>>> [Integer(2), Integer(2), Integer(0)] in L       # in L.list()
True
>>> [Integer(2), Integer(2), Integer(0), Integer(0)] in L    # not in L.list() !
True
>>> [Integer(2), Integer(2), Integer(0), Integer(0), Integer(0)] in L
False
```

Specifying functions as input for the floor or ceiling

We construct all lists of sum 4 and length 4 such that `l[i] <= i`:

```
sage: list(IntegerListsLex(4, length=4, ceiling=lambda i: i, check=False))
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), length=Integer(4), ceiling=lambda i: i,␣
↪check=False))
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]
```

Warning

When passing a function as `floor` or `ceiling`, it may become undecidable to detect improper inverse lexicographic enumeration. For example, the following example has a finite enumeration:

```
sage: L = IntegerListsLex(3, floor=lambda i: 1 if i>=2 else 0, check=False)
sage: L.list()
[[3],
 [2, 1],
 [2, 0, 1],
 [1, 2],
 [1, 1, 1],
 [1, 0, 2],
 [1, 0, 1, 1],
 [0, 3],
 [0, 2, 1],
 [0, 1, 2],
 [0, 1, 1, 1],
 [0, 0, 3],
 [0, 0, 2, 1],
 [0, 0, 1, 2],
 [0, 0, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), floor=lambda i: Integer(1) if i>
↪=Integer(2) else Integer(0), check=False)
>>> L.list()
[[3],
 [2, 1],
 [2, 0, 1],
 [1, 2],
 [1, 1, 1],
 [1, 0, 2],
 [1, 0, 1, 1],
 [0, 3],
 [0, 2, 1],
 [0, 1, 2],
 [0, 1, 1, 1],
 [0, 0, 3],
 [0, 0, 2, 1],
```

but one cannot decide whether the following has an improper inverse lexicographic enumeration without computing the floor all the way to `Infinity`:

```
sage: L = IntegerListsLex(3, floor=lambda i: 0, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), floor=lambda i: Integer(0), check=False)
>>> it = iter(L)
>>> [next(it) for i in range(Integer(6))]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

Hence a warning is raised when a function is specified as input, unless the waiver is signed by setting `check=False`:

```
sage: L = IntegerListsLex(3, floor=lambda i: 1 if i>=2 else 0)
doctest:...
A function has been given as input of the floor=[...] or ceiling=[...]
arguments of IntegerListsLex. Please see the documentation for the caveats.
If you know what you are doing, you can set check=False to skip this warning.
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), floor=lambda i: Integer(1) if i>
↪=Integer(2) else Integer(0))
doctest:...
A function has been given as input of the floor=[...] or ceiling=[...]
arguments of IntegerListsLex. Please see the documentation for the caveats.
If you know what you are doing, you can set check=False to skip this warning.
```

Similarly, the algorithm may need to search forever for a solution when the ceiling is ultimately zero:

```
sage: L = IntegerListsLex(2,ceiling=lambda i:0, check=False)
sage: L.first()           # not tested: will hang forever
sage: L = IntegerListsLex(2,ceiling=lambda i:0 if i<20 else 1, check=False)
sage: it = iter(L)
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1]
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1]
sage: next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(2),ceiling=lambda i:Integer(0), check=False)
>>> L.first()           # not tested: will hang forever
>>> L = IntegerListsLex(Integer(2),ceiling=lambda i:Integer(0) if i
↪<Integer(20) else Integer(1), check=False)
>>> it = iter(L)
>>> next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1]
>>> next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1]
>>> next(it)
[0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1]
```

Tip: using disjoint union enumerated sets for additional flexibility

Sometimes, specifying a range for the sum or the length may be too restrictive. One would want instead to specify a list, or iterable L, of acceptable values. This is easy to achieve using a `disjoint union of enumerated sets`. Here we want to accept the values $n = 0, 2, 3$:

```
sage: C = DisjointUnionEnumeratedSets(Family([0,2,3],
....:         lambda n: IntegerListsLex(n, length=2)))
sage: C
Disjoint union of Finite family
{0: Integer lists of sum 0 satisfying certain constraints,
 2: Integer lists of sum 2 satisfying certain constraints,
 3: Integer lists of sum 3 satisfying certain constraints}
sage: C.list()
[[0, 0],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

```
>>> from sage.all import *
>>> C = DisjointUnionEnumeratedSets(Family([Integer(0),Integer(2),Integer(3)],
...         lambda n: IntegerListsLex(n, length=Integer(2))))
>>> C
Disjoint union of Finite family
{0: Integer lists of sum 0 satisfying certain constraints,
 2: Integer lists of sum 2 satisfying certain constraints,
 3: Integer lists of sum 3 satisfying certain constraints}
>>> C.list()
[[0, 0],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

The price to pay is that the enumeration order is now *graded lexicographic* instead of lexicographic: first choose the value according to the order specified by L, and use lexicographic order within each value. Here is we reverse L:

```
sage: DisjointUnionEnumeratedSets(Family([3,2,0],
....:     lambda n: IntegerListsLex(n, length=2))).list()
[[3, 0], [2, 1], [1, 2], [0, 3],
 [2, 0], [1, 1], [0, 2],
 [0, 0]]
```

```
>>> from sage.all import *
>>> DisjointUnionEnumeratedSets(Family([Integer(3),Integer(2),Integer(0)],
...     lambda n: IntegerListsLex(n, length=Integer(2)))).list()
[[3, 0], [2, 1], [1, 2], [0, 3],
 [2, 0], [1, 1], [0, 2],
 [0, 0]]
```

Note that if a given value appears several times, the corresponding elements will be enumerated several times, which may, or not, be what one wants:

```
sage: DisjointUnionEnumeratedSets(Family([2,2],
....:     lambda n: IntegerListsLex(n, length=2))).list()
[[2, 0], [1, 1], [0, 2], [2, 0], [1, 1], [0, 2]]
```

```
>>> from sage.all import *
>>> DisjointUnionEnumeratedSets(Family([Integer(2),Integer(2)],
...     lambda n: IntegerListsLex(n, length=Integer(2)))).list()
[[2, 0], [1, 1], [0, 2], [2, 0], [1, 1], [0, 2]]
```

Here is a variant where we specify acceptable values for the length:

```
sage: DisjointUnionEnumeratedSets(Family([0,1,3],
....:     lambda l: IntegerListsLex(2, length=l))).list()
[[2],
 [2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

```
>>> from sage.all import *
>>> DisjointUnionEnumeratedSets(Family([Integer(0),Integer(1),Integer(3)],
...     lambda l: IntegerListsLex(Integer(2), length=l))).list()
[[2],
 [2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

This technique can also be useful to obtain a proper enumeration on infinite sets by using a graded lexicographic enumeration:

```
sage: C = DisjointUnionEnumeratedSets(Family(NN,
....:         lambda n: IntegerListsLex(n, length=2)))
sage: C
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
sage: it = iter(C)
sage: [next(it) for i in range(10)]
[[0, 0],
 [1, 0], [0, 1],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

```
>>> from sage.all import *
>>> C = DisjointUnionEnumeratedSets(Family(NN,
...         lambda n: IntegerListsLex(n, length=Integer(2))))
>>> C
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
>>> it = iter(C)
>>> [next(it) for i in range(Integer(10))]
[[0, 0],
 [1, 0], [0, 1],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

Specifying how to construct elements

This is the list of all monomials of degree 4 which divide the monomial $x^3y^1z^2$ (a monomial being identified with its exponent vector):

```
sage: R.<x,y,z> = QQ[]
sage: m = [3,1,2]
sage: def term(exponents):
....:     return x^exponents[0] * y^exponents[1] * z^exponents[2]
sage: list(IntegerListsLex(4, length=len(m), ceiling=m, element_constructor=term))
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

```
>>> from sage.all import *
>>> R = QQ['x, y, z']; (x, y, z,) = R._first_ngens(3)
>>> m = [Integer(3),Integer(1),Integer(2)]
>>> def term(exponents):
...     return x**exponents[Integer(0)] * y**exponents[Integer(1)] *␣
↪z**exponents[Integer(2)]
>>> list(IntegerListsLex(Integer(4), length=len(m), ceiling=m, element_
↪constructor=term))
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

Note the use of the `element_constructor` option to specify how to construct elements from a plain list.

A variant is to specify a class for the elements. With the default element constructor, this class should take as input the parent `self` and a list.

Warning

The protocol for specifying the element class and constructor is subject to changes.

ALGORITHM:

The iteration algorithm uses a depth first search through the prefix tree of the list of integers (see also *Lexicographic generation of lists of integers*). While doing so, it does some lookahead heuristics to attempt to cut dead branches.

In most practical use cases, most dead branches are cut. Then, roughly speaking, the time needed to iterate through all the elements of S is proportional to the number of elements, where the proportion factor is controlled by the length l of the longest element of S. In addition, the memory usage is also controlled by l, which is to say negligible in practice.

Still, there remains much room for efficiency improvements; see Issue #18055, Issue #18056.

Note

The generation algorithm could in principle be extended to deal with non-constant slope constraints and with negative parts.

TESTS from comments on Issue #17979

Comment 191:

```
sage: list(IntegerListsLex(1, min_length=2, min_slope=0, max_slope=0))
[]
```

```
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(1), min_length=Integer(2), min_slope=Integer(0),␣
↪max_slope=Integer(0)))
[]
```

Comment 240:

```
sage: L = IntegerListsLex(min_length=2, max_part=0)
sage: L.list()
[[0, 0]]
```

```
>>> from sage.all import *
>>> L = IntegerListsLex(min_length=Integer(2), max_part=Integer(0))
>>> L.list()
[[0, 0]]
```

Tests on the element constructor feature and mutability

Internally, the iterator works on a single list that is mutated along the way. Therefore, you need to make sure that the `element_constructor` actually **copies** its input. This example shows what can go wrong:

```
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_
↪constructor=lambda x: x)
sage: list(P)
[[], [], []]
```

```
>>> from sage.all import *
>>> P = IntegerListsLex(n=Integer(3), max_slope=Integer(0), min_part=Integer(1),␣
↪element_constructor=lambda x: x)
>>> list(P)
[[], [], []]
```

However, specifying `list()` as constructor solves this problem:

```
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_constructor=list)
sage: list(P)
[[3], [2, 1], [1, 1, 1]]
```

```
>>> from sage.all import *
>>> P = IntegerListsLex(n=Integer(3), max_slope=Integer(0), min_part=Integer(1),␣
↪element_constructor=list)
>>> list(P)
[[3], [2, 1], [1, 1, 1]]
```

Same, step by step:

```
sage: it = iter(P)
sage: a = next(it); a
[3]
sage: b = next(it); b
[2, 1]
sage: a
```

(continues on next page)

(continued from previous page)

```
[3]
sage: a is b
False
```

```
>>> from sage.all import *
>>> it = iter(P)
>>> a = next(it); a
[3]
>>> b = next(it); b
[2, 1]
>>> a
[3]
>>> a is b
False
```

Tests from MuPAD-Combinat:

```
sage: IntegerListsLex(7, min_length=2, max_length=6, floor=[0,0,2,0,0,1],␣
↪ceiling=[3,2,3,2,1,2]).cardinality()

This used to hang (see comment 389 and fix in *Envelope.__init__*):

```
sage: IntegerListsLex(7, max_part=0, ceiling=lambda i:i, check=False).list()
[]
```

```
>>> from sage.all import *
>>> IntegerListsLex(Integer(7), max_part=Integer(0), ceiling=lambda i:i,␣
↪check=False).list()
[]
```

backend_class

alias of *IntegerListsBackend_invlex*

class sage.combinat.integer_lists.invlex.**IntegerListsLexIter**(*backend*)

Bases: object

Iterator class for IntegerListsLex.

Let `T` be the prefix tree of all lists of nonnegative integers that satisfy all constraints except possibly for `min_length` and `min_sum`; let the children of a list be sorted decreasingly according to their last part.

The iterator is based on a depth-first search exploration of a subtree of this tree, trying to cut branches that do not contain a valid list. Each call of `next` iterates through the nodes of this tree until it finds a valid list to return.

Here are the attributes describing the current state of the iterator, and their invariants:

- `backend` – the *IntegerListsBackend* object this is iterating on;
- `_current_list` – the list corresponding to the current node of the tree;
- `_j` – the index of the last element of `_current_list`: `self._j == len(self._current_list) - 1`;

- `_current_sum` – the sum of the parts of `_current_list`;
- `_search_ranges` – list of same length as `_current_list`: the range for each part

Furthermore, we assume that there is no obvious contradiction in the constraints:

- `self.backend.min_length <= self.backend.max_length`;
- `self.backend.min_slope <= self.backend.max_slope` unless `self.backend.min_length <= 1`.

Along this iteration, `next` switches between the following states:

- LOOKAHEAD: determine whether the current list could be a prefix of a valid list;
- PUSH: go deeper into the prefix tree by appending the largest possible part to the current list;
- ME: check whether the current list is valid and if yes return it
- DECREASE: decrease the last part;
- POP: pop the last part of the current list;
- STOP: the iteration is finished.

The attribute `_next_state` contains the next state `next` should enter in.

Enumerated set of lists of integers with constraints: base classes

- *IntegerListsBackend*: base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.
- *Envelope*: a utility class for upper (lower) envelope of a function under constraints.

class sage.combinat.integer_lists.base.**Envelope**

Bases: object

The (currently approximated) upper (lower) envelope of a function under the specified constraints.

INPUT:

- `f` – a function, list, or tuple; if `f` is a list, it is considered as the function `f(i)=f[i]`, completed for larger i with `f(i)=max_part`.
- `min_part`, `max_part`, `min_slope`, `max_slope`, … as for *IntegerListsLex* (please consult for details).
- `sign` – (+1 or -1) multiply the input values with `sign` and multiply the output with `sign`. Setting this to -1 can be used to implement a lower envelope.

The *upper envelope* $U(f)$ of f is the (pointwise) largest function which is bounded above by f and satisfies the `max_part` and `max_slope` conditions. Furthermore, for `i,i+1<min_length`, the upper envelope also satisfies the `min_slope` condition.

Upon computing $U(f)(i)$, all the previous values for $j \leq i$ are computed and cached; in particular $f(i)$ will be computed at most once for each i.

Todo

- This class is a good candidate for Cythonization, especially to get the critical path in `__call__` super fast.
- To get full envelopes, we would want both the `min_slope` and `max_slope` conditions to always be satisfied. This is only properly defined for the restriction of f to a finite interval $0, .., k$, and depends on k.

- This is the core "data structure" of `IntegerListsLex`. Improving the lookahead there essentially depends on having functions with a good complexity to compute the area below an envelope; and in particular how it evolves when increasing the length.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
```

Trivial upper and lower envelopes:

```
sage: f = Envelope([3,2,2])
sage: [f(i) for i in range(10)]
[3, 2, 2, inf, inf, inf, inf, inf, inf, inf]
sage: f = Envelope([3,2,2], sign=-1)
sage: [f(i) for i in range(10)]
[3, 2, 2, 0, 0, 0, 0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(3),Integer(2),Integer(2)])
>>> [f(i) for i in range(Integer(10))]
[3, 2, 2, inf, inf, inf, inf, inf, inf, inf]
>>> f = Envelope([Integer(3),Integer(2),Integer(2)], sign=-Integer(1))
>>> [f(i) for i in range(Integer(10))]
[3, 2, 2, 0, 0, 0, 0, 0, 0, 0]
```

A more interesting lower envelope:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1))
>>> [f(i) for i in range(Integer(10))]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

Currently, adding `max_slope` has no effect:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1), max_slope=Integer(0))
>>> [f(i) for i in range(Integer(10))]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

unless `min_length` is large enough:

```
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0,␣
↪min_length=2)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0,␣
↪min_length=4)
sage: [f(i) for i in range(10)]
[5, 5, 5, 4, 5, 4, 3, 2, 2, 2]

sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0,␣
↪min_length=5)
sage: [f(i) for i in range(10)]
[5, 5, 5, 5, 5, 4, 3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1), max_slope=Integer(0),␣
↪min_length=Integer(2))
>>> [f(i) for i in range(Integer(10))]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1), max_slope=Integer(0),␣
↪min_length=Integer(4))
>>> [f(i) for i in range(Integer(10))]
[5, 5, 5, 4, 5, 4, 3, 2, 2, 2]

>>> f = Envelope([Integer(4),Integer(1),Integer(5),Integer(3),Integer(5)], sign=-
↪Integer(1), min_part=Integer(2), min_slope=-Integer(1), max_slope=Integer(0),␣
↪min_length=Integer(5))
>>> [f(i) for i in range(Integer(10))]
[5, 5, 5, 5, 5, 4, 3, 2, 2, 2]
```

A non trivial upper envelope:

```
sage: f = Envelope([9,1,5,4], max_part=7, max_slope=2)
sage: [f(i) for i in range(10)]
[7, 1, 3, 4, 6, 7, 7, 7, 7, 7]
```

```
>>> from sage.all import *
>>> f = Envelope([Integer(9),Integer(1),Integer(5),Integer(4)], max_
↪part=Integer(7), max_slope=Integer(2))
>>> [f(i) for i in range(Integer(10))]
[7, 1, 3, 4, 6, 7, 7, 7, 7, 7]
```

__init__(*f*, *min_part=0*, *max_part='Infinity'*, *min_slope='MInfinity'*, *max_slope='Infinity'*, *min_length=0*, *max_length='Infinity'*, *sign=1*)

Initialize this envelope.

adapt(*m*, *j*)

Return this envelope adapted to an additional local constraint.

INPUT:

- m – nonnegative integer (starting value)
- j – nonnegative integer (position)

This method adapts this envelope to the additional local constraint imposed by having a part m at position j. Namely, this returns a function which computes, for any $i > j$, the minimum of the ceiling function and the value restriction given by the slope conditions.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
sage: f = Envelope(3)
sage: g = f.adapt(1,1)
sage: g is f
True
sage: [g(i) for i in range(10)]
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3]

sage: f = Envelope(3, max_slope=1)
sage: g = f.adapt(1,1)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
>>> f = Envelope(Integer(3))
>>> g = f.adapt(Integer(1),Integer(1))
>>> g is f
True
>>> [g(i) for i in range(Integer(10))]
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3]

>>> f = Envelope(Integer(3), max_slope=Integer(1))
>>> g = f.adapt(Integer(1),Integer(1))
>>> [g(i) for i in range(Integer(10))]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

Note that, in both cases above, the adapted envelope is only guaranteed to be valid for $i > j$! This is to leave potential room in the future for sharing similar adapted envelopes:

```
sage: g = f.adapt(0,0)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

sage: g = f.adapt(2,2)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

sage: g = f.adapt(3,3)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

```
>>> from sage.all import *
>>> g = f.adapt(Integer(0),Integer(0))
>>> [g(i) for i in range(Integer(10))]
```

(continues on next page)

(continued from previous page)

```
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

>>> g = f.adapt(Integer(2),Integer(2))
>>> [g(i) for i in range(Integer(10))]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

>>> g = f.adapt(Integer(3),Integer(3))
>>> [g(i) for i in range(Integer(10))]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```

Now with a lower envelope:

```
sage: f = Envelope(1, sign=-1, min_slope=-1)
sage: g = f.adapt(2,2)
sage: [g(i) for i in range(10)]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
sage: g = f.adapt(1,3)
sage: [g(i) for i in range(10)]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> f = Envelope(Integer(1), sign=-Integer(1), min_slope=-Integer(1))
>>> g = f.adapt(Integer(2),Integer(2))
>>> [g(i) for i in range(Integer(10))]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
>>> g = f.adapt(Integer(1),Integer(3))
>>> [g(i) for i in range(Integer(10))]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
```

limit()

Return a bound on the limit of `self`.

OUTPUT: nonnegative integer or ∞

This returns some upper bound for the accumulation points of this upper envelope. For a lower envelope, a lower bound is returned instead.

In particular this gives a bound for the value of `self` at i for i large enough. Special case: for a lower envelop, and when the limit is ∞, the envelope is guaranteed to tend to ∞ instead.

When `s=self.limit_start()` is finite, this bound is guaranteed to be valid for $i >= s$.

Sometimes it's better to have a loose bound that starts early; sometimes the converse holds. At this point which specific bound and starting point is returned is not set in stone, in order to leave room for later optimizations.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit()
inf
sage: Envelope([4,1,5], max_part=2).limit()
2
sage: Envelope([4,1,5], max_slope=0).limit()
1
```

(continues on next page)

(continued from previous page)

```
sage: Envelope(lambda x: 3, max_part=2).limit()
2
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
>>> Envelope([Integer(4),Integer(1),Integer(5)]).limit()
inf
>>> Envelope([Integer(4),Integer(1),Integer(5)], max_part=Integer(2)).limit()
2
>>> Envelope([Integer(4),Integer(1),Integer(5)], max_slope=Integer(0)).limit()
1
>>> Envelope(lambda x: Integer(3), max_part=Integer(2)).limit()
2
```

Lower envelopes:

```
sage: Envelope(lambda x: 3, min_part=2, sign=-1).limit()
2
sage: Envelope([4,1,5], min_slope=0, sign=-1).limit()
5
sage: Envelope([4,1,5], sign=-1).limit()
0
```

```
>>> from sage.all import *
>>> Envelope(lambda x: Integer(3), min_part=Integer(2), sign=-Integer(1)).
↪limit()
2
>>> Envelope([Integer(4),Integer(1),Integer(5)], min_slope=Integer(0), sign=-
↪Integer(1)).limit()
5
>>> Envelope([Integer(4),Integer(1),Integer(5)], sign=-Integer(1)).limit()
0
```

See also

limit_start()

limit_start()

Return from which i on the bound returned by `limit` holds.

See also

limit() for the precise specifications.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit_start()
3
```

(continues on next page)

(continued from previous page)

```
sage: Envelope([4,1,5], sign=-1).limit_start()
3

sage: Envelope([4,1,5], max_part=2).limit_start()
3

sage: Envelope(4).limit_start()
0
sage: Envelope(4, sign=-1).limit_start()
0

sage: Envelope(lambda x: 3).limit_start() == Infinity
True
sage: Envelope(lambda x: 3, max_part=2).limit_start() == Infinity
True

sage: Envelope(lambda x: 3, sign=-1, min_part=2).limit_start() == Infinity
True
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
>>> Envelope([Integer(4),Integer(1),Integer(5)]).limit_start()
3
>>> Envelope([Integer(4),Integer(1),Integer(5)], sign=-Integer(1)).limit_
↪start()
3

>>> Envelope([Integer(4),Integer(1),Integer(5)], max_part=Integer(2)).limit_
↪start()
3

>>> Envelope(Integer(4)).limit_start()
0
>>> Envelope(Integer(4), sign=-Integer(1)).limit_start()
0

>>> Envelope(lambda x: Integer(3)).limit_start() == Infinity
True
>>> Envelope(lambda x: Integer(3), max_part=Integer(2)).limit_start() ==␣
↪Infinity
True

>>> Envelope(lambda x: Integer(3), sign=-Integer(1), min_part=Integer(2)).
↪limit_start() == Infinity
True
```

max_part

max_slope

min_slope

sign

class sage.combinat.integer_lists.base.**IntegerListsBackend**

Bases: object

Base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.

This base implements the basic operations, including checking for containment using *_contains*, but not iteration. For iteration, subclass this class and implement an `_iter()` method.

EXAMPLES:

```
sage: from sage.combinat.integer_lists.base import IntegerListsBackend
sage: L = IntegerListsBackend(6, max_slope=-1)
sage: L._contains([3,2,1])
True
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists.base import IntegerListsBackend
>>> L = IntegerListsBackend(Integer(6), max_slope=-Integer(1))
>>> L._contains([Integer(3),Integer(2),Integer(1)])
True
```

_contains(*comp*)

Return `True` if `comp` meets the constraints imposed by the arguments.

EXAMPLES:

```
sage: C = IntegerListsLex(n=2, max_length=3, min_slope=0)
sage: all(l in C for l in C)  # indirect doctest
True
```

```
>>> from sage.all import *
>>> C = IntegerListsLex(n=Integer(2), max_length=Integer(3), min_
↪slope=Integer(0))
>>> all(l in C for l in C)  # indirect doctest
True
```

ceiling

min_length

min_part

min_slope

min_sum

Enumerated set of lists of integers with constraints: front-end

- *IntegerLists*: class which models an enumerated set of lists of integers with certain constraints. This is a Python front-end where all user-accessible functionality should be implemented.

class sage.combinat.integer_lists.lists.**IntegerList**

Bases: ClonableArray

Element class for *IntegerLists*.

check()

Check to make sure this is a valid element in its *IntegerLists* parent.

EXAMPLES:

```
sage: C = IntegerListsLex(4)
sage: C([4]).check()
True
sage: C([5]).check()
False
```

```
>>> from sage.all import *
>>> C = IntegerListsLex(Integer(4))
>>> C([Integer(4)]).check()
True
>>> C([Integer(5)]).check()
False
```

class sage.combinat.integer_lists.lists.**IntegerLists**(**args*, ***kwds*)

Bases: Parent

Enumerated set of lists of integers with constraints.

Currently, this is simply an abstract base class which should not be used by itself. See *IntegerListsLex* for a class which can be used by end users.

IntegerLists is just a Python front-end, acting as a Parent, supporting element classes and so on. The attribute .backend which is an instance of *sage.combinat.integer_lists.base.IntegerListsBackend* is the Cython back-end which implements all operations such as iteration.

The front-end (i.e. this class) and the back-end are supposed to be orthogonal: there is no imposed correspondence between front-ends and back-ends.

For example, the set of partitions of 5 and the set of weakly decreasing sequences which sum to 5 might be implemented by the same back-end, but they will be presented to the user by a different front-end.

EXAMPLES:

```
sage: from sage.combinat.integer_lists import IntegerLists
sage: L = IntegerLists(5)
sage: L
Integer lists of sum 5 satisfying certain constraints

sage: IntegerListsLex(2, length=3, name="A given name")
A given name
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import IntegerLists
```

(continues on next page)

(continued from previous page)

```
>>> L = IntegerLists(Integer(5))
>>> L
Integer lists of sum 5 satisfying certain constraints

>>> IntegerListsLex(Integer(2), length=Integer(3), name="A given name")
A given name
```

Element

alias of *IntegerList*

backend = None

backend_class

alias of *IntegerListsBackend*

Lists of nonnegative integers with constraints.

sage.combinat.integer_lists.nn.**IntegerListsNN**(***kwds*)

Lists of nonnegative integers with constraints.

This function returns the union of `IntegerListsLex(n, **kwds)` where n ranges over all nonnegative integers.

EXAMPLES:

```
sage: from sage.combinat.integer_lists.nn import IntegerListsNN
sage: L = IntegerListsNN(max_length=3, max_slope=-1)
sage: L
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
sage: it = iter(L)
sage: for _ in range(20):
....:     print(next(it))
[]

4.1.7 sage.combinat.matrices

Combinatorics on matrices

- *Dancing Links internal pyx code*
- *Dancing links C++ wrapper*
- *Hadamard matrices*
- *Latin squares*

Dancing Links internal pyx code

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x
Dancing links solver for 6 columns and 6 rows
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),Integer(5)],␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]]
>>> x = dlx_solver(rows)
>>> x
Dancing links solver for 6 columns and 6 rows
```

The number of solutions:

```
sage: x.number_of_solutions()
3
```

```
>>> from sage.all import *
>>> x.number_of_solutions()
3
```

Iterate over the solutions:

```
sage: sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

All solutions (computed in parallel):

```
sage: sorted(map(sorted, x.all_solutions()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> sorted(map(sorted, x.all_solutions()))
[[0, 1], [2, 3], [4, 5]]
```

Return the first solution found when the computation is done in parallel:

```
sage: sorted(x.one_solution(ncpus=2)) # random
[0, 1]
```

```
>>> from sage.all import *
>>> sorted(x.one_solution(ncpus=Integer(2))) # random
[0, 1]
```

Find all solutions using some specific rows:

```
sage: x_using_row_2 = x.restrict([2])
sage: x_using_row_2
Dancing links solver for 7 columns and 6 rows
sage: sorted(map(sorted, x_using_row_2.solutions_iterator()))
[[2, 3]]
```

```
>>> from sage.all import *
>>> x_using_row_2 = x.restrict([Integer(2)])
```

(continues on next page)

(continued from previous page)

```
>>> x_using_row_2
Dancing links solver for 7 columns and 6 rows
>>> sorted(map(sorted, x_using_row_2.solutions_iterator()))
[[2, 3]]
```

The two basic methods that are wrapped in this class are `search` which returns `1` if a solution is found or `0` otherwise and `get_solution` which return the current solution:

```
sage: x = dlx_solver(rows)
sage: x.search()
1
sage: x.get_solution()
[0, 1]
sage: x.search()
1
sage: x.get_solution()
[2, 3]
sage: x.search()
1
sage: x.get_solution()
[4, 5]
sage: x.search()
0
```

```
>>> from sage.all import *
>>> x = dlx_solver(rows)
>>> x.search()
1
>>> x.get_solution()
[0, 1]
>>> x.search()
1
>>> x.get_solution()
[2, 3]
>>> x.search()
1
>>> x.get_solution()
[4, 5]
>>> x.search()
0
```

There is also a method `reinitialize` to reinitialize the algorithm:

```
sage: x.reinitialize()
sage: x.search()
1
sage: x.get_solution()
[0, 1]
```

```
>>> from sage.all import *
>>> x.reinitialize()
>>> x.search()
```

(continues on next page)

(continued from previous page)

```
1
>>> x.get_solution()
[0, 1]
```

class sage.combinat.matrices.dancing_links.**dancing_linksWrapper**

Bases: object

A simple class that implements dancing links.

The main methods to list the solutions are *search()* and *get_solution()*. You can also use *number_of_solutions()* to count them.

This class simply wraps a C++ implementation of Carlo Hamalainen.

all_solutions(*ncpus=None*, *column=None*)

Return all solutions found after splitting the problem to allow parallel computation.

INPUT:

- ncpus – integer (default: None); maximal number of subprocesses to use at the same time. If None, it detects the number of effective CPUs in the system using sage.parallel.ncpus.ncpus().
- column – integer (default: None); the column used to split the problem, if None a random column is chosen

OUTPUT: list of solutions

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: S = d.all_solutions()
sage: sorted(sorted(s) for s in S)
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> S = d.all_solutions()
>>> sorted(sorted(s) for s in S)
[[0, 1], [2, 3], [4, 5]]
```

The number of CPUs can be specified as input:

```
sage: S = Subsets(range(4))
sage: rows = map(list, S)
sage: dlx = dlx_solver(rows)
sage: dlx
Dancing links solver for 4 columns and 16 rows
sage: dlx.number_of_solutions()
15
```

(continues on next page)

(continued from previous page)

```
sage: sorted(sorted(s) for s in dlx.all_solutions(ncpus=2))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

```
>>> from sage.all import *
>>> S = Subsets(range(Integer(4)))
>>> rows = map(list, S)
>>> dlx = dlx_solver(rows)
>>> dlx
Dancing links solver for 4 columns and 16 rows
>>> dlx.number_of_solutions()
15
>>> sorted(sorted(s) for s in dlx.all_solutions(ncpus=Integer(2)))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

If `ncpus=1`, the computation is not done in parallel:

```
sage: sorted(sorted(s) for s in dlx.all_solutions(ncpus=1))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
```

(continues on next page)

(continued from previous page)

```
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

```
>>> from sage.all import *
>>> sorted(sorted(s) for s in dlx.all_solutions(ncpus=Integer(1)))
[[1, 2, 3, 4],
 [1, 2, 10],
 [1, 3, 9],
 [1, 4, 8],
 [1, 14],
 [2, 3, 7],
 [2, 4, 6],
 [2, 13],
 [3, 4, 5],
 [3, 12],
 [4, 11],
 [5, 10],
 [6, 9],
 [7, 8],
 [15]]
```

get_solution()

Return the current solution.

After a new solution is found using the method *search()* this method return the rows that make up the current solution.

ncols()

Return the number of columns.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0], [3,4,5]]
sage: dlx = dlx_solver(rows)
sage: dlx.ncols()
6
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(1),Integer(2)],␣
↪[Integer(0)], [Integer(3),Integer(4),Integer(5)]]
>>> dlx = dlx_solver(rows)
>>> dlx.ncols()
6
```

nrows()

Return the number of rows.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0], [3,4,5]]
sage: dlx = dlx_solver(rows)
sage: dlx.nrows()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(1),Integer(2)],␣
↪[Integer(0)], [Integer(3),Integer(4),Integer(5)]]
>>> dlx = dlx_solver(rows)
>>> dlx.nrows()
4
```

number_of_solutions(*ncpus=None*, *column=None*)

Return the number of distinct solutions.

INPUT:

- `ncpus` – integer (default: `None`); maximal number of subprocesses to use at the same time. If `ncpus>1` the dancing links problem is split into independent subproblems to allow parallel computation. If `None`, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`.
- `column` – integer (default: `None`); the column used to split the problem, if `None` a random column is chosen (this argument is ignored if `ncpus` is `1`)

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows += [[0,2]]
sage: rows += [[1]]
sage: rows += [[3]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions()
2
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows += [[Integer(0),Integer(2)]]
>>> rows += [[Integer(1)]]
>>> rows += [[Integer(3)]]
>>> x = dlx_solver(rows)
>>> x.number_of_solutions()
2
```

The number of CPUs can be specified as input:

```
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions(ncpus=2, column=3)
3
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> x = dlx_solver(rows)
>>> x.number_of_solutions(ncpus=Integer(2), column=Integer(3))
3
```

```
sage: S = Subsets(range(5))
sage: rows = map(list, S)
sage: d = dlx_solver(rows)
sage: d.number_of_solutions()
52
```

```
>>> from sage.all import *
>>> S = Subsets(range(Integer(5)))
>>> rows = map(list, S)
>>> d = dlx_solver(rows)
>>> d.number_of_solutions()
52
```

one_solution(*ncpus=None*, *column=None*)

Return the first solution found.

This method allows parallel computations which might be useful for some kind of problems when it is very hard just to find one solution.

INPUT:

- `ncpus` – integer (default: `None`); maximal number of subprocesses to use at the same time. If `None`, it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`. If `ncpus=1`, the first solution is searched serially.
- `column` – integer (default: `None`); the column used to split the problem (see *`restrict()`*). If `None`, a random column is chosen. This argument is ignored if `ncpus=1`.

OUTPUT: list of rows or `None` if no solution is found

Note

For some case, increasing the number of cpus makes it faster. For other instances, `ncpus=1` is faster. It all depends on problem which is considered.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
```

(continues on next page)

(continued from previous page)

```
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: sorted(d.one_solution()) in solutions
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> solutions = [[Integer(0),Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4),Integer(5)]]
>>> sorted(d.one_solution()) in solutions
True
```

The number of CPUs can be specified as input:

```
sage: sorted(d.one_solution(ncpus=2)) in solutions
True
```

```
>>> from sage.all import *
>>> sorted(d.one_solution(ncpus=Integer(2))) in solutions
True
```

The column used to split the problem for parallel computations can be given:

```
sage: sorted(d.one_solution(ncpus=2, column=4)) in solutions
True
```

```
>>> from sage.all import *
>>> sorted(d.one_solution(ncpus=Integer(2), column=Integer(4))) in solutions
True
```

When no solution is found:

```
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution() is None
True
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(2),Integer(3),
↪Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3)]]
>>> d = dlx_solver(rows)
>>> d.one_solution() is None
True
```

one_solution_using_milp_solver(*solver=None*, *integrality_tolerance=0.001*)

Return a solution found using a MILP solver.

INPUT:

- `solver` – string or `None` (default: `None`); possible values include `'GLPK'`, `'GLPK/exact'`, `'Coin'`, `'CPLEX'`, `'Gurobi'`, `'CVXOPT'`, `'PPL'`, `'InteractiveLP'`

OUTPUT: list of rows or `None` if no solution is found

> **Note**
>
> When comparing the time taken by method `one_solution`, have in mind that `one_solution_using_milp_solver` first creates (and caches) the MILP solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: d.one_solution_using_milp_solver() in solutions                    #␣
↪needs sage.numerical.mip
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> solutions = [[Integer(0),Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4),Integer(5)]]
>>> d.one_solution_using_milp_solver() in solutions                    #␣
↪needs sage.numerical.mip
True
```

Using optional solvers:

```
sage: # optional - gurobi sage_numerical_backends_gurobi, needs sage.
↪numerical.mip
sage: s = d.one_solution_using_milp_solver('gurobi')
sage: s in solutions
True
```

```
>>> from sage.all import *
>>> # optional - gurobi sage_numerical_backends_gurobi, needs sage.numerical.
↪mip
>>> s = d.one_solution_using_milp_solver('gurobi')
>>> s in solutions
True
```

When no solution is found:

```
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
```

(continues on next page)

(continued from previous page)

```
sage: d.one_solution_using_milp_solver() is None                              #␣
↪needs sage.numerical.mip
True
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(2),Integer(3),
↪Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3)]]
>>> d = dlx_solver(rows)
>>> d.one_solution_using_milp_solver() is None                                #␣
↪needs sage.numerical.mip
True
```

one_solution_using_sat_solver(*solver=None*)

Return a solution found using a SAT solver.

INPUT:

- `solver` – string or `None` (default: `None`), possible values include `'picosat'`, `'cryptominisat'`, `'LP'`, `'glucose'`, `'glucose-syrup'`.

OUTPUT: list of rows or `None` if no solution is found

Note

When comparing the time taken by method `one_solution`, have in mind that `one_solution_using_sat_solver` first creates the SAT solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: d.one_solution_using_sat_solver() in solutions
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> solutions = [[Integer(0),Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4),Integer(5)]]
>>> d.one_solution_using_sat_solver() in solutions
True
```

Using optional solvers:

```
sage: s = d.one_solution_using_sat_solver('glucose')                    #␣
↪optional - glucose
sage: s in solutions                                                    #␣
↪optional - glucose
True
```

```
>>> from sage.all import *
>>> s = d.one_solution_using_sat_solver('glucose')                # optional -
↪ glucose
>>> s in solutions                                                # optional -
↪ glucose
True
```

When no solution is found:

```
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution_using_sat_solver() is None
True
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(2),Integer(3),
↪Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3)]]
>>> d = dlx_solver(rows)
>>> d.one_solution_using_sat_solver() is None
True
```

reinitialize()

Reinitialization of the search algorithm.

This recreates an empty `dancing_links` object and adds the rows to the instance of `dancing_links`.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> x = dlx_solver(rows)
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]
```

Reinitialization of the algorithm:

```
sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None
```

```
>>> from sage.all import *
>>> x.reinitialize()
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]
>>> x.get_solution() if x.search() else None
[4, 5]
>>> x.get_solution() if x.search() else None
```

Reinitialization works after solutions are exhausted:

```
sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None
```

```
>>> from sage.all import *
>>> x.reinitialize()
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]
>>> x.get_solution() if x.search() else None
[4, 5]
>>> x.get_solution() if x.search() else None
```

restrict(*indices*)

Return a dancing links solver solving the subcase which uses some given rows.

For every row that is wanted in the solution, we add a new column to the row to make sure it is in the solution.

INPUT:

- `indices` – list; row indices to be found in the solution

OUTPUT: dancing links solver

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> d
Dancing links solver for 6 columns and 6 rows
>>> sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

To impose that the 0-th row is part of the solution, the rows of the new problem are:

```
sage: d_using_0 = d.restrict([0])
sage: d_using_0
Dancing links solver for 7 columns and 6 rows
sage: d_using_0.rows()
[[0, 1, 2, 6], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

```
>>> from sage.all import *
>>> d_using_0 = d.restrict([Integer(0)])
>>> d_using_0
Dancing links solver for 7 columns and 6 rows
>>> d_using_0.rows()
[[0, 1, 2, 6], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

After restriction the subproblem has one more columns and the same number of rows as the original one:

```
sage: d.restrict([1]).rows()
[[0, 1, 2], [3, 4, 5, 6], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
sage: d.restrict([2]).rows()
[[0, 1, 2], [3, 4, 5], [0, 1, 6], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

```
>>> from sage.all import *
>>> d.restrict([Integer(1)]).rows()
[[0, 1, 2], [3, 4, 5, 6], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
>>> d.restrict([Integer(2)]).rows()
[[0, 1, 2], [3, 4, 5], [0, 1, 6], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

This method allows to find solutions where the 0-th row is part of a solution:

```
sage: sorted(map(sorted, d.restrict([0]).solutions_iterator()))
[[0, 1]]
```

```
>>> from sage.all import *
>>> sorted(map(sorted, d.restrict([Integer(0)]).solutions_iterator()))
[[0, 1]]
```

Some other examples:

```
sage: sorted(map(sorted, d.restrict([1]).solutions_iterator()))
[[0, 1]]
sage: sorted(map(sorted, d.restrict([2]).solutions_iterator()))
[[2, 3]]
sage: sorted(map(sorted, d.restrict([3]).solutions_iterator()))
[[2, 3]]
```

```
>>> from sage.all import *
>>> sorted(map(sorted, d.restrict([Integer(1)]).solutions_iterator()))
[[0, 1]]
>>> sorted(map(sorted, d.restrict([Integer(2)]).solutions_iterator()))
[[2, 3]]
>>> sorted(map(sorted, d.restrict([Integer(3)]).solutions_iterator()))
[[2, 3]]
```

Here there are no solutions using both 0th and 3rd row:

```
sage: list(d.restrict([0,3]).solutions_iterator())
[]
```

```
>>> from sage.all import *
>>> list(d.restrict([Integer(0),Integer(3)]).solutions_iterator())
[]
```

rows()

Return the list of rows.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0]]
sage: x = dlx_solver(rows)
sage: x.rows()
[[0, 1, 2], [1, 2], [0]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(1),Integer(2)],␣
↪[Integer(0)]]
>>> x = dlx_solver(rows)
>>> x.rows()
[[0, 1, 2], [1, 2], [0]]
```

search()

Search for a new solution.

Return `1` if a new solution is found and `0` otherwise. To recover the solution, use the method *get_solution()*.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows+= [[Integer(0),Integer(2)]]
>>> rows+= [[Integer(1)]]
>>> rows+= [[Integer(3)]]
>>> x = dlx_solver(rows)
>>> print(x.search())
1
>>> print(x.get_solution())
[3, 0]
```

solutions_iterator()

Return an iterator of the solutions.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
...Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
...Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
...Integer(5)]]
>>> d = dlx_solver(rows)
>>> sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

split(*column*)

Return a dict of independent solvers.

For each `i`-th row containing a `1` in the `column`, the dict associates the solver giving all solution using the `i`-th row.

This is used for parallel computations.

INPUT:

- `column` – integer; the column used to split the problem into independent subproblems

OUTPUT: dict where keys are row numbers and values are dlx solvers

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
↪Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
↪Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)]]
>>> d = dlx_solver(rows)
>>> d
Dancing links solver for 6 columns and 6 rows
>>> sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

After the split each subproblem has one more column and the same number of rows as the original problem:

```
sage: D = d.split(0)
sage: D
{0: Dancing links solver for 7 columns and 6 rows,
 2: Dancing links solver for 7 columns and 6 rows,
 4: Dancing links solver for 7 columns and 6 rows}
```

```
>>> from sage.all import *
>>> D = d.split(Integer(0))
>>> D
{0: Dancing links solver for 7 columns and 6 rows,
 2: Dancing links solver for 7 columns and 6 rows,
 4: Dancing links solver for 7 columns and 6 rows}
```

The (disjoint) union of the solutions of the subproblems is equal to the set of solutions shown above:

```
sage: for x in D.values(): sorted(map(sorted, x.solutions_iterator()))
[[0, 1]]
[[2, 3]]
[[4, 5]]
```

```
>>> from sage.all import *
>>> for x in D.values(): sorted(map(sorted, x.solutions_iterator()))
[[0, 1]]
[[2, 3]]
[[4, 5]]
```

to_milp(*solver=None*)

Return the mixed integer linear program (MILP) representing an equivalent problem.

See also `sage.numerical.mip.MixedIntegerLinearProgram`.

INPUT:

- `solver` – string or `None` (default: `None`); possible values include `'GLPK'`, `'GLPK/exact'`, `'Coin'`, `'CPLEX'`, `'Gurobi'`, `'CVXOPT'`, `'PPL'`, `'InteractiveLP'`

OUTPUT:

- MixedIntegerLinearProgram instance
- MIPVariable with binary components

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
sage: d = dlx_solver(rows)
sage: p,x = d.to_milp()                                                    #␣
↪needs sage.numerical.mip
sage: p                                                                    #␣
↪needs sage.numerical.mip
Boolean Program (no objective, 4 variables, ... constraints)
sage: x                                                                    #␣
↪needs sage.numerical.mip
MIPVariable with 4 binary components
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(0),Integer(2)],␣
↪[Integer(1)], [Integer(3)]]
>>> d = dlx_solver(rows)
>>> p,x = d.to_milp()                                                      #␣
↪needs sage.numerical.mip
>>> p                                                                      #␣
↪needs sage.numerical.mip
Boolean Program (no objective, 4 variables, ... constraints)
>>> x                                                                      #␣
↪needs sage.numerical.mip
MIPVariable with 4 binary components
```

In the reduction, the boolean variable x_i is `True` if and only if the i-th row is in the solution:

```
sage: p.show()                                                             #␣
↪needs sage.numerical.mip
Constraints:...
  one 1 in 0-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 1-th column: 1.0 <= x_0 + x_2 <= 1.0
  one 1 in 2-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 3-th column: 1.0 <= x_3 <= 1.0
Variables:
  x_0 is a... variable (min=0.0, max=1.0)
  x_1 is a... variable (min=0.0, max=1.0)
```

(continues on next page)

(continued from previous page)

```
  x_2 is a... variable (min=0.0, max=1.0)
  x_3 is a... variable (min=0.0, max=1.0)
```

```
>>> from sage.all import *
>>> p.show()                                                              #␣
↪needs sage.numerical.mip
Constraints:...
  one 1 in 0-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 1-th column: 1.0 <= x_0 + x_2 <= 1.0
  one 1 in 2-th column: 1.0 <= x_0 + x_1 <= 1.0
  one 1 in 3-th column: 1.0 <= x_3 <= 1.0
Variables:
  x_0 is a... variable (min=0.0, max=1.0)
  x_1 is a... variable (min=0.0, max=1.0)
  x_2 is a... variable (min=0.0, max=1.0)
  x_3 is a... variable (min=0.0, max=1.0)
```

Using some optional MILP solvers:

```
sage: d.to_milp('gurobi')           # optional - gurobi sage_numerical_
↪backends_gurobi, needs sage.numerical.mip
(Boolean Program (no objective, 4 variables, 4 constraints),
 MIPVariable with 4 binary components)
```

```
>>> from sage.all import *
>>> d.to_milp('gurobi')           # optional - gurobi sage_numerical_backends_
↪gurobi, needs sage.numerical.mip
(Boolean Program (no objective, 4 variables, 4 constraints),
 MIPVariable with 4 binary components)
```

to_sat_solver(*solver=None*)

Return the SAT solver solving an equivalent problem.

Note that row index i in the dancing links solver corresponds to the boolean variable index $i + 1$ for the SAT solver to avoid the variable index 0.

See also `sage.sat.solvers.satsolver`.

INPUT:

- `solver` – string or `None` (default: `None`), possible values include `'picosat'`, `'cryptominisat'`, `'LP'`, `'glucose'`, `'glucose-syrup'`.

OUTPUT: SAT solver instance

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
sage: x = dlx_solver(rows)
sage: s = x.to_sat_solver()
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
```

(continues on next page)

(continued from previous page)

```
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(0),Integer(2)],␣
↪[Integer(1)], [Integer(3)]]
>>> x = dlx_solver(rows)
>>> s = x.to_sat_solver()
```

Using some optional SAT solvers:

```
sage: x.to_sat_solver('cryptominisat')      # optional - pycryptosat
CryptoMiniSat solver: 4 variables, 7 clauses.
```

```
>>> from sage.all import *
>>> x.to_sat_solver('cryptominisat')      # optional - pycryptosat
CryptoMiniSat solver: 4 variables, 7 clauses.
```

sage.combinat.matrices.dancing_links.**dlx_solver**(*rows*)

Internal-use wrapper for the dancing links C++ code.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 1, 2]
sage: print(x.search())
0
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows+= [[Integer(0),Integer(2)]]
>>> rows+= [[Integer(1)]]
>>> rows+= [[Integer(3)]]
>>> x = dlx_solver(rows)
>>> print(x.search())
1
>>> print(x.get_solution())
[3, 0]
>>> print(x.search())
1
>>> print(x.get_solution())
[3, 1, 2]
>>> print(x.search())
```

(continues on next page)

(continued from previous page)

```
0
```

sage.combinat.matrices.dancing_links.**make_dlxwrapper**(*s*)

Create a dlx wrapper from a Python *string* s.

This was historically used in unpickling and is kept for backwards compatibility. We expect s to be `dumps(rows)` where rows is the list of rows used to instantiate the object.

Dancing links C++ wrapper

sage.combinat.matrices.dlxcpp.**AllExactCovers**(*M*)

Solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES: No exact covers:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])                                    #␣
↪needs sage.modules
sage: [cover for cover in AllExactCovers(M)]                                   #␣
↪needs sage.modules
[]
```

```
>>> from sage.all import *
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(1),Integer(1)]])                               ␣
↪     # needs sage.modules
>>> [cover for cover in AllExactCovers(M)]                                     #␣
↪needs sage.modules
[]
```

Two exact covers:

```
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])                            #␣
↪needs sage.modules
sage: [cover for cover in AllExactCovers(M)]                                   #␣
↪needs sage.modules
[[(1, 1, 0), (0, 0, 1)], [(1, 0, 1), (0, 1, 0)]]
```

```
>>> from sage.all import *
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
↪Integer(1)],[Integer(0),Integer(0),Integer(1)],[Integer(0),Integer(1),
↪Integer(0)]])                                  # needs sage.modules
>>> [cover for cover in AllExactCovers(M)]                                     #␣
↪needs sage.modules
[[(1, 1, 0), (0, 0, 1)], [(1, 0, 1), (0, 1, 0)]]
```

sage.combinat.matrices.dlxcpp.**DLXCPP**(*rows*)

Solve the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix M with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1s.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form:

```
[
 [i_11,i_12,...,i_1r]
 ...
 [i_m1,i_m2,...,i_ms]
]
```

where M[j][i_jk] = 1.

The first example below corresponds to the matrix:

```
1110
1010
0100
0001
```

which is exactly covered by:

```
1110
0001
```

and

```
1010
0100
0001
```

If soln is a solution given by DLXCPP(rows) then

[rows[soln[0]], rows[soln[1]], … rows[soln[len(soln)-1]]]

is an exact cover.

Solutions are given as a list.

EXAMPLES:

```
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: [x for x in DLXCPP(rows)]
[[3, 0], [3, 1, 2]]
```

```
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows+= [[Integer(0),Integer(2)]]
>>> rows+= [[Integer(1)]]
>>> rows+= [[Integer(3)]]
>>> [x for x in DLXCPP(rows)]
[[3, 0], [3, 1, 2]]
```

sage.combinat.matrices.dlxcpp.**OneExactCover**(*M*)

Solve the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```
sage: # needs sage.modules
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])  # no exact covers
sage: print(OneExactCover(M))
None
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) # two exact covers
sage: OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
...Integer(1)],[Integer(0),Integer(1),Integer(1)]])  # no exact covers
>>> print(OneExactCover(M))
None
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),

Hadamard matrices

A Hadamard matrix is an $n \times n$ matrix H whose entries are either $+1$ or -1 and whose rows are mutually orthogonal. For example, the matrix H_2 defined by

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

is a Hadamard matrix. An $n \times n$ matrix H whose entries are either $+1$ or -1 is a Hadamard matrix if and only if:

(a) $|det(H)| = n^{n/2}$ or

(b) $H * H^t = n \cdot I_n$, where I_n is the identity matrix.

In general, the tensor product of an $m \times m$ Hadamard matrix and an $n \times n$ Hadamard matrix is an $(mn) \times (mn)$ matrix. In particular, if there is an $n \times n$ Hadamard matrix then there is a $(2n) \times (2n)$ Hadamard matrix (since one may tensor with H_2). This particular case is sometimes called the Sylvester construction.

The Hadamard conjecture (possibly due to Paley) states that a Hadamard matrix of order n exists if and only if $n = 1, 2$ or n is a multiple of 4.

The module below implements constructions of Hadamard and skew Hadamard matrices for all known orders ≤ 1200, plus some more greater than 1200. It also allows you to pull a Hadamard matrix from the database at [SloaHada].

The following code will test that a construction for all known orders $\leq 4k$ is implemented. The assertion above can be verified by setting `k=300` (note that it will take a long time to run):

```
sage: from sage.combinat.matrices.hadamard_matrix import (hadamard_matrix,
....:                                 skew_hadamard_matrix, is_hadamard_matrix,
....:                                 is_skew_hadamard_matrix)
sage: k = 20
sage: unknown_hadamard = [668, 716, 892, 1132]
sage: unknown_skew_hadamard = [356, 404, 428, 476, 596, 612, 668, 708, 712, 716,
....:                          764, 772, 804, 808, 820, 836, 856, 892, 900, 916,
....:                          932, 940, 952, 980, 996, 1004, 1012, 1028, 1036,
....:                          1044, 1060, 1076, 1100, 1108, 1132, 1140, 1148,
```

(continues on next page)

(continued from previous page)

```
....:                          1156, 1180, 1192, 1196]
sage: for n in range(1, k+1):
....:     if 4*n not in unknown_hadamard:
....:         H = hadamard_matrix(4*n, check=False)
....:         assert is_hadamard_matrix(H)
....:     if 4*n not in unknown_skew_hadamard:
....:         H = skew_hadamard_matrix(4*n, check=False)
....:         assert is_skew_hadamard_matrix(H)
```

```

sage.combinat.matrices.hadamard_matrix.**GS_skew_hadamard_smallcases**(*n*, *existence=False*, *check=True*)

Data for Williamson-Goethals-Seidel construction of skew Hadamard matrices.

Here we keep the data for this construction. Namely, it needs 4 circulant matrices with extra properties, as described in *sage.combinat.matrices.hadamard_matrix.williamson_goethals_seidel_skew_hadamard_matrix()* Matrices are taken from:

- $n = 36, 52$: [GS70s]
- $n = 92$: [Wall71]
- $n = 188$: [Djo2008a]
- $n = 236$: [FKS2004]
- $n = 276$: [Djo2023a]

Additional data is obtained from skew supplementary difference sets contained in *sage.combinat.designs.difference_family.skew_supplementary_difference_set()*, using the construction described in [Djo1992a].

INPUT:

- `n` – integer; the order of the matrix
- `existence` – boolean (default: `True`); if `True`, only check that we can do the construction
- `check` – boolean (default: `False`); if `True`, check the result

sage.combinat.matrices.hadamard_matrix.**RSHCD_324**(*e*)

Return a size 324x324 Regular Symmetric Hadamard Matrix with Constant Diagonal.

We build the matrix M for the case $n = 324$, $\epsilon = 1$ directly from `JankoKharaghaniTonchevGraph` and for the case $\epsilon = -1$ from the "twist" M' of M, using Lemma 11 in [HX2010]. Namely, it turns out that the matrix

$$M' = \begin{pmatrix} M_{12} & M_{11} \\ M_{11}^\top & M_{21} \end{pmatrix}, \quad \text{where} \quad M = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix},$$

and the M_{ij} are 162x162-blocks, also RSHCD, its diagonal blocks having zero row sums, as needed by [loc.cit.]. Interestingly, the corresponding $(324, 152, 70, 72)$-strongly regular graph has a vertex-transitive automorphism group of order 2592, twice the order of the (intransitive) automorphism group of the graph corresponding to M. Cf. [CP2016].

INPUT:

- `e` – -1 or $+1$; the value of ϵ

REFERENCE:

- [CP2016]

sage.combinat.matrices.hadamard_matrix.**amicable_hadamard_matrices**(*n*, *existence=False*, *check=True*)

Construct amicable Hadamard matrices of order `n` using the available methods.

INPUT:

- `n` – positive integer; the order of the amicable Hadamard matrices
- `existence` – boolean (default: `False`); if `True`, only return whether amicable Hadamard matrices of order n can be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrices are amicable Hadamard matrices before returning them

OUTPUT:

If `existence` is true, the function returns a boolean representing whether amicable Hadamard matrices of order n can be constructed. If `existence` is false, returns two amicable Hadamard matrices, or raises an error if the matrices cannot be constructed.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_
↪matrices
sage: amicable_hadamard_matrices(2)
(
[ 1  1]  [ 1  1]
[-1  1], [ 1 -1]
)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices
>>> amicable_hadamard_matrices(Integer(2))
(
[ 1  1]  [ 1  1]
[-1  1], [ 1 -1]
)
```

If `existence` is true, the function returns a boolean:

```
sage: amicable_hadamard_matrices(16, existence=True)
False
```

```
>>> from sage.all import *
>>> amicable_hadamard_matrices(Integer(16), existence=True)
False
```

sage.combinat.matrices.hadamard_matrix.**amicable_hadamard_matrices_wallis**(*n*, *check=True*)

Construct amicable Hadamard matrices of order $n = q + 1$ where q is a prime power.

If q is a prime power $\equiv 3 \mod 4$, then amicable Hadamard matrices of order $q+1$ can be constructed as described in [Wal1970b].

INPUT:

- `n` – integer; the order of the matrices to be constructed
- `check` – boolean (default: `True`); if `True`, check that the resulting matrices are amicable Hadamard before returning them

OUTPUT:

The function returns two amicable Hadamard matrices, or raises an error if such matrices cannot be created using this construction.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_
↪matrices_wallis
sage: M, N = amicable_hadamard_matrices_wallis(28)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices_
↪wallis
>>> M, N = amicable_hadamard_matrices_wallis(Integer(28))
```

sage.combinat.matrices.hadamard_matrix.**are_amicable_hadamard_matrices**(*M*, *N*, *verbose=False*)

Check if `M` and `N` are amicable Hadamard matrices.

Two matrices M and N of order n are called amicable if they satisfy the following conditions (see [Seb2017]):

- M is a skew Hadamard matrix
- N is a symmetric Hadamard matrix
- $MN^T = NM^T$

INPUT:

- `M` – a square matrix
- `N` – a square matrix
- `verbose` – boolean (default: `False`); whether to be verbose when the matrices are not amicable Hadamard matrices

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import are_amicable_hadamard_
↪matrices
sage: M = matrix([[1, 1], [-1, 1]])
sage: N = matrix([[1, 1], [1, -1]])
sage: are_amicable_hadamard_matrices(M, N)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import are_amicable_hadamard_
↪matrices
>>> M = matrix([[Integer(1), Integer(1)], [-Integer(1), Integer(1)]])
>>> N = matrix([[Integer(1), Integer(1)], [Integer(1), -Integer(1)]])
>>> are_amicable_hadamard_matrices(M, N)
True
```

If `verbose` is true, the function will be verbose when returning False:

```
sage: N = matrix([[1, 1], [1, 1]])
sage: are_amicable_hadamard_matrices(M, N, verbose=True)
The second matrix is not Hadamard
False
```

```
>>> from sage.all import *
>>> N = matrix([[Integer(1), Integer(1)], [Integer(1), Integer(1)]])
>>> are_amicable_hadamard_matrices(M, N, verbose=True)
The second matrix is not Hadamard
False
```

sage.combinat.matrices.hadamard_matrix.**construction_four_symbol_delta_code_I**(X, Y, Z, W)

Construct 4-symbol δ code of length $2n + 1$.

The 4-symbol δ code is constructed from sequences X, Y, Z, W of length $n + 1$, $n + 1$, n, n satisfying for all $s > 0$:

$$N_X(s) + N_Y(s) + N_Z(s) + N_W(s) = 0$$

where $N_A(s)$ is the nonperiodic correlation function:

$$N_A(s) = \sum_{i=1}^{n-s} a_i a_{i+s}$$

The construction (detailed in [Tur1974]) is as follows:

$$T_1 = X; Z$$
$$T_2 = X; -Z$$
$$T_3 = Y; W$$
$$T_4 = Y; -W$$

INPUT:

- X – list; the first sequence (length $n + 1$)
- Y – list; the second sequence (length $n + 1$)
- Z – list; the third sequence (length n)
- W – list; the fourth sequence (length n)

OUTPUT: tuple containing the 4-symbol δ code of length $2n + 1$

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_
↪delta_code_I
sage: construction_four_symbol_delta_code_I([1, 1], [1, -1], [1], [1])
([1, 1, 1], [1, 1, -1], [1, -1, 1], [1, -1, -1])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_
↪delta_code_I
>>> construction_four_symbol_delta_code_I([Integer(1), Integer(1)], [Integer(1), -
↪Integer(1)], [Integer(1)], [Integer(1)])
([1, 1, 1], [1, 1, -1], [1, -1, 1], [1, -1, -1])
```

sage.combinat.matrices.hadamard_matrix.**construction_four_symbol_delta_code_II**(*X*, *Y*, *Z*, *W*)

Construct 4-symbol δ code of length $4n + 3$.

The 4-symbol δ code is constructed from sequences X, Y, Z, W of length $n + 1$, $n + 1$, n, n satisfying for all $s > 0$:

$$N_X(s) + N_Y(s) + N_Z(s) + N_W(s) = 0$$

where $N_A(s)$ is the nonperiodic correlation function:

$$N_A(s) = \sum_{i=1}^{n-s} a_i a_{i+s}$$

The construction (detailed in [Tur1974]) is as follows (writing A/B to mean A alternated with B):

$$T_1 = X/Z; Y/W; 1$$
$$T_2 = X/Z; Y/-W; -1$$
$$T_3 = X/Z; -Y/-W; 1$$
$$T_4 = X/Z; -Y/W; -1$$

INPUT:

- X – list; the first sequence (length $n + 1$)

- Y – list; the second sequence (length $n+1$)
- Z – list; the third sequence (length n)
- W – list; the fourth sequence (length n)

OUTPUT: tuple containing the four 4-symbol δ code of length $4n+3$

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_
↪delta_code_II
sage: construction_four_symbol_delta_code_II([1, 1], [1, -1], [1], [1])
([1, 1, 1, 1, 1, -1, 1],
 [1, 1, 1, 1, -1, -1, -1],
 [1, 1, 1, -1, -1, 1, 1],
 [1, 1, 1, -1, 1, 1, -1])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_
↪delta_code_II
>>> construction_four_symbol_delta_code_II([Integer(1), Integer(1)], [Integer(1),␣
↪-Integer(1)], [Integer(1)], [Integer(1)])
([1, 1, 1, 1, 1, -1, 1],
 [1, 1, 1, 1, -1, -1, -1],
 [1, 1, 1, -1, -1, 1, 1],
 [1, 1, 1, -1, 1, 1, -1])
```

sage.combinat.matrices.hadamard_matrix.**four_symbol_delta_code_smallcases**(*n*, *existence=False*)

Return the 4-symobl δ code of length n if available.

The 4-symbol δ codes are constructed using *construction_four_symbol_delta_code_I()* or *construction_four_symbol_delta_code_II()*. The base sequences used are taken from [Tur1974].

INPUT:

- n – integer; the length of the desired 4-symbol δ code
- existence – boolean (default: False); if True, only check if the sequences are available

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import four_symbol_delta_code_
↪smallcases
sage: four_symbol_delta_code_smallcases(3)
([1, -1, 1], [1, -1, -1], [1, 1, 1], [1, 1, -1])
sage: four_symbol_delta_code_smallcases(3, existence=True)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import four_symbol_delta_code_
↪smallcases
>>> four_symbol_delta_code_smallcases(Integer(3))
([1, -1, 1], [1, -1, -1], [1, 1, 1], [1, 1, -1])
>>> four_symbol_delta_code_smallcases(Integer(3), existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix**(*n*, *existence=False*, *check=True*, *construction_name=False*)

This function is available as hadamard_matrix(...) and matrix.hadamard(...).

Try to construct a Hadamard matrix using the available methods.

Currently all orders ≤ 1200 for which a construction is known are implemented. For $n > 1200$, only some orders are available.

INPUT:

- `n` – integer; dimension of the matrix
- `existence` – boolean (default: `False`); whether to build the matrix or merely query if a construction is available in Sage. When set to `True`, the function returns:
  - `True` – meaning that Sage knows how to build the matrix
  - `Unknown` – meaning that Sage does not know how to build the matrix, although the matrix may exist (see `sage.misc.unknown`).
  - `False` – meaning that the matrix does not exist
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `construction_name` – boolean (default: `False`); if it is `True`, `existence` is `True`, and a matrix exists, output the construction name. It has no effect if `existence` is set to `False`.

EXAMPLES:

```
sage: hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
sage: hadamard_matrix(1)
[1]
sage: hadamard_matrix(2)
[ 1  1]
[ 1 -1]
sage: hadamard_matrix(8) # random
[ 1  1  1  1  1  1  1  1]
[ 1 -1  1 -1  1 -1  1 -1]
[ 1  1 -1 -1  1  1 -1 -1]
[ 1 -1 -1  1  1 -1 -1  1]
[ 1  1  1  1 -1 -1 -1 -1]
[ 1 -1  1 -1 -1  1 -1  1]
[ 1  1 -1 -1 -1 -1  1  1]
[ 1 -1 -1  1 -1  1  1 -1]
sage: hadamard_matrix(8).det() == 8^4
True
```

```
>>> from sage.all import *
>>> hadamard_matrix(Integer(12)).det()
2985984
>>> Integer(12)**Integer(6)
2985984
>>> hadamard_matrix(Integer(1))
```

(continues on next page)

(continued from previous page)

```
[1]
>>> hadamard_matrix(Integer(2))
[ 1  1]
[ 1 -1]
>>> hadamard_matrix(Integer(8)) # random
[ 1  1  1  1  1  1  1  1]
[ 1 -1  1 -1  1 -1  1 -1]
[ 1  1 -1 -1  1  1 -1 -1]
[ 1 -1 -1  1  1 -1 -1  1]
[ 1  1  1  1 -1 -1 -1 -1]
[ 1 -1  1 -1 -1  1 -1  1]
[ 1  1 -1 -1 -1 -1  1  1]
[ 1 -1 -1  1 -1  1  1 -1]
>>> hadamard_matrix(Integer(8)).det() == Integer(8)**Integer(4)
True
```

We note that *hadamard_matrix()* returns a normalised Hadamard matrix (the entries in the first row and column are all +1)

```
sage: hadamard_matrix(12) # random
[ 1  1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1 -1|-1  1|-1  1|-1  1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1 -1| 1  1|-1 -1|-1 -1| 1  1]
[ 1  1|-1 -1| 1 -1|-1  1|-1  1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1| 1 -1| 1  1|-1 -1|-1 -1]

```
[ 1 -1|-1 -1|-1 -1| 1  1| 1 -1| 1  1]
[ 1  1|-1  1|-1  1| 1 -1|-1 -1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1|-1 -1|-1 -1| 1  1| 1 -1]
[ 1  1| 1 -1|-1  1|-1  1| 1 -1|-1 -1]
```

To find how the matrix is obtained, use `construction_name`

```
sage: matrix.hadamard(476, existence=True, construction_name=True)
'cooper-wallis small cases: 476'
```

```
>>> from sage.all import *
>>> matrix.hadamard(Integer(476), existence=True, construction_name=True)
'cooper-wallis small cases: 476'
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_156**()

Construct a Hadamard matrix of order 156.

The matrix is created using the construction detailed in [BH1965]. This uses four circulant matrices of size 13×13, which are composed into a 156×156 block matrix.

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_cooper_wallis_construction**(*x1*, *x2*, *x3*, *x4*, *A*, *B*, *C*, *D*, *check=True*)

Create a Hadamard matrix using the construction detailed in [CW1972].

Given four circulant matrices X_1, X_2, X_3, X_4` of order n with entries (0, 1, -1) such that the entrywise product of two distinct matrices is always equal to 0 and that $\sum_{i=1}^{4} X_i X_i^\top = nI_n$ holds, and four matrices A, B, C, D of order m with elements (1, -1) such that $MN^\top = NM^\top$ for all distinct M, N and $AA^\top + BB^\top + CC^\top + DD^\top = 4mI_n$ holds, we construct a Hadamard matrix of order $4nm$.

INPUT:

- `x1` – list or vector; the first row of the circulant matrix X_1
- `x2` – list or vector; the first row of the circulant matrix X_2
- `x3` – list or vector; the first row of the circulant matrix X_3
- `x4` – list or vector; the first row of the circulant matrix X_4
- `A` – the matrix described above
- `B` – the matrix described above
- `C` – the matrix described above
- `D` – the matrix described above
- `check` – boolean (default: `True`); if `True`, check that the resulting matrix is Hadamard before returning it

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_
↪wallis_construction
sage: from sage.combinat.t_sequences import T_sequences_smallcases
```

(continues on next page)

(continued from previous page)

```
sage: seqs = T_sequences_smallcases(19)
sage: hadamard_matrix_cooper_wallis_construction(seqs[0], seqs[1], seqs[2],␣
↪seqs[3], matrix([1]), matrix([1]), matrix([1]), matrix([1]))
76 x 76 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_
↪wallis_construction
>>> from sage.combinat.t_sequences import T_sequences_smallcases
>>> seqs = T_sequences_smallcases(Integer(19))
>>> hadamard_matrix_cooper_wallis_construction(seqs[Integer(0)], seqs[Integer(1)],
↪ seqs[Integer(2)], seqs[Integer(3)], matrix([Integer(1)]), matrix([Integer(1)]),
↪ matrix([Integer(1)]), matrix([Integer(1)]))
76 x 76 dense matrix over Integer Ring...
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_cooper_wallis_smallcases**(*n*, *check=True*, *existence=False*)

Construct Hadamard matrices using the Cooper-Wallis construction for some small values of n.

This function calls the function *hadamard_matrix_cooper_wallis_construction()* with the appropriate arguments. It constructs the matrices X_1, X_2, X_3, X_4 using either T-matrices or the T-sequences from *sage.combinat.t_sequences.T_sequences_smallcases()*. The matrices A, B, C, D are taken from *williamson_type_quadruples_smallcases()*.

Data for T-matrices of order 67 is taken from [Saw1985].

INPUT:

- `n` – integer; the order of the matrix to be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard matrix before returning
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists

OUTPUT:

If `existence=False`, returns the Hadamard matrix of order n. It raises an error if no data is available to construct the matrix of the given order. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

See also

hadamard_matrix_cooper_wallis_construction()

EXAMPLES:

By default The function returns the Hadamard matrix

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_
↪wallis_smallcases
sage: hadamard_matrix_cooper_wallis_smallcases(28)
28 x 28 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_
↪wallis_smallcases
>>> hadamard_matrix_cooper_wallis_smallcases(Integer(28))
28 x 28 dense matrix over Integer Ring...
```

If `existence` is set to True, the function returns a boolean

```
sage: hadamard_matrix_cooper_wallis_smallcases(20, existence=True)
True
```

```
>>> from sage.all import *
>>> hadamard_matrix_cooper_wallis_smallcases(Integer(20), existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_from_sds**(*n*, *existence=False*, *check=True*)

Construction of Hadamard matrices from supplementary difference sets.

Given four SDS with parameters $4-\{n;n_1,n_2,n_3,n_4;\lambda\}$ with $n_1+n_2+n_3+n_4=n+\lambda$ we can construct four (-1,+1) sequences $a_i=(a_{i,0},...,a_{i,n-1})$ where $a_{i,j}=-1$ iff $j\in S_i$. These will be the fist rows of four circulant matrices A_1,A_2,A_3,A_4 which, when plugged into the Goethals-Seidel array, create an Hadamard matrix of order $4n$ (see [Djo1994b]).

The supplementary difference sets are taken from *sage.combinat.designs.difference_family.supplementary_difference_set_hadamard()*.

INPUT:

- `n` – integer; the order of the matrix to be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard before returning
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists

OUTPUT:

If `existence=False`, returns the Hadamard matrix of order n. It raises an error if no data is available to construct the matrix of the given order, or if n is not a multiple of 4. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

By default The function returns the Hadamard matrix

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_from_sds
sage: hadamard_matrix_from_sds(148)
148 x 148 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_from_sds
>>> hadamard_matrix_from_sds(Integer(148))
148 x 148 dense matrix over Integer Ring...
```

If `existence` is set to True, the function returns a boolean

```
sage: hadamard_matrix_from_sds(764, existence=True)
True
```

```
>>> from sage.all import *
>>> hadamard_matrix_from_sds(Integer(764), existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_from_symmetric_conference_matrix**(*n*, *existence=False*, *check=True*)

Construct a Hadamard matrix of order n from a symmetric conference matrix of order $n/2$.

The construction is described in Theorem 4.3.24 of [IS2006]. The symmetric conference matrices are obtained from *sage.combinat.matrices.hadamard_matrix.symmetric_conference_matrix()*.

INPUT:

- `n` – integer; the order of the matrix to be constructed
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard before returning

OUTPUT:

If `existence=False`, returns the Hadamard matrix of order n. It raises an error if no data is available to construct the matrix of the given order, or if n does not satisfies the constraints. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

By default the function returns the Hadamard matrix

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_from_
↪symmetric_conference_matrix
sage: hadamard_matrix_from_symmetric_conference_matrix(20)
20 x 20 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_from_
↪symmetric_conference_matrix
>>> hadamard_matrix_from_symmetric_conference_matrix(Integer(20))
20 x 20 dense matrix over Integer Ring...
```

If `existence` is set to True, the function returns True if the matrix exists, False if the conference matrix does not exist, and Unknown if the conference matrix cannot be constructed yet

```
sage: hadamard_matrix_from_symmetric_conference_matrix(12, existence=True)
True
sage: hadamard_matrix_from_symmetric_conference_matrix(4*787, existence=True)
True
```

```
>>> from sage.all import *
>>> hadamard_matrix_from_symmetric_conference_matrix(Integer(12), existence=True)
True
>>> hadamard_matrix_from_symmetric_conference_matrix(Integer(4)*Integer(787),␣
↪existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_miyamoto_construction**(*n*, *existence=False*, *check=True*)

Construct Hadamard matrix using the Miyamoto construction.

If $q = n/4$ is a prime power, and there exists a Hadamard matrix of order $q-1$, then a Hadamard matrix of order n can be constructed (see [Miy1991]).

INPUT:

- `n` – integer; the order of the matrix to be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard before returning
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists

OUTPUT:

If `existence=False`, returns the Hadamard matrix of order n. It raises an error if no data is available to construct the matrix of the given order, or if n does not satisfies the constraints. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

By default the function returns the Hadamard matrix

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_miyamoto_
↪construction
sage: hadamard_matrix_miyamoto_construction(20)
20 x 20 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_miyamoto_
↪construction
>>> hadamard_matrix_miyamoto_construction(Integer(20))
20 x 20 dense matrix over Integer Ring...
```

If `existence` is set to True, the function returns a boolean

```
sage: hadamard_matrix_miyamoto_construction(36, existence=True)
True
```

```
>>> from sage.all import *
>>> hadamard_matrix_miyamoto_construction(Integer(36), existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_paleyI**(*n*, *normalize=True*)

Implement the Paley type I construction.

The Paley type I case corresponds to the case $p = n - 1 \cong 3 \mod 4$ for a prime power p (see [Hora]).

INPUT:

- `n` – the matrix size
- `normalize` – boolean (default: `True`); whether to normalize the result

EXAMPLES:

We note that this method by default returns a normalised Hadamard matrix

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_paleyI
sage: hadamard_matrix_paleyI(4)
[ 1  1  1  1]
[ 1 -1  1 -1]
[ 1 -1 -1  1]
[ 1  1 -1 -1]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_paleyI
>>> hadamard_matrix_paleyI(Integer(4))
[ 1  1  1  1]
[ 1 -1  1 -1]
[ 1 -1 -1  1]
[ 1  1 -1 -1]
```

Otherwise, it returns a skew Hadamard matrix H, i.e. $H = S + I$, with $S = -S^\top$

```
sage: M = hadamard_matrix_paleyI(4, normalize=False); M
[ 1  1  1  1]
[-1  1  1 -1]
[-1 -1  1  1]
[-1  1 -1  1]
sage: S = M - identity_matrix(4); -S == S.T
True
```

```
>>> from sage.all import *
>>> M = hadamard_matrix_paleyI(Integer(4), normalize=False); M
[ 1  1  1  1]
[-1  1  1 -1]
[-1 -1  1  1]
[-1  1 -1  1]
>>> S = M - identity_matrix(Integer(4)); -S == S.T
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_paleyII**(n)

Implement the Paley type II construction.

The Paley type II case corresponds to the case $p = n/2 - 1 \cong 1 \mod 4$ for a prime power p (see [Hora]).

EXAMPLES:

```
sage: sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(12).det()
2985984
sage: 12^6
2985984
```

```
>>> from sage.all import *
>>> sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(Integer(12)).
↪det()
2985984
>>> Integer(12)**Integer(6)
2985984
```

We note that the method returns a normalised Hadamard matrix

```
sage: sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(12)
[ 1  1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1 -1|-1  1|-1  1|-1  1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1 -1| 1  1|-1 -1|-1 -1| 1  1]
[ 1  1|-1 -1| 1 -1|-1  1|-1  1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1| 1 -1| 1  1|-1 -1|-1 -1]
[ 1  1| 1 -1|-1 -1| 1 -1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1|-1 -1| 1  1| 1 -1| 1  1|-1 -1]
[ 1  1|-1  1| 1 -1|-1 -1| 1 -1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1|-1 -1|-1 -1| 1  1| 1 -1| 1  1]
[ 1  1|-1  1|-1  1| 1 -1|-1 -1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1|-1 -1|-1 -1| 1  1| 1 -1]
[ 1  1| 1 -1|-1  1|-1  1| 1 -1|-1 -1]
```

```
>>> from sage.all import *
>>> sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(Integer(12))
[ 1  1| 1  1| 1  1| 1  1| 1  1| 1  1]
[ 1 -1|-1  1|-1  1|-1  1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1 -1| 1  1|-1 -1|-1 -1| 1  1]
[ 1  1|-1 -1| 1 -1|-1  1|-1  1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1| 1 -1| 1  1|-1 -1|-1 -1]
[ 1  1| 1 -1|-1 -1| 1 -1|-1  1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1|-1 -1| 1  1| 1 -1| 1  1|-1 -1]
[ 1  1|-1  1| 1 -1|-1 -1| 1 -1|-1  1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1|-1 -1|-1 -1| 1  1| 1 -1| 1  1]
[ 1  1|-1  1|-1  1| 1 -1|-1 -1| 1 -1]
[-----+-----+-----+-----+-----+-----]
[ 1 -1| 1  1|-1 -1|-1 -1| 1  1| 1 -1]
[ 1  1| 1 -1|-1  1|-1  1| 1 -1|-1 -1]
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_spence_construction**(*n*, *existence=False*, *check=True*)

Create a Hadamard matrix of order n using the Spence construction.

This construction (detailed in [Spe1975]), uses supplementary difference sets implemented in *sage.combinat.designs.difference_family.supplementary_difference_set_from_rel_diff_set()* to create the desired matrix.

INPUT:

- `n` – integer; the order of the matrix to be constructed
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard matrix before returning

OUTPUT:

If `existence=True`, returns a boolean representing whether the Hadamard matrix can be constructed. Otherwise, returns the Hadamard matrix, or raises an error if it cannot be constructed.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_spence_
↪construction
sage: hadamard_matrix_spence_construction(36)
36 x 36 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_spence_
↪construction
>>> hadamard_matrix_spence_construction(Integer(36))
36 x 36 dense matrix over Integer Ring...
```

If `existence` is `True`, the function returns a boolean

```
sage: hadamard_matrix_spence_construction(52, existence=True)
True
```

```
>>> from sage.all import *
>>> hadamard_matrix_spence_construction(Integer(52), existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_turyn_type**(*a*, *b*, *c*, *d*, *e1*, *e2*, *e3*, *e4*, *check=True*)

Construction of Turyn type Hadamard matrix.

Given $n \times n$ circulant matrices A, B, C, D with 1,-1 entries, satisfying $AA^\top + BB^\top + CC^\top + DD^\top = 4nI$, and a set of Baumert-Hall units of order $4t$, one can construct a Hadamard matrix of order $4tn$ as detailed by Turyn in [Tur1974].

INPUT:

- `a` – 1,-1 list; the 1st row of A
- `b` – 1,-1 list; the 1st row of B
- `d` – 1,-1 list; the 1st row of C
- `c` – 1,-1 list; the 1st row of D
- `e1` – matrix; the first Baumert-Hall unit
- `e2` – matrix; the second Baumert-Hall unit
- `e3` – matrix; the third Baumert-Hall unit
- `e4` – matrix; the fourth Baumert-Hall unit
- `check` – boolean (default: `True`); whether to check that the output is a Hadamard matrix before returning it

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_turyn_
↪type, _get_baumert_hall_units
sage: A, B, C, D = _get_baumert_hall_units(28)
```

(continues on next page)

(continued from previous page)

```
sage: hadamard_matrix_turyn_type([1], [1], [1], [1], A, B, C, D)
28 x 28 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_turyn_type,
↪ _get_baumert_hall_units
>>> A, B, C, D = _get_baumert_hall_units(Integer(28))
>>> hadamard_matrix_turyn_type([Integer(1)], [Integer(1)], [Integer(1)],␣
↪[Integer(1)], A, B, C, D)
28 x 28 dense matrix over Integer Ring...
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_williamson_type**(*a*, *b*, *c*, *d*, *check=True*)

Construction of Williamson type Hadamard matrix.

Given $n \times n$ circulant matrices A, B, C, D with 1,-1 entries, and satisfying $AA^\top + BB^\top + CC^\top + DD^\top = 4nI$, one can construct a Hadamard matrix of order $4n$, cf. [Ha83].

INPUT:

- `a` – (1,-1) list; the 1st row of A
- `b` – (1,-1) list; the 1st row of B
- `d` – (1,-1) list; the 1st row of C
- `c` – (1,-1) list; the 1st row of D
- `check` – boolean (default: `True`); whether to check that the output is a Hadamard matrix before returning it

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_
↪williamson_type
sage: a = [ 1,  1, 1]
sage: b = [ 1, -1, -1]
sage: c = [ 1, -1, -1]
sage: d = [ 1, -1, -1]
sage: M = hadamard_matrix_williamson_type(a,b,c,d,check=True)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_williamson_
↪type
>>> a = [ Integer(1),  Integer(1), Integer(1)]
>>> b = [ Integer(1), -Integer(1), -Integer(1)]
>>> c = [ Integer(1), -Integer(1), -Integer(1)]
>>> d = [ Integer(1), -Integer(1), -Integer(1)]
>>> M = hadamard_matrix_williamson_type(a,b,c,d,check=True)
```

sage.combinat.matrices.hadamard_matrix.**hadamard_matrix_www**(*url_file*, *comments=False*)

Pull file from Sloane's database and return the corresponding Hadamard matrix as a Sage matrix.

You must input a filename of the form "had.n.xxx.txt" as described on the webpage http://neilsloane.com/hadamard/, where "xxx" could be empty or a number of some characters.

If `comments=True` then the "Automorphism…" line of the had.n.xxx.txt file is printed if it exists. Otherwise nothing is done.

EXAMPLES:

```
sage: hadamard_matrix_www("had.4.txt")       # optional - internet
[ 1  1  1  1]
[ 1 -1  1 -1]
[ 1  1 -1 -1]
[ 1 -1 -1  1]
sage: hadamard_matrix_www("had.16.2.txt",comments=True)    # optional - internet
Automorphism group has order = 49152 = 2^14 * 3
[ 1  1  1  1  1  1  1  1  1  1  1  1  1  1  1  1]
[ 1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1  1 -1]
[ 1  1 -1 -1  1  1 -1 -1  1  1 -1 -1  1  1 -1 -1]
[ 1 -1 -1  1  1 -1 -1  1  1 -1 -1  1  1 -1 -1  1]
[ 1  1  1  1 -1 -1 -1 -1  1  1  1  1 -1 -1 -1 -1]
[ 1 -1  1 -1 -1  1 -1  1  1 -1  1 -1 -1  1 -1  1]
[ 1  1 -1 -1 -1 -1  1  1  1  1 -1 -1 -1 -1  1  1]
[ 1 -1 -1  1 -1  1  1 -1  1 -1 -1  1 -1  1  1 -1]
[ 1  1  1  1  1  1  1  1 -1 -1 -1 -1 -1 -1 -1 -1]
[ 1  1  1  1 -1 -1 -1 -1 -1 -1 -1 -1  1  1  1  1]
[ 1  1 -1 -1  1 -1  1 -1 -1 -1  1  1 -1  1 -1  1]

```

sage.combinat.matrices.hadamard_matrix.**is_hadamard_matrix**(*M*, *normalized=False*, *skew=False*, *verbose=False*)

Test if `M` is a Hadamard matrix.

INPUT:

- `M` – a matrix
- `normalized` – boolean (default: `False`); whether to test if `M` is a normalized Hadamard matrix, i.e. has its first row/column filled with +1
- `skew` – boolean (default: `False`); whether to test if `M` is a skew Hadamard matrix, i.e. $M = S + I$ for $-S = S^\top$, and I the identity matrix
- `verbose` – boolean (default: `False`); whether to be verbose when the matrix is not Hadamard

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
sage: h = matrix.hadamard(12)
sage: is_hadamard_matrix(h)
True
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
sage: h = skew_hadamard_matrix(12)
sage: is_hadamard_matrix(h, skew=True)
True
sage: h = matrix.hadamard(12)
sage: h[0,0] = 2
sage: is_hadamard_matrix(h,verbose=True)
The matrix does not only contain +1 and -1 entries, e.g. 2
False
sage: h = matrix.hadamard(12)
sage: for i in range(12):
....:     h[i,2] = -h[i,2]
sage: is_hadamard_matrix(h,verbose=True,normalized=True)
The matrix is not normalized
False
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
>>> h = matrix.hadamard(Integer(12))
>>> is_hadamard_matrix(h)
True
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
>>> h = skew_hadamard_matrix(Integer(12))
>>> is_hadamard_matrix(h, skew=True)
True
>>> h = matrix.hadamard(Integer(12))
>>> h[Integer(0),Integer(0)] = Integer(2)
>>> is_hadamard_matrix(h,verbose=True)
The matrix does not only contain +1 and -1 entries, e.g. 2
False
>>> h = matrix.hadamard(Integer(12))
>>> for i in range(Integer(12)):
...     h[i,Integer(2)] = -h[i,Integer(2)]
>>> is_hadamard_matrix(h,verbose=True,normalized=True)
The matrix is not normalized
False
```

sage.combinat.matrices.hadamard_matrix.**is_skew_hadamard_matrix**(*M*, *normalized=False*, *verbose=False*)

Test if `M` is a skew Hadamard matrix.

this is a wrapper around the function *is_hadamard_matrix()*

INPUT:

- `M` – a matrix
- `normalized` – boolean (default: `False`); whether to test if `M` is a skew-normalized Hadamard matrix, i.e. has its first row filled with +1
- `verbose` – boolean (default: `False`); whether to be verbose when the matrix is not skew Hadamard

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import is_skew_hadamard_matrix,␣
↪skew_hadamard_matrix
sage: h = matrix.hadamard(12)
sage: is_skew_hadamard_matrix(h, verbose=True)
The matrix is not skew
False
sage: h = skew_hadamard_matrix(12)
sage: is_skew_hadamard_matrix(h)
True
sage: from sage.combinat.matrices.hadamard_matrix import normalise_hadamard
sage: h = normalise_hadamard(skew_hadamard_matrix(12), skew=True)
sage: is_skew_hadamard_matrix(h, verbose=True, normalized=True)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import is_skew_hadamard_matrix,␣
↪skew_hadamard_matrix
>>> h = matrix.hadamard(Integer(12))
>>> is_skew_hadamard_matrix(h, verbose=True)
The matrix is not skew
False
>>> h = skew_hadamard_matrix(Integer(12))
>>> is_skew_hadamard_matrix(h)
True
>>> from sage.combinat.matrices.hadamard_matrix import normalise_hadamard
>>> h = normalise_hadamard(skew_hadamard_matrix(Integer(12)), skew=True)
>>> is_skew_hadamard_matrix(h, verbose=True, normalized=True)
True
```

sage.combinat.matrices.hadamard_matrix.**normalise_hadamard**(*H*, *skew=False*)

Return the normalised Hadamard matrix corresponding to `H`.

The normalised Hadamard matrix corresponding to a Hadamard matrix H is a matrix whose every entry in the first row and column is +1.

If `skew` is True, the matrix returned will be skew-normal: a skew Hadamard matrix with first row of all $+1$.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import normalise_hadamard, is_
↪hadamard_matrix, skew_hadamard_matrix
sage: H = normalise_hadamard(hadamard_matrix(4))
```

(continues on next page)

(continued from previous page)

```
sage: H == hadamard_matrix(4)
True
sage: H = normalise_hadamard(skew_hadamard_matrix(20, skew_normalize=False),␣
↪skew=True)
sage: is_hadamard_matrix(H, skew=True, normalized=True)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import normalise_hadamard, is_
↪hadamard_matrix, skew_hadamard_matrix
>>> H = normalise_hadamard(hadamard_matrix(Integer(4)))
>>> H == hadamard_matrix(Integer(4))
True
>>> H = normalise_hadamard(skew_hadamard_matrix(Integer(20), skew_
↪normalize=False), skew=True)
>>> is_hadamard_matrix(H, skew=True, normalized=True)
True
```

If `skew` is `True` but the Hadamard matrix is not skew, the matrix returned will not be normalized:

```
sage: H = normalise_hadamard(hadamard_matrix(92), skew=True)
sage: is_hadamard_matrix(H, normalized=True)
False
```

```
>>> from sage.all import *
>>> H = normalise_hadamard(hadamard_matrix(Integer(92)), skew=True)
>>> is_hadamard_matrix(H, normalized=True)
False
```

sage.combinat.matrices.hadamard_matrix.**regular_symmetric_hadamard_matrix_with_constant_diagonal**(*n*, *e*, *existence=*

Return a Regular Symmetric Hadamard Matrix with Constant Diagonal.

A Hadamard matrix is said to be *regular* if its rows all sum to the same value.

For $\epsilon \in \{-1, +1\}$, we say that M is a $(n, \epsilon) - RSHCD$ if M is a regular symmetric Hadamard matrix with constant diagonal $\delta \in \{-1, +1\}$ and row sums all equal to $\delta\epsilon\sqrt{(n)}$. For more information, see [HX2010] or 10.5.1 in [BH2012]. For the case $n = 324$, see *RSHCD_324()* and [CP2016].

INPUT:

- `n` – integer; side of the matrix
- `e` – -1 or $+1$; the value of ϵ

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import regular_symmetric_
↪hadamard_matrix_with_constant_diagonal
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(4,1)
[ 1  1  1 -1]
```

(continues on next page)

(continued from previous page)

```
[ 1  1 -1  1]
[ 1 -1  1  1]
[-1  1  1  1]
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(4,-1)
[ 1 -1 -1 -1]
[-1  1 -1 -1]
[-1 -1  1 -1]
[-1 -1 -1  1]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import regular_symmetric_hadamard_
↪matrix_with_constant_diagonal
>>> regular_symmetric_hadamard_matrix_with_constant_diagonal(Integer(4),
↪Integer(1))
[ 1  1  1 -1]
[ 1  1 -1  1]
[ 1 -1  1  1]
[-1  1  1  1]
>>> regular_symmetric_hadamard_matrix_with_constant_diagonal(Integer(4),-
↪Integer(1))
[ 1 -1 -1 -1]
[-1  1 -1 -1]
[-1 -1  1 -1]
[-1 -1 -1  1]
```

Other hardcoded values:

```
sage: for n,e in [(36,1),(36,-1),(100,1),(100,-1),(196, 1)]:  # long time
....:     print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n,
↪e)))
36 x 36 dense matrix over Integer Ring
36 x 36 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
196 x 196 dense matrix over Integer Ring

sage: for n,e in [(324,1),(324,-1)]: # not tested - long time, tested in RSHCD_324
....:     print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n,
↪e)))
324 x 324 dense matrix over Integer Ring
324 x 324 dense matrix over Integer Ring
```

```
>>> from sage.all import *
>>> for n,e in [(Integer(36),Integer(1)),(Integer(36),-Integer(1)),(Integer(100),
↪Integer(1)),(Integer(100),-Integer(1)),(Integer(196), Integer(1))]:  # long time
...     print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n,e)))
36 x 36 dense matrix over Integer Ring
36 x 36 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
196 x 196 dense matrix over Integer Ring
```

(continues on next page)

(continued from previous page)

```
>>> for n,e in [(Integer(324),Integer(1)),(Integer(324),-Integer(1))]: # not␣
↪tested - long time, tested in RSHCD_324
...     print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n,e)))
324 x 324 dense matrix over Integer Ring
324 x 324 dense matrix over Integer Ring
```

From two close prime powers:

```
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(64,-1)
64 x 64 dense matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
```

```
>>> from sage.all import *
>>> regular_symmetric_hadamard_matrix_with_constant_diagonal(Integer(64),-
↪Integer(1))
64 x 64 dense matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
```

From a prime power and a conference matrix:

```
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(676,1)  # long time
676 x 676 dense matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
```

```
>>> from sage.all import *
>>> regular_symmetric_hadamard_matrix_with_constant_diagonal(Integer(676),
↪Integer(1))  # long time
676 x 676 dense matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
```

Recursive construction:

```
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(144,-1)
144 x 144 dense matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
```

```
>>> from sage.all import *
>>> regular_symmetric_hadamard_matrix_with_constant_diagonal(Integer(144),-
↪Integer(1))
144 x 144 dense matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
```

REFERENCE:

- [BH2012]
- [HX2010]

sage.combinat.matrices.hadamard_matrix.**rshcd_from_close_prime_powers**(*n*)

Return a $(n^2, 1)$-RSHCD when $n-1$ and $n+1$ are odd prime powers and $n = 0 \pmod 4$.

The construction implemented here appears in Theorem 4.3 from [GS1970].

Note that the authors of [SWW1972] claim in Corollary 5.12 (page 342) to have proved the same result without the $n = 0 \pmod 4$ restriction with a *very* similar construction. So far, however, I (Nathann Cohen) have not been

able to make it work.

INPUT:

- `n` – integer congruent to $0 \pmod 4$

```

REFERENCE:

- [SWW1972]

sage.combinat.matrices.hadamard_matrix.**rshcd_from_prime_power_and_conference_matrix**(*n*)

Return a $((n-1)^2, 1)$-RSHCD if n is prime power, and symmetric $(n-1)$-conference matrix exists.

The construction implemented here is Theorem 16 (and Corollary 17) from [WW1972].

In [SWW1972] this construction (Theorem 5.15 and Corollary 5.16) is reproduced with a typo. Note that [WW1972] refers to [Sz1969] for the construction, provided by *szekeres_difference_set_pair()*, of complementary difference sets, and the latter has a typo.

From a *symmetric_conference_matrix()*, we only need the Seidel adjacency matrix of the underlying strongly regular conference (i.e. Paley type) graph, which we construct directly.

INPUT:

- `n` – integer

See also

regular_symmetric_hadamard_matrix_with_constant_diagonal()

EXAMPLES:

A 36x36 example

```
sage: from sage.combinat.matrices.hadamard_matrix import rshcd_from_prime_power_
↪and_conference_matrix
sage: from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
sage: H = rshcd_from_prime_power_and_conference_matrix(7); H
36 x 36 dense matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
sage: H == H.T and is_hadamard_matrix(H) and H.diagonal() == [1]*36 and␣
↪list(sum(H)) == [6]*36
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import rshcd_from_prime_power_and_
↪conference_matrix
>>> from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
>>> H = rshcd_from_prime_power_and_conference_matrix(Integer(7)); H
36 x 36 dense matrix over Integer Ring (use the '.str()' method to see the␣
↪entries)
>>> H == H.T and is_hadamard_matrix(H) and H.diagonal() ==␣
↪[Integer(1)]*Integer(36) and list(sum(H)) == [Integer(6)]*Integer(36)
True
```

Bigger examples, only provided by this construction

```
sage: H = rshcd_from_prime_power_and_conference_matrix(27)  # long time
sage: H == H.T and is_hadamard_matrix(H)                    # long time
True
sage: H.diagonal() == [1]*676 and list(sum(H)) == [26]*676  # long time
True
```

```
>>> from sage.all import *
>>> H = rshcd_from_prime_power_and_conference_matrix(Integer(27))  # long time
>>> H == H.T and is_hadamard_matrix(H)                            # long time
True
>>> H.diagonal() == [Integer(1)]*Integer(676) and list(sum(H)) ==␣
↪[Integer(26)]*Integer(676)  # long time
True
```

In this example the conference matrix is not Paley, as 45 is not a prime power

```
sage: H = rshcd_from_prime_power_and_conference_matrix(47)  # not tested (long␣
↪time)
```

```
>>> from sage.all import *
>>> H = rshcd_from_prime_power_and_conference_matrix(Integer(47))  # not tested␣
↪(long time)
```

REFERENCE:

- [WW1972]

sage.combinat.matrices.hadamard_matrix.**skew_hadamard_matrix**(*n*, *existence=False*, *skew_normalize=True*, *check=True*, *construction_name=False*)

Try to construct a skew Hadamard matrix.

A Hadamard matrix H is called skew if $H = S - I$, for I the identity matrix and $-S = S^\top$. Currently all orders ≤ 1200 for which a construction is known are implemented. For $n > 1200$, only some orders are available.

INPUT:

- `n` – integer; dimension of the matrix
- `existence` – boolean (default: `False`); whether to build the matrix or merely query if a construction is available in Sage. When set to `True`, the function returns:
  - `True` – meaning that Sage knows how to build the matrix
  - `Unknown` – meaning that Sage does not know how to build the matrix, but that the design may exist (see `sage.misc.unknown`).
  - `False` – meaning that the matrix does not exist
- `skew_normalize` – boolean (default: `True`); whether to make the 1st row all-one, and adjust the 1st column accordingly
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `construction_name` – boolean (default: `False`); if it is `True`, `existence` is `True`, and a matrix exists, output the construction name. It has no effect if `existence` is set to `False`.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
sage: skew_hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
```

(continues on next page)

(continued from previous page)

- [Ha83]

sage.combinat.matrices.hadamard_matrix.**skew_hadamard_matrix_from_complementary_difference_sets**(*n*, *existence=False*, *check=True*)

Construct a skew Hadamard matrix of order $n = 4(m+1)$ from complementary difference sets.

If A, B are complementary difference sets over a group of order $2m+1$, then they can be used to construct a skew Hadamard matrix, as described in [BS1969].

The complementary difference sets are constructed using the function *sage.combinat.designs.difference_family.complementary_difference_sets()*.

INPUT:

- `n` – positive integer; the order of the matrix to be constructed
- `existence` – boolean (default: `False`); if `True`, only return whether the skew Hadamard matrix can be constructed
- `check` – boolean (default: `True`); if `True`, check that the result is a skew Hadamard matrix before returning it

OUTPUT:

If `existence=False`, returns the skew Hadamard matrix of order n. It raises an error if n does not satisfy the required conditions. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪from_complementary_difference_sets
sage: skew_hadamard_matrix_from_complementary_difference_sets(20)
20 x 20 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_from_complementary_difference_sets(52, existence=True)
True
```

```

↪complementary_difference_sets
>>> skew_hadamard_matrix_from_complementary_difference_sets(Integer(20))
20 x 20 dense matrix over Integer Ring...
>>> skew_hadamard_matrix_from_complementary_difference_sets(Integer(52),␣
↪existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**skew_hadamard_matrix_from_good_matrices**(*a*, *b*, *c*, *d*, *check=True*)

Construct skew Hadamard matrix from good matrices.

Given good matrices A, B, C, D (A circulant, B, C, D back-circulant) they can be used to construct a skew Hadamard matrix using the following block matrix (as described in [Sze1988]):

$$\begin{pmatrix} A & B & C & D \\ -B & A & D & -C \\ -C & -D & A & B \\ -D & C & -B & A \end{pmatrix}$$

INPUT:

- `a` – (1,-1) list; the 1st row of A
- `b` – (1,-1) list; the 1st row of B
- `d` – (1,-1) list; the 1st row of C
- `c` – (1,-1) list; the 1st row of D
- `check` – boolean (default: `True`); if `True`, check that the matrix is a skew Hadamard matrix before returning it

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪from_good_matrices
sage: a, b, c, d = ([1, 1, 1, -1, -1], [1, -1, 1, 1, -1], [1, -1, -1, -1, -1], [1,
↪ -1, -1, -1, -1])
sage: skew_hadamard_matrix_from_good_matrices(a, b, c, d)
20 x 20 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_
↪good_matrices
>>> a, b, c, d = ([Integer(1), Integer(1), Integer(1), -Integer(1), -Integer(1)],␣
↪[Integer(1), -Integer(1), Integer(1), Integer(1), -Integer(1)], [Integer(1), -
↪Integer(1), -Integer(1), -Integer(1), -Integer(1)], [Integer(1), -Integer(1), -
```

(continues on next page)

(continued from previous page)

```
↪Integer(1), -Integer(1), -Integer(1)])
>>> skew_hadamard_matrix_from_good_matrices(a, b, c, d)
20 x 20 dense matrix over Integer Ring...
```

sage.combinat.matrices.hadamard_matrix.**skew_hadamard_matrix_from_good_matrices_smallcases**(*n*, *existence=False*, *check=True*)

Construct skew Hadamard matrices from good matrices for some small values of $n = 4m$, with m odd.

The function stores good matrices of odd orders ≤ 31, taken from [Sze1988]. These are used to create skew Hadamard matrices of order $4m$, $1 \leq m \leq 31$ (m odd), using the function *skew_hadamard_matrix_from_good_matrices()*.

ALGORITHM:

Given four sequences (stored in `E_sequences`) of length m, they can be used to construct four $E - sequences$ of length $n = 2m + 1$, as follows:

$$a = 1, a_0, a_1, ..., a_m, -a_m, -a_{m-1}, ..., -a_0$$
$$b = 1, b_0, b_1, ..., b_m, b_m, b_{m-1}, ..., b_0$$
$$c = 1, c_0, c_1, ..., c_m, c_m, c_{m-1}, ..., c_0$$
$$d = 1, d_0, d_1, ..., d_m, d_m, d_{m-1}, ..., d_0$$

These E-sequences will be the first rows of the four good matrices needed to construct a skew Hadamard matrix of order $4n$.

INPUT:

- `n` – integer; the order of the skew Hadamard matrix to be constructed
- `existence` – boolean (default: `False`); if `True`, only return whether the Hadamard matrix can be constructed
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard matrix before returning it

OUTPUT:

If `existence=False`, returns the skew Hadamard matrix of order n. It raises an error if no data is available to construct the matrix of the given order. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪from_good_matrices_smallcases
sage: skew_hadamard_matrix_from_good_matrices_smallcases(20)
20 x 20 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_from_good_matrices_smallcases(20, existence=True)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_
↪good_matrices_smallcases
```

(continues on next page)

(continued from previous page)

```
>>> skew_hadamard_matrix_from_good_matrices_smallcases(Integer(20))
20 x 20 dense matrix over Integer Ring...
>>> skew_hadamard_matrix_from_good_matrices_smallcases(Integer(20),␣
↪existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**skew_hadamard_matrix_from_orthogonal_design**(*n*, *existence=False*, *check=True*)

Construct skew Hadamard matrices of order $mn(n-1)$ if suitable orthogonal designs exist.

In [Seb1978] is proved that if amicable Hadamard matrices of order n and an orthogonal design of type $(1, m, mn-m-1)$ in order mn exist, then a skew Hadamard matrix of order $mn(n-1)$ can be constructed. The paper uses amicable orthogonal designs instead of amicable Hadamard matrices, but the two are equivalent (see [Seb2017]).

Amicable Hadamard matrices are constructed using *amicable_hadamard_matrices()*, and the orthogonal designs are constructed using the Goethals-Seidel array, with data taken from [Seb2017].

INPUT:

- `n` – positive integer; the order of the matrix to be constructed
- `existence` – boolean (default: `False`); if `True`, only return whether the skew Hadamard matrix can be constructed
- `check` – boolean (default: `True`); if `True`, check that the result is a skew Hadamard matrix before returning it

OUTPUT:

If `existence=False`, returns the skew Hadamard matrix of order n. It raises an error if a construction for order n is not yet implemented, or if n does not satisfy the constraint. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪from_orthogonal_design
sage: skew_hadamard_matrix_from_orthogonal_design(756)
756 x 756 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_
↪orthogonal_design
>>> skew_hadamard_matrix_from_orthogonal_design(Integer(756))
756 x 756 dense matrix over Integer Ring...
```

If `existence` is True, the function returns a boolean:

```
sage: skew_hadamard_matrix_from_orthogonal_design(200, existence=True)
False
```

```
>>> from sage.all import *
>>> skew_hadamard_matrix_from_orthogonal_design(Integer(200), existence=True)
False
```

sage.combinat.matrices.hadamard_matrix.**skew_hadamard_matrix_spence_1975**(*n*, *existence=False*, *check=True*)

Construct a skew Hadamard matrix of order $n = 4(1 + q + q^2)$ using the Spence construction.

If $n = 4(1 + q + q^2)$ where q is a prime power such that either $1 + q + q^2$ is a prime congruent to $3, 5, 7$ mod 8 or $3 + 2q + 2q^2$ is a prime power, then a skew Hadamard matrix of order n can be constructed using the Goethals Seidel array. The four matrices A, B, C, D plugged into the GS-array are created using complementary difference sets of order $1 + q + q^2$ (which exist if q satisfies the conditions above), and a cyclic planar difference set with parameters $(1 + q^2 + q^4, 1 + q^2, 1)$. These are constructed by the functions *sage.combinat.designs.difference_family.complementary_difference_sets()* and *sage.combinat.designs.difference_family.difference_family()*.

For more details, see [Spe1975b].

INPUT:

- `n` – positive integer; the order of the matrix to be constructed
- `existence` – boolean (default: `False`); if `True`, only return whether the Hadamard matrix can be constructed
- `check` – boolean (default: `True`); check that the result is a skew Hadamard matrix before returning it

OUTPUT:

If `existence=False`, returns the skew Hadamard matrix of order n. It raises an error if n does not satisfy the required conditions. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪spence_1975
sage: skew_hadamard_matrix_spence_1975(52)
52 x 52 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪spence_1975
>>> skew_hadamard_matrix_spence_1975(Integer(52))
52 x 52 dense matrix over Integer Ring...
```

If `existence` is True, the function returns a boolean:

```
sage: skew_hadamard_matrix_spence_1975(52, existence=True)
True
```

```
>>> from sage.all import *
>>> skew_hadamard_matrix_spence_1975(Integer(52), existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.**skew_hadamard_matrix_spence_construction**(*n*, *check=True*)

Construct skew Hadamard matrix of order n using Spence construction.

This function will construct skew Hadamard matrix of order $n = 2(q + 1)$ where q is a prime power with $q = 5$ (mod 8). The construction is taken from [Spe1977], and the relative difference sets are constructed using *sage.combinat.designs.difference_family.relative_difference_set_from_homomorphism()*.

INPUT:

- `n` – positive integer
- `check` – boolean (default: `True`); if `True`, check that the resulting matrix is Hadamard before returning it

OUTPUT:

If `n` satisfies the requirements described above, the function returns a $n \times n$ Hadamard matrix. Otherwise, an exception is raised.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪spence_construction
sage: skew_hadamard_matrix_spence_construction(28)
28 x 28 dense matrix over Integer Ring...
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪spence_construction
>>> skew_hadamard_matrix_spence_construction(Integer(28))
28 x 28 dense matrix over Integer Ring...
```

sage.combinat.matrices.hadamard_matrix.**skew_hadamard_matrix_whiteman_construction**(*n*, *existence=False*, *check=True*)

Construct a skew Hadamard matrix of order $n = 2(q+1)$ where $q = p^t$ is a prime power with $p \cong 5 \mod 8$ and $t \cong 2 \mod 4$.

Assuming n satisfies the conditions above, it is possible to construct two supplementary difference sets A, B (see [Whi1971]), and these can be used to construct a skew Hadamard matrix, as described in [BS1969].

INPUT:

- `n` – positive integer; the order of the matrix to be constructed
- `existence` – boolean (default: `False`); if `True`, only return whether the Hadamard matrix can be constructed
- `check` – boolean (default: `True`); if `True`, check that the result is a skew Hadamard matrix before returning it

OUTPUT:

If `existence=False`, returns the skew Hadamard matrix of order n. It raises an error if n does not satisfy the required conditions. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪whiteman_construction
sage: skew_hadamard_matrix_whiteman_construction(52)
52 x 52 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_whiteman_construction(52, existence=True)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_
↪whiteman_construction
>>> skew_hadamard_matrix_whiteman_construction(Integer(52))
52 x 52 dense matrix over Integer Ring...
>>> skew_hadamard_matrix_whiteman_construction(Integer(52), existence=True)
True
```

Note

A more general version of this construction is *skew_hadamard_matrix_from_complementary_difference_sets()*.

sage.combinat.matrices.hadamard_matrix.**symmetric_conference_matrix**(*n*, *check=True*, *existence=False*)

Try to construct a symmetric conference matrix.

A conference matrix is an $n \times n$ matrix C with 0s on the main diagonal and 1s and -1s elsewhere, satisfying $CC^\top = (n-1)I$. If $C = C^\top$ then $n \cong 2 \mod 4$ and C is Seidel adjacency matrix of a graph, whose descendent graphs are strongly regular graphs with parameters $(n-1, (n-2)/2, (n-6)/4, (n-2)/4)$, see Sec.10.4 of [BH2012]. Thus we build C from the Seidel adjacency matrix of the latter by adding row and column of 1s.

INPUT:

- `n` – integer; dimension of the matrix
- `check` – boolean (default: `True`); whether to check that output is correct before returning it. As this is expected to be useless, you may want to disable it whenever you want speed.
- `existence` – boolean (default: `False`); if true, only check that such a matrix exists.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import symmetric_conference_
↪matrix
sage: C = symmetric_conference_matrix(10); C
[ 0  1  1  1  1  1  1  1  1  1]
[ 1  0 -1 -1  1 -1  1  1  1 -1]
[ 1 -1  0 -1  1  1 -1 -1  1  1]
[ 1 -1 -1  0 -1  1  1  1 -1  1]
[ 1  1  1 -1  0 -1 -1  1 -1  1]
[ 1 -1  1  1 -1  0 -1  1  1 -1]
[ 1  1 -1  1 -1 -1  0 -1  1  1]
[ 1  1 -1  1  1  1 -1  0 -1 -1]
[ 1  1  1 -1 -1  1  1 -1  0 -1]
[ 1 -1  1  1  1 -1  1 -1 -1  0]
sage: C^2 == 9*identity_matrix(10) and C == C.T
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import symmetric_conference_matrix
>>> C = symmetric_conference_matrix(Integer(10)); C
[ 0  1  1  1  1  1  1  1  1  1]
[ 1  0 -1 -1  1 -1  1  1  1 -1]
```

(continues on next page)

(continued from previous page)

```
[ 1 -1  0 -1  1  1 -1 -1  1  1]
[ 1 -1 -1  0 -1  1  1  1 -1  1]
[ 1  1  1 -1  0 -1 -1  1 -1  1]
[ 1 -1  1  1 -1  0 -1  1  1 -1]
[ 1  1 -1  1 -1 -1  0 -1  1  1]
[ 1  1 -1  1  1  1 -1  0 -1 -1]
[ 1  1  1 -1 -1  1  1 -1  0 -1]

>>> C**Integer(2) == Integer(9)*identity_matrix(Integer(10)) and C == C.T
True
```

sage.combinat.matrices.hadamard_matrix.**symmetric_conference_matrix_paley**(*n*)

Construct a symmetric conference matrix of order n.

A conference matrix is an $n \times n$ matrix C with 0s on the main diagonal and 1s and -1s elsewhere, satisfying $CC^\top = (n-1)I$. This construction assumes that $q = n - 1$ is a prime power, with $q \cong 1 \mod 4$. See [Hora] or [Lon2013].

These matrices are used in *hadamard_matrix_paleyII()*.

INPUT:

- n – integer; the order of the symmetric conference matrix to construct

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import symmetric_conference_
↪matrix_paley
sage: symmetric_conference_matrix_paley(6)
[ 0  1  1  1  1  1]
[ 1  0  1 -1 -1  1]
[ 1  1  0  1 -1 -1]
[ 1 -1  1  0  1 -1]
[ 1 -1 -1  1  0  1]
[ 1  1 -1 -1  1  0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import symmetric_conference_
↪matrix_paley
>>> symmetric_conference_matrix_paley(Integer(6))
[ 0  1  1  1  1  1]
[ 1  0  1 -1 -1  1]
[ 1  1  0  1 -1 -1]
[ 1 -1  1  0  1 -1]
[ 1 -1 -1  1  0  1]
[ 1  1 -1 -1  1  0]
```

sage.combinat.matrices.hadamard_matrix.**szekeres_difference_set_pair**(*m*, *check=True*)

Construct Szekeres $(2m+1, m, 1)$-cyclic difference family.

Let $4m+3$ be a prime power. Theorem 3 in [Sz1969] contains a construction of a pair of *complementary difference sets* A, B in the subgroup G of the quadratic residues in F^*_{4m+3}. Namely $|A| = |B| = m$, $a \in A$ whenever $a - 1 \in G$, $b \in B$ whenever $b + 1 \in G$. See also Theorem 2.6 in [SWW1972] (there the formula for B is correct, as opposed to (4.2) in [Sz1969], where the sign before 1 is wrong.

In modern terminology, for $m > 1$ the sets A and B form a *difference family* with parameters $(2m+1, m, 1)$. I.e. each non-identity $g \in G$ can be expressed uniquely as xy^{-1} for $x, y \in A$ or $x, y \in B$. Other, specific to this construction, properties of A and B are: for a in A one has a^{-1} not in A, whereas for b in B one has b^{-1} in B.

INPUT:

- `m` – integer; dimension of the matrix
- `check` – boolean (default: `True`); whether to check A and B for correctness

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import szekeres_difference_set_
↪pair
sage: G,A,B=szekeres_difference_set_pair(6)
sage: G,A,B=szekeres_difference_set_pair(7)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import szekeres_difference_set_
↪pair
>>> G,A,B=szekeres_difference_set_pair(Integer(6))
>>> G,A,B=szekeres_difference_set_pair(Integer(7))
```

REFERENCE:

- [Sz1969]

sage.combinat.matrices.hadamard_matrix.**turyn_type_hadamard_matrix_smallcases**(*n*, *existence=False*, *check=True*)

Construct a Hadamard matrix of order n from available 4-symbol δ codes and Williamson quadruples.

The function looks for Baumert-Hall units and Williamson type matrices from *four_symbol_delta_code_smallcases()* and *williamson_type_quadruples_smallcases()* and use them to construct a Hadamard matrix with the Turyn construction defined in *hadamard_matrix_turyn_type()*.

INPUT:

- `n` – integer; the order of the matrix to be constructed
- `existence` – boolean (default: `False`); if `True`, only check if the matrix exists
- `check` – boolean (default: `True`); if `True`, check that the matrix is a Hadamard matrix before returning

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import turyn_type_hadamard_
↪matrix_smallcases
sage: turyn_type_hadamard_matrix_smallcases(28, existence=True)
True
sage: turyn_type_hadamard_matrix_smallcases(28)
28 x 28 dense matrix over Integer Ring...
```

```

>>> from sage.combinat.matrices.hadamard_matrix import szekeres_difference_set_
↪pair
>>> from sage.combinat.matrices.hadamard_matrix import typeI_matrix_difference_set
>>> G,A,B=szekeres_difference_set_pair(Integer(2))
>>> typeI_matrix_difference_set(G,A)
[-1  1 -1 -1  1]
[-1 -1 -1  1  1]
[ 1  1 -1 -1 -1]
[ 1 -1  1 -1 -1]
[-1 -1  1  1 -1]
```

sage.combinat.matrices.hadamard_matrix.**williamson_goethals_seidel_skew_hadamard_matrix**(a, b, c, d, *check=True*)

Williamson-Goethals-Seidel construction of a skew Hadamard matrix.

Given $n \times n$ (anti)circulant matrices A, B, C, D with 1,-1 entries, and satisfying $A + A^\top = 2I$, $AA^\top + BB^\top + CC^\top + DD^\top = 4nI$, one can construct a skew Hadamard matrix of order $4n$, cf. [GS70s].

INPUT:

- `a` – 1,-1 list; the 1st row of A
- `b` – 1,-1 list; the 1st row of B
- `d` – 1,-1 list; the 1st row of C
- `c` – 1,-1 list; the 1st row of D
- `check` – boolean (default: `True`); if `True`, check that the resulting matrix is skew Hadamard before returning it

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import williamson_goethals_
↪seidel_skew_hadamard_matrix as WGS
sage: a = [ 1,  1, 1, -1,  1, -1,  1, -1, -1]
sage: b = [ 1, -1, 1,  1, -1, -1,  1,  1, -1]
sage: c = [-1, -1]+[1]*6+[-1]
sage: d = [ 1,  1, 1, -1,  1,  1, -1,  1,  1]
sage: M = WGS(a,b,c,d,check=True)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import williamson_goethals_seidel_
↪skew_hadamard_matrix as WGS
>>> a = [ Integer(1),  Integer(1), Integer(1), -Integer(1),  Integer(1), -
↪Integer(1),  Integer(1), -Integer(1), -Integer(1)]
>>> b = [ Integer(1), -Integer(1), Integer(1),  Integer(1), -Integer(1), -
↪Integer(1),  Integer(1),  Integer(1), -Integer(1)]
>>> c = [-Integer(1), -Integer(1)]+[Integer(1)]*Integer(6)+[-Integer(1)]
>>> d = [ Integer(1),  Integer(1), Integer(1), -Integer(1),  Integer(1), ␣
↪Integer(1), -Integer(1),  Integer(1),  Integer(1)]
>>> M = WGS(a,b,c,d,check=True)
```

sage.combinat.matrices.hadamard_matrix.**williamson_hadamard_matrix_smallcases**(*n*, *existence=False*, *check=True*)

Construct Williamson type Hadamard matrices for some small values of n.

This function uses the data contained in *sage.combinat.matrices.hadamard_matrix.williamson_type_quadruples_smallcases()* to create Hadamard matrices of the Williamson type, using the construction from *sage.combinat.matrices.hadamard_matrix.hadamard_matrix_williamson_type()*.

INPUT:

- `n` – integer; the order of the matrix
- `existence` – boolean (default: `False`); if `True`, only check that we can do the construction
- `check` – boolean (default: `True`); if `True` check the result

sage.combinat.matrices.hadamard_matrix.**williamson_type_quadruples_smallcases**(*n*, *existence=False*)

Quadruples of matrices that can be used to construct Williamson type Hadamard matrices.

This function contains for some values of n, four $n \times n$ matrices used in the Williamson construction of Hadamard matrices. Namely, the function returns the first row of 4 $n \times n$ circulant matrices with the properties described in *sage.combinat.matrices.hadamard_matrix.hadamard_matrix_williamson_type()*. The matrices for $n = 3, 5, ..., 29, 37, 43$ are given in [Ha83]. The matrices for $n = 31, 33, 39, 41, 45, 49, 51, 55, 57, 61, 63$ are given in [Lon2013].

INPUT:

- `n` – integer; the order of the matrices to be returned
- `existence` – boolean (default: `False`); if `True`, only check that we have the quadruple

OUTPUT:

If `existence` is false, returns a tuple containing four vectors, each being the first line of one of the four matrices. It raises an error if no such matrices are available. If `existence` is true, returns a boolean representing whether the matrices are available or not.

EXAMPLES:

```

Latin squares

A *latin square* of order n is an $n \times n$ array such that each symbol $s \in \{0, 1, \ldots, n-1\}$ appears precisely once in each row, and precisely once in each column. A *partial latin square* of order n is an $n \times n$ array such that each symbol $s \in \{0, 1, \ldots, n-1\}$ appears at most once in each row, and at most once in each column. Empty cells are denoted by -1. A latin square L is a *completion* of a partial latin square P if $P \subseteq L$. If P completes to just L then P *has unique completion*.

A *latin bitrade* (T_1, T_2) is a pair of partial latin squares such that:

1. $\{(i, j) \mid (i, j, k) \in T_1$ for some symbol $k\} = \{(i, j) \mid (i, j, k') \in T_2$ for some symbol $k'\}$;
2. for each $(i, j, k) \in T_1$ and $(i, j, k') \in T_2$, $k \neq k'$;
3. the symbols appearing in row i of T_1 are the same as those of row i of T_2; the symbols appearing in column j of T_1 are the same as those of column j of T_2.

Intuitively speaking, a bitrade gives the difference between two latin squares, so if (T_1, T_2) is a bitrade for the pair of latin squares (L_1, L_2), then $L1 = (L2 \setminus T_1) \cup T_2$ and $L2 = (L1 \setminus T_2) \cup T_1$.

This file contains

1. LatinSquare class definition;
2. some named latin squares (back circulant, forward circulant, abelian 2-group);
3. methods *is_partial_latin_square()* and *is_latin_square()* to test if a *LatinSquare* object satisfies the definition of a latin square or partial latin square, respectively;
4. tests for completion and unique completion (these use the C++ implementation of Knuth's dancing links algorithm to solve the problem as a instance of $0-1$ matrix exact cover);
5. functions for calculating the τ_i representation of a bitrade and the genus of the associated hypermap embedding;
6. Markov chain of Jacobson and Matthews (1996) for generating latin squares uniformly at random (provides a generator interface);
7. a few examples of τ_i representations of bitrades constructed from the action of a group on itself by right multiplication, functions for converting to a pair of *LatinSquare* objects.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: B.is_latin_square()
True
sage: B[0, 1] = 0
sage: B.is_latin_square()
False

sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: T1, T2 = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
sage: T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
sage: T1.n_filled_cells()
12
sage: genus(T1, T2)
1
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
```

(continues on next page)

(continued from previous page)

```
>>> B = back_circulant(Integer(5))
>>> B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
>>> B.is_latin_square()
True
>>> B[Integer(0), Integer(1)] = Integer(0)
>>> B.is_latin_square()
False

>>> a, b, c, G = alternating_group_bitrade_generators(Integer(1))
>>> T1, T2 = bitrade_from_group(a, b, c, G)

[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
>>> T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
>>> T1.n_filled_cells()
12
>>> genus(T1, T2)
1
```

Todo

1. Latin squares with symbols from a ring instead of the integers $\{0, 1, \ldots, n-1\}$.
2. Isotopism testing of latin squares and bitrades via graph isomorphism (nauty?).
3. Combinatorial constructions for bitrades.

AUTHORS:

- Carlo Hamalainen (2008-03-23): initial version

class sage.combinat.matrices.latin.**LatinSquare**(**args*)

Bases: object

Latin squares.

This class implements a latin square of order n with rows and columns indexed by the set 0, 1, ..., n-1 and symbols from the same set. The underlying latin square is a matrix(ZZ, n, n). If L is a latin square, then the cell at row r, column c is empty if and only if L[r, c] < 0. In this way we allow partial latin squares and can speak of completions to latin squares, etc.

There are two ways to declare a latin square:

Empty latin square of order n:

```
sage: n = 3
sage: L = LatinSquare(n)
sage: L
[-1 -1 -1]
[-1 -1 -1]
[-1 -1 -1]
```

```
>>> from sage.all import *
>>> n = Integer(3)
>>> L = LatinSquare(n)
>>> L
[-1 -1 -1]
[-1 -1 -1]
[-1 -1 -1]
```

Latin square from a matrix:

```
sage: M = matrix(ZZ, [[0, 1], [2, 3]])
sage: LatinSquare(M)
[0 1]
[2 3]
```

```
>>> from sage.all import *
>>> M = matrix(ZZ, [[Integer(0), Integer(1)], [Integer(2), Integer(3)]])
>>> LatinSquare(M)
[0 1]
[2 3]
```

actual_row_col_sym_sizes()

Bitrades sometimes end up in partial latin squares with unused rows, columns, or symbols. This function works out the actual number of used rows, columns, and symbols.

Warning

We assume that the unused rows/columns occur in the lower right of self, and that the used symbols are in the range {0, 1, …, m} (no holes in that list).

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0,2] = B[1,2] = B[2,2] = -1
sage: B[0,0] = B[2,1] = -1
sage: B
[-1  1 -1]
[ 1  2 -1]
[ 2 -1 -1]
sage: B.actual_row_col_sym_sizes()
(3, 2, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B = back_circulant(Integer(3))
>>> B[Integer(0),Integer(2)] = B[Integer(1),Integer(2)] = B[Integer(2),
↪Integer(2)] = -Integer(1)
>>> B[Integer(0),Integer(0)] = B[Integer(2),Integer(1)] = -Integer(1)
>>> B
[-1  1 -1]
[ 1  2 -1]
[ 2 -1 -1]
>>> B.actual_row_col_sym_sizes()
(3, 2, 2)
```

apply_isotopism(*row_perm*, *col_perm*, *sym_perm*)

An isotopism is a permutation of the rows, columns, and symbols of a partial latin square `self`. Use isotopism() to convert a tuple (indexed from 0) to a Permutation object.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: alpha = isotopism((0,1,2,3,4))
sage: beta  = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B.apply_isotopism(alpha, beta, gamma)
[3 4 2 0 1]
[0 2 3 1 4]
[1 3 0 4 2]
[4 0 1 2 3]
[2 1 4 3 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B = back_circulant(Integer(5))
>>> B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
>>> alpha = isotopism((Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(4)))
>>> beta  = isotopism((Integer(1),Integer(0),Integer(2),Integer(3),
↪Integer(4)))
>>> gamma = isotopism((Integer(2),Integer(1),Integer(0),Integer(3),
↪Integer(4)))
>>> B.apply_isotopism(alpha, beta, gamma)
```

(continues on next page)

(continued from previous page)

```
[3 4 2 0 1]
[0 2 3 1 4]
[1 3 0 4 2]
[4 0 1 2 3]
[2 1 4 3 0]
```

clear_cells()

Mark every cell in `self` as being empty.

EXAMPLES:

```
sage: A = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: A.clear_cells()
sage: A
[-1 -1]
[-1 -1]
```

```
>>> from sage.all import *
>>> A = LatinSquare(matrix(ZZ, [[Integer(0), Integer(1)], [Integer(2),␣
↪Integer(3)]]))
>>> A.clear_cells()
>>> A
[-1 -1]
[-1 -1]
```

column(x)

Return column x of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).column(0)
(0, 1, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(3)).column(Integer(0))
(0, 1, 2)
```

contained_in(Q)

Return `True` if `self` is a subset of Q.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = elementary_abelian_2group(2)
sage: P[0, 0] = -1
sage: P.contained_in(elementary_abelian_2group(2))
True
sage: back_circulant(4).contained_in(elementary_abelian_2group(2))
False
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> P = elementary_abelian_2group(Integer(2))
>>> P[Integer(0), Integer(0)] = -Integer(1)
>>> P.contained_in(elementary_abelian_2group(Integer(2)))
True
>>> back_circulant(Integer(4)).contained_in(elementary_abelian_
↪2group(Integer(2)))
False
```

disjoint_mate_dlxcpp_rows_and_map(*allow_subtrade*)

Internal function for find_disjoint_mates.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: B.disjoint_mate_dlxcpp_rows_and_map(allow_subtrade = True)
([[0, 16, 32],

  (15, 27, 43): (2, 3, 3),
  (15, 31, 47): (3, 3, 3)})
```

dlxcpp_has_unique_completion()

Check if the partial latin square `self` of order n can be embedded in precisely one latin square of order n.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2).dlxcpp_has_unique_completion()
True
sage: P = LatinSquare(2)
sage: P.dlxcpp_has_unique_completion()
False
sage: P[0, 0] = 0
sage: P.dlxcpp_has_unique_completion()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(2)).dlxcpp_has_unique_completion()
True
>>> P = LatinSquare(Integer(2))
>>> P.dlxcpp_has_unique_completion()
False
>>> P[Integer(0), Integer(0)] = Integer(0)
>>> P.dlxcpp_has_unique_completion()
True
```

dumps()

Since the latin square class does not hold any other private variables we just call dumps on self.square:

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2) == loads(dumps(back_circulant(2)))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(2)) == loads(dumps(back_circulant(Integer(2))))
True
```

filled_cells_map()

Number the filled cells of `self` with integers from {1, 2, 3, ...}.

INPUT:

- `self` – partial latin square `self` (empty cells have negative values)

OUTPUT:

A dictionary `cells_map` where `cells_map[(i,j)] = m` means that `(i,j)` is the `m`-th filled cell in `P`, while `cells_map[m] = (i,j)`.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: T1, T2 = bitrade_from_group(a, b, c, G)
sage: D = T1.filled_cells_map()
sage: {i: v for i,v in D.items() if i in ZZ}
{1: (0, 0),
 2: (0, 2),
 3: (0, 3),
 4: (1, 1),
 5: (1, 2),
 6: (1, 3),
 7: (2, 0),
 8: (2, 1),
 9: (2, 2),
 10: (3, 0),
 11: (3, 1),
 12: (3, 3)}
sage: {i: v for i,v in D.items() if i not in ZZ}
{(0, 0): 1,
 (0, 2): 2,
 (0, 3): 3,
 (1, 1): 4,
 (1, 2): 5,
 (1, 3): 6,
 (2, 0): 7,
 (2, 1): 8,
 (2, 2): 9,
 (3, 0): 10,
 (3, 1): 11,
 (3, 3): 12}
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> a, b, c, G = alternating_group_bitrade_generators(Integer(1))
>>> T1, T2 = bitrade_from_group(a, b, c, G)
>>> D = T1.filled_cells_map()
```

(continues on next page)

(continued from previous page)

```
>>> {i: v for i,v in D.items() if i in ZZ}
{1: (0, 0),
 2: (0, 2),
 3: (0, 3),
 4: (1, 1),
 5: (1, 2),
 6: (1, 3),
 7: (2, 0),
 8: (2, 1),
 9: (2, 2),
 10: (3, 0),
 11: (3, 1),
 12: (3, 3)}
>>> {i: v for i,v in D.items() if i not in ZZ}
{(0, 0): 1,
 (0, 2): 2,
 (0, 3): 3,
 (1, 1): 4,
 (1, 2): 5,
 (1, 3): 6,
 (2, 0): 7,
 (2, 1): 8,
 (2, 2): 9,
 (3, 0): 10,
 (3, 1): 11,
 (3, 3): 12}
```

find_disjoint_mates(*nr_to_find=None*, *allow_subtrade=False*)

> **Warning**
>
> If allow_subtrade is `True` then we may return a partial latin square that is *not* disjoint to `self`. In that case, use bitrade(P, Q) to get an actual bitrade.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: g = B.find_disjoint_mates(allow_subtrade = True)
sage: B1 = next(g)
sage: B0, B1 = bitrade(B, B1)
sage: assert is_bitrade(B0, B1)
sage: print(B0)
[-1  1  2 -1]
[-1  2 -1  0]
[-1 -1 -1 -1]
[-1  0  1  2]
sage: print(B1)
[-1  2  1 -1]
[-1  0 -1  2]
[-1 -1 -1 -1]
```

(continues on next page)

(continued from previous page)

```
[-1  1  2  0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B = back_circulant(Integer(4))
>>> g = B.find_disjoint_mates(allow_subtrade = True)
>>> B1 = next(g)
>>> B0, B1 = bitrade(B, B1)
>>> assert is_bitrade(B0, B1)
>>> print(B0)
[-1  1  2 -1]
[-1  2 -1  0]
[-1 -1 -1 -1]
[-1  0  1  2]
>>> print(B1)
[-1  2  1 -1]
[-1  0 -1  2]
[-1 -1 -1 -1]
[-1  1  2  0]
```

gcs()

A greedy critical set of a latin square `self` is found by successively removing elements in a row-wise (bottom-up) manner, checking for unique completion at each step.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: A = elementary_abelian_2group(3)
sage: G = A.gcs()
sage: A
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
sage: G
[ 0  1  2  3  4  5  6 -1]
[ 1  0  3  2  5  4 -1 -1]
[ 2  3  0  1  6 -1  4 -1]
[ 3  2  1  0 -1 -1 -1 -1]
[ 4  5  6 -1  0  1  2 -1]
[ 5  4 -1 -1  1  0 -1 -1]
[ 6 -1  4 -1  2 -1  0 -1]
[-1 -1 -1 -1 -1 -1 -1 -1]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> A = elementary_abelian_2group(Integer(3))
>>> G = A.gcs()
```

(continues on next page)

(continued from previous page)

```
>>> A
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
>>> G
[ 0  1  2  3  4  5  6 -1]
[ 1  0  3  2  5  4 -1 -1]
[ 2  3  0  1  6 -1  4 -1]
[ 3  2  1  0 -1 -1 -1 -1]
[ 4  5  6 -1  0  1  2 -1]
[ 5  4 -1 -1  1  0 -1 -1]
[ 6 -1  4 -1  2 -1  0 -1]
[-1 -1 -1 -1 -1 -1 -1 -1]
```

is_completable()

Return `True` if the partial latin square can be completed to a latin square.

EXAMPLES:

The following partial latin square has no completion because there is nowhere that we can place the symbol 0 in the third row:

```
sage: B = LatinSquare(3)
```

```
>>> from sage.all import *
>>> B = LatinSquare(Integer(3))
```

```
sage: B[0, 0] = 0
sage: B[1, 1] = 0
sage: B[2, 2] = 1
```

```
>>> from sage.all import *
>>> B[Integer(0), Integer(0)] = Integer(0)
>>> B[Integer(1), Integer(1)] = Integer(0)
>>> B[Integer(2), Integer(2)] = Integer(1)
```

```
sage: B
[ 0 -1 -1]
[-1  0 -1]
[-1 -1  1]
```

```
>>> from sage.all import *
>>> B
[ 0 -1 -1]
[-1  0 -1]
[-1 -1  1]
```

```
sage: B.is_completable()
False
```

```
>>> from sage.all import *
>>> B.is_completable()
False
```

```
sage: B[2, 2] = 0
sage: B.is_completable()
True
```

```
>>> from sage.all import *
>>> B[Integer(2), Integer(2)] = Integer(0)
>>> B.is_completable()
True
```

is_empty_column(*c*)

Check if column c of the partial latin square `self` is empty.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_column(0)
False
sage: L[0,0] = L[1,0] = L[2,0] = L[3,0] = -1
sage: L.is_empty_column(0)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> L = back_circulant(Integer(4))
>>> L.is_empty_column(Integer(0))
False
>>> L[Integer(0),Integer(0)] = L[Integer(1),Integer(0)] = L[Integer(2),
↪Integer(0)] = L[Integer(3),Integer(0)] = -Integer(1)
>>> L.is_empty_column(Integer(0))
True
```

is_empty_row(*r*)

Check if row r of the partial latin square `self` is empty.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(4)
sage: L.is_empty_row(0)
False
sage: L[0,0] = L[0,1] = L[0,2] = L[0,3] = -1
sage: L.is_empty_row(0)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> L = back_circulant(Integer(4))
>>> L.is_empty_row(Integer(0))
False
>>> L[Integer(0),Integer(0)] = L[Integer(0),Integer(1)] = L[Integer(0),
↪Integer(2)] = L[Integer(0),Integer(3)] = -Integer(1)
>>> L.is_empty_row(Integer(0))
True
```

is_latin_square()

self is a latin square if it is an n by n matrix, and each symbol in [0, 1, …, n-1] appears exactly once in each row, and exactly once in each column.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(4).is_latin_square()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> elementary_abelian_2group(Integer(4)).is_latin_square()
True
```

```
sage: forward_circulant(7).is_latin_square()
True
```

```
>>> from sage.all import *
>>> forward_circulant(Integer(7)).is_latin_square()
True
```

is_partial_latin_square()

self is a partial latin square if it is an n by n matrix, and each symbol in [0, 1, …, n-1] appears at most once in each row, and at most once in each column.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(4).is_partial_latin_square()
True
sage: back_circulant(3).gcs().is_partial_latin_square()
True
sage: back_circulant(6).is_partial_latin_square()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> LatinSquare(Integer(4)).is_partial_latin_square()
True
>>> back_circulant(Integer(3)).gcs().is_partial_latin_square()
True
```

(continues on next page)

(continued from previous page)

```
>>> back_circulant(Integer(6)).is_partial_latin_square()
True
```

is_uniquely_completable()

Return `True` if the partial latin square `self` has exactly one completion to a latin square. This is just a wrapper for the current best-known algorithm, Dancing Links by Knuth. See dancing_links.spyx

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(4).gcs().is_uniquely_completable()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(4)).gcs().is_uniquely_completable()
True
```

```
sage: G = elementary_abelian_2group(3).gcs()
sage: G.is_uniquely_completable()
True
```

```
>>> from sage.all import *
>>> G = elementary_abelian_2group(Integer(3)).gcs()
>>> G.is_uniquely_completable()
True
```

```
sage: G[0, 0] = -1
sage: G.is_uniquely_completable()
False
```

```
>>> from sage.all import *
>>> G[Integer(0), Integer(0)] = -Integer(1)
>>> G.is_uniquely_completable()
False
```

latex()

Return LaTeX code for the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: print(back_circulant(3).latex())
\begin{array}{|c|c|c|}\hline 0 & 1 & 2\\\hline 1 & 2 & 0\\\hline 2 & 0 & 1\\\
↪hline\end{array}
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> print(back_circulant(Integer(3)).latex())
\begin{array}{|c|c|c|}\hline 0 & 1 & 2\\\hline 1 & 2 & 0\\\hline 2 & 0 & 1\\\
↪hline\end{array}
```

list()

Convert the latin square into a list, in a row-wise manner.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).list()
[0, 1, 2, 1, 2, 0, 2, 0, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(3)).list()
[0, 1, 2, 1, 2, 0, 2, 0, 1]
```

n_distinct_symbols()

Return the number of distinct symbols in the partial latin square `self`.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5).n_distinct_symbols()
5
sage: L = LatinSquare(10)
sage: L.n_distinct_symbols()
0
sage: L[0, 0] = 0
sage: L[0, 1] = 1
sage: L.n_distinct_symbols()
2
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(5)).n_distinct_symbols()
5
>>> L = LatinSquare(Integer(10))
>>> L.n_distinct_symbols()
0
>>> L[Integer(0), Integer(0)] = Integer(0)
>>> L[Integer(0), Integer(1)] = Integer(1)
>>> L.n_distinct_symbols()
2
```

n_filled_cells()

Return the number of filled cells (i.e. cells with a positive value) in the partial latin square `self`.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(matrix([[0, -1], [-1, 0]])).n_filled_cells()
2
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> LatinSquare(matrix([[Integer(0), -Integer(1)], [-Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(0)]])).n_filled_cells()
2
```

ncols()

Number of columns in the latin square.

EXAMPLES:

```
sage: LatinSquare(3).ncols()
3
```

```
>>> from sage.all import *
>>> LatinSquare(Integer(3)).ncols()
3
```

nr_distinct_symbols()

alias of *n_distinct_symbols()*.

nr_filled_cells()

alias of *n_filled_cells()*.

nrows()

Number of rows in the latin square.

EXAMPLES:

```
sage: LatinSquare(3).nrows()
3
```

```
>>> from sage.all import *
>>> LatinSquare(Integer(3)).nrows()
3
```

permissable_values(*r*, *c*)

Find all values that do not appear in row r and column c of the latin square `self`. If `self[r, c]` is filled then we return the empty list.

INPUT:

- `self` – LatinSquare
- `r` – integer; row of the latin square
- `c` – integer; column of the latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(5)
sage: L[0, 0] = -1
sage: L.permissable_values(0, 0)
[0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> L = back_circulant(Integer(5))
>>> L[Integer(0), Integer(0)] = -Integer(1)
>>> L.permissable_values(Integer(0), Integer(0))
[0]
```

random_empty_cell()

Find an empty cell of self, uniformly at random.

INPUT:

- `self` – LatinSquare

OUTPUT:

- `[r, c]` – cell such that `self[r, c]` is empty, or returns `None` if `self` is a (full) latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = back_circulant(2)
sage: P[1,1] = -1
sage: P.random_empty_cell()
[1, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> P = back_circulant(Integer(2))
>>> P[Integer(1),Integer(1)] = -Integer(1)
>>> P.random_empty_cell()
[1, 1]
```

row(x)

Return row x of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).row(0)
(0, 1, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(3)).row(Integer(0))
(0, 1, 2)
```

set_immutable()

A latin square is immutable if the underlying matrix is immutable.

EXAMPLES:

```
sage: L = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: L.set_immutable()
sage: {L : 0}   # this would fail without set_immutable()
```

(continues on next page)

(continued from previous page)

```
{[0 1]
[2 3]: 0}
```

```
>>> from sage.all import *
>>> L = LatinSquare(matrix(ZZ, [[Integer(0), Integer(1)], [Integer(2),␣
↪Integer(3)]]))
>>> L.set_immutable()
>>> {L : Integer(0)}   # this would fail without set_immutable()
{[0 1]
[2 3]: 0}
```

top_left_empty_cell()

Return the least `[r, c]` such that `self[r, c]` is an empty cell. If all cells are filled then we return `None`.

INPUT:

- `self` – LatinSquare

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B[3, 4] = -1
sage: B.top_left_empty_cell()
[3, 4]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B = back_circulant(Integer(5))
>>> B[Integer(3), Integer(4)] = -Integer(1)
>>> B.top_left_empty_cell()
[3, 4]
```

vals_in_col(*c*)

Return a dictionary with key e if and only if column c of `self` has the symbol e.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
sage: back_circulant(3).vals_in_col(0)
{0: True, 1: True, 2: True}
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B = back_circulant(Integer(3))
>>> B[Integer(0), Integer(0)] = -Integer(1)
>>> back_circulant(Integer(3)).vals_in_col(Integer(0))
{0: True, 1: True, 2: True}
```

vals_in_row(*r*)

Return a dictionary with key e if and only if row r of `self` has the symbol e.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
sage: back_circulant(3).vals_in_row(0)
{0: True, 1: True, 2: True}
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B = back_circulant(Integer(3))
>>> B[Integer(0), Integer(0)] = -Integer(1)
>>> back_circulant(Integer(3)).vals_in_row(Integer(0))
{0: True, 1: True, 2: True}
```

sage.combinat.matrices.latin.**LatinSquare_generator**(*L_start*, *check_assertions=False*)

Generator for a sequence of uniformly distributed latin squares, given L_start as the initial latin square.

This code implements the Markov chain algorithm of Jacobson and Matthews (1996), see below for the BibTex entry. This generator will never throw the `StopIteration` exception, so it provides an infinite sequence of latin squares.

EXAMPLES:

Use the back circulant latin square of order 4 as the initial square and print the next two latin squares given by the Markov chain:

```
sage: from sage.combinat.matrices.latin import *
sage: g = LatinSquare_generator(back_circulant(4))
sage: next(g).is_latin_square()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> g = LatinSquare_generator(back_circulant(Integer(4)))
>>> next(g).is_latin_square()
True
```

REFERENCES:

sage.combinat.matrices.latin.**alternating_group_bitrade_generators**(*m*)

Construct generators a, b, c for the alternating group on 3m+1 points, such that a*b*c = 1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (a, b, c, G)
((1,2,3), (1,4,2), (2,4,3), Permutation Group with generators [(1,2,3), (1,4,2)])
sage: a*b*c
()
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> a, b, c, G = alternating_group_bitrade_generators(Integer(1))
```

(continues on next page)

(continued from previous page)

```
>>> (a, b, c, G)
((1,2,3), (1,4,2), (2,4,3), Permutation Group with generators [(1,2,3), (1,4,2)])
>>> a*b*c
()
```

```
sage: T1, T2 = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
sage: T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
```

```
>>> from sage.all import *
>>> T1, T2 = bitrade_from_group(a, b, c, G)
>>> T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
>>> T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
```

sage.combinat.matrices.latin.**back_circulant**(*n*)

The back-circulant latin square of order n is the Cayley table for (Z_n, +), the integers under addition modulo n.

INPUT:

- n – integer; order of the latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5)
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(5))
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
```

(continues on next page)

(continued from previous page)

```
[3 4 0 1 2]
[4 0 1 2 3]
```

sage.combinat.matrices.latin.**beta1**(*rce*, *T1*, *T2*)

Find the unique (x, c, e) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` – tuple (or list) (r, c, e) in T1
- `T1`, `T2` – latin bitrade

OUTPUT: (x, c, e) in T2

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta1([0, 0, 0], T1, T2)
(1, 0, 0)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> T1 = back_circulant(Integer(5))
>>> x = isotopism( (Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)) )
>>> y = isotopism(Integer(5)) # identity
>>> z = isotopism(Integer(5)) # identity
>>> T2 = T1.apply_isotopism(x, y, z)
>>> is_bitrade(T1, T2)
True
>>> beta1([Integer(0), Integer(0), Integer(0)], T1, T2)
(1, 0, 0)
```

sage.combinat.matrices.latin.**beta2**(*rce*, *T1*, *T2*)

Find the unique (r, x, e) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` – tuple (or list) (r, c, e) in T1
- `T1`, `T2` – latin bitrade

OUTPUT: (r, x, e) in T2

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
```

(continues on next page)

(continued from previous page)

```
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta2([0, 0, 0], T1, T2)
(0, 1, 0)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> T1 = back_circulant(Integer(5))
>>> x = isotopism( (Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)) )
>>> y = isotopism(Integer(5)) # identity
>>> z = isotopism(Integer(5)) # identity
>>> T2 = T1.apply_isotopism(x, y, z)
>>> is_bitrade(T1, T2)
True
>>> beta2([Integer(0), Integer(0), Integer(0)], T1, T2)
(0, 1, 0)
```

sage.combinat.matrices.latin.**beta3**(*rce*, *T1*, *T2*)

Find the unique (r, c, x) in T2 such that (r, c, e) is in T1.

INPUT:

- `rce` – tuple (or list) (r, c, e) in T1
- `T1, T2` – latin bitrade

OUTPUT: (r, c, x) in T2.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta3([0, 0, 0], T1, T2)
(0, 0, 4)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> T1 = back_circulant(Integer(5))
>>> x = isotopism( (Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)) )
>>> y = isotopism(Integer(5)) # identity
>>> z = isotopism(Integer(5)) # identity
>>> T2 = T1.apply_isotopism(x, y, z)
>>> is_bitrade(T1, T2)
True
>>> beta3([Integer(0), Integer(0), Integer(0)], T1, T2)
(0, 0, 4)
```

sage.combinat.matrices.latin.**bitrade**(*T1*, *T2*)

Form the bitrade (Q1, Q2) from (T1, T2) by setting empty the cells (r, c) such that T1[r, c] == T2[r, c].

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: B1 = back_circulant(5)
sage: alpha = isotopism((0,1,2,3,4))
sage: beta  = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B2 = B1.apply_isotopism(alpha, beta, gamma)
sage: T1, T2 = bitrade(B1, B2)
sage: T1
[ 0  1 -1  3  4]
[ 1 -1 -1  4  0]
[ 2 -1  4  0  1]
[ 3  4  0  1  2]
[ 4  0  1  2  3]
sage: T2
[ 3  4 -1  0  1]
[ 0 -1 -1  1  4]
[ 1 -1  0  4  2]
[ 4  0  1  2  3]
[ 2  1  4  3  0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B1 = back_circulant(Integer(5))
>>> alpha = isotopism((Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)))
>>> beta  = isotopism((Integer(1),Integer(0),Integer(2),Integer(3),Integer(4)))
>>> gamma = isotopism((Integer(2),Integer(1),Integer(0),Integer(3),Integer(4)))
>>> B2 = B1.apply_isotopism(alpha, beta, gamma)
>>> T1, T2 = bitrade(B1, B2)
>>> T1
[ 0  1 -1  3  4]
[ 1 -1 -1  4  0]
[ 2 -1  4  0  1]
[ 3  4  0  1  2]
[ 4  0  1  2  3]
>>> T2
[ 3  4 -1  0  1]
[ 0 -1 -1  1  4]
[ 1 -1  0  4  2]
[ 4  0  1  2  3]
[ 2  1  4  3  0]
```

sage.combinat.matrices.latin.**bitrade_from_group**(*a*, *b*, *c*, *G*)

Given group elements a, b, c in G such that abc = 1 and the subgroups a, b, c intersect (pairwise) only in the identity, construct a bitrade (T1, T2) where rows, columns, and symbols correspond to cosets of a, b, and c, respectively.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
```

(continues on next page)

(continued from previous page)

```
sage: T1, T2 = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
sage: T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> a, b, c, G = alternating_group_bitrade_generators(Integer(1))
>>> T1, T2 = bitrade_from_group(a, b, c, G)
>>> T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
>>> T2
[ 1 -1  0  3]
[-1  0  2  1]
[ 2  1  3 -1]
[ 0  3 -1  2]
```

sage.combinat.matrices.latin.**cells_map_as_square**(*cells_map*, *n*)

Return a LatinSquare with cells numbered from 1, 2, … to given the dictionary cells_map.

Note

The value n should be the maximum of the number of rows and columns of the original partial latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: T1, T2 = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> a, b, c, G = alternating_group_bitrade_generators(Integer(1))
>>> T1, T2 = bitrade_from_group(a, b, c, G)
>>> T1
```

(continues on next page)

(continued from previous page)

```
[ 0 -1  3  1]
[-1  1  0  2]
[ 1  3  2 -1]
[ 2  0 -1  3]
```

There are 12 filled cells in T:

```
sage: cells_map_as_square(T1.filled_cells_map(), max(T1.nrows(), T1.ncols()))
[ 1 -1  2  3]
[-1  4  5  6]
[ 7  8  9 -1]
[10 11 -1 12]
```

```
>>> from sage.all import *
>>> cells_map_as_square(T1.filled_cells_map(), max(T1.nrows(), T1.ncols()))
[ 1 -1  2  3]
[-1  4  5  6]
[ 7  8  9 -1]
[10 11 -1 12]
```

sage.combinat.matrices.latin.**check_bitrade_generators**(*a*, *b*, *c*)

Three group elements a, b, c will generate a bitrade if a*b*c = 1 and the subgroups a, b, c intersect (pairwise) in just the identity.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = p3_group_bitrade_generators(3)
sage: check_bitrade_generators(a, b, c)
True
sage: check_bitrade_generators(a, b, libgap.CycleFromList([]))
False
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> a, b, c, G = p3_group_bitrade_generators(Integer(3))
>>> check_bitrade_generators(a, b, c)
True
>>> check_bitrade_generators(a, b, libgap.CycleFromList([]))
False
```

sage.combinat.matrices.latin.**coin**()

Simulate a fair coin (returns `True` or `False`) using ZZ.random_element(2).

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import coin
sage: x = coin()
sage: x == 0 or x == 1
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import coin
>>> x = coin()
>>> x == Integer(0) or x == Integer(1)
True
```

sage.combinat.matrices.latin.**column_containing_sym**(*L*, *r*, *x*)

Given an improper latin square L with L[r, c1] = L[r, c2] = x, return c1 or c2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([(1, 0, 2, 3), (0, 2, 3, 0), (2, 3, 0, 1), (3, 0, 1, 2)])
sage: L
[1 0 2 3]
[0 2 3 0]
[2 3 0 1]
[3 0 1 2]
sage: c = column_containing_sym(L, 1, 0)
sage: c == 0 or c == 3
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> L = matrix([(Integer(1), Integer(0), Integer(2), Integer(3)), (Integer(0),␣
↪Integer(2), Integer(3), Integer(0)), (Integer(2), Integer(3), Integer(0),␣
↪Integer(1)), (Integer(3), Integer(0), Integer(1), Integer(2))])
>>> L
[1 0 2 3]
[0 2 3 0]
[2 3 0 1]
[3 0 1 2]
>>> c = column_containing_sym(L, Integer(1), Integer(0))
>>> c == Integer(0) or c == Integer(3)
True
```

sage.combinat.matrices.latin.**direct_product**(*L1*, *L2*, *L3*, *L4*)

The 'direct product' of four latin squares L1, L2, L3, L4 of order n is the latin square of order 2n consisting of

```
-----------
| L1 | L2 |
-----------
| L3 | L4 |
-----------
```

where the subsquares L2 and L3 have entries offset by n.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: direct_product(back_circulant(4), back_circulant(4), elementary_abelian_
↪2group(2), elementary_abelian_2group(2))
[0 1 2 3 4 5 6 7]
```

(continues on next page)

(continued from previous page)

```
[1 2 3 0 5 6 7 4]
[2 3 0 1 6 7 4 5]
[3 0 1 2 7 4 5 6]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> direct_product(back_circulant(Integer(4)), back_circulant(Integer(4)),␣
↪elementary_abelian_2group(Integer(2)), elementary_abelian_2group(Integer(2)))
[0 1 2 3 4 5 6 7]
[1 2 3 0 5 6 7 4]
[2 3 0 1 6 7 4 5]
[3 0 1 2 7 4 5 6]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

sage.combinat.matrices.latin.**dlxcpp_find_completions**(*P*, *nr_to_find=None*)

Return a list of all latin squares L of the same order as P such that P is contained in L. The optional parameter nr_to_find limits the number of latin squares that are found.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_find_completions(LatinSquare(2))
[[0 1]
[1 0], [1 0]
[0 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> dlxcpp_find_completions(LatinSquare(Integer(2)))
[[0 1]
[1 0], [1 0]
[0 1]]
```

```
sage: dlxcpp_find_completions(LatinSquare(2), 1)
[[0 1]
[1 0]]
```

```
>>> from sage.all import *
>>> dlxcpp_find_completions(LatinSquare(Integer(2)), Integer(1))
[[0 1]
[1 0]]
```

sage.combinat.matrices.latin.**dlxcpp_rows_and_map**(*P*)

Internal function for `dlxcpp_find_completions`. Given a partial latin square P we construct a list of rows of a 0-1 matrix M such that an exact cover of M corresponds to a completion of P to a latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_rows_and_map(LatinSquare(2))
([[0, 4, 8],
  [1, 5, 8],
  [2, 4, 9],
  [3, 5, 9],
  [0, 6, 10],
  [1, 7, 10],
  [2, 6, 11],
  [3, 7, 11]],
 {(0, 4, 8): (0, 0, 0),
  (0, 6, 10): (1, 0, 0),
  (1, 5, 8): (0, 0, 1),
  (1, 7, 10): (1, 0, 1),
  (2, 4, 9): (0, 1, 0),
  (2, 6, 11): (1, 1, 0),
  (3, 5, 9): (0, 1, 1),
  (3, 7, 11): (1, 1, 1)})
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> dlxcpp_rows_and_map(LatinSquare(Integer(2)))
([[0, 4, 8],
  [1, 5, 8],
  [2, 4, 9],
  [3, 5, 9],
  [0, 6, 10],
  [1, 7, 10],
  [2, 6, 11],
  [3, 7, 11]],
 {(0, 4, 8): (0, 0, 0),
  (0, 6, 10): (1, 0, 0),
  (1, 5, 8): (0, 0, 1),
  (1, 7, 10): (1, 0, 1),
  (2, 4, 9): (0, 1, 0),
  (2, 6, 11): (1, 1, 0),
  (3, 5, 9): (0, 1, 1),
  (3, 7, 11): (1, 1, 1)})
```

sage.combinat.matrices.latin.**elementary_abelian_2group**(*s*)

Return the latin square based on the Cayley table for the elementary abelian 2-group of order 2s.

INPUT:

- `s` – integer; order of the latin square will be 2s

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(3)
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
```

(continues on next page)

(continued from previous page)

```
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> elementary_abelian_2group(Integer(3))
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
```

sage.combinat.matrices.latin.**forward_circulant**(*n*)

The forward-circulant latin square of order n is the Cayley table for the operation r + c = (n-c+r) mod n.

INPUT:

- n – integer; order of the latin square

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: forward_circulant(5)
[0 4 3 2 1]
[1 0 4 3 2]
[2 1 0 4 3]
[3 2 1 0 4]
[4 3 2 1 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> forward_circulant(Integer(5))
[0 4 3 2 1]
[1 0 4 3 2]
[2 1 0 4 3]
[3 2 1 0 4]
[4 3 2 1 0]
```

sage.combinat.matrices.latin.**genus**(*T1*, *T2*)

Return the genus of hypermap embedding associated with the bitrade (T1, T2).

Informally, we compute the [tau_1, tau_2, tau_3] permutation representation of the bitrade. Each cycle of tau_1, tau_2, and tau_3 gives a rotation scheme for a black, white, and star vertex (respectively). The genus then comes from Euler's formula.

For more details see Carlo Hamalainen: *Partitioning 3-homogeneous latin bitrades*. To appear in Geometriae Dedicata, available at arXiv 0710.0938

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: T1, T2 = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
1
sage: a, b, c, G = pq_group_bitrade_generators(3, 7)
sage: T1, T2 = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
3
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> a, b, c, G = alternating_group_bitrade_generators(Integer(1))
>>> T1, T2 = bitrade_from_group(a, b, c, G)
>>> genus(T1, T2)
1
>>> a, b, c, G = pq_group_bitrade_generators(Integer(3), Integer(7))
>>> T1, T2 = bitrade_from_group(a, b, c, G)
>>> genus(T1, T2)
3
```

sage.combinat.matrices.latin.**group_to_LatinSquare**(*G*)

Construct a latin square on the symbols [0, 1, …, n-1] for a group with an n by n Cayley table.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import group_to_LatinSquare

sage: group_to_LatinSquare(DihedralGroup(2))
[0 1 2 3]
[1 0 3 2]
[2 3 0 1]
[3 2 1 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import group_to_LatinSquare

>>> group_to_LatinSquare(DihedralGroup(Integer(2)))
[0 1 2 3]
[1 0 3 2]
[2 3 0 1]
[3 2 1 0]
```

```
sage: G = libgap.Group(PermutationGroupElement((1,2,3)))
sage: group_to_LatinSquare(G)
[0 1 2]
[1 2 0]
[2 0 1]
```

```
>>> from sage.all import *
>>> G = libgap.Group(PermutationGroupElement((Integer(1),Integer(2),Integer(3))))
>>> group_to_LatinSquare(G)
```

(continues on next page)

(continued from previous page)

```
[0 1 2]
[1 2 0]
[2 0 1]
```

sage.combinat.matrices.latin.**is_bitrade**(*T1*, *T2*)

Combinatorially, a pair (T1, T2) of partial latin squares is a bitrade if they are disjoint, have the same shape, and have row and column balance. For definitions of each of these terms see the relevant function in this file.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> T1 = back_circulant(Integer(5))
>>> x = isotopism( (Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)) )
>>> y = isotopism(Integer(5)) # identity
>>> z = isotopism(Integer(5)) # identity
>>> T2 = T1.apply_isotopism(x, y, z)
>>> is_bitrade(T1, T2)
True
```

sage.combinat.matrices.latin.**is_disjoint**(*T1*, *T2*)

The partial latin squares T1 and T2 are disjoint if T1[r, c] != T2[r, c] or T1[r, c] == T2[r, c] == -1 for each cell [r, c].

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import is_disjoint, back_circulant,␣
↪isotopism
sage: is_disjoint(back_circulant(2), back_circulant(2))
False
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import is_disjoint, back_circulant,␣
↪isotopism
>>> is_disjoint(back_circulant(Integer(2)), back_circulant(Integer(2)))
False
```

```
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_disjoint(T1, T2)
True
```

```
>>> from sage.all import *
>>> T1 = back_circulant(Integer(5))
>>> x = isotopism( (Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)) )
>>> y = isotopism(Integer(5)) # identity
>>> z = isotopism(Integer(5)) # identity
>>> T2 = T1.apply_isotopism(x, y, z)
>>> is_disjoint(T1, T2)
True
```

sage.combinat.matrices.latin.**is_primary_bitrade**(*a*, *b*, *c*, *G*)

A bitrade generated from elements a, b, c is primary if a, b, c = G.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = p3_group_bitrade_generators(5)
sage: is_primary_bitrade(a, b, c, G)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> a, b, c, G = p3_group_bitrade_generators(Integer(5))
>>> is_primary_bitrade(a, b, c, G)
True
```

sage.combinat.matrices.latin.**is_row_and_col_balanced**(*T1*, *T2*)

Partial latin squares T1 and T2 are balanced if the symbols appearing in row r of T1 are the same as the symbols appearing in row r of T2, for each r, and if the same condition holds on columns.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: T2 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
True
sage: T2 = matrix([[0,3,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: is_row_and_col_balanced(T1, T2)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> T1 = matrix([[Integer(0),Integer(1),-Integer(1),-Integer(1)], [-Integer(1),-
↪Integer(1),-Integer(1),-Integer(1)], [-Integer(1),-Integer(1),-Integer(1),-
↪Integer(1)], [-Integer(1),-Integer(1),-Integer(1),-Integer(1)]])
>>> T2 = matrix([[Integer(0),Integer(1),-Integer(1),-Integer(1)], [-Integer(1),-
↪Integer(1),-Integer(1),-Integer(1)], [-Integer(1),-Integer(1),-Integer(1),-
↪Integer(1)], [-Integer(1),-Integer(1),-Integer(1),-Integer(1)]])
>>> is_row_and_col_balanced(T1, T2)
True
>>> T2 = matrix([[Integer(0),Integer(3),-Integer(1),-Integer(1)], [-Integer(1),-
↪Integer(1),-Integer(1),-Integer(1)], [-Integer(1),-Integer(1),-Integer(1),-
↪Integer(1)], [-Integer(1),-Integer(1),-Integer(1),-Integer(1)]])
```

(continues on next page)

(continued from previous page)

```
>>> is_row_and_col_balanced(T1, T2)
False
```

sage.combinat.matrices.latin.**is_same_shape**(*T1*, *T2*)

Two partial latin squares T1, T2 have the same shape if T1[r, c] = 0 if and only if T2[r, c] = 0.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: is_same_shape(elementary_abelian_2group(2), back_circulant(4))
True
sage: is_same_shape(LatinSquare(5), LatinSquare(5))
True
sage: is_same_shape(forward_circulant(5), LatinSquare(5))
False
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> is_same_shape(elementary_abelian_2group(Integer(2)), back_
↪circulant(Integer(4)))
True
>>> is_same_shape(LatinSquare(Integer(5)), LatinSquare(Integer(5)))
True
>>> is_same_shape(forward_circulant(Integer(5)), LatinSquare(Integer(5)))
False
```

sage.combinat.matrices.latin.**isotopism**(*p*)

Return a Permutation object that represents an isotopism (for rows, columns or symbols of a partial latin square).

Technically, all this function does is take as input a representation of a permutation of $0, ..., n-1$ and return a *Permutation* object defined on $1, ..., n$.

For a definition of isotopism, see the wikipedia section on isotopism.

INPUT:

According to the type of input (see examples below):

- an integer n – the function returns the identity on $1, ..., n$
- a string representing a permutation in disjoint cycles notation, e.g. $(0, 1, 2)(3, 4, 5)$ – the corresponding permutation is returned, shifted by 1 to act on $1, ..., n$
- list/tuple of tuples – assumes disjoint cycle notation, see previous entry
- a list of integers – the function adds 1 to each member of the list, and returns the corresponding permutation
- a `PermutationGroupElement` `p` – returns a permutation describing `p` **without** any shift

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: isotopism(5) # identity on 5 points
[1, 2, 3, 4, 5]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
```

(continues on next page)

(continued from previous page)

```
>>> isotopism(Integer(5)) # identity on 5 points
[1, 2, 3, 4, 5]
```

```
sage: G = PermutationGroup(['(1,2,3)(4,5)'])
sage: g = G.gen(0)
sage: isotopism(g)
[2, 3, 1, 5, 4]
```

```
>>> from sage.all import *
>>> G = PermutationGroup(['(1,2,3)(4,5)'])
>>> g = G.gen(Integer(0))
>>> isotopism(g)
[2, 3, 1, 5, 4]
```

```
sage: isotopism([0,3,2,1]) # 0 goes to 0, 1 goes to 3, etc.
[1, 4, 3, 2]
```

```
>>> from sage.all import *
>>> isotopism([Integer(0),Integer(3),Integer(2),Integer(1)]) # 0 goes to 0, 1␣
↪goes to 3, etc.
[1, 4, 3, 2]
```

```
sage: isotopism( (0,1,2) ) # single cycle, presented as a tuple
[2, 3, 1]
```

```
>>> from sage.all import *
>>> isotopism( (Integer(0),Integer(1),Integer(2)) ) # single cycle, presented as␣
↪a tuple
[2, 3, 1]
```

```
sage: x = isotopism( ((0,1,2), (3,4)) ) # tuple of cycles
sage: x
[2, 3, 1, 5, 4]
sage: x.to_cycles()
[(1, 2, 3), (4, 5)]
```

```
>>> from sage.all import *
>>> x = isotopism( ((Integer(0),Integer(1),Integer(2)), (Integer(3),Integer(4)))␣
↪) # tuple of cycles
>>> x
[2, 3, 1, 5, 4]
>>> x.to_cycles()
[(1, 2, 3), (4, 5)]
```

sage.combinat.matrices.latin.**next_conjugate**(L)

Permute L[r, c] = e to the conjugate L[c, e] = r.

We assume that L is an n by n matrix and has values in the range 0, 1, …, n-1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(6)
sage: L
[0 1 2 3 4 5]
[1 2 3 4 5 0]
[2 3 4 5 0 1]
[3 4 5 0 1 2]
[4 5 0 1 2 3]
[5 0 1 2 3 4]
sage: next_conjugate(L)
[0 1 2 3 4 5]
[5 0 1 2 3 4]
[4 5 0 1 2 3]
[3 4 5 0 1 2]
[2 3 4 5 0 1]
[1 2 3 4 5 0]
sage: L == next_conjugate(next_conjugate(next_conjugate(L)))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> L = back_circulant(Integer(6))
>>> L
[0 1 2 3 4 5]
[1 2 3 4 5 0]
[2 3 4 5 0 1]
[3 4 5 0 1 2]
[4 5 0 1 2 3]
[5 0 1 2 3 4]
>>> next_conjugate(L)
[0 1 2 3 4 5]
[5 0 1 2 3 4]
[4 5 0 1 2 3]
[3 4 5 0 1 2]
[2 3 4 5 0 1]
[1 2 3 4 5 0]
>>> L == next_conjugate(next_conjugate(next_conjugate(L)))
True
```

sage.combinat.matrices.latin.**p3_group_bitrade_generators**(*p*)

Generators for a group of order p3 where p is a prime.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: p3_group_bitrade_generators(3)  # random output
((2,6,7)(3,8,9),
 (1,2,3)(4,7,8)(5,6,9),
 (1,9,2)(3,7,4)(5,8,6),
 Permutation Group with generators [(2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9)])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
```

(continues on next page)

(continued from previous page)

```
>>> p3_group_bitrade_generators(Integer(3))  # random output
((2,6,7)(3,8,9),
 (1,2,3)(4,7,8)(5,6,9),
 (1,9,2)(3,7,4)(5,8,6),
 Permutation Group with generators [(2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9)])
```

sage.combinat.matrices.latin.**pq_group_bitrade_generators**(*p*, *q*)

Generators for a group of order pq where p and q are primes such that (q % p) == 1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: pq_group_bitrade_generators(3,7)
((2,3,5)(4,7,6), (1,2,3,4,5,6,7), (1,4,2)(3,5,6), Permutation Group with␣
↪generators [(2,3,5)(4,7,6), (1,2,3,4,5,6,7)])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> pq_group_bitrade_generators(Integer(3),Integer(7))
((2,3,5)(4,7,6), (1,2,3,4,5,6,7), (1,4,2)(3,5,6), Permutation Group with␣
↪generators [(2,3,5)(4,7,6), (1,2,3,4,5,6,7)])
```

sage.combinat.matrices.latin.**row_containing_sym**(*L*, *c*, *x*)

Given an improper latin square L with L[r1, c] = L[r2, c] = x, return r1 or r2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([(0, 1, 0, 3), (3, 0, 2, 1), (1, 0, 3, 2), (2, 3, 1, 0)])
sage: L
[0 1 0 3]
[3 0 2 1]
[1 0 3 2]
[2 3 1 0]
sage: c = row_containing_sym(L, 1, 0)
sage: c == 1 or c == 2
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> L = matrix([(Integer(0), Integer(1), Integer(0), Integer(3)), (Integer(3),␣
↪Integer(0), Integer(2), Integer(1)), (Integer(1), Integer(0), Integer(3),␣
↪Integer(2)), (Integer(2), Integer(3), Integer(1), Integer(0))])
>>> L
[0 1 0 3]
[3 0 2 1]
[1 0 3 2]
[2 3 1 0]
>>> c = row_containing_sym(L, Integer(1), Integer(0))
>>> c == Integer(1) or c == Integer(2)
True
```

sage.combinat.matrices.latin.**tau1**(*T1*, *T2*, *cells_map*)

The definition of τ_1 is

$$\tau_1 : T1 \to T1$$
$$\tau_1 = \beta_2^{-1}\beta_3$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the i-th coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: cells_map, t1, t2, t3 = tau123(T1, T2)
sage: t1 = tau1(T1, T2, cells_map)
sage: t1
[2, 3, 4, 5, 1, 7, 8, 9, 10, 6, 12, 13, 14, 15, 11, 17, 18, 19, 20, 16, 22, 23,␣
↪24, 25, 21]
sage: t1.to_cycles()
[(1, 2, 3, 4, 5), (6, 7, 8, 9, 10), (11, 12, 13, 14, 15), (16, 17, 18, 19, 20),␣
↪(21, 22, 23, 24, 25)]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> T1 = back_circulant(Integer(5))
>>> x = isotopism( (Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)) )
>>> y = isotopism(Integer(5)) # identity
>>> z = isotopism(Integer(5)) # identity
>>> T2 = T1.apply_isotopism(x, y, z)
>>> is_bitrade(T1, T2)
True
>>> cells_map, t1, t2, t3 = tau123(T1, T2)
>>> t1 = tau1(T1, T2, cells_map)
>>> t1
[2, 3, 4, 5, 1, 7, 8, 9, 10, 6, 12, 13, 14, 15, 11, 17, 18, 19, 20, 16, 22, 23,␣
↪24, 25, 21]
>>> t1.to_cycles()
[(1, 2, 3, 4, 5), (6, 7, 8, 9, 10), (11, 12, 13, 14, 15), (16, 17, 18, 19, 20),␣
↪(21, 22, 23, 24, 25)]
```

sage.combinat.matrices.latin.**tau123**(*T1*, *T2*)

Compute the tau_i representation for a bitrade (T1, T2).

See the functions tau1, tau2, and tau3 for the mathematical definitions.

OUTPUT:

- (cells_map, t1, t2, t3)

where cells_map is a map to/from the filled cells of T1, and t1, t2, t3 are the tau1, tau2, tau3 permutations.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = pq_group_bitrade_generators(3, 7)
sage: T1, T2 = bitrade_from_group(a, b, c, G)
sage: T1

The product t1*t2*t3 is the identity, i.e. it fixes every point:

```
sage: len((t1*t2*t3).fixed_points()) == T1.n_filled_cells()
True
```

```
>>> from sage.all import *
>>> len((t1*t2*t3).fixed_points()) == T1.n_filled_cells()
True
```

sage.combinat.matrices.latin.**tau2**(*T1*, *T2*, *cells_map*)

The definition of τ_2 is

$$\tau_2 : T1 \to T1$$
$$\tau_2 = \beta_3^{-1}\beta_1$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the i-th coordinate of a triple.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: cells_map, t1, t2, t3 = tau123(T1, T2)
sage: t2 = tau2(T1, T2, cells_map)
```

[10, 6, 7, 8, 9, 15, 11, 12, 13, 14, 20, 16, 17, 18, 19, 25, 21, 22, 23, 24, 5, 1,
↪ 2, 3, 4]
>>> t3.to_cycles()
[(1, 10, 14, 18, 22), (2, 6, 15, 19, 23), (3, 7, 11, 20, 24), (4, 8, 12, 16, 25),␣
↪(5, 9, 13, 17, 21)]
```

sage.combinat.matrices.latin.**tau_to_bitrade**(*t1*, *t2*, *t3*)

Given permutations t1, t2, t3 that represent a latin bitrade, convert them to an explicit latin bitrade (T1, T2). The result is unique up to isotopism.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: _, t1, t2, t3 = tau123(T1, T2)
sage: U1, U2 = tau_to_bitrade(t1, t2, t3)
sage: assert is_bitrade(U1, U2)
sage: U1
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: U2
[4 0 1 2 3]
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> T1 = back_circulant(Integer(5))
>>> x = isotopism( (Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)) )
>>> y = isotopism(Integer(5)) # identity
>>> z = isotopism(Integer(5)) # identity
>>> T2 = T1.apply_isotopism(x, y, z)
```

(continues on next page)

(continued from previous page)

```
>>> _, t1, t2, t3 = tau123(T1, T2)
>>> U1, U2 = tau_to_bitrade(t1, t2, t3)
>>> assert is_bitrade(U1, U2)
>>> U1
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
>>> U2
[4 0 1 2 3]
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
```

4.1.8 sage.combinat.ncsf_qsym

Common combinatorial tools

REFERENCES:

sage.combinat.ncsf_qsym.combinatorics.**coeff_dab**(I, J)

Return the number of standard composition tableaux of shape I with descent composition J.

INPUT:

- I, J – compositions

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_dab
sage: coeff_dab(Composition([2,1]),Composition([2,1]))
1
sage: coeff_dab(Composition([1,1,2]),Composition([1,2,1]))
0
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import coeff_dab
>>> coeff_dab(Composition([Integer(2),Integer(1)]),Composition([Integer(2),
↪Integer(1)]))
1
>>> coeff_dab(Composition([Integer(1),Integer(1),Integer(2)]),
↪Composition([Integer(1),Integer(2),Integer(1)]))
0
```

sage.combinat.ncsf_qsym.combinatorics.**coeff_ell**(J, I)

Return the coefficient $\ell_{J,I}$ as defined in [NCSF].

INPUT:

- J – a composition
- I – a composition refining J

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_ell
sage: coeff_ell(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_ell(Composition([2,1]), Composition([3]))
2
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import coeff_ell
>>> coeff_ell(Composition([Integer(1),Integer(1),Integer(1)]),␣
↪Composition([Integer(2),Integer(1)]))
2
>>> coeff_ell(Composition([Integer(2),Integer(1)]), Composition([Integer(3)]))
2
```

sage.combinat.ncsf_qsym.combinatorics.**coeff_lp**(J, I)

Return the coefficient $lp_{J,I}$ as defined in [NCSF].

INPUT:

- `J` – a composition
- `I` – a composition refining `J`

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_lp
sage: coeff_lp(Composition([1,1,1]), Composition([2,1]))
1
sage: coeff_lp(Composition([2,1]), Composition([3]))
1
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import coeff_lp
>>> coeff_lp(Composition([Integer(1),Integer(1),Integer(1)]),␣
↪Composition([Integer(2),Integer(1)]))
1
>>> coeff_lp(Composition([Integer(2),Integer(1)]), Composition([Integer(3)]))
1
```

sage.combinat.ncsf_qsym.combinatorics.**coeff_pi**(J, I)

Return the coefficient $\pi_{J,I}$ as defined in [NCSF].

INPUT:

- `J` – a composition
- `I` – a composition refining `J`

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_pi
sage: coeff_pi(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_pi(Composition([2,1]), Composition([3]))
6
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import coeff_pi
>>> coeff_pi(Composition([Integer(1),Integer(1),Integer(1)]),␣
↪Composition([Integer(2),Integer(1)]))
2
>>> coeff_pi(Composition([Integer(2),Integer(1)]), Composition([Integer(3)]))
6
```

sage.combinat.ncsf_qsym.combinatorics.**coeff_sp**(J, I)

Return the coefficient $sp_{J,I}$ as defined in [NCSF].

INPUT:

- `J` – a composition
- `I` – a composition refining `J`

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_sp
sage: coeff_sp(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_sp(Composition([2,1]), Composition([3]))
4
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import coeff_sp
>>> coeff_sp(Composition([Integer(1),Integer(1),Integer(1)]),␣
↪Composition([Integer(2),Integer(1)]))
2
>>> coeff_sp(Composition([Integer(2),Integer(1)]), Composition([Integer(3)]))
4
```

sage.combinat.ncsf_qsym.combinatorics.**compositions_order**(n)

Return the compositions of n ordered as defined in [QSCHUR].

Let $S(\gamma)$ return the composition γ after sorting. For compositions α and β, we order $\alpha \rhd \beta$ if

1) $S(\alpha) > S(\beta)$ lexicographically, or

2) $S(\alpha) = S(\beta)$ and $\alpha > \beta$ lexicographically.

INPUT:

- `n` – positive integer

OUTPUT: list of the compositions of n sorted into decreasing order by $\rhd$

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import compositions_order
sage: compositions_order(3)
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: compositions_order(4)
[[4], [3, 1], [1, 3], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import compositions_order
>>> compositions_order(Integer(3))
[[3], [2, 1], [1, 2], [1, 1, 1]]
>>> compositions_order(Integer(4))
[[4], [3, 1], [1, 3], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

sage.combinat.ncsf_qsym.combinatorics.**m_to_s_stat**(*R*, *I*, *K*)

Return the coefficient of the complete non-commutative symmetric function S^K in the expansion of the monomial non-commutative symmetric function M^I with respect to the complete basis over the ring R. This is the coefficient in formula (36) of Tevlin's paper [Tev2007].

INPUT:

- `R` – a ring; supposed to be a $\mathbf{Q}$-algebra
- `I`, `K` – compositions

OUTPUT:

- The coefficient of S^K in the expansion of M^I in the complete basis of the non-commutative symmetric functions over `R`.

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import m_to_s_stat
sage: m_to_s_stat(QQ, Composition([2,1]), Composition([1,1,1]))
-1
sage: m_to_s_stat(QQ, Composition([3]), Composition([1,2]))
-2
sage: m_to_s_stat(QQ, Composition([2,1,2]), Composition([2,1,2]))
8/3
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import m_to_s_stat
>>> m_to_s_stat(QQ, Composition([Integer(2),Integer(1)]), Composition([Integer(1),
↪Integer(1),Integer(1)]))
-1
>>> m_to_s_stat(QQ, Composition([Integer(3)]), Composition([Integer(1),
↪Integer(2)]))
-2
>>> m_to_s_stat(QQ, Composition([Integer(2),Integer(1),Integer(2)]),␣
↪Composition([Integer(2),Integer(1),Integer(2)]))
8/3
```

sage.combinat.ncsf_qsym.combinatorics.**number_of_SSRCT**(*shape_comp*)

The number of semi-standard reverse composition tableaux.

The dual quasisymmetric-Schur functions satisfy a left Pieri rule where $S_n dQS_\gamma$ is a sum over dual quasisymmetric-Schur functions indexed by compositions which contain the composition γ. The definition of an

SSRCT comes from this rule. The number of SSRCT of content β and shape α is equal to the number of SSRCT of content $(\beta_2, \ldots, \beta_\ell)$ and shape γ where dQS_α appears in the expansion of $S_{\beta_1} dQS_\gamma$.

In sage the recording tableau for these objects are called *CompositionTableaux*.

INPUT:

- `content_comp`, `shape_comp` – compositions

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_SSRCT
sage: number_of_SSRCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_SSRCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_SSRCT(Composition([1,1,2,2]), Composition([3,3]))
2
sage: all(CompositionTableaux(be).cardinality()
....:     == sum(number_of_SSRCT(al,be)*binomial(4,len(al))
....:            for al in Compositions(4))
....:     for be in Compositions(4))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import number_of_SSRCT
>>> number_of_SSRCT(Composition([Integer(3),Integer(1)]), Composition([Integer(1),
↪Integer(3)]))
0
>>> number_of_SSRCT(Composition([Integer(1),Integer(2),Integer(1)]),␣
↪Composition([Integer(1),Integer(3)]))
1
>>> number_of_SSRCT(Composition([Integer(1),Integer(1),Integer(2),Integer(2)]),␣
↪Composition([Integer(3),Integer(3)]))
2
>>> all(CompositionTableaux(be).cardinality()
...     == sum(number_of_SSRCT(al,be)*binomial(Integer(4),len(al))
...            for al in Compositions(Integer(4)))
...     for be in Compositions(Integer(4)))
True
```

sage.combinat.ncsf_qsym.combinatorics.**number_of_fCT**(*shape_comp*)

Return the number of Immaculate tableaux of shape `shape_comp` and content `content_comp`.

See [BBSSZ2012], Definition 3.9, for the notion of an immaculate tableau.

INPUT:

- `content_comp`, `shape_comp` – compositions

OUTPUT: integer

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_fCT
sage: number_of_fCT(Composition([3,1]), Composition([1,3]))
```

(continues on next page)

(continued from previous page)

```
0
sage: number_of_fCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_fCT(Composition([1,1,3,1]), Composition([2,1,3]))
2
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import number_of_fCT
>>> number_of_fCT(Composition([Integer(3),Integer(1)]), Composition([Integer(1),
↪Integer(3)]))
0
>>> number_of_fCT(Composition([Integer(1),Integer(2),Integer(1)]),␣
↪Composition([Integer(1),Integer(3)]))
1
>>> number_of_fCT(Composition([Integer(1),Integer(1),Integer(3),Integer(1)]),␣
↪Composition([Integer(2),Integer(1),Integer(3)]))
2
```

Generic code for bases

This is a collection of code that is shared by bases of noncommutative symmetric functions and quasisymmetric functions.

AUTHORS:

- Jason Bandlow
- Franco Saliola
- Chris Berg

class sage.combinat.ncsf_qsym.generic_basis_code.**AlgebraMorphism**(*domain*, *on_generators*, *position=0*, *codomain=None*, *category=None*, *anti=False*)

Bases: ModuleMorphismByLinearity

A class for algebra morphism defined on a free algebra from the image of the generators

class sage.combinat.ncsf_qsym.generic_basis_code.**BasesOfQSymOrNCSF**(*parent_with_realization*)

Bases: Category_realization_of_parent

class ElementMethods

Bases: object

degree()

The maximum of the degrees of the homogeneous summands.

See also

homogeneous_degree()

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: x, y = S[2], S[3]
```

(continues on next page)

(continued from previous page)

```
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> x, y = S[Integer(2)], S[Integer(3)]
>>> x.degree()
2
>>> (x**Integer(3) + Integer(4)*y**Integer(2)).degree()
6
>>> ((Integer(1) + x)**Integer(3)).degree()
6
```

```
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: x, y = F[2], F[3]
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6
```

```
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(QQ).F()
>>> x, y = F[Integer(2)], F[Integer(3)]
>>> x.degree()
2
>>> (x**Integer(3) + Integer(4)*y**Integer(2)).degree()
6
>>> ((Integer(1) + x)**Integer(3)).degree()
6
```

degree_negation()

Return the image of `self` under the degree negation automorphism of the parent of `self`.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

Calling `degree_negation(self)` is equivalent to calling `self.parent().degree_negation(self)`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: f = 2*S[2,1] + 4*S[1,1] - 5*S[1,2] - 3*S[[]]
sage: f.degree_negation()
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]
```

-2*dI[1] + 4*dI[2] + 3*dI[2, 1]
```

Todo

Generalize this to all graded vector spaces?

duality_pairing(*y*)

The duality pairing between elements of $NSym$ and elements of $QSym$.

The complete basis is dual to the monomial basis with respect to this pairing.

INPUT:

- `y` – an element of the dual Hopf algebra of `self`

OUTPUT: the result of pairing `self` with `y`

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R[1,1,2].duality_pairing(F[1,1,2])
1
sage: R[1,2,1].duality_pairing(F[1,1,2])
0
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> R[Integer(1),Integer(1),Integer(2)].duality_pairing(F[Integer(1),
↪Integer(1),Integer(2)])
1
>>> R[Integer(1),Integer(2),Integer(1)].duality_pairing(F[Integer(1),
↪Integer(1),Integer(2)])
0
```

```
sage: L = NonCommutativeSymmetricFunctions(QQ).Elementary()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: L[1,2].duality_pairing(F[1,2])
0
sage: L[1,1,1].duality_pairing(F[1,2])
1
```

```
>>> from sage.all import *
>>> L = NonCommutativeSymmetricFunctions(QQ).Elementary()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> L[Integer(1),Integer(2)].duality_pairing(F[Integer(1),Integer(2)])
0
>>> L[Integer(1),Integer(1),Integer(1)].duality_pairing(F[Integer(1),
...Integer(2)])
1
```

skew_by(*y*, *side='left'*)

The operation which is dual to multiplication by `y`, where `y` is an element of the dual space of `self`.

This is calculated through the coproduct of `self` and the expansion of `y` in the dual basis.

INPUT:

- `y` – an element of the dual Hopf algebra of `self`
- `side` – (default: `'left'`) either `'left'` or `'right'`

OUTPUT: the result of skewing `self` by `y`, on the side `side`

EXAMPLES:

Skewing an element of NCSF by an element of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R([2,2,2]).skew_by(F[1,1])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 2*R[2, 2] + R[3, 1] +␣
↪R[4]
sage: R([2,2,2]).skew_by(F[2])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 3*R[2, 2] + R[3, 1] +␣
↪R[4]
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> R([Integer(2),Integer(2),Integer(2)]).skew_by(F[Integer(1),
...Integer(1)])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 2*R[2, 2] + R[3, 1] +␣
↪R[4]
>>> R([Integer(2),Integer(2),Integer(2)]).skew_by(F[Integer(2)])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 3*R[2, 2] + R[3, 1] +␣
↪R[4]
```

```

class ParentMethods

Bases: object

alternating_sum_of_compositions(*n*)

Alternating sum over compositions of n.

Note that this differs from the method *alternating_sum_of_finer_compositions()* because the coefficient of the composition 1^n is positive. This method is used in the expansion of the elementary generators into the complete generators and vice versa.

INPUT:

- n – positive integer

OUTPUT:

- The expansion of the complete generator indexed by n into the elementary basis.

EXAMPLES:

```
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: L.alternating_sum_of_compositions(0)
L[]
sage: L.alternating_sum_of_compositions(1)
L[1]
sage: L.alternating_sum_of_compositions(2)
L[1, 1] - L[2]
sage: L.alternating_sum_of_compositions(3)
L[1, 1, 1] - L[1, 2] - L[2, 1] + L[3]
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.alternating_sum_of_compositions(3)
S[1, 1, 1] - S[1, 2] - S[2, 1] + S[3]
```

```
>>> from sage.all import *
>>> L = NonCommutativeSymmetricFunctions(QQ).L()
>>> L.alternating_sum_of_compositions(Integer(0))
L[]
>>> L.alternating_sum_of_compositions(Integer(1))
L[1]
>>> L.alternating_sum_of_compositions(Integer(2))
```

(continues on next page)

(continued from previous page)

```
L[1, 1] - L[2]
>>> L.alternating_sum_of_compositions(Integer(3))
L[1, 1, 1] - L[1, 2] - L[2, 1] + L[3]
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S.alternating_sum_of_compositions(Integer(3))
S[1, 1, 1] - S[1, 2] - S[2, 1] + S[3]
```

alternating_sum_of_fatter_compositions(*composition*)

Return the alternating sum of fatter compositions in a basis of the non-commutative symmetric functions.

INPUT:

- `composition` – a composition

OUTPUT:

- The alternating sum of the compositions fatter than `composition`, in the basis `self`. The alternation is upon the length of the compositions, and is normalized so that `composition` has coefficient 1.

EXAMPLES:

```
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_fatter_compositions(Composition([2,2,
↪1]))
L[2, 2, 1] - L[2, 3] - L[4, 1] + L[5]
sage: elementary.alternating_sum_of_fatter_compositions(Composition([1,
↪2]))
L[1, 2] - L[3]
```

```
>>> from sage.all import *
>>> NCSF=NonCommutativeSymmetricFunctions(QQ)
>>> elementary = NCSF.elementary()
>>> elementary.alternating_sum_of_fatter_
↪compositions(Composition([Integer(2),Integer(2),Integer(1)]))
L[2, 2, 1] - L[2, 3] - L[4, 1] + L[5]
>>> elementary.alternating_sum_of_fatter_
↪compositions(Composition([Integer(1),Integer(2)]))
L[1, 2] - L[3]
```

alternating_sum_of_finer_compositions(*composition*, *conjugate=False*)

Return the alternating sum of finer compositions in a basis of the non-commutative symmetric functions.

INPUT:

- `composition` – a composition
- `conjugate` – boolean (default: `False`)

OUTPUT:

- The alternating sum of the compositions finer than `composition`, in the basis `self`. The alternation is upon the length of the compositions, and is normalized so that `composition` has coefficient 1. If the variable `conjugate` is set to `True`, then the conjugate of `composition` is used instead of `composition`.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_finer_compositions(Composition([2,2,
```

(continues on next page)

(continued from previous page)

```
↪1]))
L[1, 1, 1, 1, 1] - L[1, 1, 2, 1] - L[2, 1, 1, 1] + L[2, 2, 1]
sage: elementary.alternating_sum_of_finer_compositions(Composition([1,2]))
-L[1, 1, 1] + L[1, 2]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> elementary = NCSF.elementary()
>>> elementary.alternating_sum_of_finer_
↪compositions(Composition([Integer(2),Integer(2),Integer(1)]))
L[1, 1, 1, 1, 1] - L[1, 1, 2, 1] - L[2, 1, 1, 1] + L[2, 2, 1]
>>> elementary.alternating_sum_of_finer_
↪compositions(Composition([Integer(1),Integer(2)]))
-L[1, 1, 1] + L[1, 2]
```

counit_on_basis(*I*)

The counit is defined by sending all elements of positive degree to zero.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.counit_on_basis([1,3])
0
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.counit_on_basis([1,3])
0
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S.counit_on_basis([Integer(1),Integer(3)])
0
>>> M = QuasiSymmetricFunctions(QQ).M()
>>> M.counit_on_basis([Integer(1),Integer(3)])
0
```

degree_negation(*element*)

Return the image of `element` under the degree negation automorphism of `self`.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

INPUT:

- `element` – element of `self`

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: f = 2*S[2,1] + 4*S[1,1] - 5*S[1,2] - 3*S[[]]
sage: S.degree_negation(f)
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dualImmaculate()
```

(continues on next page)

(continued from previous page)

```
sage: f = -3*dI[2,1] + 4*dI[2] + 2*dI[1]
sage: dI.degree_negation(f)
-2*dI[1] + 4*dI[2] + 3*dI[2, 1]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> f = Integer(2)*S[Integer(2),Integer(1)] + Integer(4)*S[Integer(1),
↪Integer(1)] - Integer(5)*S[Integer(1),Integer(2)] - Integer(3)*S[[]]
>>> S.degree_negation(f)
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]

>>> QSym = QuasiSymmetricFunctions(QQ)
>>> dI = QSym.dualImmaculate()
>>> f = -Integer(3)*dI[Integer(2),Integer(1)] + Integer(4)*dI[Integer(2)]␣
↪+ Integer(2)*dI[Integer(1)]
>>> dI.degree_negation(f)
-2*dI[1] + 4*dI[2] + 3*dI[2, 1]
```

Todo

Generalize this to all graded vector spaces?

degree_on_basis(*I*)

Return the degree of the basis element indexed by I.

INPUT:

- `I` – a composition

OUTPUT:

- The degree of the non-commutative symmetric function basis element of `self` indexed by `I`. By definition, this is the size of the composition `I`.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.degree_on_basis(Composition([2,3]))
5
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M.degree_on_basis(Composition([3,2]))
5
sage: M.degree_on_basis(Composition([]))
0
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
>>> R.degree_on_basis(Composition([Integer(2),Integer(3)]))
5
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> M.degree_on_basis(Composition([Integer(3),Integer(2)]))
5
>>> M.degree_on_basis(Composition([]))
0
```

duality_pairing(*x*, *y*)

The duality pairing between elements of $NSym$ and elements of $QSym$.

This is a default implementation that uses `self.realizations_of().a_realization()` and its dual basis.

INPUT:

- `x` – an element of `self`
- `y` – an element in the dual basis of `self`

OUTPUT:

- The result of pairing the function `x` from `self` with the function `y` from the dual basis of `self`

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing(R[1,1,2], F[1,1,2])
1
sage: R.duality_pairing(R[1,2,1], F[1,1,2])
0
sage: F.duality_pairing(F[1,2,1], R[1,1,2])
0
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> R.duality_pairing(R[Integer(1),Integer(1),Integer(2)], F[Integer(1),
↪Integer(1),Integer(2)])
1
>>> R.duality_pairing(R[Integer(1),Integer(2),Integer(1)], F[Integer(1),
↪Integer(1),Integer(2)])
0
>>> F.duality_pairing(F[Integer(1),Integer(2),Integer(1)], R[Integer(1),
↪Integer(1),Integer(2)])
0
```

```
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing(S[1,1,2], M[1,1,2])
1
sage: S.duality_pairing(S[1,2,1], M[1,1,2])
0
sage: M.duality_pairing(M[1,1,2], S[1,1,2])
1
sage: M.duality_pairing(M[1,2,1], S[1,1,2])
0
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).Complete()
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> S.duality_pairing(S[Integer(1),Integer(1),Integer(2)], M[Integer(1),
↪Integer(1),Integer(2)])
1
>>> S.duality_pairing(S[Integer(1),Integer(2),Integer(1)], M[Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1),Integer(2)])
0
>>> M.duality_pairing(M[Integer(1),Integer(1),Integer(2)], S[Integer(1),
↪Integer(1),Integer(2)])
1
>>> M.duality_pairing(M[Integer(1),Integer(2),Integer(1)], S[Integer(1),
↪Integer(1),Integer(2)])
0
```

```
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.duality_pairing(S[1,2], F[1,1,1])
0
sage: S.duality_pairing(S[1,1,1,1], F[4])
1
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).Complete()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> S.duality_pairing(S[Integer(1),Integer(2)], F[Integer(1),Integer(1),
↪Integer(1)])
0
>>> S.duality_pairing(S[Integer(1),Integer(1),Integer(1),Integer(1)],␣
↪F[Integer(4)])
1
```

duality_pairing_by_coercion(*x*, *y*)

The duality pairing between elements of NSym and elements of QSym.

This is a default implementation that uses `self.realizations_of().a_realization()` and its dual basis.

INPUT:

- `x` – an element of `self`
- `y` – an element in the dual basis of `self`

OUTPUT:

- The result of pairing the function `x` from `self` with the function `y` from the dual basis of `self`

EXAMPLES:

```
sage: L = NonCommutativeSymmetricFunctions(QQ).Elementary()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: L.duality_pairing_by_coercion(L[1,2], F[1,2])
0
sage: F.duality_pairing_by_coercion(F[1,2], L[1,2])
0
sage: L.duality_pairing_by_coercion(L[1,1,1], F[1,2])
1
sage: F.duality_pairing_by_coercion(F[1,2], L[1,1,1])
1
```

```
>>> from sage.all import *
>>> L = NonCommutativeSymmetricFunctions(QQ).Elementary()
```

(continues on next page)

(continued from previous page)

```
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> L.duality_pairing_by_coercion(L[Integer(1),Integer(2)], F[Integer(1),
↪Integer(2)])
0
>>> F.duality_pairing_by_coercion(F[Integer(1),Integer(2)], L[Integer(1),
↪Integer(2)])
0
>>> L.duality_pairing_by_coercion(L[Integer(1),Integer(1),Integer(1)],␣
↪F[Integer(1),Integer(2)])
1
>>> F.duality_pairing_by_coercion(F[Integer(1),Integer(2)], L[Integer(1),
↪Integer(1),Integer(1)])
1
```

duality_pairing_matrix(*basis*, *degree*)

The matrix of scalar products between elements of NSym and elements of QSym.

INPUT:

- `basis` – a basis of the dual Hopf algebra
- `degree` – nonnegative integer

OUTPUT:

- The matrix of scalar products between the basis `self` and the basis `basis` in the dual Hopf algebra in degree `degree`.

EXAMPLES:

The ribbon basis of NCSF is dual to the fundamental basis of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing_matrix(F, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: F.duality_pairing_matrix(R, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> R.duality_pairing_matrix(F, Integer(3))
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
>>> F.duality_pairing_matrix(R, Integer(3))
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

The complete basis of NCSF is dual to the monomial basis of QSym:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing_matrix(M, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: M.duality_pairing_matrix(S, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).complete()
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> S.duality_pairing_matrix(M, Integer(3))
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
>>> M.duality_pairing_matrix(S, Integer(3))
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

The matrix between the ribbon basis of NCSF and the monomial basis of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: R.duality_pairing_matrix(M, 3)
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
sage: M.duality_pairing_matrix(R, 3)
[ 1  0  0  0]
[-1  1  0  0]
[-1  0  1  0]
[ 1 -1 -1  1]
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> R.duality_pairing_matrix(M, Integer(3))
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
>>> M.duality_pairing_matrix(R, Integer(3))
```

(continues on next page)

(continued from previous page)

```
[ 1  0  0  0]
[-1  1  0  0]
[-1  0  1  0]
[ 1 -1 -1  1]
```

The matrix between the complete basis of NCSF and the fundamental basis of QSym:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.duality_pairing_matrix(F, 3)
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).complete()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> S.duality_pairing_matrix(F, Integer(3))
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

A base case test:

```
sage: R.duality_pairing_matrix(M,0)
[1]
```

```
>>> from sage.all import *
>>> R.duality_pairing_matrix(M,Integer(0))
[1]
```

one_basis()

Return the empty composition.

OUTPUT: the empty composition

EXAMPLES:

```
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: parent(L)
<class 'sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions.
↪Elementary_with_category'>
sage: parent(L).one_basis()
[]
```

```
>>> from sage.all import *
>>> L = NonCommutativeSymmetricFunctions(QQ).L()
>>> parent(L)
<class 'sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions.
↪Elementary_with_category'>
```

(continues on next page)

(continued from previous page)

```
>>> parent(L).one_basis()
[]
```

skew(*x*, *y*, *side='left'*)

Return a function `x` in `self` skewed by a function `y` in the Hopf dual of `self`.

INPUT:

- `x` – a non-commutative or quasi-symmetric function; it is an element of `self`
- `y` – a quasi-symmetric or non-commutative symmetric function; it is an element of the dual algebra of `self`
- `side` – (default: `'left'`) either `'left'` or `'right'`

OUTPUT:

- The result of skewing the element `x` by the Hopf algebra element `y` (either from the left or from the right, as determined by `side`), written in the basis `self`.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.skew(S[2,2,2], F[1,1])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1]
sage: S.skew(S[2,2,2], F[2])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1] + 3*S[2, 2]
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).complete()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> S.skew(S[Integer(2),Integer(2),Integer(2)], F[Integer(1),Integer(1)])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1]
>>> S.skew(S[Integer(2),Integer(2),Integer(2)], F[Integer(2)])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1] + 3*S[2, 2]
```

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.skew(R[2,2,2], F[1,1])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 2*R[2, 2] + R[3, 1] +␣
↪R[4]
sage: R.skew(R[2,2,2], F[2])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 3*R[2, 2] + R[3, 1] +␣
↪R[4]
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> R.skew(R[Integer(2),Integer(2),Integer(2)], F[Integer(1),Integer(1)])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 2*R[2, 2] + R[3, 1] +␣
↪R[4]
>>> R.skew(R[Integer(2),Integer(2),Integer(2)], F[Integer(2)])
R[1, 1, 2] + R[1, 2, 1] + R[1, 3] + R[2, 1, 1] + 3*R[2, 2] + R[3, 1] +␣
↪R[4]
```

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
```

(continues on next page)

(continued from previous page)

```
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.skew(M[3,2], S[2])
0
sage: M.skew(M[3,2], S[2], side='right')
M[3]
sage: M.skew(M[3,2], S[3])
M[2]
sage: M.skew(M[3,2], S[3], side='right')
0
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> R = NonCommutativeSymmetricFunctions(QQ).R()
>>> M = QuasiSymmetricFunctions(QQ).M()
>>> M.skew(M[Integer(3),Integer(2)], S[Integer(2)])
0
>>> M.skew(M[Integer(3),Integer(2)], S[Integer(2)], side='right')
M[3]
>>> M.skew(M[Integer(3),Integer(2)], S[Integer(3)])
M[2]
>>> M.skew(M[Integer(3),Integer(2)], S[Integer(3)], side='right')
0
```

sum_of_fatter_compositions(*composition*)

Return the sum of all fatter compositions.

INPUT:

- `composition` – a composition

OUTPUT:

- the sum of all basis elements which are indexed by compositions fatter (coarser?) than `composition`.

EXAMPLES:

```
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_fatter_compositions(Composition([2,1]))
L[2, 1] + L[3]
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_fatter_compositions(Composition([1,3]))
R[1, 3] + R[4]
```

```
>>> from sage.all import *
>>> L = NonCommutativeSymmetricFunctions(QQ).L()
>>> L.sum_of_fatter_compositions(Composition([Integer(2),Integer(1)]))
L[2, 1] + L[3]
>>> R = NonCommutativeSymmetricFunctions(QQ).R()
>>> R.sum_of_fatter_compositions(Composition([Integer(1),Integer(3)]))
R[1, 3] + R[4]
```

sum_of_finer_compositions(*composition*)

Return the sum of all finer compositions.

INPUT:

- composition – a composition

OUTPUT:

- The sum of all basis self elements which are indexed by compositions finer than composition.

EXAMPLES:

```
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_finer_compositions(Composition([2,1]))
L[1, 1, 1] + L[2, 1]
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_finer_compositions(Composition([1,3]))
R[1, 1, 1, 1] + R[1, 1, 2] + R[1, 2, 1] + R[1, 3]
```

```
>>> from sage.all import *
>>> L = NonCommutativeSymmetricFunctions(QQ).L()
>>> L.sum_of_finer_compositions(Composition([Integer(2),Integer(1)]))
L[1, 1, 1] + L[2, 1]
>>> R = NonCommutativeSymmetricFunctions(QQ).R()
>>> R.sum_of_finer_compositions(Composition([Integer(1),Integer(3)]))
R[1, 1, 1, 1] + R[1, 1, 2] + R[1, 2, 1] + R[1, 3]
```

sum_of_partition_rearrangements(*par*)

Return the sum of all basis elements indexed by compositions which can be sorted to obtain a given partition.

INPUT:

- par – a partition

OUTPUT:

- The sum of all self basis elements indexed by compositions which are permutations of par (without multiplicity).

EXAMPLES:

```
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.sum_of_partition_rearrangements(Partition([2,2,1]))
L[1, 2, 2] + L[2, 1, 2] + L[2, 2, 1]
sage: elementary.sum_of_partition_rearrangements(Partition([3,2,1]))
L[1, 2, 3] + L[1, 3, 2] + L[2, 1, 3] + L[2, 3, 1] + L[3, 1, 2] + L[3, 2,␣
↪1]
sage: elementary.sum_of_partition_rearrangements(Partition([]))
L[]
```

```
>>> from sage.all import *
>>> NCSF=NonCommutativeSymmetricFunctions(QQ)
>>> elementary = NCSF.elementary()
>>> elementary.sum_of_partition_rearrangements(Partition([Integer(2),
↪Integer(2),Integer(1)]))
L[1, 2, 2] + L[2, 1, 2] + L[2, 2, 1]
>>> elementary.sum_of_partition_rearrangements(Partition([Integer(3),
↪Integer(2),Integer(1)]))
L[1, 2, 3] + L[1, 3, 2] + L[2, 1, 3] + L[2, 3, 1] + L[3, 1, 2] + L[3, 2,␣
↪1]
>>> elementary.sum_of_partition_rearrangements(Partition([]))
L[]
```

super_categories()

class sage.combinat.ncsf_qsym.generic_basis_code.**GradedModulesWithInternalProduct**(*base*, *name=None*)

Bases: Category_over_base_ring

Construct the class of modules with internal product. This is used to give an internal product structure to the non-commutative symmetric functions.

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.generic_basis_code import␣
↪GradedModulesWithInternalProduct
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R in GradedModulesWithInternalProduct(QQ)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.generic_basis_code import␣
↪GradedModulesWithInternalProduct
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> R = N.ribbon()
>>> R in GradedModulesWithInternalProduct(QQ)
True
```

class ElementMethods

Bases: object

internal_product(*other*)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions f and g and any quasi-symmetric function h satisfy

$$\langle f * g, h\rangle = \sum_i \langle f, h'_i\rangle \langle g, h''_i\rangle,$$

where we write $\Delta^{\times}(h)$ as $\sum_i h'_i \otimes h''_i$. Here, $f * g$ denotes the internal product of the non-commutative symmetric functions f and g.

If f and g are two homogeneous elements of $NSym$ having distinct degrees, then the internal product $f * g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If I and J are two compositions of lengths p and q, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions S^I and S^J have internal product

$$S^I * S^J = \sum S^{\operatorname{comp} M},$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbf{N}^{p\times q}$ (with nonnegative integers as entries) whose row sum vector is I (that is, the sum of the entries of the r-th row is the r-th part of I for all r) and whose column sum vector is J (that is, the sum of all entries of the s-th row is the s-th part of J for all s). Here, for any $M \in \mathbf{N}^{p\times q}$, we denote by $\operatorname{comp} M$ the composition obtained by reading the entries

of the matrix M in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let I and J be two compositions of lengths p and q, respectively, having the same size $|I| = |J|$. We denote by Ψ^K the element of the Psi basis corresponding to any composition K.

- If $p > q$, then $\Psi^I * \Psi^J$ is plainly 0.
- Assume that $p = q$. Let $\widetilde{\delta}_{I,J}$ denote the integer 1 if the compositions I and J are permutations of each other, and the integer 0 otherwise. For every positive integer i, let m_i denote the number of parts of I equal to i. Then, $\Psi^I * \Psi^J$ equals $\widetilde{\delta}_{I,J} \prod_{i>0} i^{m_i} m_i! \Psi^I$.
- Now assume that $p < q$. Write the composition I as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_s)$, denote by Γ_K the non-commutative symmetric function $k_1[\ldots[[\Psi_{k_1}, \Psi_{k_2}], \Psi_{k_3}], \ldots \Psi_{k_s}]$. For any subset A of $\{1, 2, \ldots, q\}$, let J_A be the composition obtained from J by removing the r-th parts for all $r \notin A$ (while keeping the r-th parts for all $r \in A$ in order). Then, $\Psi^I * \Psi^J$ equals the sum of $\Gamma_{J_{K_1}} \Gamma_{J_{K_2}} \cdots \Gamma_{J_{K_p}}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1, 2, \ldots, q\}$ into p parts such that each $1 \leq k \leq p$ satisfies $|J_{K_k}| = i_k$. (See *OrderedSetPartition()* for the meaning of "ordered set partition".)

Aliases for *internal_product()* are *itensor()* and *kronecker_product()*.

INPUT:

- `other` – another non-commutative symmetric function

OUTPUT:

- The result of taking the internal product of `self` with `other`.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> S = N.complete()
>>> x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
>>> x.internal_product(S[Integer(2)])
3*S[1, 1]
>>> x.internal_product(S[Integer(1)])
2*S[1]
>>> S[Integer(1),Integer(2)].internal_product(S[Integer(1),Integer(2)])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \
↪right> \left< g, h''_i \right>
```

(continues on next page)

(continued from previous page)

```
....:     result = h.base_ring().zero()
....:     h_parent = h.parent()
....:     for partition_pair, coeff in h.internal_coproduct().monomial_
↪coefficients().items():
....:         result += coeff * f.duality_pairing(h_parent[partition_
↪pair[0]]) * g.duality_pairing(h_parent[partition_pair[1]])
....:     return result
sage: def testall(n):
....:     return all( all( all( tensor_incopr(S[u], S[v], M[w]) == (S[u].
↪itensor(S[v])).duality_pairing(M[w])
....:                           for w in Compositions(n) )
....:                     for v in Compositions(n) )
....:                 for u in Compositions(n) )
sage: testall(2)
True
sage: testall(3)  # long time
True
sage: testall(4)  # not tested, too long
True
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(FiniteField(Integer(29))).M()
>>> S = NonCommutativeSymmetricFunctions(FiniteField(Integer(29))).S()
>>> def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \right>␣
↪\left< g, h''_i \right>
...     result = h.base_ring().zero()
...     h_parent = h.parent()
...     for partition_pair, coeff in h.internal_coproduct().monomial_
↪coefficients().items():
...         result += coeff * f.duality_pairing(h_parent[partition_
↪pair[Integer(0)]]) * g.duality_pairing(h_parent[partition_
↪pair[Integer(1)]])
...     return result
>>> def testall(n):
...     return all( all( all( tensor_incopr(S[u], S[v], M[w]) == (S[u].
↪itensor(S[v])).duality_pairing(M[w])
...                           for w in Compositions(n) )
...                     for v in Compositions(n) )
...                 for u in Compositions(n) )
>>> testall(Integer(2))
True
>>> testall(Integer(3))  # long time
True
>>> testall(Integer(4))  # not tested, too long
True
```

The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

```
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: e = SymmetricFunctions(ZZ).e()
sage: def int_pr_of_S_in_e(I, J):
```

(continues on next page)

(continued from previous page)

```
....:     return (S[I].internal_product(S[J])).to_symmetric_function()
sage: all( all( int_pr_of_S_in_e(I, J)
....:           == S[I].to_symmetric_function().internal_product(S[J].to_
↪symmetric_function())
....:           for I in Compositions(3) )
....:       for J in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(ZZ).S()
>>> e = SymmetricFunctions(ZZ).e()
>>> def int_pr_of_S_in_e(I, J):
...     return (S[I].internal_product(S[J])).to_symmetric_function()
>>> all( all( int_pr_of_S_in_e(I, J)
...           == S[I].to_symmetric_function().internal_product(S[J].to_
↪symmetric_function())
...           for I in Compositions(Integer(3)) )
...       for J in Compositions(Integer(3)) )
True
```

itensor(*other*)

alias of *internal_product()*.

kronecker_product(*other*)

alias of *internal_product()*.

class ParentMethods

Bases: object

internal_product()

The bilinear product inherited from the isomorphism with the descent algebra.

This is constructed by extending the method *internal_product_on_basis()* bilinearly, if available, or using the method *internal_product_by_coercion()*.

OUTPUT:

- The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Complete basis
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)

↪R[Integer(1),Integer(1)])
R[2]
>>> R.internal_product(R[Integer(2),Integer(2)], R[Integer(1),Integer(2)])
0
```

internal_product_on_basis(I, J)

The internal product of the two basis elements indexed by `I` and `J` (optional)

INPUT:

- `I`, `J` – compositions indexing two elements of the basis of self

Returns the internal product of the corresponding basis elements. If this method is implemented, the internal product is defined from it by linearity.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2], [1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product_on_basis([2,2], [2,1])
0
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> S = N.complete()
>>> S.internal_product_on_basis([Integer(2),Integer(2)], [Integer(1),
↪Integer(2),Integer(1)])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
>>> S.internal_product_on_basis([Integer(2),Integer(2)], [Integer(2),
```

(continues on next page)

(continued from previous page)

class Realizations(*category*, **args*)

Bases: RealizationsCategory

class ParentMethods

Bases: object

internal_product_by_coercion(*left*, *right*)

Internal product of `left` and `right`.

This is a default implementation that computes the internal product in the realization specified by `self.realization_of().a_realization()`.

INPUT:

- `left` – an element of the non-commutative symmetric functions
- `right` – an element of the non-commutative symmetric functions

OUTPUT: the internal product of `left` and `right`

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.internal_product_by_coercion(S[2,1], S[3])
S[2, 1]
sage: S.internal_product_by_coercion(S[2,1], S[4])
0
```

```

Introduction to quasisymmetric functions

In this document we briefly explain the quasisymmetric function bases and related functionality in Sage. We assume the reader is familiar with the package *SymmetricFunctions*.

Quasisymmetric functions, denoted $QSym$, form a subring of the power series ring in countably many variables. $QSym$ contains the symmetric functions. These functions first arose in the theory of P-partitions. The initial ideas in this field are attributed to MacMahon, Knuth, Kreweras, Glânffrwd Thomas, Stanley. In 1984, Gessel formalized the study of quasisymmetric functions and introduced the basis of fundamental quasisymmetric functions [Ges]. In 1995, Gelfand, Krob, Lascoux, Leclerc, Retakh, and Thibon showed that the ring of quasisymmetric functions is Hopf dual to the non-commutative symmetric functions [NCSF]. Many results have built on these.

One advantage of working in $QSym$ is that many interesting families of symmetric functions have explicit expansions in fundamental quasisymmetric functions such as Schur functions [Ges], Macdonald polynomials [HHL05], and plethysm of Schur functions [LW12].

For more background see Wikipedia article Quasisymmetric_function.

To begin, initialize the ring. Below we chose to use the rational numbers **Q**. Other options include the integers **Z** and **C**:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym
Quasisymmetric functions over the Rational Field

sage: QSym = QuasiSymmetricFunctions(CC); QSym
Quasisymmetric functions over the Complex Field with 53 bits of precision

sage: QSym = QuasiSymmetricFunctions(ZZ); QSym
Quasisymmetric functions over the Integer Ring
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QSym
Quasisymmetric functions over the Rational Field

>>> QSym = QuasiSymmetricFunctions(CC); QSym
Quasisymmetric functions over the Complex Field with 53 bits of precision

>>> QSym = QuasiSymmetricFunctions(ZZ); QSym
Quasisymmetric functions over the Integer Ring
```

All bases of $QSym$ are indexed by compositions e.g. $[3, 1, 1, 4]$. The convention is to use capital letters for bases of $QSym$ and lowercase letters for bases of the symmetric functions Sym. Next set up names for the known bases by running `inject_shorthands()`. As with symmetric functions, you do not need to run this command and you could assign these bases other names.

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.inject_shorthands()
Defining M as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Monomial basis
Defining F as shorthand for Quasisymmetric functions over the Rational Field in the␣
```

(continues on next page)

(continued from previous page)

```
↪Fundamental basis
Defining E as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Essential basis
Defining dI as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪dualImmaculate basis
Defining QS as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Quasisymmetric Schur basis
Defining YQS as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Young Quasisymmetric Schur basis
Defining phi as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪phi basis
Defining psi as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪psi basis
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QSym.inject_shorthands()
Defining M as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Monomial basis
Defining F as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Fundamental basis
Defining E as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Essential basis
Defining dI as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪dualImmaculate basis
Defining QS as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Quasisymmetric Schur basis
Defining YQS as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪Young Quasisymmetric Schur basis
Defining phi as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪phi basis
Defining psi as shorthand for Quasisymmetric functions over the Rational Field in the␣
↪psi basis
```

Now one can start constructing quasisymmetric functions.

Note

It is best to use variables other than `M` and `F`.

```
sage: x = M[2,1] + M[1,2]
sage: x
M[1, 2] + M[2, 1]

sage: y = 3*M[1,2] + M[3]^2; y
3*M[1, 2] + 2*M[3, 3] + M[6]

sage: F[3,1,3] + 7*F[2,1]
7*F[2, 1] + F[3, 1, 3]

sage: 3*F[2,1,2] + F[3]^2
```

(continues on next page)

(continued from previous page)

```
F[1, 2, 2, 1] + F[1, 2, 3] + 2*F[1, 3, 2] + F[1, 4, 1] + F[1, 5] + 3*F[2, 1, 2]
 + 2*F[2, 2, 2] + 2*F[2, 3, 1] + 2*F[2, 4] + F[3, 2, 1] + 3*F[3, 3] + 2*F[4, 2] + F[5,
↪ 1] + F[6]
```

```
>>> from sage.all import *
>>> x = M[Integer(2),Integer(1)] + M[Integer(1),Integer(2)]
>>> x
M[1, 2] + M[2, 1]

>>> y = Integer(3)*M[Integer(1),Integer(2)] + M[Integer(3)]**Integer(2); y
3*M[1, 2] + 2*M[3, 3] + M[6]

>>> F[Integer(3),Integer(1),Integer(3)] + Integer(7)*F[Integer(2),Integer(1)]
7*F[2, 1] + F[3, 1, 3]

>>> Integer(3)*F[Integer(2),Integer(1),Integer(2)] + F[Integer(3)]**Integer(2)
F[1, 2, 2, 1] + F[1, 2, 3] + 2*F[1, 3, 2] + F[1, 4, 1] + F[1, 5] + 3*F[2, 1, 2]
 + 2*F[2, 2, 2] + 2*F[2, 3, 1] + 2*F[2, 4] + F[3, 2, 1] + 3*F[3, 3] + 2*F[4, 2] + F[5,
↪ 1] + F[6]
```

To convert from one basis to another is easy:

```
sage: z = M[1,2,1]
sage: z
M[1, 2, 1]

sage: F(z)
-F[1, 1, 1, 1] + F[1, 2, 1]

sage: M(F(z))
M[1, 2, 1]
```

```
>>> from sage.all import *
>>> z = M[Integer(1),Integer(2),Integer(1)]
>>> z
M[1, 2, 1]

>>> F(z)
-F[1, 1, 1, 1] + F[1, 2, 1]

>>> M(F(z))
M[1, 2, 1]
```

To expand in variables, one can specify a finite size alphabet $x_1, x_2, \ldots, x_m$:

```
sage: y = M[1,2,1]
sage: y.expand(4)
x0*x1^2*x2 + x0*x1^2*x3 + x0*x2^2*x3 + x1*x2^2*x3
```

```
>>> from sage.all import *
>>> y = M[Integer(1),Integer(2),Integer(1)]
```

(continues on next page)

(continued from previous page)

```
>>> y.expand(Integer(4))
x0*x1^2*x2 + x0*x1^2*x3 + x0*x2^2*x3 + x1*x2^2*x3
```

The usual methods on free modules are available such as coefficients, degrees, and the support:

```
sage: z = 3*M[1,2]+M[3]^2; z
3*M[1, 2] + 2*M[3, 3] + M[6]

sage: z.coefficient([1,2])
3

sage: z.degree()
6

sage: sorted(z.coefficients())
[1, 2, 3]

sage: sorted(z.monomials(), key=lambda x: tuple(x.support()))
[M[1, 2], M[3, 3], M[6]]

sage: z.monomial_coefficients()
{[1, 2]: 3, [3, 3]: 2, [6]: 1}
```

```
>>> from sage.all import *
>>> z = Integer(3)*M[Integer(1),Integer(2)]+M[Integer(3)]**Integer(2); z
3*M[1, 2] + 2*M[3, 3] + M[6]

>>> z.coefficient([Integer(1),Integer(2)])
3

>>> z.degree()
6

>>> sorted(z.coefficients())
[1, 2, 3]

>>> sorted(z.monomials(), key=lambda x: tuple(x.support()))
[M[1, 2], M[3, 3], M[6]]

>>> z.monomial_coefficients()
{[1, 2]: 3, [3, 3]: 2, [6]: 1}
```

As with the symmetric functions package, the quasisymmetric function `1` has several instantiations. However, the most obvious way to write `1` leads to an error (this is due to the semantics of python):

```
sage: M[[]]
M[]
sage: M.one()
M[]
sage: M(1)
M[]
sage: M[[]] == 1
```

(continues on next page)

(continued from previous page)

```
True
sage: M[]
Traceback (most recent call last):
...
SyntaxError: invalid ...
```

```
>>> from sage.all import *
>>> M[[]]
M[]
>>> M.one()
M[]
>>> M(Integer(1))
M[]
>>> M[[]] == Integer(1)
True
>>> M[]
Traceback (most recent call last):
...
SyntaxError: invalid ...
```

Working with symmetric functions

The quasisymmetric functions are a ring which contains the symmetric functions as a subring. The Monomial quasisymmetric functions are related to the monomial symmetric functions by $m_\lambda = \sum_{\mathrm{sort}(c)=\lambda} M_c$, where $\mathrm{sort}(c)$ means the partition obtained by sorting the composition c:

```
sage: SymmetricFunctions(QQ).inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the elementary␣
↪basis
Defining f as shorthand for Symmetric Functions over Rational Field in the forgotten␣
↪basis
Defining h as shorthand for Symmetric Functions over Rational Field in the␣
↪homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial␣
↪basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum␣
↪basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis

sage: m[2,1]
m[2, 1]
sage: M(m[2,1])
M[1, 2] + M[2, 1]
sage: M(s[2,1])
2*M[1, 1, 1] + M[1, 2] + M[2, 1]
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the elementary␣
↪basis
Defining f as shorthand for Symmetric Functions over Rational Field in the forgotten␣
```

(continues on next page)

(continued from previous page)

```
↪basis
Defining h as shorthand for Symmetric Functions over Rational Field in the␣
↪homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial␣
↪basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum␣
↪basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis

>>> m[Integer(2),Integer(1)]
m[2, 1]
>>> M(m[Integer(2),Integer(1)])
M[1, 2] + M[2, 1]
>>> M(s[Integer(2),Integer(1)])
2*M[1, 1, 1] + M[1, 2] + M[2, 1]
```

There are methods to test if an expression f in the quasisymmetric functions is a symmetric function:

```
sage: f = M[1,1,2] + M[1,2,1]
sage: f.is_symmetric()
False
sage: f = M[3,1] + M[1,3]
sage: f.is_symmetric()
True
```

```
>>> from sage.all import *
>>> f = M[Integer(1),Integer(1),Integer(2)] + M[Integer(1),Integer(2),Integer(1)]
>>> f.is_symmetric()
False
>>> f = M[Integer(3),Integer(1)] + M[Integer(1),Integer(3)]
>>> f.is_symmetric()
True
```

If f is symmetric, there are methods to convert f to an expression in the symmetric functions:

```
sage: f.to_symmetric_function()
m[3, 1]
```

```
>>> from sage.all import *
>>> f.to_symmetric_function()
m[3, 1]
```

The expansion of the Schur function in terms of the Fundamental quasisymmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

```
sage: f = F[3,2] + F[2,2,1] + F[2,3] + F[1,3,1] + F[1,2,2]
sage: f.is_symmetric()
True
sage: f.to_symmetric_function()
5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
sage: s(f.to_symmetric_function())
s[3, 2]
```

```
>>> from sage.all import *
>>> f = F[Integer(3),Integer(2)] + F[Integer(2),Integer(2),Integer(1)] + F[Integer(2),
↪Integer(3)] + F[Integer(1),Integer(3),Integer(1)] + F[Integer(1),Integer(2),
↪Integer(2)]
>>> f.is_symmetric()
True
>>> f.to_symmetric_function()
5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
>>> s(f.to_symmetric_function())
s[3, 2]
```

It is also possible to convert any symmetric function to the quasisymmetric function expansion in any known basis. The converse is not true:

```
sage: M( m[3,1,1] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: F( s[2,2,1] )
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1]

sage: s(M[2,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= M[2, 1]) an element of self
```

```
>>> from sage.all import *
>>> M( m[Integer(3),Integer(1),Integer(1)] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
>>> F( s[Integer(2),Integer(2),Integer(1)] )
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1]

>>> s(M[Integer(2),Integer(1)])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= M[2, 1]) an element of self
```

It is possible to experiment with the quasisymmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

```
sage: R = QQ['t']
sage: Qp = SymmetricFunctions(R).hall_littlewood().Qp()
sage: QSymt = QuasiSymmetricFunctions(R)
sage: Ft = QSymt.F()
sage: Ft( Qp[2,2] )
F[1, 2, 1] + t*F[1, 3] + (t+1)*F[2, 2] + t*F[3, 1] + t^2*F[4]
```

```
>>> from sage.all import *
>>> R = QQ['t']
>>> Qp = SymmetricFunctions(R).hall_littlewood().Qp()
>>> QSymt = QuasiSymmetricFunctions(R)
>>> Ft = QSymt.F()
>>> Ft( Qp[Integer(2),Integer(2)] )
F[1, 2, 1] + t*F[1, 3] + (t+1)*F[2, 2] + t*F[3, 1] + t^2*F[4]
```

```
sage: K = QQ['q','t'].fraction_field()
sage: Ht = SymmetricFunctions(K).macdonald().Ht()
sage: Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
sage: Fqt(Ht[2,1])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

```
>>> from sage.all import *
>>> K = QQ['q','t'].fraction_field()
>>> Ht = SymmetricFunctions(K).macdonald().Ht()
>>> Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
>>> Fqt(Ht[Integer(2),Integer(1)])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

The following will raise an error because the base ring of `F` is not equal to the base ring of `Ht`:

```
sage: F(Ht[2,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self␣
↪(=Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

```
>>> from sage.all import *
>>> F(Ht[Integer(2),Integer(1)])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self␣
↪(=Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

QSym is a Hopf algebra

The product on $QSym$ is commutative and is inherited from the product by the realization within the polynomial ring:

```
sage: M[3]*M[1,1] == M[1,1]*M[3]
True
sage: M[3]*M[1,1]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[3, 1, 1] + M[4, 1]
sage: F[3]*F[1,1]
F[1, 1, 3] + F[1, 2, 2] + F[1, 3, 1] + F[1, 4] + F[2, 1, 2] + F[2, 2, 1] + F[2, 3] +␣
↪F[3, 1, 1] + F[3, 2] + F[4, 1]
sage: M[3]*F[2]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[2, 3] + M[3, 1, 1] + M[3, 2] + M[4, 1] + M[5]
sage: F[2]*M[3]
F[1, 1, 1, 2] - F[1, 2, 2] + F[2, 1, 1, 1] - F[2, 1, 2] - F[2, 2, 1] + F[5]
```

```
>>> from sage.all import *
>>> M[Integer(3)]*M[Integer(1),Integer(1)] == M[Integer(1),Integer(1)]*M[Integer(3)]
True
>>> M[Integer(3)]*M[Integer(1),Integer(1)]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[3, 1, 1] + M[4, 1]
>>> F[Integer(3)]*F[Integer(1),Integer(1)]
F[1, 1, 3] + F[1, 2, 2] + F[1, 3, 1] + F[1, 4] + F[2, 1, 2] + F[2, 2, 1] + F[2, 3] +␣
↪F[3, 1, 1] + F[3, 2] + F[4, 1]
```

(continues on next page)

(continued from previous page)

```
>>> M[Integer(3)]*F[Integer(2)]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[2, 3] + M[3, 1, 1] + M[3, 2] + M[4, 1] + M[5]
>>> F[Integer(2)]*M[Integer(3)]
F[1, 1, 1, 2] - F[1, 2, 2] + F[2, 1, 1, 1] - F[2, 1, 2] - F[2, 2, 1] + F[5]
```

There is a coproduct on this ring as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The co-product is non-co-commutative:

```
sage: M[1,3,1].coproduct()
M[] # M[1, 3, 1] + M[1] # M[3, 1] + M[1, 3] # M[1] + M[1, 3, 1] # M[]
sage: F[1,3,1].coproduct()
F[] # F[1, 3, 1] + F[1] # F[3, 1] + F[1, 1] # F[2, 1] + F[1, 2] # F[1, 1] + F[1, 3] #␣
↪F[1] + F[1, 3, 1] # F[]
```

```
>>> from sage.all import *
>>> M[Integer(1),Integer(3),Integer(1)].coproduct()
M[] # M[1, 3, 1] + M[1] # M[3, 1] + M[1, 3] # M[1] + M[1, 3, 1] # M[]
>>> F[Integer(1),Integer(3),Integer(1)].coproduct()
F[] # F[1, 3, 1] + F[1] # F[3, 1] + F[1, 1] # F[2, 1] + F[1, 2] # F[1, 1] + F[1, 3] #␣
↪F[1] + F[1, 3, 1] # F[]
```

The Duality Pairing with Non-Commutative Symmetric Functions

These two operations endow $QSym$ with the structure of a Hopf algebra. It is the dual Hopf algebra of the non-commutative symmetric functions $NCSF$. Under this duality, the Monomial basis of $QSym$ is dual to the Complete basis of $NCSF$, and the Fundamental basis of $QSym$ is dual to the Ribbon basis of $NCSF$ (see [MR]):

```
sage: S = M.dual(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: M[1,3,1].duality_pairing( S[1,3,1] )
1
sage: M.duality_pairing_matrix( S, degree=4 )

```

Let H and G be elements of $QSym$ and h an element of $NCSF$. Then if we represent the duality pairing with the mathematical notation $[\cdot,\cdot]$, we have:

$$[H \cdot G, h] = [H \otimes G, \Delta(h)].$$

For example, the coefficient of `M[2,1,4,1]` in `M[1,3]*M[2,1,1]` may be computed with the duality pairing:

```
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I]*M[J]).duality_pairing(S[2,1,4,1])
1
```

```
>>> from sage.all import *
>>> I, J = Composition([Integer(1),Integer(3)]), Composition([Integer(2),Integer(1),
↪Integer(1)])
>>> (M[I]*M[J]).duality_pairing(S[Integer(2),Integer(1),Integer(4),Integer(1)])
1
```

And the coefficient of `S[1,3] # S[2,1,1]` in `S[2,1,4,1].coproduct()` is equal to this result:

```
sage: S[2,1,4,1].coproduct()
S[] # S[2, 1, 4, 1] + ... + S[1, 3] # S[2, 1, 1] + ... + S[4, 1] # S[2, 1]
```

```
>>> from sage.all import *
>>> S[Integer(2),Integer(1),Integer(4),Integer(1)].coproduct()
S[] # S[2, 1, 4, 1] + ... + S[1, 3] # S[2, 1, 1] + ... + S[4, 1] # S[2, 1]
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method *duality_pairing()* is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
....:     return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

```
>>> from sage.all import *
>>> X = S[Integer(2),Integer(1),Integer(4),Integer(1)].coproduct()
>>> def linear_morphism(x, y):
...     return x.duality_pairing(M[Integer(1),Integer(3)]) * y.duality_
↪pairing(M[Integer(2),Integer(1),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

Similarly, if H is an element of $QSym$ and g and h are elements of $NCSF$, then

$$[H, g \cdot h] = [\Delta(H), g \otimes h].$$

For example, the coefficient of `R[2,3,1]` in `R[2,1]*R[2,1]` is computed with the duality pairing by the following command:

```
sage: (R[2,1]*R[2,1]).duality_pairing(F[2,3,1])
1
sage: R[2,1]*R[2,1]
R[2, 1, 2, 1] + R[2, 3, 1]
```

```
>>> from sage.all import *
>>> (R[Integer(2),Integer(1)]*R[Integer(2),Integer(1)]).duality_pairing(F[Integer(2),
↪Integer(3),Integer(1)])
1
>>> R[Integer(2),Integer(1)]*R[Integer(2),Integer(1)]
R[2, 1, 2, 1] + R[2, 3, 1]
```

This coefficient should then be equal to the coefficient of `F[2,1] # F[2,1]` in `F[2,3,1].coproduct()`:

```
sage: F[2,3,1].coproduct()
F[] # F[2, 3, 1] + ... + F[2, 1] # F[2, 1]  + ... + F[2, 3, 1] # F[]
```

```
>>> from sage.all import *
>>> F[Integer(2),Integer(3),Integer(1)].coproduct()
F[] # F[2, 3, 1] + ... + F[2, 1] # F[2, 1]  + ... + F[2, 3, 1] # F[]
```

This can also be computed by the duality pairing on the tensor space, as above:

```
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
....:     return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

```
>>> from sage.all import *
>>> X = F[Integer(2),Integer(3),Integer(1)].coproduct()
>>> def linear_morphism(x, y):
...     return x.duality_pairing(R[Integer(2),Integer(1)]) * y.duality_
↪pairing(R[Integer(2),Integer(1)])
>>> X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

The Operation Adjoint to Multiplication by a Non-Commutative Symmetric Function

Let $g \in NCSF$ and consider the linear endomorphism of $NCSF$ defined by left (respectively, right) multiplication by g. Since there is a duality between $QSym$ and $NCSF$, this linear transformation induces an operator $g^{\perp}$ on $QSym$ satisfying

$$[g^{\perp}(H), h] = [H, g \cdot h].$$

for any non-commutative symmetric function h.

This is implemented by the method *skew_by()*. Explicitly, if `H` is a quasisymmetric function and `g` a non-commutative symmetric function, then `H.skew_by(g)` and `H.skew_by(g, side='right')` are expressions that satisfy, for any non-commutative symmetric function `h`, the following identities:

```
H.skew_by(g).duality_pairing(h) == H.duality_pairing(g*h)
H.skew_by(g, side='right').duality_pairing(h) == H.duality_pairing(h*g)
```

For example, `M[J].skew_by(S[I])` is 0 unless the composition J begins with I and `M(J).skew_by(S(I), side='right')` is 0 unless the composition J ends with I:

```
sage: M[3,2,2].skew_by(S[3])
M[2, 2]
sage: M[3,2,2].skew_by(S[2])
0
sage: M[3,2,2].coproduct().apply_multilinear_morphism( lambda x,y: x.duality_
↪pairing(S[3])*y )
M[2, 2]
sage: M[3,2,2].skew_by(S[3], side='right')
0
sage: M[3,2,2].skew_by(S[2], side='right')
M[3, 2]
```

```
>>> from sage.all import *
>>> M[Integer(3),Integer(2),Integer(2)].skew_by(S[Integer(3)])
M[2, 2]
>>> M[Integer(3),Integer(2),Integer(2)].skew_by(S[Integer(2)])
0
>>> M[Integer(3),Integer(2),Integer(2)].coproduct().apply_multilinear_morphism(␣
↪lambda x,y: x.duality_pairing(S[Integer(3)])*y )
M[2, 2]
>>> M[Integer(3),Integer(2),Integer(2)].skew_by(S[Integer(3)], side='right')
0
>>> M[Integer(3),Integer(2),Integer(2)].skew_by(S[Integer(2)], side='right')
M[3, 2]
```

The antipode

The antipode sends the Fundamental basis element indexed by the composition I to -1 to the size of I times the Fundamental basis element indexed by the conjugate composition to I:

```
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
sage: M[3,2,2].antipode()
-M[2, 2, 3] - M[2, 5] - M[4, 3] - M[7]
```

```
>>> from sage.all import *
>>> F[Integer(3),Integer(2),Integer(2)].antipode()
-F[1, 2, 2, 1, 1]
>>> Composition([Integer(3),Integer(2),Integer(2)]).conjugate()
```

(continues on next page)

(continued from previous page)

```
[1, 2, 2, 1, 1]
>>> M[Integer(3),Integer(2),Integer(2)].antipode()
-M[2, 2, 3] - M[2, 5] - M[4, 3] - M[7]
```

We demonstrate here the defining relation of the antipode:

```
sage: X = F[3,2,2].coproduct()
sage: X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
sage: X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

```
>>> from sage.all import *
>>> X = F[Integer(3),Integer(2),Integer(2)].coproduct()
>>> X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
>>> X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

Noncommutative symmetric functions

class sage.combinat.ncsf_qsym.ncsf.**NonCommutativeSymmetricFunctions**(R)

Bases: UniqueRepresentation, Parent

The abstract algebra of non-commutative symmetric functions.

We construct the abstract algebra of non-commutative symmetric functions over the rational numbers:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field
sage: S = NCSF.complete()
sage: R = NCSF.ribbon()
sage: S[2,1]*R[1,2]
S[2, 1, 1, 2] - S[2, 1, 3]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> NCSF
Non-Commutative Symmetric Functions over the Rational Field
>>> S = NCSF.complete()
>>> R = NCSF.ribbon()
>>> S[Integer(2),Integer(1)]*R[Integer(1),Integer(2)]
S[2, 1, 1, 2] - S[2, 1, 3]
```

NCSF is the unique free (non-commutative!) graded connected algebra with one generator in each degree:

```
sage: NCSF.category()
Join of Category of Hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of monoids with realizations
```

(continues on next page)

(continued from previous page)

```
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
    and Category of cocommutative coalgebras over Rational Field

sage: [S[i].degree() for i in range(10)]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
>>> from sage.all import *
>>> NCSF.category()
Join of Category of Hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
    and Category of cocommutative coalgebras over Rational Field

>>> [S[i].degree() for i in range(Integer(10))]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We use the Sage standard renaming idiom to get shorter outputs:

```
sage: NCSF.rename('NCSF')
sage: NCSF
NCSF
```

```
>>> from sage.all import *
>>> NCSF.rename('NCSF')
>>> NCSF
NCSF
```

NCSF has many representations as a concrete algebra. Each of them has a distinguished basis, and its elements are expanded in this basis. Here is the Ψ (*Psi*) representation:

```
sage: Psi = NCSF.Psi()
sage: Psi
NCSF in the Psi basis
```

```
>>> from sage.all import *
>>> Psi = NCSF.Psi()
>>> Psi
NCSF in the Psi basis
```

Elements of `Psi` are linear combinations of basis elements indexed by compositions:

```
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

```
>>> from sage.all import *
>>> Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

The basis itself is accessible through:

```
sage: Psi.basis()
Lazy family (Term map from Compositions of nonnegative integers...
sage: Psi.basis().keys()
Compositions of nonnegative integers
```

```
>>> from sage.all import *
>>> Psi.basis()
Lazy family (Term map from Compositions of nonnegative integers...
>>> Psi.basis().keys()
Compositions of nonnegative integers
```

To construct an element one can therefore do:

```
sage: Psi.basis()[Composition([2,1,3])]
Psi[2, 1, 3]
```

```
>>> from sage.all import *
>>> Psi.basis()[Composition([Integer(2),Integer(1),Integer(3)])]
Psi[2, 1, 3]
```

As this is rather cumbersome, the following abuses of notation are allowed:

```
sage: Psi[Composition([2, 1, 3])]
Psi[2, 1, 3]
sage: Psi[[2, 1, 3]]
Psi[2, 1, 3]
sage: Psi[2, 1, 3]
Psi[2, 1, 3]
```

```
>>> from sage.all import *
>>> Psi[Composition([Integer(2), Integer(1), Integer(3)])]
Psi[2, 1, 3]
>>> Psi[[Integer(2), Integer(1), Integer(3)]]
Psi[2, 1, 3]
>>> Psi[Integer(2), Integer(1), Integer(3)]
Psi[2, 1, 3]
```

or even:

```
sage: Psi[(i for i in [2, 1, 3])]
Psi[2, 1, 3]
```

```
>>> from sage.all import *
>>> Psi[(i for i in [Integer(2), Integer(1), Integer(3)])]
Psi[2, 1, 3]
```

Unfortunately, due to a limitation in Python syntax, one cannot use:

```
sage: Psi[]       # not implemented
```

```
>>> from sage.all import *
>>> Psi[]       # not implemented
```

Instead, you can use:

```
sage: Psi[[]]
Psi[]
```

```
>>> from sage.all import *
>>> Psi[[]]
Psi[]
```

Now, we can construct linear combinations of basis elements:

```
sage: Psi[2,1,3] + 2 * (Psi[4] + Psi[2,1])
2*Psi[2, 1] + Psi[2, 1, 3] + 2*Psi[4]
```

```
>>> from sage.all import *
>>> Psi[Integer(2),Integer(1),Integer(3)] + Integer(2) * (Psi[Integer(4)] +␣
↪Psi[Integer(2),Integer(1)])
2*Psi[2, 1] + Psi[2, 1, 3] + 2*Psi[4]
```

Algebra structure

To start with, `Psi` is a graded algebra, the grading being induced by the size of compositions. The one is the basis element indexed by the empty composition:

```
sage: Psi.one()
Psi[]
sage: S.one()
S[]
sage: R.one()
R[]
```

```
>>> from sage.all import *
>>> Psi.one()
Psi[]
>>> S.one()
S[]
>>> R.one()
R[]
```

As we have seen above, the `Psi` basis is multiplicative; that is multiplication is induced by linearity from the concatenation of compositions:

```
sage: Psi[1,3] * Psi[2,1]
Psi[1, 3, 2, 1]
sage: (Psi.one() + 2 * Psi[1,3]) * Psi[2, 4]
2*Psi[1, 3, 2, 4] + Psi[2, 4]
```

```
>>> from sage.all import *
>>> Psi[Integer(1),Integer(3)] * Psi[Integer(2),Integer(1)]
Psi[1, 3, 2, 1]
>>> (Psi.one() + Integer(2) * Psi[Integer(1),Integer(3)]) * Psi[Integer(2),␣
↪Integer(4)]
2*Psi[1, 3, 2, 4] + Psi[2, 4]
```

Hopf algebra structure

Psi is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; those are primitive:

```
sage: Psi[1].coproduct()
Psi[] # Psi[1] + Psi[1] # Psi[]
sage: Psi[2].coproduct()
Psi[] # Psi[2] + Psi[2] # Psi[]
```

```
>>> from sage.all import *
>>> Psi[Integer(1)].coproduct()
Psi[] # Psi[1] + Psi[1] # Psi[]
>>> Psi[Integer(2)].coproduct()
Psi[] # Psi[2] + Psi[2] # Psi[]
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```
sage: Psi[1,2].coproduct()
Psi[] # Psi[1, 2] + Psi[1] # Psi[2] + Psi[1, 2] # Psi[] + Psi[2] # Psi[1]
```

```
>>> from sage.all import *
>>> Psi[Integer(1),Integer(2)].coproduct()
Psi[] # Psi[1, 2] + Psi[1] # Psi[2] + Psi[1, 2] # Psi[] + Psi[2] # Psi[1]
```

The algebra and coalgebra structures on Psi combine to form a bialgebra structure, which cooperates with the grading to form a connected graded bialgebra. Thus, as any connected graded bialgebra, Psi is a Hopf algebra. Over QQ (or any other **Q**-algebra), this Hopf algebra Psi is isomorphic to the universal enveloping algebra of its space of primitive elements. Here, the primitives form a countably generated free Lie algebra, so Psi is isomorphic to the tensor algebra on a countably infinite dimensional vector space.

The antipode is an anti-algebra morphism; in the Psi basis, it sends the generators to their opposites and changes their sign if they are of odd degree:

```
sage: Psi[3].antipode()
-Psi[3]
sage: Psi[1,3,2].antipode()
-Psi[2, 3, 1]
sage: Psi[1,3,2].coproduct().apply_multilinear_morphism(lambda be,ga:␣
↪Psi(be)*Psi(ga).antipode())
0
```

```
>>> from sage.all import *
>>> Psi[Integer(3)].antipode()
-Psi[3]
>>> Psi[Integer(1),Integer(3),Integer(2)].antipode()
-Psi[2, 3, 1]
>>> Psi[Integer(1),Integer(3),Integer(2)].coproduct().apply_multilinear_
↪morphism(lambda be,ga: Psi(be)*Psi(ga).antipode())
0
```

The counit is defined by sending all elements of positive degree to zero:

```
sage: S[3].degree(), S[3,1,2].degree(), S.one().degree()
(3, 6, 0)
sage: S[3].counit()
0
sage: S[3,1,2].counit()
0
sage: S.one().counit()
1
sage: (S[3] - 2*S[3,1,2] + 7).counit()
7
sage: (R[3] - 2*R[3,1,2] + 7).counit()
7
```

```
>>> from sage.all import *
>>> S[Integer(3)].degree(), S[Integer(3),Integer(1),Integer(2)].degree(), S.one().
↪degree()
(3, 6, 0)
>>> S[Integer(3)].counit()
0
>>> S[Integer(3),Integer(1),Integer(2)].counit()
0
>>> S.one().counit()
1
>>> (S[Integer(3)] - Integer(2)*S[Integer(3),Integer(1),Integer(2)] + Integer(7)).
↪counit()
7
>>> (R[Integer(3)] - Integer(2)*R[Integer(3),Integer(1),Integer(2)] + Integer(7)).
↪counit()
7
```

It is possible to change the prefix used to display the basis elements using the method `print_options()`. Say that for instance one wanted to display the *Complete* basis as having a prefix `H` instead of the default `S`:

```
sage: H = NCSF.complete()
sage: H.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
sage: H.print_options(prefix='H')
sage: H.an_element()
2*H[] + 2*H[1] + 3*H[1, 1]
sage: H.print_options(prefix='S') #restore to 'S'
```

```
>>> from sage.all import *
>>> H = NCSF.complete()
>>> H.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
>>> H.print_options(prefix='H')
>>> H.an_element()
2*H[] + 2*H[1] + 3*H[1, 1]
>>> H.print_options(prefix='S') #restore to 'S'
```

Concrete representations

NCSF admits the concrete realizations defined in [NCSF1]:

```
sage: Phi         = NCSF.Phi()
sage: Psi         = NCSF.Psi()
sage: ribbon      = NCSF.ribbon()
sage: complete    = NCSF.complete()
sage: elementary = NCSF.elementary()
```

```
>>> from sage.all import *
>>> Phi         = NCSF.Phi()
>>> Psi         = NCSF.Psi()
>>> ribbon      = NCSF.ribbon()
>>> complete    = NCSF.complete()
>>> elementary = NCSF.elementary()
```

To change from one basis to another, one simply does:

```
sage: Phi(Psi[1])
Phi[1]
sage: Phi(Psi[3])
-1/4*Phi[1, 2] + 1/4*Phi[2, 1] + Phi[3]
```

```
>>> from sage.all import *
>>> Phi(Psi[Integer(1)])
Phi[1]
>>> Phi(Psi[Integer(3)])
-1/4*Phi[1, 2] + 1/4*Phi[2, 1] + Phi[3]
```

In general, one can mix up different bases in computations:

```
sage: Phi[1] * Psi[1]
Phi[1, 1]
```

```
>>> from sage.all import *
>>> Phi[Integer(1)] * Psi[Integer(1)]
Phi[1, 1]
```

Some of the changes of basis are easy to guess:

```
sage: ribbon(complete[1,3,2])
R[1, 3, 2] + R[1, 5] + R[4, 2] + R[6]
```

```
>>> from sage.all import *
>>> ribbon(complete[Integer(1),Integer(3),Integer(2)])
R[1, 3, 2] + R[1, 5] + R[4, 2] + R[6]
```

This is the sum of all fatter compositions. Using the usual Möbius function for the boolean lattice, the inverse change of basis is given by the alternating sum of all fatter compositions:

```
sage: complete(ribbon[1,3,2])
S[1, 3, 2] - S[1, 5] - S[4, 2] + S[6]
```

```
>>> from sage.all import *
>>> complete(ribbon[Integer(1),Integer(3),Integer(2)])
S[1, 3, 2] - S[1, 5] - S[4, 2] + S[6]
```

The analogue of the elementary basis is the sum over all finer compositions than the 'complement' of the composition in the ribbon basis:

```
sage: Composition([1,3,2]).complement()
[2, 1, 2, 1]
sage: ribbon(elementary([1,3,2]))
R[1, 1, 1, 1, 1, 1] + R[1, 1, 1, 2, 1] + R[2, 1, 1, 1, 1] + R[2, 1, 2, 1]
```

```
>>> from sage.all import *
>>> Composition([Integer(1),Integer(3),Integer(2)]).complement()
[2, 1, 2, 1]
>>> ribbon(elementary([Integer(1),Integer(3),Integer(2)]))
R[1, 1, 1, 1, 1, 1] + R[1, 1, 1, 2, 1] + R[2, 1, 1, 1, 1] + R[2, 1, 2, 1]
```

By Möbius inversion on the composition poset, the ribbon basis element corresponding to a composition I is then the alternating sum over all compositions fatter than the complement composition of I in the elementary basis:

```
sage: elementary(ribbon[2,1,2,1])
L[1, 3, 2] - L[1, 5] - L[4, 2] + L[6]
```

```
>>> from sage.all import *
>>> elementary(ribbon[Integer(2),Integer(1),Integer(2),Integer(1)])
L[1, 3, 2] - L[1, 5] - L[4, 2] + L[6]
```

The Φ (*Phi*) and Ψ bases are computed by changing to and from the *Complete* basis. The expansion of Ψ basis is given in Proposition 4.5 of [NCSF1] by the formulae

$$S^I = \sum_{J \geq I} \frac{1}{\pi_u(J,I)} \Psi^J$$

and

$$\Psi^I = \sum_{J \geq I} (-1)^{\ell(J)-\ell(I)} lp(J,I) S^J$$

where the coefficients $\pi_u(J,I)$ and $lp(J,I)$ are coefficients in the methods *coeff_pi()* and *coeff_lp()* respectively. For example:

```
sage: Psi(complete[3])
1/6*Psi[1, 1, 1] + 1/3*Psi[1, 2] + 1/6*Psi[2, 1] + 1/3*Psi[3]
sage: complete(Psi[3])
S[1, 1, 1] - 2*S[1, 2] - S[2, 1] + 3*S[3]
```

```
>>> from sage.all import *
>>> Psi(complete[Integer(3)])
1/6*Psi[1, 1, 1] + 1/3*Psi[1, 2] + 1/6*Psi[2, 1] + 1/3*Psi[3]
>>> complete(Psi[Integer(3)])
S[1, 1, 1] - 2*S[1, 2] - S[2, 1] + 3*S[3]
```

The *Phi* basis is another analogue of the power sum basis from the algebra of symmetric functions and the expansion in the Complete basis is given in Proposition 4.9 of [NCSF1] by the formulae

$$S^I = \sum_{J \geq I} \frac{1}{sp(J,I)} \Phi^J$$

and

$$\Phi^I = \sum_{J \geq I} (-1)^{\ell(J)-\ell(I)} \frac{\prod_i I_i}{\ell(J,I)} S^J$$

where the coefficients $sp(J,I)$ and $\ell(J,I)$ are coefficients in the methods *coeff_sp()* and *coeff_ell()* respectively. For example:

```
sage: Phi(complete[3])
1/6*Phi[1, 1, 1] + 1/4*Phi[1, 2] + 1/4*Phi[2, 1] + 1/3*Phi[3]
sage: complete(Phi[3])
S[1, 1, 1] - 3/2*S[1, 2] - 3/2*S[2, 1] + 3*S[3]
```

```
>>> from sage.all import *
>>> Phi(complete[Integer(3)])
1/6*Phi[1, 1, 1] + 1/4*Phi[1, 2] + 1/4*Phi[2, 1] + 1/3*Phi[3]
>>> complete(Phi[Integer(3)])
S[1, 1, 1] - 3/2*S[1, 2] - 3/2*S[2, 1] + 3*S[3]
```

Here is how to fetch the conversion morphisms:

```
sage: f = complete.coerce_map_from(elementary); f
Generic morphism:
  From: NCSF in the Elementary basis
  To:   NCSF in the Complete basis
sage: g = elementary.coerce_map_from(complete); g
Generic morphism:
  From: NCSF in the Complete basis
  To:   NCSF in the Elementary basis
sage: f.category()
Category of homsets of unital magmas and right modules over Rational Field and
  left modules over Rational Field
sage: f(elementary[1,2,2])
S[1, 1, 1, 1, 1] - S[1, 1, 1, 2] - S[1, 2, 1, 1] + S[1, 2, 2]
sage: g(complete[1,2,2])
L[1, 1, 1, 1, 1] - L[1, 1, 1, 2] - L[1, 2, 1, 1] + L[1, 2, 2]
sage: h = f*g; h
Composite map:
  From: NCSF in the Complete basis
  To:   NCSF in the Complete basis
  Defn:   Generic morphism:
          From: NCSF in the Complete basis
          To:   NCSF in the Elementary basis
        then
          Generic morphism:
          From: NCSF in the Elementary basis
          To:   NCSF in the Complete basis
sage: h(complete[1,3,2])
S[1, 3, 2]
```

```
>>> from sage.all import *
>>> f = complete.coerce_map_from(elementary); f
Generic morphism:
  From: NCSF in the Elementary basis
  To:   NCSF in the Complete basis
>>> g = elementary.coerce_map_from(complete); g
Generic morphism:
  From: NCSF in the Complete basis
  To:   NCSF in the Elementary basis
>>> f.category()
Category of homsets of unital magmas and right modules over Rational Field and
  left modules over Rational Field
>>> f(elementary[Integer(1),Integer(2),Integer(2)])
S[1, 1, 1, 1, 1] - S[1, 1, 1, 2] - S[1, 2, 1, 1] + S[1, 2, 2]
>>> g(complete[Integer(1),Integer(2),Integer(2)])
L[1, 1, 1, 1, 1] - L[1, 1, 1, 2] - L[1, 2, 1, 1] + L[1, 2, 2]
>>> h = f*g; h
Composite map:
  From: NCSF in the Complete basis

S[1, 3, 2]
```

Additional concrete representations

NCSF has some additional bases which appear in the literature:

```
sage: Monomial                 = NCSF.Monomial()
sage: Immaculate               = NCSF.Immaculate()
sage: dualQuasisymmetric_Schur = NCSF.dualQuasisymmetric_Schur()
```

```
>>> from sage.all import *
>>> Monomial                 = NCSF.Monomial()
>>> Immaculate               = NCSF.Immaculate()
>>> dualQuasisymmetric_Schur = NCSF.dualQuasisymmetric_Schur()
```

The *Monomial* basis was introduced in [Tev2007] and the *Immaculate* basis was introduced in [BBSSZ2012]. The *Quasisymmetric_Schur* were defined in [QSCHUR] and the dual basis is implemented here as *dualQuasisymmetric_Schur*. Refer to the documentation for the use and definition of these bases.

Todo

- implement fundamental, forgotten, and simple (coming from the simple modules of HS_n) bases.

We revert back to the original name from our custom short name NCSF:

```
sage: NCSF
NCSF
sage: NCSF.rename()
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field
```

```
>>> from sage.all import *
>>> NCSF
NCSF
>>> NCSF.rename()
>>> NCSF
Non-Commutative Symmetric Functions over the Rational Field
```

class Bases(*parent_with_realization*)

Bases: Category_realization_of_parent

Category of bases of non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.Bases()
Category of bases of Non-Commutative Symmetric Functions over the Rational␣
↪Field
sage: R = N.Ribbon()
sage: R in N.Bases()
True
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> N.Bases()
Category of bases of Non-Commutative Symmetric Functions over the Rational␣
↪Field
>>> R = N.Ribbon()
>>> R in N.Bases()
True
```

class ElementMethods

Bases: object

bernstein_creation_operator(*n*)

Return the image of `self` under the n-th Bernstein creation operator.

Let n be an integer. The n-th Bernstein creation operator $\mathbb{B}_n$ is defined as the endomorphism of the space $NSym$ of noncommutative symmetric functions which sends every f to

$$\sum_{i \geq 0} (-1)^i H_{n+i} F_{1^i}^{\perp},$$

where usual notations are in place (the letter H stands for the complete basis of $NSym$, the letter F stands for the fundamental basis of the algebra $QSym$ of quasisymmetric functions, and $F_{1^i}^{\perp}$ means skewing (*skew_by()*) by F_{1^i}). Notice that F_{1^i} is nothing other than the elementary symmetric function e_i.

This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions (*bernstein_creation_operator()*), and studied further

in [BBSSZ2012], mainly in the context of immaculate functions (*Immaculate*). In fact, if $(\alpha_1, \alpha_2, \ldots, \alpha_m)$ is an m-tuple of integers, then

$$\mathbb{B}_n I_{(\alpha_1,\alpha_2,\ldots,\alpha_m)} = I_{(n,\alpha_1,\alpha_2,\ldots,\alpha_m)},$$

where $I_{(\alpha_1,\alpha_2,\ldots,\alpha_m)}$ is the immaculate function associated to the m-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_m)$ (see *immaculate_function()*).

EXAMPLES:

We get the immaculate functions by repeated application of Bernstein creation operators:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: I = NSym.I()
sage: S = NSym.S()
sage: def immaculate_by_bernstein(xs):
....:     # immaculate function corresponding to integer
....:     # tuple ``xs``, computed by iterated application
....:     # of Bernstein creation operators.
....:     res = S.one()
....:     for i in reversed(xs):
....:         res = res.bernstein_creation_operator(i)
....:     return res
sage: import itertools
sage: all( immaculate_by_bernstein(p) == I.immaculate_function(p)
....:      for p in itertools.product(range(-1, 3), repeat=3))
True
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> I = NSym.I()
>>> S = NSym.S()
>>> def immaculate_by_bernstein(xs):
...     # immaculate function corresponding to integer
...     # tuple ``xs``, computed by iterated application
...     # of Bernstein creation operators.
...     res = S.one()
...     for i in reversed(xs):
...         res = res.bernstein_creation_operator(i)
...     return res
>>> import itertools
>>> all( immaculate_by_bernstein(p) == I.immaculate_function(p)
...      for p in itertools.product(range(-Integer(1), Integer(3)),␣
↪repeat=Integer(3)))
True
```

Some examples:

```
sage: S[3,2].bernstein_creation_operator(-2)
S[2, 1]
sage: S[3,2].bernstein_creation_operator(-1)
S[1, 2, 1] - S[2, 2] - S[3, 1]
sage: S[3,2].bernstein_creation_operator(0)
-S[1, 2, 2] - S[1, 3, 1] + S[2, 2, 1] + S[3, 2]
sage: S[3,2].bernstein_creation_operator(1)
```

(continues on next page)

(continued from previous page)

```
S[1, 3, 2] - S[2, 2, 2] - S[2, 3, 1] + S[3, 2, 1]
sage: S[3,2].bernstein_creation_operator(2)
S[2, 3, 2] - S[3, 2, 2] - S[3, 3, 1] + S[4, 2, 1]
```

```
>>> from sage.all import *
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(-Integer(2))
S[2, 1]
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(-Integer(1))
S[1, 2, 1] - S[2, 2] - S[3, 1]
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(Integer(0))
-S[1, 2, 2] - S[1, 3, 1] + S[2, 2, 1] + S[3, 2]
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(Integer(1))
S[1, 3, 2] - S[2, 2, 2] - S[2, 3, 1] + S[3, 2, 1]
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(Integer(2))
S[2, 3, 2] - S[3, 2, 2] - S[3, 3, 1] + S[4, 2, 1]
```

chi()

alias of *to_symmetric_function()*.

expand(*n*, *alphabet='x'*)

Expand the noncommutative symmetric function into an element of a free algebra in n indeterminates of an alphabet, which by default is `'x'`.

INPUT:

- `n` – nonnegative integer; the number of variables in the expansion
- `alphabet` – (default: `'x'`) the alphabet in which `self` is to be expanded

OUTPUT: an expansion of `self` into the n variables specified by `alphabet`

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[3].expand(3)
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1^2 + x0*x1*x2
 + x0*x2^2 + x1^3 + x1^2*x2 + x1*x2^2 + x2^3
sage: L = NSym.L()
sage: L[3].expand(3)
x2*x1*x0
sage: L[2].expand(3)
x1*x0 + x2*x0 + x2*x1
sage: L[3].expand(4)
x2*x1*x0 + x3*x1*x0 + x3*x2*x0 + x3*x2*x1
sage: Psi = NSym.Psi()
sage: Psi[2, 1].expand(3)
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1*x0 + x0*x1^2 + x0*x1*x2
 + x0*x2*x0 + x0*x2*x1 + x0*x2^2 - x1*x0^2 - x1*x0*x1
 - x1*x0*x2 + x1^2*x0 + x1^3 + x1^2*x2 + x1*x2*x0
 + x1*x2*x1 + x1*x2^2 - x2*x0^2 - x2*x0*x1 - x2*x0*x2
 - x2*x1*x0 - x2*x1^2 - x2*x1*x2 + x2^2*x0 + x2^2*x1 + x2^3
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> S = NSym.S()
```

(continues on next page)

(continued from previous page)

```
>>> S[Integer(3)].expand(Integer(3))
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1^2 + x0*x1*x2
 + x0*x2^2 + x1^3 + x1^2*x2 + x1*x2^2 + x2^3
>>> L = NSym.L()
>>> L[Integer(3)].expand(Integer(3))
x2*x1*x0
>>> L[Integer(2)].expand(Integer(3))
x1*x0 + x2*x0 + x2*x1
>>> L[Integer(3)].expand(Integer(4))
x2*x1*x0 + x3*x1*x0 + x3*x2*x0 + x3*x2*x1
>>> Psi = NSym.Psi()
>>> Psi[Integer(2), Integer(1)].expand(Integer(3))
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1*x0 + x0*x1^2 + x0*x1*x2
 + x0*x2*x0 + x0*x2*x1 + x0*x2^2 - x1*x0^2 - x1*x0*x1
 - x1*x0*x2 + x1^2*x0 + x1^3 + x1^2*x2 + x1*x2*x0
 + x1*x2*x1 + x1*x2^2 - x2*x0^2 - x2*x0*x1 - x2*x0*x2
 - x2*x1*x0 - x2*x1^2 - x2*x1*x2 + x2^2*x0 + x2^2*x1 + x2^3
```

One can use a different set of variables by adding an optional argument `alphabet=...`:

```
sage: L[3].expand(4, alphabet='y')
y2*y1*y0 + y3*y1*y0 + y3*y2*y0 + y3*y2*y1
```

```
>>> from sage.all import *
>>> L[Integer(3)].expand(Integer(4), alphabet='y')
y2*y1*y0 + y3*y1*y0 + y3*y2*y0 + y3*y2*y1
```

Todo

So far this is only implemented on the elementary basis, and everything else goes through coercion. Maybe it is worth shortcutting some of the other bases?

left_padded_kronecker_product(*x*)

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two non-commutative symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the internal product (*internal_product()*) on the space of non-commutative symmetric functions. For any composition I, let S^I denote the complete homogeneous symmetric function indexed by I. For any compositions α, β, γ, let $g^{\gamma}_{\alpha,\beta}$ denote the coefficient of S^γ in the internal product $S^\alpha * S^\beta$. For every composition $I = (i_1, i_2, \ldots, i_k)$ and every integer $n > |I|$, define the *`n`-completion of `I`* to be the composition $(n - |I|, i_1, i_2, \ldots, i_k)$; this n-completion is denoted by $I[n]$. Then, for any compositions α and β and every integer $n > |\alpha| + |\beta|$, we can write the internal product $S^{\alpha[n]} * S^{\beta[n]}$ in the form

$$S^{\alpha[n]} * S^{\beta[n]} = \sum_\gamma g^{\gamma[n]}_{\alpha[n],\beta[n]} S^{\gamma[n]}$$

with γ ranging over all compositions. The coefficients $g^{\gamma[n]}_{\alpha[n],\beta[n]}$ are independent on n. These coefficients $g^{\gamma[n]}_{\alpha[n],\beta[n]}$ are denoted by $\widetilde{g}^{\gamma}_{\alpha,\beta}$, and the non-commutative symmetric function

$$\sum_\gamma \widetilde{g}^{\gamma}_{\alpha,\beta} S^\gamma$$

is said to be the *left-padded Kronecker product* of S^α and S^β. By bilinearity, this extends to a definition of a left-padded Kronecker product of any two non-commutative symmetric functions.

The left-padded Kronecker product on the non-commutative symmetric functions lifts the left-padded Kronecker product on the symmetric functions. More precisely: Let π denote the canonical projection (*to_symmetric_function()*) from the non-commutative symmetric functions to the symmetric functions. Then, any two non-commutative symmetric functions f and g satisfy

$$\pi(f \overline{*} g) = \pi(f) \overline{*} \pi(g),$$

where the $\overline{*}$ on the left-hand side denotes the left-padded Kronecker product on the non-commutative symmetric functions, and the $\overline{*}$ on the right-hand side denotes the left-padded Kronecker product on the symmetric functions.

INPUT:

- `x` – element of the ring of non-commutative symmetric functions over the same base ring as `self`

OUTPUT:

- the left-padded Kronecker product of `self` with `x` (an element of the ring of non-commutative symmetric functions in the same basis as `self`)

AUTHORS:

- Darij Grinberg (15 Mar 2014)

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[2,1].left_padded_kronecker_product(S[3])
S[1, 1, 1, 1] + S[1, 2, 1] + S[2, 1] + S[2, 1, 1, 1] + S[2, 2, 1] +␣

↪product(S[Integer(2)])
S[1, 1] + 2*S[1, 1, 1] + S[2, 1, 1]
```

(continues on next page)

(continued from previous page)

```
>>> S[Integer(1)].left_padded_kronecker_product(S[Integer(1),
↪Integer(2),Integer(1)])
S[1, 1, 1, 1] + S[1, 2, 1] + S[1, 2, 1, 1] + S[2, 1, 1]
>>> S[Integer(2)].left_padded_kronecker_product(S[Integer(3)])
S[1, 2] + S[2, 1, 1] + S[3, 2]
```

Taking the left-padded Kronecker product with $1 = S$ is the identity map on the ring of non-commutative symmetric functions:

```
sage: all( S[Composition([])].left_padded_kronecker_product(S[lam])
....:       == S[lam].left_padded_kronecker_product(S[Composition([])])
....:       == S[lam] for i in range(4)
....:       for lam in Compositions(i) )
True
```

```
>>> from sage.all import *
>>> all( S[Composition([])].left_padded_kronecker_product(S[lam])
...       == S[lam].left_padded_kronecker_product(S[Composition([])])
...       == S[lam] for i in range(Integer(4))
...       for lam in Compositions(i) )
True
```

Here is a rule for the left-padded Kronecker product of S_1 (this is the same as $S^{(1)}$) with any complete homogeneous function: Let I be a composition. Then, the left-padded Kronecker product of S_1 and S^I is $\sum_K a_K S^K$, where the sum runs over all compositions K, and the coefficient a_K is defined as the number of ways to obtain K from I by one of the following two operations:

- Insert a 1 at the end of I.
- Subtract 1 from one of the entries of I (and remove the entry if it thus becomes 0), and insert a 1 at the end of I.

We check this for compositions of size ≤ 4:

```
sage: def mults1(I):
....:     # Left left-padded Kronecker multiplication by S[1].
....:     res = S[I[:] + [1]]
....:     for k in range(len(I)):
....:         I2 = I[:]
....:         if I2[k] == 1:
....:             I2 = I2[:k] + I2[k+1:]
....:         else:
....:             I2[k] -= 1
....:         res += S[I2 + [1]]
....:     return res
sage: all( mults1(I) == S[1].left_padded_kronecker_product(S[I])
....:      for i in range(5) for I in Compositions(i) )
True
```

```
>>> from sage.all import *
>>> def mults1(I):
...     # Left left-padded Kronecker multiplication by S[1].
...     res = S[I[:] + [Integer(1)]]
...     for k in range(len(I)):
...         I2 = I[:]
```

(continues on next page)

(continued from previous page)

```
...         if I2[k] == Integer(1):
...             I2 = I2[:k] + I2[k+Integer(1):]
...         else:
...             I2[k] -= Integer(1)
...         res += S[I2 + [Integer(1)]]
...     return res
>>> all( mults1(I) == S[Integer(1)].left_padded_kronecker_product(S[I])
...      for i in range(Integer(5)) for I in Compositions(i) )
True
```

A similar rule can be made for the left-padded Kronecker product of any complete homogeneous function with S_1: Let I be a composition. Then, the left-padded Kronecker product of S^I and S_1 is $\sum_K b_K S^K$, where the sum runs over all compositions K, and the coefficient b_K is defined as the number of ways to obtain K from I by one of the following two operations:

- Insert a 1 at the front of I.
- Subtract 1 from one of the entries of I (and remove the entry if it thus becomes 0), and insert a 1 right after this entry.

We check this for compositions of size ≤ 4:

```
sage: def mults2(I):
....:     # Left left-padded Kronecker multiplication by S[1].
....:     res = S[[1] + I[:]]
....:     for k in range(len(I)):
....:         I2 = I[:]
....:         i2k = I2[k]
....:         if i2k != 1:
....:             I2 = I2[:k] + [i2k-1, 1] + I2[k+1:]
....:         res += S[I2]
....:     return res
sage: all( mults2(I) == S[I].left_padded_kronecker_product(S[1])
....:      for i in range(5) for I in Compositions(i) )
True
```

```
>>> from sage.all import *
>>> def mults2(I):
...     # Left left-padded Kronecker multiplication by S[1].
...     res = S[[Integer(1)] + I[:]]
...     for k in range(len(I)):
...         I2 = I[:]
...         i2k = I2[k]
...         if i2k != Integer(1):
...             I2 = I2[:k] + [i2k-Integer(1), Integer(1)] +␣
↪I2[k+Integer(1):]
...         res += S[I2]
...     return res
>>> all( mults2(I) == S[I].left_padded_kronecker_product(S[Integer(1)])
...      for i in range(Integer(5)) for I in Compositions(i) )
True
```

Checking the $\pi(f \overline{*} g) = \pi(f) \overline{*} \pi(g)$ equality:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
```

(continues on next page)

(continued from previous page)

```
sage: R = NSym.R()

```

omega_involution()

Return the image of the noncommutative symmetric function `self` under the omega involution.

The omega involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to the n-th elementary non-commutative symmetric function Λ_n. This omega involution is denoted by ω. It can be shown that every composition I satisfies

$$\omega(S^I) = \Lambda^{I^r}, \quad \omega(\Lambda^I) = S^{I^r}, \quad \omega(R_I) = R_{I^t}, \quad \omega(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^{I^r}, \omega(\Psi^I) = (-1)^{|I|-\ell(I)}\Psi^{I^r},$$

where I^r denotes the reversed composition of I, and I^t denotes the conjugate composition of I, and $\ell(I)$ denotes the length of the composition I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, Φ for that of the power-sums of the second kind, and Ψ for that of the power-sums of the first kind). More generally, if f is a homogeneous element of $NCSF$ of degree n, then

$$\omega(f) = (-1)^n S(f),$$

where S denotes the antipode of $NCSF$.

The omega involution ω is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. If π denotes the projection from $NCSF$ to the

ring of symmetric functions (*to_symmetric_function()*), then $\pi(\omega(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The omega involution on $NCSF$ is adjoint to the omega involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The omega involution has been denoted by ω in [LMvW13], section 3.6. See [NCSF1], section 3.1 for the properties of this map.

...           == M(I).duality_pairing(S(J).omega_involution())
...           for I in Compositions(Integer(2)) )
...       for J in Compositions(Integer(3)) )
True
```

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $NCSF \to NCSF$ which, for every composition I, sends the complete noncommutative symmetric function S^I to the elementary noncommutative symmetric function Λ^I. It can be shown that every composition I satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^I$$

where I^c denotes the complement of the composition I, and $\ell(I)$ denotes the length of I, and where standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, Φ for the basis of the power sums of the second kind, and R for the ribbon basis). The map ψ is an involution and a graded Hopf algebra automorphism of $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (*to_symmetric_function()*), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The involution ψ of $NCSF$ is adjoint to the involution ψ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

>>> Phi = NSym.Phi()
>>> Phi([Integer(2),Integer(1)]).psi_involution()
-Phi[2, 1]
>>> Phi([Integer(3),Integer(1)]).psi_involution()
Phi[3, 1]
```

The Psi basis doesn't behave as nicely:

```
sage: Psi = NSym.Psi()
sage: Psi([2,1]).psi_involution()
-Psi[2, 1]
sage: Psi([3,1]).psi_involution()
```

(continues on next page)

(continued from previous page)

```
1/2*Psi[1, 2, 1] - 1/2*Psi[2, 1, 1] + Psi[3, 1]
```

```
>>> from sage.all import *
>>> Psi = NSym.Psi()
>>> Psi([Integer(2),Integer(1)]).psi_involution()
-Psi[2, 1]
>>> Psi([Integer(3),Integer(1)]).psi_involution()
1/2*Psi[1, 2, 1] - 1/2*Psi[2, 1, 1] + Psi[3, 1]
```

The involution ψ commutes with the antipode:

```
sage: all( R(I).psi_involution().antipode()
....:      == R(I).antipode().psi_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( R(I).psi_involution().antipode()
...      == R(I).antipode().psi_involution()
...      for I in Compositions(Integer(4)) )
True
```

Testing the $\pi(\psi(f)) = \omega(\pi(f))$ relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).psi_involution().to_symmetric_function()
....:      == R(I).to_symmetric_function().omega()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> R = NSym.R()
>>> all( R(I).psi_involution().to_symmetric_function()
...      == R(I).to_symmetric_function().omega()
...      for I in Compositions(Integer(4)) )
True
```

The involution ψ of $QSym$ is adjoint to the involution ψ of $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).psi_involution().duality_pairing(S(J))
....:           == M(I).duality_pairing(S(J).psi_involution())
....:           for I in Compositions(2) )
....:      for J in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> M = QSym.M()
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> S = NSym.S()
>>> all( all( M(I).psi_involution().duality_pairing(S(J))
...           == M(I).duality_pairing(S(J).psi_involution())
...           for I in Compositions(Integer(2)) )
...      for J in Compositions(Integer(3)) )
True
```

star_involution()

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to S_n. Denoting by f^* the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition I satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where I^r denotes the reversed composition of I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, and Φ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the n-th graded component of $NCSF$ and the descent algebra of the symmetric group S_n (see *to_descent_algebra()*), the star involution (restricted to the n-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where ω_n is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If π denotes the projection from $NCSF$ to the ring of symmetric functions (*to_symmetric_function()*), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = NSym.Phi()
>>> Phi([Integer(2),Integer(1)]).star_involution()
Phi[1, 2]
```

The Psi basis doesn't behave as nicely:

```
sage: Psi = NSym.Psi()
sage: Psi([2,1]).star_involution()
Psi[1, 2]
sage: Psi([3,1]).star_involution()
1/2*Psi[1, 1, 2] - 1/2*Psi[1, 2, 1] + Psi[1, 3]
```

```
>>> from sage.all import *
>>> Psi = NSym.Psi()
>>> Psi([Integer(2),Integer(1)]).star_involution()
Psi[1, 2]
>>> Psi([Integer(3),Integer(1)]).star_involution()
1/2*Psi[1, 1, 2] - 1/2*Psi[1, 2, 1] + Psi[1, 3]
```

The star involution commutes with the antipode:

```
sage: all( R(I).star_involution().antipode()
....:      == R(I).antipode().star_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( R(I).star_involution().antipode()
...      == R(I).antipode().star_involution()
...      for I in Compositions(Integer(4)) )
True
```

Checking the relation with the descent algebra described above:

```
sage: def descent_test(n):
....:     DA = DescentAlgebra(QQ, n)
....:     NSym = NonCommutativeSymmetricFunctions(QQ)
....:     S = NSym.S()
....:     DAD = DA.D()
....:     w_n = DAD(set(range(1, n)))
....:     for I in Compositions(n):
....:         if not (S[I].star_involution()
....:                 == w_n * S[I].to_descent_algebra(n) * w_n):
....:             return False
....:         return True
sage: all( descent_test(i) for i in range(4) )
True
sage: all( descent_test(i) for i in range(6) ) # long time
True
```

```
>>> from sage.all import *
>>> def descent_test(n):
...     DA = DescentAlgebra(QQ, n)
...     NSym = NonCommutativeSymmetricFunctions(QQ)

...                 == w_n * S[I].to_descent_algebra(n) * w_n):
...             return False
...         return True
>>> all( descent_test(i) for i in range(Integer(4)) )
True
>>> all( descent_test(i) for i in range(Integer(6)) ) # long time
True
```

Testing the $\pi(f^*) = \pi(f)$ relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).star_involution().to_symmetric_function()
```

(continues on next page)

(continued from previous page)

```
....:       == R(I).to_symmetric_function()
....:       for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> R = NSym.R()
>>> all( R(I).star_involution().to_symmetric_function()
...       == R(I).to_symmetric_function()
...       for I in Compositions(Integer(4)) )
True
```

The star involution on $QSym$ is adjoint to the star involution on $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).star_involution().duality_pairing(S(J))
....:           == M(I).duality_pairing(S(J).star_involution())
....:           for I in Compositions(2) )
....:       for J in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> M = QSym.M()
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> S = NSym.S()
>>> all( all( M(I).star_involution().duality_pairing(S(J))
...           == M(I).duality_pairing(S(J).star_involution())
...           for I in Compositions(Integer(2)) )
...       for J in Compositions(Integer(3)) )
True
```

to_descent_algebra(*n=None*)

Return the image of the `n`-th degree homogeneous component of `self` in the descent algebra of S_n over the same base ring as `self`.

This is based upon the canonical isomorphism from the n-th degree homogeneous component of the algebra of noncommutative symmetric functions to the descent algebra of S_n. This isomorphism maps the inner product of noncommutative symmetric functions either to the product in the descent algebra of S_n or to its opposite (depending on how the latter is defined).

If `n` is not specified, it will be taken to be the highest homogeneous component of `self`.

OUTPUT:

- The image of the `n`-th homogeneous component of `self` under the isomorphism into the descent algebra of S_n over the same base ring as `self`.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: S[2,1].to_descent_algebra(3)
B[2, 1]
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(4)
-3*B[1, 1, 2] + B[1, 2, 1]
sage: S[2,1].to_descent_algebra(2)
0
sage: S[2,1].to_descent_algebra()
B[2, 1]
sage: S.zero().to_descent_algebra().parent()
Descent algebra of 0 over Integer Ring in the subset basis
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(1)
0
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(ZZ).S()
>>> S[Integer(2),Integer(1)].to_descent_algebra(Integer(3))

0
```

to_fqsym()

Return the image of the non-commutative symmetric function `self` under the morphism $\iota : NSym \to FQSym$.

This morphism is the injective algebra homomorphism $NSym \to FQSym$ that sends each Complete generator S_n to $F_{[1,2,\ldots,n]}$. It is the inclusion map, if we regard both $NSym$ and $FQSym$ as rings of noncommutative power series.

See also

FreeQuasisymmetricFunctions for a definition of $FQSym$.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = 2*R[[]] + 2*R[1] + 3*R[2]
sage: x.to_fqsym()
2*F[] + 2*F[1] + 3*F[1, 2]
sage: R[2,1].to_fqsym()
F[1, 3, 2] + F[3, 1, 2]
```

(continues on next page)

(continued from previous page)

```
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_fqsym()
2*F[] + 2*F[1] + 3*F[2, 1]

sage: y = N.Phi()[1,2]
sage: y.to_fqsym()
F[1, 2, 3] - F[1, 3, 2] + F[2, 1, 3] + F[2, 3, 1]
 - F[3, 1, 2] - F[3, 2, 1]

sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S[2].to_fqsym()
F[1, 2]
sage: S[1,2].to_fqsym()
F[1, 2, 3] + F[2, 1, 3] + F[2, 3, 1]
sage: S[2,1].to_fqsym()
F[1, 2, 3] + F[1, 3, 2] + F[3, 1, 2]
sage: S[1,2,1].to_fqsym()
F[1, 2, 3, 4] + F[1, 2, 4, 3] + F[1, 4, 2, 3]
 + F[2, 1, 3, 4] + F[2, 1, 4, 3] + F[2, 3, 1, 4]
 + F[2, 3, 4, 1] + F[2, 4, 1, 3] + F[2, 4, 3, 1]
 + F[4, 1, 2, 3] + F[4, 2, 1, 3] + F[4, 2, 3, 1]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> R = N.ribbon()
>>> x = Integer(2)*R[[]] + Integer(2)*R[Integer(1)] +␣
↪Integer(3)*R[Integer(2)]
>>> x.to_fqsym()
2*F[] + 2*F[1] + 3*F[1, 2]
>>> R[Integer(2),Integer(1)].to_fqsym()
F[1, 3, 2] + F[3, 1, 2]
>>> x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
>>> x.to_fqsym()
2*F[] + 2*F[1] + 3*F[2, 1]

>>> y = N.Phi()[Integer(1),Integer(2)]
>>> y.to_fqsym()
F[1, 2, 3] - F[1, 3, 2] + F[2, 1, 3] + F[2, 3, 1]
 - F[3, 1, 2] - F[3, 2, 1]

>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S[Integer(2)].to_fqsym()
F[1, 2]
>>> S[Integer(1),Integer(2)].to_fqsym()
F[1, 2, 3] + F[2, 1, 3] + F[2, 3, 1]
>>> S[Integer(2),Integer(1)].to_fqsym()
F[1, 2, 3] + F[1, 3, 2] + F[3, 1, 2]
>>> S[Integer(1),Integer(2),Integer(1)].to_fqsym()
F[1, 2, 3, 4] + F[1, 2, 4, 3] + F[1, 4, 2, 3]
 + F[2, 1, 3, 4] + F[2, 1, 4, 3] + F[2, 3, 1, 4]
```

(continues on next page)

(continued from previous page)

```
 + F[2, 3, 4, 1] + F[2, 4, 1, 3] + F[2, 4, 3, 1]
 + F[4, 1, 2, 3] + F[4, 2, 1, 3] + F[4, 2, 3, 1]
```

to_fsym()

Return the image of `self` under the natural map to $FSym$.

There is an injective Hopf algebra morphism from $NSym$ to $FSym$ (see *FreeSymmetricFunctions*), which maps the ribbon R_α indexed by a composition α to the sum of all tableaux whose descent composition is α. If we regard $NSym$ as a Hopf subalgebra of $FQSym$ via the morphism $\iota : NSym \to FQSym$ (implemented as *to_fqsym()*), then this injective morphism is just the inclusion map.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = 2*R[[]] + 2*R[1] + 3*R[2]
sage: x.to_fsym()
2*G[] + 2*G[1] + 3*G[12]
sage: R[2,1].to_fsym()
G[12|3]
sage: R[1,2].to_fsym()
G[13|2]
sage: R[2,1,2].to_fsym()
G[12|35|4] + G[125|3|4]
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_fsym()
2*G[] + 2*G[1] + 3*G[1|2]

sage: y = N.Phi()[1,2]
sage: y.to_fsym()
-G[1|2|3] - G[12|3] + G[123] + G[13|2]

sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S[2].to_fsym()
G[12]
sage: S[2,1].to_fsym()
G[12|3] + G[123]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> R = N.ribbon()
>>> x = Integer(2)*R[[]] + Integer(2)*R[Integer(1)] +␣
↪Integer(3)*R[Integer(2)]
>>> x.to_fsym()
2*G[] + 2*G[1] + 3*G[12]
>>> R[Integer(2),Integer(1)].to_fsym()
G[12|3]
>>> R[Integer(1),Integer(2)].to_fsym()
G[13|2]
>>> R[Integer(2),Integer(1),Integer(2)].to_fsym()
G[12|35|4] + G[125|3|4]
```

(continues on next page)

(continued from previous page)

```
>>> x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
>>> x.to_fsym()
2*G[] + 2*G[1] + 3*G[1|2]

>>> y = N.Phi()[Integer(1),Integer(2)]
>>> y.to_fsym()
-G[1|2|3] - G[12|3] + G[123] + G[13|2]

>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S[Integer(2)].to_fsym()
G[12]
>>> S[Integer(2),Integer(1)].to_fsym()
G[12|3] + G[123]
```

to_ncsym()

Return the image of `self` under the injective algebra homomorphism $\kappa : NSym \to NCSym$ that fixes the symmetric functions.

As usual, $NCSym$ denotes the ring of symmetric functions in non-commuting variables. Let S_n denote a generator of the complete basis. The algebra homomorphism $\kappa : NSym \to NCSym$ is defined by

$$S_n \mapsto \sum_{A \vdash [n]} \frac{\lambda(A)!\lambda(A)^!}{n!} \mathbf{m}_A.$$

It has the property that the canonical maps $\chi : NCSym \to Sym$ and $\rho : NSym \to Sym$ satisfy $\chi \circ \kappa = \rho$.

Note

A remark in [BRRZ08] makes it clear that the embedding of $NSym$ into $NCSym$ that preserves the projection into the symmetric functions is not unique. While this seems to be a natural embedding, any free set of algebraic generators of $NSym$ can be sent to a set of free elements in $NCSym$ to form another embedding.

See also

NonCommutativeSymmetricFunctions for a definition of $NCSym$.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S[2].to_ncsym()
1/2*m{{1}, {2}} + m{{1, 2}}
sage: S[1,2,1].to_ncsym()
1/2*m{{1}, {2}, {3}, {4}} + 1/2*m{{1}, {2}, {3, 4}} + m{{1}, {2, 3},
↪{4}}
 + m{{1}, {2, 3, 4}} + 1/2*m{{1}, {2, 4}, {3}} + 1/2*m{{1, 2}, {3}, {4}
```

```

to_symmetric_function()

Return the commutative image of a non-commutative symmetric function.

OUTPUT: the commutative image of `self`; this will be a symmetric function

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_symmetric_function()
2*s[] + 2*s[1] + 3*s[1, 1]
sage: y = N.Phi()[1,3]
sage: y.to_symmetric_function()
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> R = N.ribbon()
>>> x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
>>> x.to_symmetric_function()
2*s[] + 2*s[1] + 3*s[1, 1]
>>> y = N.Phi()[Integer(1),Integer(3)]
>>> y.to_symmetric_function()
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

to_symmetric_group_algebra()

Return the image of a non-commutative symmetric function into the symmetric group algebra where the ribbon basis element indexed by a composition is associated with the sum of all permutations which have descent set equal to said composition. In compliance with the anti- isomorphism between the descent algebra and the non-commutative symmetric functions, we index descent positions by the reversed composition.

OUTPUT:

- The image of `self` under the embedding of the n-th degree homogeneous component of the non-commutative symmetric functions in the symmetric group algebra of S_n. This can behave unexpectedly when `self` is not homogeneous.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R[2,1].to_symmetric_group_algebra()
[1, 3, 2] + [2, 3, 1]
sage: R([]).to_symmetric_group_algebra()
[]
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).R()
>>> R[Integer(2),Integer(1)].to_symmetric_group_algebra()
[1, 3, 2] + [2, 3, 1]
>>> R([]).to_symmetric_group_algebra()
[]
```

verschiebung(n)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (*verschiebung()*) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

See also

adams_operator method of QSym, *verschiebung method of Sym*

INPUT:
• `n` – positive integer
OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].verschiebung(2)
0
sage: S[6,4].verschiebung(2)
S[3, 2]
sage: (S[9,1] - S[8,2] + 2*S[6,4] - 3*S[3] + 4*S[[]]).verschiebung(2)
4*S[] + 2*S[3, 2] - S[4, 1]
sage: (S[3,3] - 2*S[2]).verschiebung(3)
S[1, 1]
sage: S([4,2]).verschiebung(1)
S[4, 2]
sage: R = NSym.R()
sage: R([4,2]).verschiebung(2)
R[2, 1]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> S[Integer(3),Integer(2)].verschiebung(Integer(2))
0
>>> S[Integer(6),Integer(4)].verschiebung(Integer(2))
S[3, 2]
>>> (S[Integer(9),Integer(1)] - S[Integer(8),Integer(2)] +␣
↪Integer(2)*S[Integer(6),Integer(4)] - Integer(3)*S[Integer(3)] +␣
↪Integer(4)*S[[]]).verschiebung(Integer(2))
4*S[] + 2*S[3, 2] - S[4, 1]
>>> (S[Integer(3),Integer(3)] - Integer(2)*S[Integer(2)]).
↪verschiebung(Integer(3))
S[1, 1]
>>> S([Integer(4),Integer(2)]).verschiebung(Integer(1))
S[4, 2]
>>> R = NSym.R()
>>> R([Integer(4),Integer(2)]).verschiebung(Integer(2))
R[2, 1]
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```
sage: all( R(I).verschiebung(2).antipode()
....:      == R(I).antipode().verschiebung(2)
```

(continues on next page)

(continued from previous page)

```
....:       for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( R(I).verschiebung(Integer(2)).antipode()
...       == R(I).antipode().verschiebung(Integer(2))
...       for I in Compositions(Integer(4)) )
True
```

They lift the Verschiebung operators of the ring of symmetric functions:

```
sage: all( S(I).verschiebung(2).to_symmetric_function()
....:       == S(I).to_symmetric_function().verschiebung(2)
....:       for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( S(I).verschiebung(Integer(2)).to_symmetric_function()
...       == S(I).to_symmetric_function().verschiebung(Integer(2))
...       for I in Compositions(Integer(4)) )
True
```

The Frobenius operators on $QSym$ are adjoint to the Verschiebung operators on $NSym$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: all( all( M(I).adams_operator(3).duality_pairing(S(J))
....:           == M(I).duality_pairing(S(J).verschiebung(3))
....:           for I in Compositions(2) )
....:       for J in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> M = QSym.M()
>>> all( all( M(I).adams_operator(Integer(3)).duality_pairing(S(J))
...           == M(I).duality_pairing(S(J).verschiebung(Integer(3)))
...           for I in Compositions(Integer(2)) )
...       for J in Compositions(Integer(3)) )
True
```

class ParentMethods

Bases: `object`

immaculate_function(*xs*)

Return the immaculate function corresponding to the integer vector `xs`, written in the basis `self`.

If α is any integer vector – i.e., an element of $\mathbf{Z}^m$ for some $m \in \mathbf{N}$ –, the *immaculate function corresponding to* α is a non-commutative symmetric function denoted by $\mathfrak{S}_\alpha$. One way to define this function is by setting

$$\mathfrak{S}_\alpha = \sum_{\sigma \in S_m} (-1)^\sigma S_{\alpha_1+\sigma(1)-1} S_{\alpha_2+\sigma(2)-2} \cdots S_{\alpha_m+\sigma(m)-m},$$

where α is written in the form $(\alpha_1, \alpha_2, \ldots, \alpha_m)$, and where S stands for the complete basis (*Complete*).

The immaculate function $\mathfrak{S}_\alpha$ first appeared in [BBSSZ2012] (where it was defined differently, but the definition we gave above appeared as Theorem 3.27).

The immaculate functions $\mathfrak{S}_\alpha$ for α running over all compositions (i.e., finite sequences of positive integers) form a basis of $NCSF$. This is the *immaculate basis* (*Immaculate*).

INPUT:
• `xs` – list (or tuple or any iterable – possibly a composition) of integers
OUTPUT:

The immaculate function $\mathfrak{S}_{xs}$ written in the basis `self`.

EXAMPLES:

Let us first check that, for `xs` a composition, we get the same as the result of `self.realization_of().I()[xs]`:

```
sage: def test_comp(xs):
....:     NSym = NonCommutativeSymmetricFunctions(QQ)
....:     I = NSym.I()
....:     return I[xs] == I.immaculate_function(xs)
sage: def test_allcomp(n):
....:     return all( test_comp(c) for c in Compositions(n) )
sage: test_allcomp(1)
True
sage: test_allcomp(2)
True
sage: test_allcomp(3)
True
```

```
>>> from sage.all import *
>>> def test_comp(xs):
...     NSym = NonCommutativeSymmetricFunctions(QQ)
...     I = NSym.I()
...     return I[xs] == I.immaculate_function(xs)
>>> def test_allcomp(n):
...     return all( test_comp(c) for c in Compositions(n) )
>>> test_allcomp(Integer(1))
True
>>> test_allcomp(Integer(2))
True
>>> test_allcomp(Integer(3))
True
```

Now some examples of non-composition immaculate functions:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: I.immaculate_function([0, 1])
0
sage: I.immaculate_function([0, 2])
-I[1, 1]
sage: I.immaculate_function([-1, 1])
```

(continues on next page)

(continued from previous page)

```
-I[]
sage: I.immaculate_function([2, -1])
0
sage: I.immaculate_function([2, 0])
I[2]
sage: I.immaculate_function([2, 0, 1])
0
sage: I.immaculate_function([1, 0, 2])
-I[1, 1, 1]
sage: I.immaculate_function([2, 0, 2])
-I[2, 1, 1]
sage: I.immaculate_function([0, 2, 0, 2])
I[1, 1, 1, 1] + I[1, 2, 1]
sage: I.immaculate_function([2, 0, 2, 0, 2])
I[2, 1, 1, 1, 1] + I[2, 1, 2, 1]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> I = NSym.I()
>>> I.immaculate_function([Integer(0), Integer(1)])
0
>>> I.immaculate_function([Integer(0), Integer(2)])
-I[1, 1]
>>> I.immaculate_function([-Integer(1), Integer(1)])
-I[]
>>> I.immaculate_function([Integer(2), -Integer(1)])
0
>>> I.immaculate_function([Integer(2), Integer(0)])
I[2]
>>> I.immaculate_function([Integer(2), Integer(0), Integer(1)])
0
>>> I.immaculate_function([Integer(1), Integer(0), Integer(2)])
-I[1, 1, 1]
>>> I.immaculate_function([Integer(2), Integer(0), Integer(2)])
-I[2, 1, 1]
>>> I.immaculate_function([Integer(0), Integer(2), Integer(0),␣
↪Integer(2)])
I[1, 1, 1, 1] + I[1, 2, 1]
>>> I.immaculate_function([Integer(2), Integer(0), Integer(2),␣
↪Integer(0), Integer(2)])
I[2, 1, 1, 1, 1] + I[2, 1, 2, 1]
```

to_symmetric_function()

Morphism to the algebra of symmetric functions.

This is constructed by extending the computation on the basis or by coercion to the complete basis.

OUTPUT:

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: R.to_symmetric_function(x)
2*s[] + 2*s[1] + 3*s[1, 1]
sage: nM = N.Monomial()
sage: nM.to_symmetric_function(nM[3,1])
h[1, 1, 1, 1] - 7/2*h[2, 1, 1] + h[2, 2] + 7/2*h[3, 1] - 2*h[4]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> R = N.ribbon()
>>> x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
>>> R.to_symmetric_function(x)
2*s[] + 2*s[1] + 3*s[1, 1]
>>> nM = N.Monomial()
>>> nM.to_symmetric_function(nM[Integer(3),Integer(1)])
h[1, 1, 1, 1] - 7/2*h[2, 1, 1] + h[2, 2] + 7/2*h[3, 1] - 2*h[4]
```

to_symmetric_function_on_basis(*I*)

The image of the basis element indexed by `I` under the map to the symmetric functions.

This default implementation does a change of basis and computes the image in the complete basis.

INPUT:

- `I` – a composition

OUTPUT:

- The image of the non-commutative basis element of `self` indexed by the composition `I` under the map from non-commutative symmetric functions to the symmetric functions. This will be a symmetric function.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: I = N.Immaculate()
sage: I.to_symmetric_function(I[1,3])
-h[2, 2] + h[3, 1]
sage: I.to_symmetric_function(I[1,2])
0
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_basis([3,1,2])==Phi.to_symmetric_
↪function(Phi[3,1,2])
True
sage: Phi.to_symmetric_function_on_basis([])
h[]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> I = N.Immaculate()
>>> I.to_symmetric_function(I[Integer(1),Integer(3)])
-h[2, 2] + h[3, 1]
>>> I.to_symmetric_function(I[Integer(1),Integer(2)])
```

(continues on next page)

(continued from previous page)

```
0
>>> Phi = N.Phi()
>>> Phi.to_symmetric_function_on_basis([Integer(3),Integer(1),
↪Integer(2)])==Phi.to_symmetric_function(Phi[Integer(3),Integer(1),
↪Integer(2)])
True
>>> Phi.to_symmetric_function_on_basis([])
h[]
```

super_categories()

Return the super categories of the category of bases of the non-commutative symmetric functions.

OUTPUT: list

class Complete(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Complete basis.

The Complete basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(S^I)_I$. It is a multiplicative basis, and is connected to the elementary generators Λ_i of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function S_n for every nonnegative integer n by the power series identity

$$\sum_{k \geq 0} t^k S_k = \left(\sum_{k \geq 0} (-t)^k \Lambda_k \right)^{-1},$$

with Λ_0 denoting 1. For every composition $(i_1, i_2, \ldots, i_k)$, we have $S^{(i_1,i_2,\ldots,i_k)} = S_{i_1} S_{i_2} \cdots S_{i_k}$.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: S = NCSF.Complete(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete␣
↪basis
sage: S.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> S = NCSF.Complete(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete␣
↪basis
>>> S.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]
```

The following are aliases for this basis:

```
sage: NCSF.complete()
Non-Commutative Symmetric Functions over the Rational Field in the Complete␣
↪basis
sage: NCSF.S()
Non-Commutative Symmetric Functions over the Rational Field in the Complete␣
↪basis
```

```
>>> from sage.all import *
>>> NCSF.complete()
Non-Commutative Symmetric Functions over the Rational Field in the Complete␣
↪basis
>>> NCSF.S()
Non-Commutative Symmetric Functions over the Rational Field in the Complete␣
↪basis
```

class Element

Bases: IndexedFreeModuleElement

An element in the Complete basis.

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $NCSF \to NCSF$ which, for every composition I, sends the complete noncommutative symmetric function S^I to the elementary noncommutative symmetric function Λ^I. It can be shown that every composition I satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^I$$

where I^c denotes the complement of the composition I, and $\ell(I)$ denotes the length of I, and where standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, Φ for the basis of the power sums of the second kind, and R for the ribbon basis). The map ψ is an involution and a graded Hopf algebra automorphism of $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (*to_symmetric_function()*), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The involution ψ of $NCSF$ is adjoint to the involution ψ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also

psi involution of NCSF, *psi involution of QSym*, *star involution of NCSF*.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: S[3,1].psi_involution()
S[1, 1, 1, 1] - S[1, 2, 1] - S[2, 1, 1] + S[3, 1]
sage: L(S[3,1].psi_involution())
L[3, 1]
sage: S[[]].psi_involution()
S[]
sage: S[1,1].psi_involution()
S[1, 1]
sage: (S[2,1] - 2*S[2]).psi_involution()
-2*S[1, 1] + S[1, 1, 1] + 2*S[2] - S[2, 1]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> L = NSym.L()
>>> S[Integer(3),Integer(1)].psi_involution()
S[1, 1, 1, 1] - S[1, 2, 1] - S[2, 1, 1] + S[3, 1]
>>> L(S[Integer(3),Integer(1)].psi_involution())
L[3, 1]
>>> S[[]].psi_involution()
S[]
>>> S[Integer(1),Integer(1)].psi_involution()
S[1, 1]
>>> (S[Integer(2),Integer(1)] - Integer(2)*S[Integer(2)]).psi_
↪involution()
-2*S[1, 1] + S[1, 1, 1] + 2*S[2] - S[2, 1]
```

The implementation at hand is tailored to the complete basis. It is equivalent to the generic implementation via the ribbon basis:

```
sage: R = NSym.R()
sage: all( R(S[I].psi_involution()) == R(S[I]).psi_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> R = NSym.R()
>>> all( R(S[I].psi_involution()) == R(S[I]).psi_involution()
...      for I in Compositions(Integer(4)) )
True
```

dual()

Return the dual basis to the complete basis of non-commutative symmetric functions. This is the Monomial basis of quasi-symmetric functions.

OUTPUT: the Monomial basis of quasi-symmetric functions

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.dual()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S.dual()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

internal_product_on_basis(I, J)

The internal product of two non-commutative symmetric complete functions.

See *internal_product()* for a thorough documentation of this operation.

INPUT:

- I, J – compositions

OUTPUT:

- The internal product of the complete non-commutative symmetric function basis elements indexed by `I` and `J`, expressed in the complete basis.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2],[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product_on_basis([2,2],[1,2])
0
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> S = N.complete()
>>> S.internal_product_on_basis([Integer(2),Integer(2)],[Integer(1),
↪Integer(2),Integer(1)])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
>>> S.internal_product_on_basis([Integer(2),Integer(2)],[Integer(1),
↪Integer(2)])
0
```

to_symmetric_function()

Morphism to the algebra of symmetric functions.

This is constructed by extending the computation on the complete basis.

OUTPUT:

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[3,1,2])
h[3, 2, 1]
sage: S.to_symmetric_function(S[[]])
h[]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> S = N.complete()
>>> S.to_symmetric_function(S[Integer(3),Integer(1),Integer(2)])
h[3, 2, 1]
>>> S.to_symmetric_function(S[[]])
h[]
```

to_symmetric_function_on_basis(*I*)

The commutative image of a complete element.

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element and the output is in the complete basis of the symmetric functions.

INPUT:

- `I` – a composition

OUTPUT:

- The commutative image of the complete basis element indexed by `I`. The result is the complete symmetric function indexed by the partition obtained by sorting `I`.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.to_symmetric_function_on_basis([2,1,3])
h[3, 2, 1]
sage: S.to_symmetric_function_on_basis([])
h[]
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).complete()
>>> S.to_symmetric_function_on_basis([Integer(2),Integer(1),Integer(3)])
h[3, 2, 1]
>>> S.to_symmetric_function_on_basis([])
h[]
```

class Elementary(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Elementary basis.

The Elementary basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(\Lambda^I)_I$. It is a multiplicative basis, and is obtained from the elementary generators Λ_i of the ring of non-commutative symmetric functions through the formula $\Lambda^{(i_1,i_2,\ldots,i_k)} = \Lambda_{i_1}\Lambda_{i_2}\cdots\Lambda_{i_k}$ for every composition $(i_1, i_2, \ldots, i_k)$.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: L = NCSF.Elementary(); L
Non-Commutative Symmetric Functions over the Rational Field in the Elementary␣
↪basis
sage: L.an_element()
2*L[] + 2*L[1] + 3*L[1, 1]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> L = NCSF.Elementary(); L
Non-Commutative Symmetric Functions over the Rational Field in the Elementary␣
↪basis
>>> L.an_element()
2*L[] + 2*L[1] + 3*L[1, 1]
```

The following are aliases for this basis:

```
sage: NCSF.elementary()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary␣
↪basis
sage: NCSF.L()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary␣
↪basis
```

```
>>> from sage.all import *
>>> NCSF.elementary()
```

(continues on next page)

(continued from previous page)

```
Non-Commutative Symmetric Functions over the Rational Field in the Elementary␣
↪basis
>>> NCSF.L()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary␣
↪basis
```

class Element

Bases: IndexedFreeModuleElement

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $NCSF \to NCSF$ which, for every composition I, sends the complete noncommutative symmetric function S^I to the elementary noncommutative symmetric function Λ^I. It can be shown that every composition I satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^I$$

where I^c denotes the complement of the composition I, and $\ell(I)$ denotes the length of I, and where standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, Φ for the basis of the power sums of the second kind, and R for the ribbon basis). The map ψ is an involution and a graded Hopf algebra automorphism of $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (*to_symmetric_function()*), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The involution ψ of $NCSF$ is adjoint to the involution ψ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also

psi involution of NCSF, *psi involution of QSym*, *star involution of NCSF*.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: L[3,1].psi_involution()
L[1, 1, 1, 1] - L[1, 2, 1] - L[2, 1, 1] + L[3, 1]
sage: S(L[3,1].psi_involution())
S[3, 1]
sage: L[[]].psi_involution()
L[]
sage: L[1,1].psi_involution()
L[1, 1]
sage: (L[2,1] - 2*L[2]).psi_involution()
-2*L[1, 1] + L[1, 1, 1] + 2*L[2] - L[2, 1]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> S = NSym.S()
>>> L = NSym.L()
>>> L[Integer(3),Integer(1)].psi_involution()
L[1, 1, 1, 1] - L[1, 2, 1] - L[2, 1, 1] + L[3, 1]
>>> S(L[Integer(3),Integer(1)].psi_involution())
S[3, 1]
>>> L[[]].psi_involution()
L[]
>>> L[Integer(1),Integer(1)].psi_involution()
L[1, 1]
>>> (L[Integer(2),Integer(1)] - Integer(2)*L[Integer(2)]).psi_
↪involution()
-2*L[1, 1] + L[1, 1, 1] + 2*L[2] - L[2, 1]
```

The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the ribbon basis:

```
sage: R = NSym.R()
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution()
....:      for I in Compositions(3) )
True
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> R = NSym.R()
>>> all( R(L[I].psi_involution()) == R(L[I]).psi_involution()
...      for I in Compositions(Integer(3)) )
True
>>> all( R(L[I].psi_involution()) == R(L[I]).psi_involution()
...      for I in Compositions(Integer(4)) )
True
```

star_involution()

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to S_n. Denoting by f^* the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition I satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where I^r denotes the reversed composition of I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, and Φ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the n-th graded component of $NCSF$ and the descent algebra of the symmetric group S_n (see *to_descent_algebra()*), the star involution (restricted to the n-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where ω_n is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If π denotes

the projection from $NCSF$ to the ring of symmetric functions (*to_symmetric_function()*), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also

star involution of NCSF, *psi involution of NCSF*, *star involution of QSym*.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L[3,3,2,3].star_involution()
L[3, 2, 3, 3]
sage: L[6,3,3].star_involution()
L[3, 3, 6]
sage: (L[1,9,1] - L[8,2] + 2*L[6,4] - 3*L[3] + 4*L[[]]).star_
↪involution()
4*L[] + L[1, 9, 1] - L[2, 8] - 3*L[3] + 2*L[4, 6]
sage: (L[3,3] - 2*L[2]).star_involution()
-2*L[2] + L[3, 3]
sage: L([4,1]).star_involution()
L[1, 4]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> L = NSym.L()
>>> L[Integer(3),Integer(3),Integer(2),Integer(3)].star_involution()
L[3, 2, 3, 3]
>>> L[Integer(6),Integer(3),Integer(3)].star_involution()
L[3, 3, 6]
>>> (L[Integer(1),Integer(9),Integer(1)] - L[Integer(8),Integer(2)] +␣
↪Integer(2)*L[Integer(6),Integer(4)] - Integer(3)*L[Integer(3)] +␣
↪Integer(4)*L[[]]).star_involution()
4*L[] + L[1, 9, 1] - L[2, 8] - 3*L[3] + 2*L[4, 6]
>>> (L[Integer(3),Integer(3)] - Integer(2)*L[Integer(2)]).star_
↪involution()
-2*L[2] + L[3, 3]
>>> L([Integer(4),Integer(1)]).star_involution()
L[1, 4]
```

The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(L[I].star_involution()) == S(L[I]).star_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> S = NSym.S()
>>> all( S(L[I].star_involution()) == S(L[I]).star_involution()
...      for I in Compositions(Integer(4)) )
True
```

verschiebung(*n*)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (*verschiebung()*) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

See also

verschiebung method of NCSF, *adams_operator method of QSym*, *verschiebung method of Sym*

INPUT:
- `n` – positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L([4,2]).verschiebung(2)
-L[2, 1]
sage: L([2,4]).verschiebung(2)
-L[1, 2]
sage: L([6]).verschiebung(2)
-L[3]
sage: L([2,1]).verschiebung(3)
0
sage: L([3]).verschiebung(2)
0
sage: L([]).verschiebung(2)
L[]

L[1] - L[2] + 2*L[3]
```

I

alias of *Immaculate*

class Immaculate(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The immaculate basis of the non-commutative symmetric functions.

The immaculate basis first appears in Berg, Bergeron, Saliola, Serrano and Zabrocki's [BBSSZ2012]. It can be described as the family $(\mathfrak{S}_\alpha)$, where α runs over all compositions, and $\mathfrak{S}_\alpha$ denotes the immaculate function corresponding to α (see *immaculate_function()*).

If α is a composition $(\alpha_1, \alpha_2, \ldots, \alpha_m)$, then

$$\mathfrak{S}_\alpha = \sum_{\sigma \in S_m} (-1)^\sigma S_{\alpha_1+\sigma(1)-1} S_{\alpha_2+\sigma(2)-2} \cdots S_{\alpha_m+\sigma(m)-m}.$$

Warning

This *basis* contains only the immaculate functions indexed by compositions (i.e., finite sequences of positive integers). To obtain the remaining immaculate functions (sensu lato), use the *immaculate_function()* method. Calling the immaculate *basis* with a list which is not a composition will currently return garbage!

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: I = NCSF.I()
sage: I([1,3,2])*I([1])
I[1, 3, 2, 1] + I[1, 3, 3] + I[1, 4, 2] + I[2, 3, 2]
sage: I([1])*I([1,3,2])
I[1, 1, 3, 2] - I[2, 2, 1, 2] - I[2, 2, 2, 1] - I[2, 2, 3] - I[3, 2, 2]
sage: I([1,3])*I([1,1])
I[1, 3, 1, 1] + I[1, 4, 1] + I[2, 3, 1] + I[2, 4]
sage: I([3,1])*I([2,1])
I[3, 1, 2, 1] + I[3, 2, 1, 1] + I[3, 2, 2] + I[3, 3, 1] + I[4, 1, 1, 1] + I[4,
↪ 1, 2] + 2*I[4, 2, 1] + I[4, 3] + I[5, 1, 1] + I[5, 2]
sage: R = NCSF.ribbon()
sage: I(R[1,3,1])
I[1, 3, 1] + I[2, 2, 1] + I[2, 3] + I[3, 1, 1] + I[3, 2]
sage: R(I(R([2,1,3])))
R[2, 1, 3]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> I = NCSF.I()
>>> I([Integer(1),Integer(3),Integer(2)])*I([Integer(1)])
I[1, 3, 2, 1] + I[1, 3, 3] + I[1, 4, 2] + I[2, 3, 2]
>>> I([Integer(1)])*I([Integer(1),Integer(3),Integer(2)])
I[1, 1, 3, 2] - I[2, 2, 1, 2] - I[2, 2, 2, 1] - I[2, 2, 3] - I[3, 2, 2]
>>> I([Integer(1),Integer(3)])*I([Integer(1),Integer(1)])
I[1, 3, 1, 1] + I[1, 4, 1] + I[2, 3, 1] + I[2, 4]
>>> I([Integer(3),Integer(1)])*I([Integer(2),Integer(1)])
I[3, 1, 2, 1] + I[3, 2, 1, 1] + I[3, 2, 2] + I[3, 3, 1] + I[4, 1, 1, 1] + I[4,
↪ 1, 2] + 2*I[4, 2, 1] + I[4, 3] + I[5, 1, 1] + I[5, 2]
>>> R = NCSF.ribbon()
>>> I(R[Integer(1),Integer(3),Integer(1)])
I[1, 3, 1] + I[2, 2, 1] + I[2, 3] + I[3, 1, 1] + I[3, 2]
>>> R(I(R([Integer(2),Integer(1),Integer(3)])))
R[2, 1, 3]
```

class Element

Bases: IndexedFreeModuleElement

An element in the Immaculate basis.

bernstein_creation_operator(n)

Return the image of `self` under the n-th Bernstein creation operator.

Let n be an integer. The n-th Bernstein creation operator $\mathbb{B}_n$ is defined as the endomorphism of the space $NSym$ of noncommutative symmetric functions given by

$$\mathbb{B}_n I_{(\alpha_1,\alpha_2,\ldots,\alpha_m)} = I_{(n,\alpha_1,\alpha_2,\ldots,\alpha_m)},$$

where $I_{(\alpha_1,\alpha_2,\ldots,\alpha_m)}$ is the immaculate function associated to the m-tuple $(\alpha_1,\alpha_2,\ldots,\alpha_m) \in \mathbf{Z}^m$.

This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions.

For more information on the n-th Bernstein creation operator, see *bernstein_creation_operator()*.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: b = I[1,3,2,1]
sage: b.bernstein_creation_operator(3)
I[3, 1, 3, 2, 1]
sage: b.bernstein_creation_operator(5)
I[5, 1, 3, 2, 1]
sage: elt = b + 3*I[4,1,2]
sage: elt.bernstein_creation_operator(1)
I[1, 1, 3, 2, 1] + 3*I[1, 4, 1, 2]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> I = NSym.I()
```

(continues on next page)

(continued from previous page)

```
>>> b = I[Integer(1),Integer(3),Integer(2),Integer(1)]
>>> b.bernstein_creation_operator(Integer(3))
I[3, 1, 3, 2, 1]
>>> b.bernstein_creation_operator(Integer(5))
I[5, 1, 3, 2, 1]
>>> elt = b + Integer(3)*I[Integer(4),Integer(1),Integer(2)]
>>> elt.bernstein_creation_operator(Integer(1))
I[1, 1, 3, 2, 1] + 3*I[1, 4, 1, 2]
```

We check that this agrees with the definition on the Complete basis:

```
sage: S = NSym.S()
sage: S(elt).bernstein_creation_operator(1) == S(elt.bernstein_
↪creation_operator(1))
True
```

```
>>> from sage.all import *
>>> S = NSym.S()
>>> S(elt).bernstein_creation_operator(Integer(1)) == S(elt.bernstein_
↪creation_operator(Integer(1)))
True
```

Check on nonpositive values of n:

```
sage: I[2,2,2].bernstein_creation_operator(-1)
I[1, 1, 1, 2] + I[1, 1, 2, 1] + I[1, 2, 1, 1] - I[1, 2, 2]
sage: I[2,3,2].bernstein_creation_operator(0)
-I[1, 1, 3, 2] - I[1, 2, 2, 2] - I[1, 2, 3, 1] + I[2, 3, 2]
```

```
>>> from sage.all import *
>>> I[Integer(2),Integer(2),Integer(2)].bernstein_creation_operator(-
↪Integer(1))
I[1, 1, 1, 2] + I[1, 1, 2, 1] + I[1, 2, 1, 1] - I[1, 2, 2]
>>> I[Integer(2),Integer(3),Integer(2)].bernstein_creation_
↪operator(Integer(0))
-I[1, 1, 3, 2] - I[1, 2, 2, 2] - I[1, 2, 3, 1] + I[2, 3, 2]
```

dual()

Return the dual basis to the Immaculate basis of NCSF.

The basis returned is the dualImmaculate basis of QSym.

OUTPUT: the dualImmaculate basis of the quasi-symmetric functions

EXAMPLES:

```
sage: I = NonCommutativeSymmetricFunctions(QQ).Immaculate()
sage: I.dual()
Quasisymmetric functions over the Rational Field in the dualImmaculate
basis
```

```
>>> from sage.all import *
>>> I = NonCommutativeSymmetricFunctions(QQ).Immaculate()
```

(continues on next page)

(continued from previous page)

```
>>> I.dual()
Quasisymmetric functions over the Rational Field in the dualImmaculate
basis
```

L

alias of *Elementary*

class Monomial(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The monomial basis defined in Tevlin's paper [Tev2007].

The monomial basis is well-defined only when the base ring is a $\mathbf{Q}$-algebra. It is the basis denoted by $(M^I)_I$ in [Tev2007].

class MultiplicativeBases(*parent_with_realization*)

Bases: Category_realization_of_parent

Category of multiplicative bases of non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBases()
Category of multiplicative bases of Non-Commutative Symmetric Functions over␣
↪the Rational Field
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> N.MultiplicativeBases()
Category of multiplicative bases of Non-Commutative Symmetric Functions over␣
↪the Rational Field
```

The complete basis is a multiplicative basis, but the ribbon basis is not:

```
sage: N.Complete() in N.MultiplicativeBases()
True
sage: N.Ribbon() in N.MultiplicativeBases()
False
```

```
>>> from sage.all import *
>>> N.Complete() in N.MultiplicativeBases()
True
>>> N.Ribbon() in N.MultiplicativeBases()
False
```

class ParentMethods

Bases: object

algebra_generators()

Return the algebra generators of a given multiplicative basis of non-commutative symmetric functions.

OUTPUT: the family of generators of the multiplicative basis `self`

EXAMPLES:

```
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: f = Psi.algebra_generators()
sage: f
Lazy family (<lambda>(i))_{i in Positive integers}
sage: f[1], f[2], f[3]
(Psi[1], Psi[2], Psi[3])
```

```
>>> from sage.all import *
>>> Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
>>> f = Psi.algebra_generators()
>>> f
Lazy family (<lambda>(i))_{i in Positive integers}
>>> f[Integer(1)], f[Integer(2)], f[Integer(3)]
(Psi[1], Psi[2], Psi[3])
```

algebra_morphism(*on_generators*, ***keywords*)

Given a map defined on the generators of the multiplicative basis `self`, return the algebra morphism that extends this map to the whole algebra of non-commutative symmetric functions.

INPUT:

- `on_generators` – a function defined on the index set of the generators (that is, on the positive integers)
- `anti` – boolean (default: `False`)
- `category` – a category (default: `None`)

OUTPUT:

- The algebra morphism of `self` which is defined by `on_generators` in the basis `self`. When `anti` is set to `True`, an algebra anti-morphism is computed instead of an algebra morphism.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi()
sage: double = lambda i: Psi[i,i]
sage: f = Psi.algebra_morphism(double, codomain = Psi)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Psi basis
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] + 3*Psi[1, 1, 3, 3, 2, 2] + Psi[2, 2, 4, 4]
sage: f.category()
Category of endsets of unital magmas and right modules over Rational␣
↪Field and left modules over Rational Field
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> Psi = NCSF.Psi()
>>> double = lambda i: Psi[i,i]
>>> f = Psi.algebra_morphism(double, codomain = Psi)
>>> f
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Psi basis
>>> f(Integer(2)*Psi[[]] + Integer(3) * Psi[Integer(1),Integer(3),
↪Integer(2)] + Psi[Integer(2),Integer(4)] )
2*Psi[] + 3*Psi[1, 1, 3, 3, 2, 2] + Psi[2, 2, 4, 4]
```

(continues on next page)

(continued from previous page)

```
>>> f.category()
Category of endsets of unital magmas and right modules over Rational␣
↪Field and left modules over Rational Field
```

When extra properties about the morphism are known, one can specify the category of which it is a morphism:

```
sage: negate = lambda i: -Psi[i]
sage: f = Psi.algebra_morphism(negate, codomain = Psi, category =␣
↪GradedHopfAlgebrasWithBasis(QQ))
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Psi basis
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] - 3*Psi[1, 3, 2] + Psi[2, 4]
sage: f.category()
Category of endsets of Hopf algebras over Rational Field and graded␣
↪modules over Rational Field
```

```
>>> from sage.all import *
>>> negate = lambda i: -Psi[i]
>>> f = Psi.algebra_morphism(negate, codomain = Psi, category =␣
↪GradedHopfAlgebrasWithBasis(QQ))
>>> f
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Psi basis
>>> f(Integer(2)*Psi[[]] + Integer(3) * Psi[Integer(1),Integer(3),
↪Integer(2)] + Psi[Integer(2),Integer(4)] )
2*Psi[] - 3*Psi[1, 3, 2] + Psi[2, 4]
>>> f.category()
Category of endsets of Hopf algebras over Rational Field and graded␣
↪modules over Rational Field
```

If `anti` is true, this returns an anti-algebra morphism:

```
sage: f = Psi.algebra_morphism(double, codomain = Psi, anti=True)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Psi basis
sage: f(2*Psi[[]] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] + 3*Psi[2, 2, 3, 3, 1, 1] + Psi[4, 4, 2, 2]
sage: f.category()
Category of endsets of modules with basis over Rational Field
```

```
>>> from sage.all import *
>>> f = Psi.algebra_morphism(double, codomain = Psi, anti=True)
>>> f
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Psi basis
>>> f(Integer(2)*Psi[[]] + Integer(3) * Psi[Integer(1),Integer(3),
↪Integer(2)] + Psi[Integer(2),Integer(4)] )
2*Psi[] + 3*Psi[2, 2, 3, 3, 1, 1] + Psi[4, 4, 2, 2]
```

(continues on next page)

(continued from previous page)

```
>>> f.category()
Category of endsets of modules with basis over Rational Field
```

antipode()

Return the antipode morphism on the basis `self`.

The antipode of $NSym$ is closely related to the omega involution; see *omega_involution()* for the latter.

OUTPUT:
• The antipode module map from non-commutative symmetric functions on basis `self`.
EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.antipode
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Complete basis
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S.antipode
Generic endomorphism of Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Complete basis
```

coproduct()

Return the coproduct morphism in the basis `self`.

OUTPUT:
• The coproduct module map from non-commutative symmetric functions on basis `self`.
EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.coproduct
Generic morphism:
  From: Non-Commutative Symmetric Functions over the Rational Field in␣
↪the Complete basis
  To:   Non-Commutative Symmetric Functions over the Rational Field in␣
↪the Complete basis # Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Complete basis
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S.coproduct
Generic morphism:
  From: Non-Commutative Symmetric Functions over the Rational Field in␣
↪the Complete basis
  To:   Non-Commutative Symmetric Functions over the Rational Field in␣
↪the Complete basis # Non-Commutative Symmetric Functions over the␣
↪Rational Field in the Complete basis
```

product_on_basis(*composition1*, *composition2*)

Return the product of two basis elements from the multiplicative basis. Multiplication is just concatenation on compositions.

INPUT:

- `composition1`, `composition2` – integer compositions

OUTPUT:

- The product of the two non-commutative symmetric functions indexed by `composition1` and `composition2` in the multiplicative basis `self`. This will be again a non-commutative symmetric function.

EXAMPLES:

```
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi[3,1,2] * Psi[4,2] == Psi[3,1,2,4,2]
True
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.product_on_basis(Composition([2,1]), Composition([1,2]))
S[2, 1, 1, 2]
```

```
>>> from sage.all import *
>>> Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
>>> Psi[Integer(3),Integer(1),Integer(2)] * Psi[Integer(4),Integer(2)]␣
↪== Psi[Integer(3),Integer(1),Integer(2),Integer(4),Integer(2)]
True
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S.product_on_basis(Composition([Integer(2),Integer(1)]),␣
↪Composition([Integer(1),Integer(2)]))
S[2, 1, 1, 2]
```

to_symmetric_function()

Morphism to the algebra of symmetric functions.

This is constructed by extending the algebra morphism by the image of the generators.

OUTPUT:

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[1,3])
h[3, 1]
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function(Phi[1,3])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
sage: Psi = N.Psi()
sage: Psi.to_symmetric_function(Psi[1,3])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> S = N.complete()
>>> S.to_symmetric_function(S[Integer(1),Integer(3)])
h[3, 1]
>>> Phi = N.Phi()
>>> Phi.to_symmetric_function(Phi[Integer(1),Integer(3)])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

(continues on next page)

(continued from previous page)

```
>>> Psi = N.Psi()
>>> Psi.to_symmetric_function(Psi[Integer(1),Integer(3)])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

to_symmetric_function_on_generators(*i*)

Morphism of the generators to symmetric functions.

This is constructed by coercion to the complete basis and applying the morphism.

OUTPUT:

- The module morphism from the basis `self` to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
sage: Phi.to_symmetric_function_on_generators(0)
h[]
sage: Psi = N.Psi()
sage: Psi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
sage: L = N.elementary()
sage: L.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 2*h[2, 1] + h[3]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = N.Phi()
>>> Phi.to_symmetric_function_on_generators(Integer(3))
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
>>> Phi.to_symmetric_function_on_generators(Integer(0))
h[]
>>> Psi = N.Psi()
>>> Psi.to_symmetric_function_on_generators(Integer(3))
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
>>> L = N.elementary()
>>> L.to_symmetric_function_on_generators(Integer(3))
h[1, 1, 1] - 2*h[2, 1] + h[3]
```

super_categories()

Return the super categories of the category of multiplicative bases of the non-commutative symmetric functions.

OUTPUT: list

class MultiplicativeBasesOnGroupLikeElements(*parent_with_realization*)

Bases: `Category_realization_of_parent`

Category of multiplicative bases on grouplike elements of non-commutative symmetric functions.

Here, a "multiplicative basis on grouplike elements" means a multiplicative basis whose generators

$(f_1, f_2, f_3, \ldots)$ satisfy

$$\Delta(f_i) = \sum_{j=0}^{i} f_j \otimes f_{i-j}$$

with $f_0 = 1$. (In other words, the generators are to form a divided power sequence in the sense of a coalgebra.) This does not mean that the generators are grouplike, but means that the element $1 + f_1 + f_2 + f_3 + \cdots$ in the completion of the ring of non-commutative symmetric functions with respect to the grading is grouplike.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnGroupLikeElements()
Category of multiplicative bases on group like elements of Non-Commutative␣
↪Symmetric Functions over the Rational Field
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> N.MultiplicativeBasesOnGroupLikeElements()
Category of multiplicative bases on group like elements of Non-Commutative␣
↪Symmetric Functions over the Rational Field
```

The complete basis is a multiplicative basis, but the ribbon basis is not:

```
sage: N.Complete() in N.MultiplicativeBasesOnGroupLikeElements()
True
sage: N.Ribbon() in N.MultiplicativeBasesOnGroupLikeElements()
False
```

```
>>> from sage.all import *
>>> N.Complete() in N.MultiplicativeBasesOnGroupLikeElements()
True
>>> N.Ribbon() in N.MultiplicativeBasesOnGroupLikeElements()
False
```

class ParentMethods

Bases: `object`

antipode_on_basis(*composition*)

Return the application of the antipode to a basis element.

INPUT:

- `composition` – a composition

OUTPUT:

- The image of the basis element indexed by `composition` under the antipode map.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.antipode_on_basis(Composition([2,1]))
-S[1, 1, 1] + S[1, 2]

0
```

coproduct_on_generators(*i*)

Return the image of the i-th generator of the algebra under the coproduct.

INPUT:

- `i` – positive integer

OUTPUT: the result of applying the coproduct to the i-th generator of `self`

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: S.coproduct_on_generators(3)
S[] # S[3] + S[1] # S[2] + S[2] # S[1] + S[3] # S[]
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).complete()
>>> S.coproduct_on_generators(Integer(3))
S[] # S[3] + S[1] # S[2] + S[2] # S[1] + S[3] # S[]
```

super_categories()

Return the super categories of the category of multiplicative bases of group-like elements of the non-commutative symmetric functions.

OUTPUT: list

class MultiplicativeBasesOnPrimitiveElements(*parent_with_realization*)

Bases: `Category_realization_of_parent`

Category of multiplicative bases of the non-commutative symmetric functions whose generators are primitive elements.

An element x of a bialgebra is *primitive* if $\Delta(x) = x \otimes 1 + 1 \otimes x$, where Δ is the coproduct of the bialgebra.

Given a multiplicative basis and knowing the coproducts and antipodes of its generators, one can compute the coproduct and the antipode of any element, since they are respectively algebra morphisms and anti-morphisms. See *antipode_on_generators()* and *coproduct_on_generators()*.

Todo

this could be generalized to any free algebra.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnPrimitiveElements()
Category of multiplicative bases on primitive elements of Non-Commutative␣
↪Symmetric Functions over the Rational Field
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> N.MultiplicativeBasesOnPrimitiveElements()
Category of multiplicative bases on primitive elements of Non-Commutative␣
↪Symmetric Functions over the Rational Field
```

The Phi and Psi bases are multiplicative bases whose generators are primitive elements, but the complete and ribbon bases are not:

```
sage: N.Phi() in N.MultiplicativeBasesOnPrimitiveElements()
True
sage: N.Psi() in N.MultiplicativeBasesOnPrimitiveElements()
True
sage: N.Complete() in N.MultiplicativeBasesOnPrimitiveElements()
False
sage: N.Ribbon() in N.MultiplicativeBasesOnPrimitiveElements()
False
```

```
>>> from sage.all import *
>>> N.Phi() in N.MultiplicativeBasesOnPrimitiveElements()
True
>>> N.Psi() in N.MultiplicativeBasesOnPrimitiveElements()
True
>>> N.Complete() in N.MultiplicativeBasesOnPrimitiveElements()
False
>>> N.Ribbon() in N.MultiplicativeBasesOnPrimitiveElements()
False
```

class ParentMethods

Bases: object

antipode_on_generators(*i*)

Return the image of a generator of a primitive basis of the non-commutative symmetric functions under the antipode map.

INPUT:
• i – positive integer
OUTPUT:

The image of the i-th generator of the multiplicative basis self under the antipode of the algebra of non-commutative symmetric functions.

EXAMPLES:

```
sage: Psi=NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi.antipode_on_generators(2)
-Psi[2]
```

```
>>> from sage.all import *
>>> Psi=NonCommutativeSymmetricFunctions(QQ).Psi()
>>> Psi.antipode_on_generators(Integer(2))
-Psi[2]
```

coproduct_on_generators(*i*)

Return the image of the i-th generator of the multiplicative basis self under the coproduct.

INPUT:
• i – positive integer
OUTPUT: the result of applying the coproduct to the i-th generator of self

EXAMPLES:

```
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi.coproduct_on_generators(3)
Psi[] # Psi[3] + Psi[3] # Psi[]
```

```
>>> from sage.all import *
>>> Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
>>> Psi.coproduct_on_generators(Integer(3))
Psi[] # Psi[3] + Psi[3] # Psi[]
```

super_categories()

Return the super categories of the category of multiplicative bases of primitive elements of the non-commutative symmetric functions.

OUTPUT: list

class Phi(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Phi basis.

The Phi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(\Phi^I)_I$. It is a multiplicative basis, and is connected to the elementary generators Λ_i of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function Φ_n for every positive integer n by the power series identity

$$\sum_{k \geq 1} t^k \frac{1}{k} \Phi_k = -\log\left(\sum_{k \geq 0} (-t)^k \Lambda_k \right),$$

with Λ_0 denoting 1. For every composition $(i_1, i_2, \ldots, i_k)$, we have $\Phi^{(i_1,i_2,\ldots,i_k)} = \Phi_{i_1} \Phi_{i_2} \cdots \Phi_{i_k}$.

The Φ-basis is well-defined only when the base ring is a $\mathbf{Q}$-algebra. The elements of the Φ-basis are known as the "power-sum non-commutative symmetric functions of the second kind".

The generators Φ_n are related to the (first) Eulerian idempotents in the descent algebras of the symmetric groups (see [NCSF1], 5.4 for details).

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NCSF.Phi(); Phi
Non-Commutative Symmetric Functions over the Rational Field in the Phi basis
sage: Phi.an_element()
2*Phi[] + 2*Phi[1] + 3*Phi[1, 1]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = NCSF.Phi(); Phi
Non-Commutative Symmetric Functions over the Rational Field in the Phi basis
>>> Phi.an_element()
2*Phi[] + 2*Phi[1] + 3*Phi[1, 1]
```

class Element

Bases: IndexedFreeModuleElement

psi_involution()

Return the image of the noncommutative symmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $NCSF \to NCSF$ which, for every composition I, sends the complete noncommutative symmetric function S^I to the elementary noncommutative symmetric function Λ^I. It can be shown that every composition I satisfies

$$\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I|-\ell(I)}\Phi^I$$

where I^c denotes the complement of the composition I, and $\ell(I)$ denotes the length of I, and where standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, Φ for the basis of the power sums of the second kind, and R for the ribbon basis). The map ψ is an involution and a graded Hopf algebra automorphism of $NCSF$. If π denotes the projection from $NCSF$ to the ring of symmetric functions (*to_symmetric_function()*), then $\pi(\psi(f)) = \omega(\pi(f))$ for every $f \in NCSF$, where the ω on the right hand side denotes the omega automorphism of Sym.

The involution ψ of $NCSF$ is adjoint to the involution ψ of $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also

psi involution of NCSF, *psi involution of QSym*, *star involution of NCSF*.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
```

(continues on next page)

(continued from previous page)

```
sage: Phi[3,2].psi_involution()
-Phi[3, 2]
sage: Phi[2,2].psi_involution()
Phi[2, 2]
sage: Phi[[]].psi_involution()
Phi[]
sage: (Phi[2,1] - 2*Phi[2]).psi_involution()
2*Phi[2] - Phi[2, 1]
sage: Phi(0).psi_involution()
0
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = NSym.Phi()
>>> Phi[Integer(3),Integer(2)].psi_involution()
-Phi[3, 2]
>>> Phi[Integer(2),Integer(2)].psi_involution()
Phi[2, 2]
>>> Phi[[]].psi_involution()
Phi[]
>>> (Phi[Integer(2),Integer(1)] - Integer(2)*Phi[Integer(2)]).psi_
↪involution()
2*Phi[2] - Phi[2, 1]
>>> Phi(Integer(0)).psi_involution()
0
```

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the ribbon basis:

```
sage: R = NSym.R()
sage: all( R(Phi[I].psi_involution()) == R(Phi[I]).psi_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> R = NSym.R()
>>> all( R(Phi[I].psi_involution()) == R(Phi[I]).psi_involution()
...      for I in Compositions(Integer(4)) )
True
```

star_involution()

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to S_n. Denoting by f^* the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition I satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where I^r denotes the reversed composition of I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, and Φ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra

automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the n-th graded component of $NCSF$ and the descent algebra of the symmetric group S_n (see *to_descent_algebra()*), the star involution (restricted to the n-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where ω_n is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If π denotes the projection from $NCSF$ to the ring of symmetric functions (*to_symmetric_function()*), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[3,1,1,4].star_involution()
Phi[4, 1, 1, 3]
sage: Phi[4,2,1].star_involution()
Phi[1, 2, 4]
sage: (Phi[1,4] - Phi[2,3] + 2*Phi[5,4] - 3*Phi[3] + 4*Phi[[]]).star_
↪involution()
4*Phi[] - 3*Phi[3] - Phi[3, 2] + Phi[4, 1] + 2*Phi[4, 5]
sage: (Phi[3,3] + 3*Phi[1]).star_involution()
3*Phi[1] + Phi[3, 3]
sage: Phi([2,1]).star_involution()
Phi[1, 2]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = NSym.Phi()
>>> Phi[Integer(3),Integer(1),Integer(1),Integer(4)].star_involution()
Phi[4, 1, 1, 3]
>>> Phi[Integer(4),Integer(2),Integer(1)].star_involution()
Phi[1, 2, 4]
>>> (Phi[Integer(1),Integer(4)] - Phi[Integer(2),Integer(3)] +␣
↪Integer(2)*Phi[Integer(5),Integer(4)] - Integer(3)*Phi[Integer(3)] +␣
↪Integer(4)*Phi[[]]).star_involution()
4*Phi[] - 3*Phi[3] - Phi[3, 2] + Phi[4, 1] + 2*Phi[4, 5]
>>> (Phi[Integer(3),Integer(3)] + Integer(3)*Phi[Integer(1)]).star_
↪involution()
3*Phi[1] + Phi[3, 3]
>>> Phi([Integer(2),Integer(1)]).star_involution()
Phi[1, 2]
```

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(Phi[I].star_involution()) == S(Phi[I]).star_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> S = NSym.S()
>>> all( S(Phi[I].star_involution()) == S(Phi[I]).star_involution()
...      for I in Compositions(Integer(4)) )
True
```

verschiebung(*n*)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (*verschiebung()*) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

↪verschiebung(Integer(1))
Phi[1] - Phi[2] + 2*Phi[3]
```

class Psi(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Psi basis.

The Psi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by $(\Psi^I)_I$. It is a multiplicative basis, and is connected to the elementary generators Λ_i of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function Ψ_n for every positive integer n by the power series identity

$$\frac{d}{dt}\sigma(t) = \sigma(t) \cdot \left(\sum_{k \geq 1} t^{k-1} \Psi_k \right),$$

where

$$\sigma(t) = \left(\sum_{k \geq 0} (-t)^k \Lambda_k \right)^{-1}$$

and where Λ_0 denotes 1. For every composition $(i_1, i_2, \ldots, i_k)$, we have $\Psi^{(i_1,i_2,\ldots,i_k)} = \Psi_{i_1} \Psi_{i_2} \cdots \Psi_{i_k}$.

The Ψ-basis is a basis only when the base ring is a $\mathbf{Q}$-algebra (although the Ψ^I can be defined over any base ring). The elements of the Ψ-basis are known as the "power-sum non-commutative symmetric functions of the first kind". The generators Ψ_n correspond to the Dynkin (quasi-)idempotents in the descent algebras of the symmetric groups (see [NCSF1], 5.2 for details).

Another (equivalent) definition of Ψ_n is

$$\Psi_n = \sum_{i=0}^{n-1} (-1)^i R_{1^i, n-i},$$

where R denotes the ribbon basis of $NCSF$, and where 1^i stands for i repetitions of the integer 1.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi(); Psi
Non-Commutative Symmetric Functions over the Rational Field in the Psi basis
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> Psi = NCSF.Psi(); Psi
Non-Commutative Symmetric Functions over the Rational Field in the Psi basis
>>> Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

Checking the equivalent definition of Ψ_n:

```
sage: def test_psi(n):
....:     NCSF = NonCommutativeSymmetricFunctions(ZZ)
....:     R = NCSF.R()
....:     Psi = NCSF.Psi()
....:     a = R.sum([(-1) ** i * R[[1]*i + [n-i]]
....:                for i in range(n)])
....:     return a == R(Psi[n])
sage: test_psi(2)
True
sage: test_psi(3)
True
sage: test_psi(4)
True
```

```
>>> from sage.all import *
>>> def test_psi(n):
...     NCSF = NonCommutativeSymmetricFunctions(ZZ)
...     R = NCSF.R()
...     Psi = NCSF.Psi()
...     a = R.sum([(-Integer(1)) ** i * R[[Integer(1)]*i + [n-i]]
...                for i in range(n)])
...     return a == R(Psi[n])
>>> test_psi(Integer(2))
True
>>> test_psi(Integer(3))
True
>>> test_psi(Integer(4))
True
```

class Element

Bases: `IndexedFreeModuleElement`

verschiebung(*n*)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative

symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (*verschiebung()*) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

Psi[1] - Psi[2] + 2*Psi[3]
```

internal_product_on_basis_by_bracketing(I, J)

The internal product of two elements of the Psi basis.

See *internal_product()* for a thorough documentation of this operation.

This is an implementation using [NCSF2] Lemma 3.10. It is fast when the length of I is small, but can get very slow otherwise. Therefore it is not being used by default for internally multiplying Psi functions.

INPUT:

- `I`, `J` – compositions

OUTPUT:

- The internal product of the elements of the Psi basis of $NSym$ indexed by `I` and `J`, expressed in the Psi basis.

AUTHORS:

- Travis Scrimshaw, 29 Mar 2014

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = N.Psi()
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1],[2,1,1])
4*Psi[1, 2, 1]
sage: Psi.internal_product_on_basis_by_bracketing([2,1,1],[1,2,1])
4*Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1], [1,1,1,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([3,1], [1,2,1])
-Psi[1, 2, 1] + Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1], [3,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2])
0
sage: Psi.internal_product_on_basis_by_bracketing([4], [1,2,1])
-Psi[1, 1, 2] + 2*Psi[1, 2, 1] - Psi[2, 1, 1]
```

```
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> Psi = N.Psi()
>>> Psi.internal_product_on_basis_by_bracketing([Integer(2),Integer(2)],
↪[Integer(1),Integer(2),Integer(1)])
0
>>> Psi.internal_product_on_basis_by_bracketing([Integer(1),Integer(2),
↪Integer(1)],[Integer(2),Integer(1),Integer(1)])
4*Psi[1, 2, 1]
>>> Psi.internal_product_on_basis_by_bracketing([Integer(2),Integer(1),
↪Integer(1)],[Integer(1),Integer(2),Integer(1)])
4*Psi[2, 1, 1]
>>> Psi.internal_product_on_basis_by_bracketing([Integer(1),Integer(2),
↪Integer(1)], [Integer(1),Integer(1),Integer(1),Integer(1)])
0
>>> Psi.internal_product_on_basis_by_bracketing([Integer(3),Integer(1)],␣
↪[Integer(1),Integer(2),Integer(1)])
-Psi[1, 2, 1] + Psi[2, 1, 1]
>>> Psi.internal_product_on_basis_by_bracketing([Integer(1),Integer(2),
↪Integer(1)], [Integer(3),Integer(1)])
0
>>> Psi.internal_product_on_basis_by_bracketing([Integer(2),Integer(2)],
↪[Integer(1),Integer(2)])
0
>>> Psi.internal_product_on_basis_by_bracketing([Integer(4)], [Integer(1),
↪Integer(2),Integer(1)])
-Psi[1, 1, 2] + 2*Psi[1, 2, 1] - Psi[2, 1, 1]
```

R

alias of *Ribbon*

class Ribbon(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Ribbon basis.

The Ribbon basis is defined in Definition 3.12 of [NCSF1], where it is denoted by $(R_I)_I$. It is connected to the complete basis of the ring of non-commutative symmetric functions by the following relation: For every composition I, we have

$$R_I = \sum_J (-1)^{\ell(I)-\ell(J)} S^J,$$

where the sum is over all compositions J which are coarser than I and $\ell(I)$ denotes the length of I. (See the proof of Proposition 4.13 in [NCSF1].)

The elements of the Ribbon basis are commonly referred to as the ribbon Schur functions.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: R = NCSF.Ribbon(); R
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon␣
↪basis
sage: R.an_element()
2*R[] + 2*R[1] + 3*R[1, 1]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> R = NCSF.Ribbon(); R
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon␣
↪basis
>>> R.an_element()
2*R[] + 2*R[1] + 3*R[1, 1]
```

The following are aliases for this basis:

```
sage: NCSF.ribbon()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon␣
↪basis
sage: NCSF.R()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon␣
↪basis
```

```
>>> from sage.all import *
>>> NCSF.ribbon()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon␣
↪basis
>>> NCSF.R()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon␣
↪basis
```

class Element

Bases: IndexedFreeModuleElement

star_involution()

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer n, sends the n-th complete non-commutative symmetric function S_n to S_n. Denoting by f^* the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition I satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_I^* = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where I^r denotes the reversed composition of I, and standard notations for classical bases of $NCSF$ are being used (S for the complete basis, Λ for the elementary basis, R for the ribbon basis, and Φ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the n-th graded component of $NCSF$ and the descent algebra of the symmetric group S_n (see *to_descent_algebra()*), the star involution (restricted to the n-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where ω_n is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If π denotes the projection from $NCSF$ to the ring of symmetric functions (*to_symmetric_function()*), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also

star involution of NCSF, *star involution of QSym*, *psi involution of NCSF*.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R[3,1,4,2].star_involution()
R[2, 4, 1, 3]
sage: R[4,1,2].star_involution()
R[2, 1, 4]
sage: (R[1] - R[2] + 2*R[5,4] - 3*R[3] + 4*R[[]]).star_involution()
4*R[] + R[1] - R[2] - 3*R[3] + 2*R[4, 5]
sage: (R[3,3] - 21*R[1]).star_involution()
-21*R[1] + R[3, 3]
sage: R([14,1]).star_involution()
R[1, 14]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> R = NSym.R()
>>> R[Integer(3),Integer(1),Integer(4),Integer(2)].star_involution()
R[2, 4, 1, 3]
>>> R[Integer(4),Integer(1),Integer(2)].star_involution()
R[2, 1, 4]
>>> (R[Integer(1)] - R[Integer(2)] + Integer(2)*R[Integer(5),
↪Integer(4)] - Integer(3)*R[Integer(3)] + Integer(4)*R[[]]).star_
↪involution()
```

(continues on next page)

(continued from previous page)

```
4*R[] + R[1] - R[2] - 3*R[3] + 2*R[4, 5]
>>> (R[Integer(3),Integer(3)] - Integer(21)*R[Integer(1)]).star_
↪involution()
-21*R[1] + R[3, 3]
>>> R([Integer(14),Integer(1)]).star_involution()
R[1, 14]
```

The implementation at hand is tailored to the ribbon basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(R[I].star_involution()) == S(R[I]).star_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> S = NSym.S()
>>> all( S(R[I].star_involution()) == S(R[I]).star_involution()
...      for I in Compositions(Integer(4)) )
True
```

verschiebung(n)

Return the image of the noncommutative symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the map from the $\mathbf{k}$-algebra of noncommutative symmetric functions to itself that sends the complete function S^I indexed by a composition $I = (i_1, i_2, \ldots, i_k)$ to $S^{(i_1/n, i_2/n, \ldots, i_k/n)}$ if all of the numbers $i_1, i_2, \ldots, i_k$ are divisible by n, and to 0 otherwise. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every positive integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(S_r) = S_{r/n}, \quad \mathbf{V}_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad \mathbf{V}_n(\Psi_r) = n\Psi_{r/n}, \quad \mathbf{V}_n(\Phi_r) = n\Phi_{r/n}$$

(where S_r denotes the r-th complete non-commutative symmetric function, Λ_r denotes the r-th elementary non-commutative symmetric function, Ψ_r denotes the r-th power-sum non-commutative symmetric function of the first kind, and Φ_r denotes the r-th power-sum non-commutative symmetric function of the second kind). For every positive integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(S_r) = \mathbf{V}_n(\Lambda_r) = \mathbf{V}_n(\Psi_r) = \mathbf{V}_n(\Phi_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (*verschiebung()*) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition I of size $n\ell$ satisfies

$$\mathbf{V}_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},$$

where J denotes the meet of the compositions I and $(\underbrace{n, n, \ldots, n}_{|I|/n \text{ times}})$, where $\ell(I)$ is the length of I, and where J/n denotes the composition obtained by dividing every entry of J by n. For a composition I of size not divisible by n, we have $\mathbf{V}_n(R_I) = 0$.

See also

verschiebung method of NCSF, *adams_operator method of QSym*, *verschiebung method of Sym*

INPUT:
- `n` – positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to `self`.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R([4,2]).verschiebung(2)
R[2, 1]
sage: R([2,1]).verschiebung(3)
-R[1]
sage: R([3]).verschiebung(2)
0
sage: R([]).verschiebung(2)
R[]
sage: R([5, 1]).verschiebung(3)
-R[2]
sage: R([5, 1]).verschiebung(6)
-R[1]
sage: R([5, 1]).verschiebung(2)
-R[3]
sage: R([1, 2, 3, 1]).verschiebung(7)
-R[1]
sage: R([1, 2, 3, 1]).verschiebung(5)
0
sage: (R[1] - R[2] + 2*R[3]).verschiebung(1)
R[1] - R[2] + 2*R[3]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> R = NSym.R()
>>> R([Integer(4),Integer(2)]).verschiebung(Integer(2))
R[2, 1]
>>> R([Integer(2),Integer(1)]).verschiebung(Integer(3))
-R[1]
>>> R([Integer(3)]).verschiebung(Integer(2))
0
>>> R([]).verschiebung(Integer(2))
R[]
>>> R([Integer(5), Integer(1)]).verschiebung(Integer(3))
-R[2]
>>> R([Integer(5), Integer(1)]).verschiebung(Integer(6))
-R[1]
>>> R([Integer(5), Integer(1)]).verschiebung(Integer(2))
```

(continues on next page)

(continued from previous page)

```
-R[3]
>>> R([Integer(1), Integer(2), Integer(3), Integer(1)]).
↪verschiebung(Integer(7))
-R[1]
>>> R([Integer(1), Integer(2), Integer(3), Integer(1)]).
↪verschiebung(Integer(5))
0
>>> (R[Integer(1)] - R[Integer(2)] + Integer(2)*R[Integer(3)]).
↪verschiebung(Integer(1))
R[1] - R[2] + 2*R[3]
```

antipode_on_basis(*composition*)

Return the application of the antipode to a basis element of the ribbon basis `self`.

INPUT:

- `composition` – a composition

OUTPUT:

- The image of the basis element indexed by `composition` under the antipode map.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.antipode_on_basis(Composition([2,1]))
-R[2, 1]
sage: R[3,1].antipode() # indirect doctest
R[2, 1, 1]
sage: R[[]].antipode() # indirect doctest
R[]
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
>>> R.antipode_on_basis(Composition([Integer(2),Integer(1)]))
-R[2, 1]
>>> R[Integer(3),Integer(1)].antipode() # indirect doctest
R[2, 1, 1]
>>> R[[]].antipode() # indirect doctest
R[]
```

We check that the implementation of the antipode at hand does not contradict the generic one:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: all( S(R[I].antipode()) == S(R[I]).antipode()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> all( S(R[I].antipode()) == S(R[I]).antipode()
...      for I in Compositions(Integer(4)) )
True
```

dual()

Return the dual basis to the ribbon basis of the non-commutative symmetric functions. This is the Fundamental basis of the quasi-symmetric functions.

OUTPUT: the fundamental basis of the quasi-symmetric functions

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.dual()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
>>> R.dual()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

product_on_basis(*I*, *J*)

Return the product of two ribbon basis elements of the non-commutative symmetric functions.

INPUT:

- I, J – compositions

OUTPUT: the product of the ribbon functions indexed by I and J

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R[1,2,1] * R[3,1]
R[1, 2, 1, 3, 1] + R[1, 2, 4, 1]
sage: ( R[1,2] + R[3] ) * ( R[3,1] + R[1,2,1] )
R[1, 2, 1, 2, 1] + R[1, 2, 3, 1] + R[1, 3, 2, 1] + R[1, 5, 1] + R[3, 1, 2,
↪ 1] + R[3, 3, 1] + R[4, 2, 1] + R[6, 1]
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
>>> R[Integer(1),Integer(2),Integer(1)] * R[Integer(3),Integer(1)]
R[1, 2, 1, 3, 1] + R[1, 2, 4, 1]
>>> ( R[Integer(1),Integer(2)] + R[Integer(3)] ) * ( R[Integer(3),
↪Integer(1)] + R[Integer(1),Integer(2),Integer(1)] )
R[1, 2, 1, 2, 1] + R[1, 2, 3, 1] + R[1, 3, 2, 1] + R[1, 5, 1] + R[3, 1, 2,
↪ 1] + R[3, 3, 1] + R[4, 2, 1] + R[6, 1]
```

to_symmetric_function_on_basis(*I*)

Return the commutative image of a ribbon basis element of the non-commutative symmetric functions.

INPUT:

- I – a composition

OUTPUT:

- The commutative image of the ribbon basis element indexed by I. This will be expressed as a symmetric function in the Schur basis.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.to_symmetric_function_on_basis(Composition([3,1,1]))
s[3, 1, 1]
sage: R.to_symmetric_function_on_basis(Composition([4,2,1]))
s[4, 2, 1] + s[5, 1, 1] + s[5, 2]
sage: R.to_symmetric_function_on_basis(Composition([]))
s[]
```

```
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).R()
>>> R.to_symmetric_function_on_basis(Composition([Integer(3),Integer(1),
↪Integer(1)]))
s[3, 1, 1]
>>> R.to_symmetric_function_on_basis(Composition([Integer(4),Integer(2),
↪Integer(1)]))
s[4, 2, 1] + s[5, 1, 1] + s[5, 2]
>>> R.to_symmetric_function_on_basis(Composition([]))
s[]
```

S

alias of *Complete*

ZL

alias of *Zassenhaus_left*

ZR

alias of *Zassenhaus_right*

class Zassenhaus_left(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of non-commutative symmetric functions in the left Zassenhaus basis.

This basis is the left-version of the basis defined in Section 2.5.1 of [HLNT09]. It is multiplicative, with Z_n defined as the element of $NCSF_n$ satisfying the equation

$$\sigma_1 = \cdots exp(Z_n) \cdots exp(Z_2) exp(Z_1),$$

where

$$\sigma_1 = \sum_{n \geq 0} S_n.$$

It can be recursively computed by the formula

$$S_n = \sum_{\lambda \vdash n} \frac{1}{m_1(\lambda)! m_2(\lambda)! m_3(\lambda)! \cdots} Z_{\lambda_1} Z_{\lambda_2} Z_{\lambda_3} \cdots$$

for all $n \geq 0$.

class Zassenhaus_right(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of non-commutative symmetric functions in the right Zassenhaus basis.

This basis is defined in Section 2.5.1 of [HLNT09]. It is multiplicative, with Z_n defined as the element of $NCSF_n$ satisfying the equation

$$\sigma_1 = exp(Z_1) exp(Z_2) exp(Z_3) \cdots exp(Z_n) \cdots$$

where

$$\sigma_1 = \sum_{n \geq 0} S_n.$$

It can be recursively computed by the formula

$$S_n = \sum_{\lambda \vdash n} \frac{1}{m_1(\lambda)! m_2(\lambda)! m_3(\lambda)! \cdots} \cdots Z_{\lambda_3} Z_{\lambda_2} Z_{\lambda_1}$$

for all $n \geq 0$.

Note that there is a variant (called the "noncommutative power sum symmetric functions of the third kind") in Definition 5.26 of [NCSF2] that satisfies:

$$\sigma_1 = exp(Z_1) exp(Z_2/2) exp(Z_3/3) \cdots exp(Z_n/n) \cdots .$$

a_realization()

Give a realization of the algebra of non-commutative symmetric functions. This particular realization is the complete basis of non-commutative symmetric functions.

OUTPUT:

- The realization of the non-commutative symmetric functions in the complete basis.

EXAMPLES:

```
sage: NonCommutativeSymmetricFunctions(ZZ).a_realization()
Non-Commutative Symmetric Functions over the Integer Ring in the Complete␣
↪basis
```

```
>>> from sage.all import *
>>> NonCommutativeSymmetricFunctions(ZZ).a_realization()
Non-Commutative Symmetric Functions over the Integer Ring in the Complete␣
↪basis
```

complete

alias of *Complete*

dQS

alias of *dualQuasisymmetric_Schur*

dYQS

alias of *dualYoungQuasisymmetric_Schur*

dual()

Return the dual to the non-commutative symmetric functions.

OUTPUT:

- The dual of the non-commutative symmetric functions over a ring. This is the algebra of quasi-symmetric functions over the ring.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF.dual()
Quasisymmetric functions over the Rational Field
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> NCSF.dual()
Quasisymmetric functions over the Rational Field
```

class dualQuasisymmetric_Schur(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The basis of NCSF dual to the Quasisymmetric-Schur basis of QSym.

The *Quasisymmetric_Schur* functions are defined in [QSCHUR] (see also Definition 5.1.1 of [LMvW13]). The dual basis in the algebra of non-commutative symmetric functions is defined by the following formula:

$$R_\alpha = \sum_T dQS_{shape(T)},$$

where the sum is over all standard composition tableaux with descent composition equal to α. The *Quasisymmetric_Schur* basis QS_α has the property that

$$s_\lambda = \sum_{sort(\alpha)=\lambda} QS_\alpha.$$

As a consequence the commutative image of a dual Quasisymmetric-Schur element in the algebra of symmetric functions (the map defined in the method *to_symmetric_function()*) is equal to the Schur function indexed by the decreasing sort of the indexing composition.

See also

CompositionTableaux, *CompositionTableau*.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dQS = NCSF.dQS()
sage: dQS([1,3,2])*dQS([1])
dQS[1, 2, 4] + dQS[1, 3, 2, 1] + dQS[1, 3, 3] + dQS[3, 2, 2]
sage: dQS([1])*dQS([1,3,2])
dQS[1, 1, 3, 2] + dQS[1, 3, 3] + dQS[1, 4, 2] + dQS[2, 3, 2]
sage: dQS([1,3])*dQS([1,1])
dQS[1, 3, 1, 1] + dQS[1, 4, 1] + dQS[3, 2, 1] + dQS[4, 2]
sage: dQS([3,1])*dQS([2,1])
dQS[1, 1, 4, 1] + dQS[1, 4, 2] + dQS[1, 5, 1] + dQS[2, 4, 1] + dQS[3, 1,
2, 1] + dQS[3, 2, 2] + dQS[3, 3, 1] + dQS[4, 3] + dQS[5, 2]
sage: dQS([1,1]).coproduct()
dQS[] # dQS[1, 1] + dQS[1] # dQS[1] + dQS[1, 1] # dQS[]
sage: dQS([3,3]).coproduct().monomial_coefficients()[(Composition([1,2]),
↪Composition([1,2]))]
-1
sage: S = NCSF.complete()
sage: dQS(S[1,3,1])
dQS[1, 3, 1] + dQS[1, 4] + dQS[3, 2] + dQS[4, 1] + dQS[5]
sage: S(dQS[1,3,1])
S[1, 3, 1] - S[3, 2] - S[4, 1] + S[5]
sage: s = SymmetricFunctions(QQ).s()
sage: s(S(dQS([2,1,3])).to_symmetric_function())
s[3, 2, 1]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> dQS = NCSF.dQS()
>>> dQS([Integer(1),Integer(3),Integer(2)])*dQS([Integer(1)])

s[3, 2, 1]
```

dual()

The dual basis to the dual Quasisymmetric-Schur basis of NCSF.

The basis returned is the *Quasisymmetric_Schur* basis of QSym.

OUTPUT: the Quasisymmetric-Schur basis of the quasi-symmetric functions

EXAMPLES:

```
sage: dQS=NonCommutativeSymmetricFunctions(QQ).dualQuasisymmetric_Schur()
sage: dQS.dual()
Quasisymmetric functions over the Rational Field in the Quasisymmetric
Schur basis
sage: dQS.duality_pairing_matrix(dQS.dual(),3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

```
>>> from sage.all import *

to_symmetric_function_on_basis(*I*)

The commutative image of a dual quasi-symmetric Schur element.

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element.

INPUT:

- `I` – a composition

OUTPUT:

- The commutative image of the dual quasi-Schur basis element indexed by `I`. The result is the Schur symmetric function indexed by the partition obtained by sorting `I`.

EXAMPLES:

```
sage: dQS=NonCommutativeSymmetricFunctions(QQ).dQS()
sage: dQS.to_symmetric_function_on_basis([2,1,3])
s[3, 2, 1]
sage: dQS.to_symmetric_function_on_basis([])
s[]
```

```
>>> from sage.all import *
>>> dQS=NonCommutativeSymmetricFunctions(QQ).dQS()
>>> dQS.to_symmetric_function_on_basis([Integer(2),Integer(1),Integer(3)])
s[3, 2, 1]
>>> dQS.to_symmetric_function_on_basis([])
s[]
```

class dualYoungQuasisymmetric_Schur(*NCSF*)

Bases: *CombinatorialFreeModule*, BindableClass

The basis of NCSF dual to the Young Quasisymmetric-Schur basis of QSym.

The *Young_Quasisymmetric_Schur* functions are given in Definition 5.2.1 of [LMvW13]. The dual basis in the algebra of non-commutative symmetric functions are related by an involution reversing the indexing composition of the complete expansion of a quasi-Schur basis element. This basis has many of the same properties as the Quasisymmetric Schur basis and is related to that basis by an algebraic transformation.

EXAMPLES:

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dYQS = NCSF.dYQS()
sage: dYQS([1,3,2])*dYQS([1])
dYQS[1, 3, 2, 1] + dYQS[1, 3, 3] + dYQS[1, 4, 2] + dYQS[2, 3, 2]
sage: dYQS([1])*dYQS([1,3,2])
dYQS[1, 1, 3, 2] + dYQS[2, 3, 2] + dYQS[3, 3, 1] + dYQS[4, 1, 2]
sage: dYQS([1,3])*dYQS([1,1])
dYQS[1, 3, 1, 1] + dYQS[1, 4, 1] + dYQS[2, 3, 1] + dYQS[2, 4]
sage: dYQS([3,1])*dYQS([2,1])
dYQS[3, 1, 2, 1] + dYQS[3, 2, 2] + dYQS[3, 3, 1] + dYQS[4, 1, 1, 1]
 + dYQS[4, 1, 2] + dYQS[4, 2, 1] + dYQS[4, 3] + dYQS[5, 1, 1]
 + dYQS[5, 2]
sage: dYQS([1,1]).coproduct()
```

class sage.combinat.ncsf_qsym.qsym.**QuasiSymmetricFunctions**(*R*)

Bases: UniqueRepresentation, Parent

The Hopf algebra of quasisymmetric functions.

Let R be a commutative ring with unity. The R-algebra of quasi-symmetric functions may be realized as an R-subalgebra of the ring of power series in countably many variables $R[[x_1, x_2, x_3, \ldots]]$. It consists of those formal power series p which are degree-bounded (i. e., the degrees of all monomials occurring with nonzero coefficient in p are bounded from above, although the bound can depend on p) and satisfy the following condition: For every tuple $(a_1, a_2, \ldots, a_m)$ of positive integers, the coefficient of the monomial $x_{i_1}^{a_1} x_{i_2}^{a_2} \cdots x_{i_m}^{a_m}$ in p is the same for all strictly increasing sequences $(i_1 < i_2 < \cdots < i_m)$ of positive integers. (In other words, the coefficient of a monomial in p depends only on the sequence of nonzero exponents in the monomial. If "sequence" were to be replaced by "multiset" here, we would obtain the definition of a symmetric function.)

The R-algebra of quasi-symmetric functions is commonly called QSym_R or occasionally just QSym (when R is clear from the context or $\mathbf{Z}$ or $\mathbf{Q}$). It is graded by the total degree of the power series. Its homogeneous elements of degree k form a free R-submodule of rank equal to the number of compositions of k (that is, 2^{k-1} if $k \geq 1$, else 1).

The two classical bases of QSym, the monomial basis $(M_I)_I$ and the fundamental basis $(F_I)_I$, are indexed by compositions $I = (I_1, I_2, \cdots, I_\ell)$ and defined by the formulas:

$$M_I = \sum_{1 \leq i_1 < i_2 < \cdots < i_\ell} x_{i_1}^{I_1} x_{i_2}^{I_2} \cdots x_{i_\ell}^{I_\ell}$$

and

$$F_I = \sum_{(j_1, j_2, \ldots, j_n)} x_{j_1} x_{j_2} \cdots x_{j_n}$$

where in the second equation the sum runs over all weakly increasing n-tuples $(j_1, j_2, \ldots, j_n)$ of positive integers (where n is the size of I) which increase strictly from j_r to j_{r+1} if r is a descent of the composition I.

These bases are related by the formula

$F_I = \sum_{J \leq I} M_J$

where the inequality $J \leq I$ indicates that J is finer than I.

The R-algebra of quasi-symmetric functions is a Hopf algebra, with the coproduct satisfying

$$\Delta M_I = \sum_{k=0}^{\ell} M_{(I_1, I_2, \cdots, I_k)} \otimes M_{(I_{k+1}, I_{k+2}, \cdots, I_\ell)}$$

for every composition $I = (I_1, I_2, \cdots, I_\ell)$.

It is possible to define an R-algebra of quasi-symmetric functions in a finite number of variables as well (but it is not a bialgebra). These quasi-symmetric functions are actual polynomials then, not just power series.

Chapter 5 of [GriRei18] and Section 11 of [HazWitt1] are devoted to quasi-symmetric functions, as are Malvenuto's thesis [Mal1993] and part of Chapter 7 of [Sta-EC2].

The implementation of the quasi-symmetric function Hopf algebra

We realize the R-algebra of quasi-symmetric functions in Sage as a graded Hopf algebra with basis elements indexed by compositions:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.category()
Join of Category of Hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of commutative algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QSym.category()
Join of Category of Hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of commutative algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
```

The most standard two bases for this R-algebra are the monomial and fundamental bases, and are accessible by the `M()` and `F()` methods:

```
sage: M = QSym.M()
sage: F = QSym.F()
sage: M(F[2,1,2])
M[1, 1, 1, 1, 1] + M[1, 1, 1, 2] + M[2, 1, 1, 1] + M[2, 1, 2]
sage: F(M[2,1,2])
F[1, 1, 1, 1, 1] - F[1, 1, 1, 2] - F[2, 1, 1, 1] + F[2, 1, 2]
```

```
>>> from sage.all import *
>>> M = QSym.M()
>>> F = QSym.F()
```

(continues on next page)

(continued from previous page)

```
>>> M(F[Integer(2),Integer(1),Integer(2)])
M[1, 1, 1, 1, 1] + M[1, 1, 1, 2] + M[2, 1, 1, 1] + M[2, 1, 2]
>>> F(M[Integer(2),Integer(1),Integer(2)])
F[1, 1, 1, 1, 1] - F[1, 1, 1, 2] - F[2, 1, 1, 1] + F[2, 1, 2]
```

The product on this space is commutative and is inherited from the product on the realization within the ring of power series:

```
sage: M[3]*M[1,1] == M[1,1]*M[3]
True
sage: M[3]*M[1,1]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[3, 1, 1] + M[4, 1]
sage: F[3]*F[1,1]
F[1, 1, 3] + F[1, 2, 2] + F[1, 3, 1] + F[1, 4] + F[2, 1, 2]
 + F[2, 2, 1] + F[2, 3] + F[3, 1, 1] + F[3, 2] + F[4, 1]
sage: M[3]*F[2]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[2, 3] + M[3, 1, 1] + M[3, 2]
 + M[4, 1] + M[5]
sage: F[2]*M[3]
F[1, 1, 1, 2] - F[1, 2, 2] + F[2, 1, 1, 1] - F[2, 1, 2] - F[2, 2, 1]
 + F[5]
```

```
>>> from sage.all import *
>>> M[Integer(3)]*M[Integer(1),Integer(1)] == M[Integer(1),
↪Integer(1)]*M[Integer(3)]
True
>>> M[Integer(3)]*M[Integer(1),Integer(1)]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[3, 1, 1] + M[4, 1]
>>> F[Integer(3)]*F[Integer(1),Integer(1)]
F[1, 1, 3] + F[1, 2, 2] + F[1, 3, 1] + F[1, 4] + F[2, 1, 2]
 + F[2, 2, 1] + F[2, 3] + F[3, 1, 1] + F[3, 2] + F[4, 1]
>>> M[Integer(3)]*F[Integer(2)]
M[1, 1, 3] + M[1, 3, 1] + M[1, 4] + M[2, 3] + M[3, 1, 1] + M[3, 2]
 + M[4, 1] + M[5]
>>> F[Integer(2)]*M[Integer(3)]
F[1, 1, 1, 2] - F[1, 2, 2] + F[2, 1, 1, 1] - F[2, 1, 2] - F[2, 2, 1]
 + F[5]
```

There is a coproduct on QSym as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The coproduct is not co-commutative:

```
sage: M[1,3,1].coproduct()
M[] # M[1, 3, 1] + M[1] # M[3, 1] + M[1, 3] # M[1] + M[1, 3, 1] # M[]
sage: F[1,3,1].coproduct()
F[] # F[1, 3, 1] + F[1] # F[3, 1] + F[1, 1] # F[2, 1]
 + F[1, 2] # F[1, 1] + F[1, 3] # F[1] + F[1, 3, 1] # F[]
```

```
>>> from sage.all import *
>>> M[Integer(1),Integer(3),Integer(1)].coproduct()
M[] # M[1, 3, 1] + M[1] # M[3, 1] + M[1, 3] # M[1] + M[1, 3, 1] # M[]
>>> F[Integer(1),Integer(3),Integer(1)].coproduct()
F[] # F[1, 3, 1] + F[1] # F[3, 1] + F[1, 1] # F[2, 1]
```

(continues on next page)

(continued from previous page)

```
 + F[1, 2] # F[1, 1] + F[1, 3] # F[1] + F[1, 3, 1] # F[]
```

The duality pairing with non-commutative symmetric functions

These two operations endow the quasi-symmetric functions QSym with the structure of a Hopf algebra. It is the graded dual Hopf algebra of the non-commutative symmetric functions $NCSF$. Under this duality, the Monomial basis of QSym is dual to the Complete basis of $NCSF$, and the Fundamental basis of QSym is dual to the Ribbon basis of $NCSF$ (see [MR]).

[-1  1  0  0  0  0  0  0]
[-1  0  1  0  0  0  0  0]
[ 1 -1 -1  1  0  0  0  0]
[-1  0  0  0  1  0  0  0]
[ 1 -1  0  0 -1  1  0  0]
[ 1  0 -1  0 -1  0  1  0]
[-1  1  1 -1  1 -1 -1  1]
```

Let H and G be elements of QSym, and h an element of $NCSF$. Then, if we represent the duality pairing with the mathematical notation $[\cdot, \cdot]$,

$$[HG, h] = [H \otimes G, \Delta(h)] .$$

For example, the coefficient of `M[2,1,4,1]` in `M[1,3]*M[2,1,1]` may be computed with the duality pairing:

```
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I]*M[J]).duality_pairing(S[2,1,4,1])
```

(continues on next page)

(continued from previous page)

```
1
```

```
>>> from sage.all import *
>>> I, J = Composition([Integer(1),Integer(3)]), Composition([Integer(2),
↪Integer(1),Integer(1)])
>>> (M[I]*M[J]).duality_pairing(S[Integer(2),Integer(1),Integer(4),Integer(1)])
1
```

And the coefficient of `S[1,3] # S[2,1,1]` in `S[2,1,4,1].coproduct()` is equal to this result:

```
sage: S[2,1,4,1].coproduct()
S[] # S[2, 1, 4, 1] + ... + S[1, 3] # S[2, 1, 1] + ... + S[4, 1] # S[2, 1]
```

```
>>> from sage.all import *
>>> S[Integer(2),Integer(1),Integer(4),Integer(1)].coproduct()
S[] # S[2, 1, 4, 1] + ... + S[1, 3] # S[2, 1, 1] + ... + S[4, 1] # S[2, 1]
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method `duality_pairing` is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
....:   return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

```
>>> from sage.all import *
>>> X = S[Integer(2),Integer(1),Integer(4),Integer(1)].coproduct()
>>> def linear_morphism(x, y):
...   return x.duality_pairing(M[Integer(1),Integer(3)]) * y.duality_
↪pairing(M[Integer(2),Integer(1),Integer(1)])
>>> X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

Similarly, if H is an element of QSym and g and h are elements of $NCSF$, then

$$[H, gh] = [\Delta(H), g \otimes h].$$

For example, the coefficient of `R[2,3,1]` in `R[2,1]*R[2,1]` is computed with the duality pairing by the following command:

```
sage: (R[2,1]*R[2,1]).duality_pairing(F[2,3,1])
1
sage: R[2,1]*R[2,1]
R[2, 1, 2, 1] + R[2, 3, 1]
```

```
>>> from sage.all import *
>>> (R[Integer(2),Integer(1)]*R[Integer(2),Integer(1)]).duality_
↪pairing(F[Integer(2),Integer(3),Integer(1)])
1
>>> R[Integer(2),Integer(1)]*R[Integer(2),Integer(1)]
R[2, 1, 2, 1] + R[2, 3, 1]
```

This coefficient should then be equal to the coefficient of `F[2,1] # F[2,1]` in `F[2,3,1].coproduct()`:

```
sage: F[2,3,1].coproduct()
F[] # F[2, 3, 1] + ... + F[2, 1] # F[2, 1]  + ... + F[2, 3, 1] # F[]
```

```
>>> from sage.all import *
>>> F[Integer(2),Integer(3),Integer(1)].coproduct()
F[] # F[2, 3, 1] + ... + F[2, 1] # F[2, 1]  + ... + F[2, 3, 1] # F[]
```

This can also be computed by the duality pairing on the tensor space, as above:

```
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
....:   return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

```
>>> from sage.all import *
>>> X = F[Integer(2),Integer(3),Integer(1)].coproduct()
>>> def linear_morphism(x, y):
...   return x.duality_pairing(R[Integer(2),Integer(1)]) * y.duality_
↪pairing(R[Integer(2),Integer(1)])
>>> X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

The operation dual to multiplication by a non-commutative symmetric function

Let $g \in NCSF$ and consider the linear endomorphism of $NCSF$ defined by left (respectively, right) multiplication by g. Since there is a duality between QSym and $NCSF$, this linear transformation induces an operator $g^\perp$ on QSym satisfying

$$[g^\perp(H), h] = [H, gh].$$

for any non-commutative symmetric function h.

This is implemented by the method *skew_by()*. Explicitly, if `H` is a quasi-symmetric function and `g` a non-commutative symmetric function, then `H.skew_by(g)` and `H.skew_by(g, side='right')` are expressions that satisfy, for any non-commutative symmetric function `h`, the following equalities:

```
H.skew_by(g).duality_pairing(h) == H.duality_pairing(g*h)
H.skew_by(g, side='right').duality_pairing(h) == H.duality_pairing(h*g)
```

For example, `M[J].skew_by(S[I])` is 0 unless the composition `J` begins with `I` and `M(J).skew_by(S(I), side='right')` is 0 unless the composition `J` ends with `I`. For example:

```
sage: M[3,2,2].skew_by(S[3])
M[2, 2]
sage: M[3,2,2].skew_by(S[2])
0
sage: M[3,2,2].coproduct().apply_multilinear_morphism( lambda x,y: x.duality_
↪pairing(S[3])*y )
M[2, 2]
sage: M[3,2,2].skew_by(S[3], side='right')
0
```

(continues on next page)

(continued from previous page)

```
sage: M[3,2,2].skew_by(S[2], side='right')
M[3, 2]
```

```
>>> from sage.all import *
>>> M[Integer(3),Integer(2),Integer(2)].skew_by(S[Integer(3)])
M[2, 2]
>>> M[Integer(3),Integer(2),Integer(2)].skew_by(S[Integer(2)])
0
>>> M[Integer(3),Integer(2),Integer(2)].coproduct().apply_multilinear_morphism(␣
↪lambda x,y: x.duality_pairing(S[Integer(3)])*y )
M[2, 2]
>>> M[Integer(3),Integer(2),Integer(2)].skew_by(S[Integer(3)], side='right')
0
>>> M[Integer(3),Integer(2),Integer(2)].skew_by(S[Integer(2)], side='right')
M[3, 2]
```

The counit

The counit is defined by sending all elements of positive degree to zero:

```
sage: M[3].degree(), M[3,1,2].degree(), M.one().degree()
(3, 6, 0)
sage: M[3].counit()
0
sage: M[3,1,2].counit()
0
sage: M.one().counit()
1
sage: (M[3] - 2*M[3,1,2] + 7).counit()
7
sage: (F[3] - 2*F[3,1,2] + 7).counit()
7
```

```
>>> from sage.all import *
>>> M[Integer(3)].degree(), M[Integer(3),Integer(1),Integer(2)].degree(), M.one().
↪degree()
(3, 6, 0)
>>> M[Integer(3)].counit()
0
>>> M[Integer(3),Integer(1),Integer(2)].counit()
0
>>> M.one().counit()
1
>>> (M[Integer(3)] - Integer(2)*M[Integer(3),Integer(1),Integer(2)] + Integer(7)).
↪counit()
7
>>> (F[Integer(3)] - Integer(2)*F[Integer(3),Integer(1),Integer(2)] + Integer(7)).
↪counit()
7
```

The antipode

The antipode sends the Fundamental basis element indexed by the composition I to $(-1)^{|I|}$ times the Fundamental basis element indexed by the conjugate composition to I (where $|I|$ stands for the size of I, that is, the sum of all entries of I).

```
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
```

```
>>> from sage.all import *
>>> F[Integer(3),Integer(2),Integer(2)].antipode()
-F[1, 2, 2, 1, 1]
>>> Composition([Integer(3),Integer(2),Integer(2)]).conjugate()
[1, 2, 2, 1, 1]
```

The antipodes of the Monomial quasisymmetric functions can also be computed easily: Every composition I satisfies

$$\omega(M_I) = (-1)^{\ell(I)} \sum M_J,$$

where the sum ranges over all compositions J of $|I|$ which are coarser than the reversed composition I^r of I. Here, $\ell(I)$ denotes the length of the composition I (that is, the number of its parts).

```
sage: M[3,2,1].antipode()
-M[1, 2, 3] - M[1, 5] - M[3, 3] - M[6]
sage: M[3,2,2].antipode()
-M[2, 2, 3] - M[2, 5] - M[4, 3] - M[7]
```

```
>>> from sage.all import *
>>> M[Integer(3),Integer(2),Integer(1)].antipode()
-M[1, 2, 3] - M[1, 5] - M[3, 3] - M[6]
>>> M[Integer(3),Integer(2),Integer(2)].antipode()
-M[2, 2, 3] - M[2, 5] - M[4, 3] - M[7]
```

We demonstrate here the defining relation of the antipode:

```
sage: X = F[3,2,2].coproduct()
sage: X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
sage: X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

```
>>> from sage.all import *
>>> X = F[Integer(3),Integer(2),Integer(2)].coproduct()
>>> X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
>>> X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

The relation with symmetric functions

The quasi-symmetric functions are a ring which contain the symmetric functions as a subring. The Monomial quasi-symmetric functions are related to the monomial symmetric functions by

$$m_\lambda = \sum_{\mathrm{sort}(I)=\lambda} M_I$$

(where $\mathrm{sort}(I)$ denotes the result of sorting the entries of I in decreasing order).

There are methods to test if an expression in the quasi-symmetric functions is a symmetric function and, if it is, send it to an expression in the symmetric functions:

```
sage: f = M[1,1,2] + M[1,2,1]
sage: f.is_symmetric()
False
sage: g = M[3,1] + M[1,3]
sage: g.is_symmetric()
True
sage: g.to_symmetric_function()
m[3, 1]
```

```
>>> from sage.all import *
>>> f = M[Integer(1),Integer(1),Integer(2)] + M[Integer(1),Integer(2),Integer(1)]
>>> f.is_symmetric()
False
>>> g = M[Integer(3),Integer(1)] + M[Integer(1),Integer(3)]
>>> g.is_symmetric()
True
>>> g.to_symmetric_function()
m[3, 1]
```

The expansion of the Schur function in terms of the Fundamental quasi-symmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

```
sage: f = F[3,2] + F[2,2,1] + F[2,3] + F[1,3,1] + F[1,2,2]
sage: f.is_symmetric()
True
sage: f.to_symmetric_function()
5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: s(f.to_symmetric_function())
s[3, 2]
```

```
>>> from sage.all import *
>>> f = F[Integer(3),Integer(2)] + F[Integer(2),Integer(2),Integer(1)] +␣
↪F[Integer(2),Integer(3)] + F[Integer(1),Integer(3),Integer(1)] + F[Integer(1),
↪Integer(2),Integer(2)]
>>> f.is_symmetric()
True
>>> f.to_symmetric_function()
5*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
>>> s = SymmetricFunctions(QQ).s()
>>> s(f.to_symmetric_function())
s[3, 2]
```

It is also possible to convert a symmetric function to a quasi-symmetric function:

```
sage: m = SymmetricFunctions(QQ).m()
sage: M( m[3,1,1] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: F( s[2,2,1] )
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> M( m[Integer(3),Integer(1),Integer(1)] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
>>> F( s[Integer(2),Integer(2),Integer(1)] )
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1]
```

It is possible to experiment with the quasi-symmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

```
sage: R = QQ['t']
sage: Qp = SymmetricFunctions(R).hall_littlewood().Qp()
sage: QSymt = QuasiSymmetricFunctions(R)
sage: Ft = QSymt.F()
sage: Ft( Qp[2,2] )
F[1, 2, 1] + t*F[1, 3] + (t+1)*F[2, 2] + t*F[3, 1] + t^2*F[4]
```

```
>>> from sage.all import *
>>> R = QQ['t']
>>> Qp = SymmetricFunctions(R).hall_littlewood().Qp()
>>> QSymt = QuasiSymmetricFunctions(R)
>>> Ft = QSymt.F()
>>> Ft( Qp[Integer(2),Integer(2)] )
F[1, 2, 1] + t*F[1, 3] + (t+1)*F[2, 2] + t*F[3, 1] + t^2*F[4]
```

```
sage: K = QQ['q','t'].fraction_field()
sage: Ht = SymmetricFunctions(K).macdonald().Ht()
sage: Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
sage: Fqt(Ht[2,1])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

```
>>> from sage.all import *
>>> K = QQ['q','t'].fraction_field()
>>> Ht = SymmetricFunctions(K).macdonald().Ht()
>>> Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
>>> Fqt(Ht[Integer(2),Integer(1)])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

The following will raise an error because the base ring of `F` is not equal to the base ring of `Ht`:

```
sage: F(Ht[2,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self␣
↪(=Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

```
>>> from sage.all import *
>>> F(Ht[Integer(2),Integer(1)])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self␣
↪(=Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

The map to the ring of polynomials

The quasi-symmetric functions can be seen as an inverse limit of a subring of a polynomial ring as the number of variables increases. Indeed, there exists a projection from the quasi-symmetric functions onto the polynomial ring $R[x_1, x_2, \ldots, x_n]$. This projection is defined by sending the variables $x_{n+1}, x_{n+2}, \cdots$ to 0, while the remaining n variables remain fixed. Note that this projection sends M_I to 0 if the length of the composition I is higher than n.

```
sage: M[1,3,1].expand(4)
x0*x1^3*x2 + x0*x1^3*x3 + x0*x2^3*x3 + x1*x2^3*x3
sage: F[1,3,1].expand(4)
x0*x1^3*x2 + x0*x1^3*x3 + x0*x1^2*x2*x3 + x0*x1*x2^2*x3 + x0*x2^3*x3 + x1*x2^3*x3
sage: M[1,3,1].expand(2)
0
```

```
>>> from sage.all import *
>>> M[Integer(1),Integer(3),Integer(1)].expand(Integer(4))
x0*x1^3*x2 + x0*x1^3*x3 + x0*x2^3*x3 + x1*x2^3*x3
>>> F[Integer(1),Integer(3),Integer(1)].expand(Integer(4))
x0*x1^3*x2 + x0*x1^3*x3 + x0*x1^2*x2*x3 + x0*x1*x2^2*x3 + x0*x2^3*x3 + x1*x2^3*x3
>>> M[Integer(1),Integer(3),Integer(1)].expand(Integer(2))
0
```

class Bases(*parent_with_realization*)

Bases: Category_realization_of_parent

Category of bases of quasi-symmetric functions.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.Bases()
Category of bases of Quasisymmetric functions over the Rational Field
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QSym.Bases()
Category of bases of Quasisymmetric functions over the Rational Field
```

class ElementMethods

Bases: object

Methods common to all elements of QuasiSymmetricFunctions.

adams_operator(*n*)

Return the image of the quasi-symmetric function self under the n-th Adams operator.

The n-th Adams operator $\mathbf{f}_n$ is defined to be the map from the R-algebra of quasi-symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \ldots)$ to $P(x_1^n, x_2^n, x_3^n, \ldots)$. This

operator $\mathbf{f}_n$ is a Hopf algebra endomorphism, and satisfies

$$f_n M_{(i_1,i_2,i_3,\ldots)} = M_{(ni_1,ni_2,ni_3,\ldots)}$$

for every composition $(i_1, i_2, i_3, \ldots)$ (where M means the monomial basis).

The n-th Adams operator is also called the n-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n-th Adams operator is the n-th Adams operator of the Λ-ring of quasi-symmetric functions over the integers.

The restriction of the n-th Adams operator to the subring formed by all symmetric functions is, not unexpectedly, the n-th Adams operator of the ring of symmetric functions.

See also

Symmetric functions plethysm

INPUT:
- `n` – positive integer

OUTPUT:

The result of applying the n-th Adams operator (on the ring of quasi-symmetric functions) to `self`.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M[3,2].adams_operator(2)
M[6, 4]
sage: (M[2,1] - 2*M[3]).adams_operator(4)
M[8, 4] - 2*M[12]
sage: M([]).adams_operator(3)
M[]
sage: F[1,1].adams_operator(2)
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> M = QSym.M()
>>> F = QSym.F()
>>> M[Integer(3),Integer(2)].adams_operator(Integer(2))
M[6, 4]
>>> (M[Integer(2),Integer(1)] - Integer(2)*M[Integer(3)]).adams_
↪operator(Integer(4))
M[8, 4] - 2*M[12]
>>> M([]).adams_operator(Integer(3))
M[]
>>> F[Integer(1),Integer(1)].adams_operator(Integer(2))
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
```

The Adams endomorphisms are multiplicative:

```
sage: all( all( M(I).adams_operator(3) * M(J).adams_operator(3)
....:           == (M(I) * M(J)).adams_operator(3)
....:           for I in Compositions(3) )
....:       for J in Compositions(2) )
True
```

```
>>> from sage.all import *
>>> all( all( M(I).adams_operator(Integer(3)) * M(J).adams_
↪operator(Integer(3))
...           == (M(I) * M(J)).adams_operator(Integer(3))
...           for I in Compositions(Integer(3)) )
...       for J in Compositions(Integer(2)) )
True
```

Being Hopf algebra endomorphisms, the Adams operators commute with the antipode:

```
sage: all( M(I).adams_operator(4).antipode()
....:       == M(I).antipode().adams_operator(4)
....:       for I in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> all( M(I).adams_operator(Integer(4)).antipode()
...       == M(I).antipode().adams_operator(Integer(4))
...       for I in Compositions(Integer(3)) )
True
```

The restriction of the Adams operators to the subring of symmetric functions are the Adams operators of the latter:

```
sage: e = SymmetricFunctions(ZZ).e()
sage: all( M(e(lam)).adams_operator(3)
....:       == M(e(lam).adams_operator(3))
....:       for lam in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(ZZ).e()
>>> all( M(e(lam)).adams_operator(Integer(3))
...       == M(e(lam).adams_operator(Integer(3)))
...       for lam in Partitions(Integer(3)) )
True
```

dendriform_leq(*other*)

Return the result of applying the dendriform smaller-or-equal operation to the two quasi-symmetric functions `self` and `other`.

The dendriform smaller-or-equal operation is a binary operation, denoted by $\preceq$ and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by $\preceq$ and written infix as well) on the ring of formal power series $R[[x_1, x_2, x_3, \ldots]]$, which is defined as follows: If m and n are two monomials in $x_1, x_2, x_3, \ldots$, then we let $m \preceq n$ be the product mn if the smallest positive integer i for which x_i occurs in m is smaller or equal to the smallest positive integer j for which x_j occurs in n (this is understood to be false when $m = 1$

and $n \neq 1$, and true when $n = 1$), and we let $m \preceq n$ be 0 otherwise. Having thus defined $\preceq$ on monomials, we extend $\preceq$ to a binary operation on $R[[x_1, x_2, x_3, \ldots]]$ by requiring it to be continuous (in both inputs) and R-bilinear. It is easily seen that $QSym \preceq QSym \subseteq QSym$, so that $\preceq$ restricts to a binary operation on $QSym$.

This operation $\preceq$ is related to the dendriform smaller relation $\prec$ (*dendriform_less()*). Namely, if we define a binary operation $\succ$ on $QSym$ by $a \succ b = b \prec a$, then $(QSym, \preceq, \succ)$ is a dendriform R-algebra. Thus, any $a, b \in QSym$ satisfy $a \preceq b = ab - b \prec a$.

See also

dendriform_less()

INPUT:

- `other` – a quasi-symmetric function over the same base ring as `self`

OUTPUT:

The quasi-symmetric function `self` $\preceq$ `other`, written in the basis of `self`.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_leq(M[1, 2])
2*M[2, 1, 1, 2] + M[2, 1, 2, 1] + M[2, 1, 3] + M[2, 2, 2]
 + M[3, 1, 2] + M[3, 2, 1] + M[3, 3]
sage: F = QSym.F()
sage: F[2, 1].dendriform_leq(F[1, 2])
F[2, 1, 1, 2] + F[2, 1, 2, 1] + F[2, 1, 3] + F[2, 2, 1, 1]
 + 2*F[2, 2, 2] + F[2, 3, 1] + F[3, 1, 2] + F[3, 2, 1] + F[3, 3]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> M = QSym.M()
>>> M[Integer(2), Integer(1)].dendriform_leq(M[Integer(1), Integer(2)])
2*M[2, 1, 1, 2] + M[2, 1, 2, 1] + M[2, 1, 3] + M[2, 2, 2]
 + M[3, 1, 2] + M[3, 2, 1] + M[3, 3]
>>> F = QSym.F()
>>> F[Integer(2), Integer(1)].dendriform_leq(F[Integer(1), Integer(2)])
F[2, 1, 1, 2] + F[2, 1, 2, 1] + F[2, 1, 3] + F[2, 2, 1, 1]
 + 2*F[2, 2, 2] + F[2, 3, 1] + F[3, 1, 2] + F[3, 2, 1] + F[3, 3]
```

dendriform_less(*other*)

Return the result of applying the dendriform smaller operation to the two quasi-symmetric functions `self` and `other`.

The dendriform smaller operation is a binary operation, denoted by $\prec$ and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by $\prec$ and written infix as well) on the ring of formal power series $R[[x_1, x_2, x_3, \ldots]]$, which is defined as follows: If m and n are two monomials in $x_1, x_2, x_3, \ldots$, then we let $m \prec n$ be the product mn if the smallest positive integer i for which x_i occurs in m is smaller than the smallest positive integer j for which x_j occurs in n (this is understood to be false when $m = 1$, and true when $m \neq 1$ and $n = 1$), and we let $m \prec n$ be 0 otherwise. Having thus defined $\prec$ on monomials, we extend $\prec$ to a binary operation on $R[[x_1, x_2, x_3, \ldots]]$ by requiring it to be continuous (in both

inputs) and R-bilinear. It is easily seen that $QSym \prec QSym \subseteq QSym$, so that $\prec$ restricts to a binary operation on $QSym$.

See also

dendriform_leq()

INPUT:
• `other` – a quasi-symmetric function over the same base ring as `self`
OUTPUT:

The quasi-symmetric function `self` $\prec$ `other`, written in the basis of `self`.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_less(M[1, 2])
2*M[2, 1, 1, 2] + M[2, 1, 2, 1] + M[2, 1, 3] + M[2, 2, 2]
sage: F = QSym.F()
sage: F[2, 1].dendriform_less(F[1, 2])
F[1, 1, 2, 1, 1] + F[1, 1, 2, 2] + F[1, 1, 3, 1]
 + F[1, 2, 1, 2] + F[1, 2, 2, 1] + F[1, 2, 3]
 + F[2, 1, 1, 2] + F[2, 1, 2, 1] + F[2, 1, 3] + F[2, 2, 2]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> M = QSym.M()
>>> M[Integer(2), Integer(1)].dendriform_less(M[Integer(1),␣
↪Integer(2)])
2*M[2, 1, 1, 2] + M[2, 1, 2, 1] + M[2, 1, 3] + M[2, 2, 2]
>>> F = QSym.F()
>>> F[Integer(2), Integer(1)].dendriform_less(F[Integer(1),␣
↪Integer(2)])
F[1, 1, 2, 1, 1] + F[1, 1, 2, 2] + F[1, 1, 3, 1]
 + F[1, 2, 1, 2] + F[1, 2, 2, 1] + F[1, 2, 3]
 + F[2, 1, 1, 2] + F[2, 1, 2, 1] + F[2, 1, 3] + F[2, 2, 2]
```

The operation $\prec$ can be used to recursively construct the dual immaculate basis: For every positive integer m and every composition I, the dual immaculate function $\mathrm{dI}_{[m,I]}$ of the composition $[m, I]$ (this composition is I with m prepended to it) is $F_{[m]} \prec \mathrm{dI}_I$.

```
sage: dI = QSym.dI()
sage: dI(F[2]).dendriform_less(dI[1, 2])
dI[2, 1, 2]
```

```
>>> from sage.all import *
>>> dI = QSym.dI()
>>> dI(F[Integer(2)]).dendriform_less(dI[Integer(1), Integer(2)])
dI[2, 1, 2]
```

We check with the identity element:

```
sage: M.one().dendriform_less(M[1,2])
0
sage: M[1,2].dendriform_less(M.one())
M[1, 2]
```

```
>>> from sage.all import *
>>> M.one().dendriform_less(M[Integer(1),Integer(2)])
0
>>> M[Integer(1),Integer(2)].dendriform_less(M.one())
M[1, 2]
```

The operation $\prec$ is not symmetric, nor if $a \prec b \neq 0$, then $b \prec a = 0$ (as it would be for a single monomial):

```
sage: M[1,2,1].dendriform_less(M[1,2])
M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3]
 + M[1, 1, 4, 1] + 2*M[1, 2, 1, 1, 2] + M[1, 2, 1, 2, 1]
 + M[1, 2, 1, 3] + M[1, 2, 2, 2] + M[1, 3, 1, 2]
 + M[1, 3, 2, 1] + M[1, 3, 3]
sage: M[1,2].dendriform_less(M[1,2,1])
M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3]
 + M[1, 1, 4, 1] + M[1, 2, 1, 2, 1] + M[1, 3, 2, 1]
```

```
>>> from sage.all import *
>>> M[Integer(1),Integer(2),Integer(1)].dendriform_less(M[Integer(1),
↪Integer(2)])
M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3]
 + M[1, 1, 4, 1] + 2*M[1, 2, 1, 1, 2] + M[1, 2, 1, 2, 1]
 + M[1, 2, 1, 3] + M[1, 2, 2, 2] + M[1, 3, 1, 2]
 + M[1, 3, 2, 1] + M[1, 3, 3]
>>> M[Integer(1),Integer(2)].dendriform_less(M[Integer(1),Integer(2),
↪Integer(1)])
M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3]
 + M[1, 1, 4, 1] + M[1, 2, 1, 2, 1] + M[1, 3, 2, 1]
```

expand(*n*, *alphabet='x'*)

Expand the quasi-symmetric function into `n` variables in an alphabet, which by default is `'x'`.

INPUT:

- `n` – nonnegative integer; the number of variables in the expansion
- `alphabet` – (default: `'x'`) the alphabet in which `self` is to be expanded

OUTPUT: an expansion of `self` into the `n` variables specified by `alphabet`

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(3)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3 + x0^2*x2 + x0*x1*x2 + x1^2*x2 + x0*x2^
↪2 + x1*x2^2 + x2^3
sage: F[2,1].expand(3)
x0^2*x1 + x0^2*x2 + x0*x1*x2 + x1^2*x2
```

```
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> F[Integer(3)].expand(Integer(3))
x0^3 + x0^2*x1 + x0*x1^2 + x1^3 + x0^2*x2 + x0*x1*x2 + x1^2*x2 + x0*x2^
↪2 + x1*x2^2 + x2^3
>>> F[Integer(2),Integer(1)].expand(Integer(3))
x0^2*x1 + x0^2*x2 + x0*x1*x2 + x1^2*x2
```

One can use a different set of variable by adding an optional argument `alphabet=...`

```
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(2,alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
```

```
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> F[Integer(3)].expand(Integer(2),alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
```

internal_coproduct()

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the R-algebra of quasi-symmetric functions) is an R-algebra homomorphism $\Delta^\times$ from the R-algebra of quasi-symmetric functions to the tensor square (over R) of quasi-symmetric functions. It can be defined in the following two ways:

1. If I is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the nonzero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is I. If A is a $(0, I)$-matrix, then $\mathrm{row}(A)$ will denote the vector of row sums of A (regarded as a composition), and $\mathrm{column}(A)$ will denote the vector of column sums of A (regarded as a composition).

   For every composition I, the internal coproduct $\Delta^\times(M_I)$ of the I-th monomial quasisymmetric function M_I is the sum

   $$\sum_{A \text{ is a } (0,I)\text{-matrix}} M_{\mathrm{row}(A)} \otimes M_{\mathrm{column}(A)}.$$

   See Section 11.39 of [HazWitt1].
2. For every permutation w, let $C(w)$ denote the descent composition of w. Then, for any composition I of size n, the internal coproduct $\Delta^\times(F_I)$ of the I-th fundamental quasisymmetric function F_I is the sum

   $$\sum_{\substack{\sigma \in S_n, \\ \tau \in S_n, \\ \tau\sigma = \pi}} F_{C(\sigma)} \otimes F_{C(\tau)},$$

   where π is any permutation in S_n having descent composition I and where permutations act from the left and multiply accordingly, so $\tau\sigma$ means first applying σ and then τ. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the R-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method *kronecker_coproduct()* is a synonym of this one.

EXAMPLES:

Let us compute the internal coproduct of M_{21} (which is short for $M_{[2,1]}$). The $(0, [2,1])$-matrices are

$$\begin{bmatrix} 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$$

so

$$\Delta^{\times}(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
M[2, 1] # M[1, 2] + M[2, 1] # M[2, 1] + M[2, 1] # M[3] + M[3] # M[2, 1]
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(ZZ).M()
>>> a = M([Integer(2),Integer(1)])
>>> a.internal_coproduct()
M[2, 1] # M[1, 2] + M[2, 1] # M[2, 1] + M[2, 1] # M[3] + M[3] # M[2, 1]
```

Further examples:

```
sage: all( M([i]).internal_coproduct() == tensor([M([i]), M([i])])
....:      for i in range(1, 4) )
True

sage: M([1, 2]).internal_coproduct()
M[1, 2] # M[1, 2] + M[1, 2] # M[2, 1] + M[1, 2] # M[3] + M[3] # M[1, 2]
```

```
>>> from sage.all import *
>>> all( M([i]).internal_coproduct() == tensor([M([i]), M([i])])
...       for i in range(Integer(1), Integer(4)) )
True

>>> M([Integer(1), Integer(2)]).internal_coproduct()
M[1, 2] # M[1, 2] + M[1, 2] # M[2, 1] + M[1, 2] # M[3] + M[3] # M[1, 2]
```

The definition of $\Delta^{\times}(M_I)$ in terms of $(0, I)$-matrices is not suitable for computation in cases where the length of I is large, but we can use it as a doctest. Here is a naive implementation:

```
sage: def naive_internal_coproduct_on_M(I):
....:     # INPUT: composition I
....:     #        (not quasi-symmetric function)
....:     # OUTPUT: interior coproduct of M_I
....:     M = QuasiSymmetricFunctions(ZZ).M()
....:     M2 = M.tensor(M)
....:     res = M2.zero()
....:     l = len(I)
....:     n = I.size()
```

(continues on next page)

(continued from previous page)

```
....:     for S in Subsets(range(l**2), l):
....:         M_list = sorted(S)
....:         row_M = [sum([I[M_list.index(l * i + j)]
....:                       for j in range(l) if
....:                       l * i + j in S])
....:                  for i in range(l)]
....:         col_M = [sum([I[M_list.index(l * i + j)]
....:                       for i in range(l) if
....:                       l * i + j in S])
....:                  for j in range(l)]
....:         if 0 in row_M:
....:             first_zero = row_M.index(0)
....:             row_M = row_M[:first_zero]
....:             if sum(row_M) != n:
....:                 continue
....:         if 0 in col_M:
....:             first_zero = col_M.index(0)
....:             col_M = col_M[:first_zero]
....:             if sum(col_M) != n:
....:                 continue
....:         res += tensor([M(Compositions(n)(row_M)),
....:                        M(Compositions(n)(col_M))])
....:     return res
sage: all( naive_internal_coproduct_on_M(I)
....:      == M(I).internal_coproduct()
....:      for I in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> def naive_internal_coproduct_on_M(I):
...     # INPUT: composition I
...     #        (not quasi-symmetric function)
...     # OUTPUT: interior coproduct of M_I
...     M = QuasiSymmetricFunctions(ZZ).M()
...     M2 = M.tensor(M)
...     res = M2.zero()
...     l = len(I)
...     n = I.size()
...     for S in Subsets(range(l**Integer(2)), l):
...         M_list = sorted(S)
...         row_M = [sum([I[M_list.index(l * i + j)]
...                       for j in range(l) if
...                       l * i + j in S])
...                  for i in range(l)]
...         col_M = [sum([I[M_list.index(l * i + j)]
...                       for i in range(l) if
...                       l * i + j in S])
...                  for j in range(l)]
...         if Integer(0) in row_M:
...             first_zero = row_M.index(Integer(0))
...             row_M = row_M[:first_zero]
...             if sum(row_M) != n:
```

(continues on next page)

(continued from previous page)

```
...                 continue
...             if Integer(0) in col_M:
...                 first_zero = col_M.index(Integer(0))
...                 col_M = col_M[:first_zero]
...                 if sum(col_M) != n:
...                     continue
...             res += tensor([M(Compositions(n)(row_M)),
...                            M(Compositions(n)(col_M))])
...         return res
>>> all( naive_internal_coproduct_on_M(I)
...       == M(I).internal_coproduct()
...       for I in Compositions(Integer(3)) )
True
```

Todo

Implement this directly on the monomial basis maybe? The $(0, I)$-matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above "further examples" should be moved to the M-method.

is_symmetric()

Return `True` if `self` is an element of the symmetric functions.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

OUTPUT:

- `True` if `self` is symmetric. `False` if `self` is not symmetric.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).is_symmetric()
False
sage: (F[1, 1, 1, 2] + F[1, 1, 3] + F[1, 3, 1] + F[2, 1, 1, 1] + F[3,␣
↪1, 1]).is_symmetric()
True
sage: F([]).is_symmetric()
True
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> F = QSym.Fundamental()
>>> (F[Integer(3),Integer(2)] + F[Integer(2),Integer(3)]).is_
↪symmetric()
False
>>> (F[Integer(1), Integer(1), Integer(1), Integer(2)] + F[Integer(1),␣
↪Integer(1), Integer(3)] + F[Integer(1), Integer(3), Integer(1)] +␣
↪F[Integer(2), Integer(1), Integer(1), Integer(1)] + F[Integer(3),␣
↪Integer(1), Integer(1)]).is_symmetric()
True
```

(continues on next page)

(continued from previous page)

```
>>> F([]).is_symmetric()
True
```

kronecker_coproduct()

alias of *internal_coproduct()*.

omega_involution()

Return the image of the quasisymmetric function `self` under the omega involution.

The omega involution is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the fundamental quasisymmetric function F_I to F_{I^t}, where I^t denotes the conjugate (*conjugate()*) of the composition I. This map is commonly denoted by ω. It is an algebra homomorphism and a coalgebra antihomomorphism; it also is an involution and an automorphism of the graded vector space $QSym$. Also, every composition I satisfies

$$\omega(M_I) = (-1)^{|I|-\ell(I)} \sum M_J,$$

where the sum ranges over all compositions J of $|I|$ which are coarser than the reversed composition I^r of I. Here, $\ell(I)$ denotes the length of the composition I (that is, the number of parts of I).

If f is a homogeneous element of $NCSF$ of degree n, then

$$\omega(f) = (-1)^n S(f),$$

where S denotes the antipode of $QSym$.

The restriction of ω to the ring of symmetric functions (which is a subring of $QSym$) is precisely the omega involution (*omega()*) of said ring.

The omega involution on $QSym$ is adjoint to the omega involution on $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The omega involution has been denoted by ω in [LMvW13], section 3.6.

See also

omega involution on NCSF, *psi involution on QSym*, *star involution on QSym*.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,2].omega_involution()
F[1, 2, 1, 1]
sage: F[6,3].omega_involution()
F[1, 1, 2, 1, 1, 1, 1, 1]
sage: (F[9,1] - F[8,2] + 2*F[2,4] - 3*F[3] + 4*F[[]]).omega_
↪involution()
4*F[] - 3*F[1, 1, 1] + 2*F[1, 1, 1, 2, 1] - F[1, 2, 1, 1, 1, 1, 1, 1,␣
↪1] + F[2, 1, 1, 1, 1, 1, 1, 1, 1]
sage: (F[3,3] - 2*F[2]).omega_involution()
-2*F[1, 1] + F[1, 1, 2, 1, 1]
sage: F([2,1,1]).omega_involution()
```

(continues on next page)

(continued from previous page)

```
F[3, 1]
sage: M = QSym.M()
sage: M([2,1]).omega_involution()
-M[1, 2] - M[3]
sage: M.zero().omega_involution()
0
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> F = QSym.F()
>>> F[Integer(3),Integer(2)].omega_involution()
F[1, 2, 1, 1]
>>> F[Integer(6),Integer(3)].omega_involution()
F[1, 1, 2, 1, 1, 1, 1, 1]
>>> (F[Integer(9),Integer(1)] - F[Integer(8),Integer(2)] +␣
↪Integer(2)*F[Integer(2),Integer(4)] - Integer(3)*F[Integer(3)] +␣
↪Integer(4)*F[[]]).omega_involution()
4*F[] - 3*F[1, 1, 1] + 2*F[1, 1, 1, 2, 1] - F[1, 2, 1, 1, 1, 1, 1, 1,␣
↪1] + F[2, 1, 1, 1, 1, 1, 1, 1, 1]
>>> (F[Integer(3),Integer(3)] - Integer(2)*F[Integer(2)]).omega_
↪involution()
-2*F[1, 1] + F[1, 1, 2, 1, 1]
>>> F([Integer(2),Integer(1),Integer(1)]).omega_involution()
F[3, 1]
>>> M = QSym.M()
>>> M([Integer(2),Integer(1)]).omega_involution()
-M[1, 2] - M[3]
>>> M.zero().omega_involution()
0
```

Testing the fact that the restriction of ω to Sym is the omega automorphism of Sym:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).omega_involution() == F(e[lam].omega())
....:      for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> e = Sym.e()
>>> all( F(e[lam]).omega_involution() == F(e[lam].omega())
...      for lam in Partitions(Integer(4)) )
True
```

psi_involution()

Return the image of the quasisymmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the fundamental quasisymmetric function F_I to F_{I^c}, where I^c denotes the complement of the composition I. The map ψ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution ψ of $QSym$ is adjoint to the involution ψ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

psi involution on NCSF, *star involution on QSym*.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,2].psi_involution()
F[1, 1, 2, 1]
sage: F[6,3].psi_involution()
F[1, 1, 1, 1, 1, 2, 1, 1]
sage: (F[9,1] - F[8,2] + 2*F[2,4] - 3*F[3] + 4*F[[]]).psi_involution()
4*F[] - 3*F[1, 1, 1] + F[1, 1, 1, 1, 1, 1, 1, 1, 2] - F[1, 1, 1, 1, 1,␣
↪1, 1, 2, 1] + 2*F[1, 2, 1, 1, 1]
sage: (F[3,3] - 2*F[2]).psi_involution()
-2*F[1, 1] + F[1, 1, 2, 1, 1]
sage: F([2,1,1]).psi_involution()
F[1, 3]
sage: M = QSym.M()
sage: M([2,1]).psi_involution()
-M[2, 1] - M[3]
sage: M.zero().psi_involution()
0
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> F = QSym.F()
>>> F[Integer(3),Integer(2)].psi_involution()
F[1, 1, 2, 1]
>>> F[Integer(6),Integer(3)].psi_involution()
F[1, 1, 1, 1, 1, 2, 1, 1]
>>> (F[Integer(9),Integer(1)] - F[Integer(8),Integer(2)] +␣
↪Integer(2)*F[Integer(2),Integer(4)] - Integer(3)*F[Integer(3)] +␣
↪Integer(4)*F[[]]).psi_involution()
4*F[] - 3*F[1, 1, 1] + F[1, 1, 1, 1, 1, 1, 1, 1, 2] - F[1, 1, 1, 1, 1,␣
↪1, 1, 2, 1] + 2*F[1, 2, 1, 1, 1]
>>> (F[Integer(3),Integer(3)] - Integer(2)*F[Integer(2)]).psi_
↪involution()
-2*F[1, 1] + F[1, 1, 2, 1, 1]
>>> F([Integer(2),Integer(1),Integer(1)]).psi_involution()
F[1, 3]
>>> M = QSym.M()
>>> M([Integer(2),Integer(1)]).psi_involution()
-M[2, 1] - M[3]
>>> M.zero().psi_involution()
0
```

The involution ψ commutes with the antipode:

```
sage: all( F(I).psi_involution().antipode()
....:      == F(I).antipode().psi_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( F(I).psi_involution().antipode()
...      == F(I).antipode().psi_involution()
...      for I in Compositions(Integer(4)) )
True
```

Testing the fact that the restriction of ψ to Sym is the omega automorphism of Sym:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).psi_involution() == F(e[lam].omega())
....:      for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> e = Sym.e()
>>> all( F(e[lam]).psi_involution() == F(e[lam].omega())
...      for lam in Partitions(Integer(4)) )
True
```

star_involution()

Return the image of the quasisymmetric function `self` under the star involution.

The star involution is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the monomial quasisymmetric function M_I to M_{I^r}. Here, if I is a composition, we denote by I^r the reversed composition of I. Denoting by f^* the image of an element $f \in QSym$ under the star involution, it can be shown that every composition I satisfies

$$(M_I)^* = M_{I^r}, \quad (F_I)^* = F_{I^r},$$

where F_I denotes the fundamental quasisymmetric function corresponding to the composition I. The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of $QSym$. It also is an automorphism of the graded vector space $QSym$, and is the identity on the subspace Sym of $QSym$. It is adjoint to the star involution on $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6.

See also

star involution on NCSF.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].star_involution()
```

(continues on next page)

(continued from previous page)

```
M[2, 3]
sage: M[6,3].star_involution()
M[3, 6]
sage: (M[9,1] - M[6,2] + 2*M[6,4] - 3*M[3] + 4*M[[]]).star_involution()
4*M[] + M[1, 9] - M[2, 6] - 3*M[3] + 2*M[4, 6]
sage: (M[3,3] - 2*M[2]).star_involution()
-2*M[2] + M[3, 3]
sage: M([4,2]).star_involution()
M[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> M = QSym.M()
>>> M[Integer(3),Integer(2)].star_involution()
M[2, 3]
>>> M[Integer(6),Integer(3)].star_involution()
M[3, 6]
>>> (M[Integer(9),Integer(1)] - M[Integer(6),Integer(2)] +␣
↪Integer(2)*M[Integer(6),Integer(4)] - Integer(3)*M[Integer(3)] +␣
↪Integer(4)*M[[]]).star_involution()
4*M[] + M[1, 9] - M[2, 6] - 3*M[3] + 2*M[4, 6]
>>> (M[Integer(3),Integer(3)] - Integer(2)*M[Integer(2)]).star_
↪involution()
-2*M[2] + M[3, 3]
>>> M([Integer(4),Integer(2)]).star_involution()
M[2, 4]
>>> dI = QSym.dI()
>>> dI([Integer(1),Integer(2)]).star_involution()
-dI[1, 2] + dI[2, 1]
>>> dI.zero().star_involution()
0
```

The star involution commutes with the antipode:

```
sage: all( M(I).star_involution().antipode()
....:      == M(I).antipode().star_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( M(I).star_involution().antipode()
...      == M(I).antipode().star_involution()
...      for I in Compositions(Integer(4)) )
True
```

The star involution is the identity on Sym:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( M(e(lam)).star_involution() == M(e(lam))
....:      for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> e = Sym.e()
>>> all( M(e(lam)).star_involution() == M(e(lam))
...      for lam in Partitions(Integer(4)) )
True
```

to_symmetric_function()

Convert a quasi-symmetric function to a symmetric function.

OUTPUT:

- If `self` is a symmetric function, then return the expansion in the monomial basis. Otherwise raise an error.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: F[2, 3] + F[3, 2] is not a symmetric function
sage: m = SymmetricFunctions(QQ).m()
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,1,1]).to_symmetric_function()
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
sage: m(s[3,1,1])
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> F = QSym.Fundamental()
>>> (F[Integer(3),Integer(2)] + F[Integer(2),Integer(3)]).to_symmetric_
↪function()
Traceback (most recent call last):
...
ValueError: F[2, 3] + F[3, 2] is not a symmetric function
>>> m = SymmetricFunctions(QQ).m()
>>> s = SymmetricFunctions(QQ).s()
>>> F(s[Integer(3),Integer(1),Integer(1)]).to_symmetric_function()
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
>>> m(s[Integer(3),Integer(1),Integer(1)])
6*m[1, 1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]
```

class ParentMethods

Bases: `object`

Methods common to all bases of `QuasiSymmetricFunctions`.

Eulerian(*n*, *j*, *k=None*)

Return the Eulerian (quasi)symmetric function $Q_{n,j}$ in terms of `self`.

INPUT:

- `n` – the value n or a partition
- `j` – the number of excedances
- `k` – (optional) if specified, determines the number of fixed points of the permutation

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M.Eulerian(3, 1)
4*M[1, 1, 1] + 3*M[1, 2] + 3*M[2, 1] + 2*M[3]
sage: M.Eulerian(4, 1, 2)
6*M[1, 1, 1, 1] + 4*M[1, 1, 2] + 4*M[1, 2, 1]
 + 2*M[1, 3] + 4*M[2, 1, 1] + 3*M[2, 2] + 2*M[3, 1] + M[4]
sage: QS = QSym.QS()
sage: QS.Eulerian(4, 2)
2*QS[1, 3] + QS[2, 2] + 2*QS[3, 1] + 3*QS[4]
sage: QS.Eulerian([2, 2, 1], 2)
QS[1, 2, 2] + QS[1, 4] + QS[2, 1, 2] + QS[2, 2, 1]
 + QS[2, 3] + QS[3, 2] + QS[4, 1] + QS[5]
sage: dI = QSym.dI()
sage: dI.Eulerian(5, 2)
-dI[1, 3, 1] - 5*dI[1, 4] + dI[2, 2, 1] + dI[3, 1, 1]
 + 5*dI[3, 2] + 6*dI[4, 1] + 6*dI[5]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> M = QSym.M()
>>> M.Eulerian(Integer(3), Integer(1))
4*M[1, 1, 1] + 3*M[1, 2] + 3*M[2, 1] + 2*M[3]
>>> M.Eulerian(Integer(4), Integer(1), Integer(2))
6*M[1, 1, 1, 1] + 4*M[1, 1, 2] + 4*M[1, 2, 1]
 + 2*M[1, 3] + 4*M[2, 1, 1] + 3*M[2, 2] + 2*M[3, 1] + M[4]
>>> QS = QSym.QS()
>>> QS.Eulerian(Integer(4), Integer(2))
2*QS[1, 3] + QS[2, 2] + 2*QS[3, 1] + 3*QS[4]
>>> QS.Eulerian([Integer(2), Integer(2), Integer(1)], Integer(2))
QS[1, 2, 2] + QS[1, 4] + QS[2, 1, 2] + QS[2, 2, 1]
 + QS[2, 3] + QS[3, 2] + QS[4, 1] + QS[5]
>>> dI = QSym.dI()
>>> dI.Eulerian(Integer(5), Integer(2))
-dI[1, 3, 1] - 5*dI[1, 4] + dI[2, 2, 1] + dI[3, 1, 1]
 + 5*dI[3, 2] + 6*dI[4, 1] + 6*dI[5]
```

from_polynomial(*f*, *check=True*)

The quasi-symmetric function expanded in this basis corresponding to the quasi-symmetric polynomial `f`.

This is a default implementation that computes the expansion in the Monomial basis and converts to this basis.

INPUT:

- `f` – a polynomial in finitely many variables over the same base ring as `self`. It is assumed that this polynomial is quasi-symmetric.
- `check` – boolean (default: `True`); checks whether the polynomial is indeed quasi-symmetric

OUTPUT: quasi-symmetric function

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: M.from_polynomial(f)
M[1]
sage: F.from_polynomial(f)
F[1]
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: M.from_polynomial(f)
M[2]
sage: F.from_polynomial(f)
-F[1, 1] + F[2]
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> P = PolynomialRing(QQ, 'x', Integer(3))
>>> x = P.gens()
>>> f = x[Integer(0)] + x[Integer(1)] + x[Integer(2)]
>>> M.from_polynomial(f)
M[1]
>>> F.from_polynomial(f)
F[1]
>>> f = x[Integer(0)]**Integer(2)+x[Integer(1)]**Integer(2)+x[Integer(2
↪)]**Integer(2)
>>> M.from_polynomial(f)
M[2]
>>> F.from_polynomial(f)
-F[1, 1] + F[2]
```

If the polynomial is not quasi-symmetric, an error is raised:

```
sage: f = x[0]^2+x[1]
sage: M.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
sage: F.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
```

```
>>> from sage.all import *
>>> f = x[Integer(0)]**Integer(2)+x[Integer(1)]
>>> M.from_polynomial(f)
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
>>> F.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
```

super_categories()

Return the super categories of bases of the Quasi-symmetric functions.

OUTPUT: list of categories

E

alias of *Essential*

class Essential(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of quasi-symmetric functions in the Essential basis.

The Essential quasi-symmetric functions are defined by

$$E_I = \sum_{J \geq I} M_J = \sum_{i_1 \leq \cdots \leq i_k} x_{i_1}^{I_1} \cdots x_{i_k}^{I_k},$$

where $I = (I_1, \ldots, I_k)$.

Note

Our convention of $\leq$ and $\geq$ of compositions is opposite that of [Hoff2015].

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: E = QSym.E()
sage: M = QSym.M()
sage: E(M[2,2])
E[2, 2] - E[4]
sage: s = SymmetricFunctions(QQ).s()
sage: E(s[3,2])
5*E[1, 1, 1, 1, 1] - 2*E[1, 1, 1, 2] - 2*E[1, 1, 2, 1]
 - 2*E[1, 2, 1, 1] + E[1, 2, 2] - 2*E[2, 1, 1, 1]
 + E[2, 1, 2] + E[2, 2, 1]
sage: (1 + E[1])^3
E[] + 3*E[1] + 6*E[1, 1] + 6*E[1, 1, 1] - 3*E[1, 2]
 - 3*E[2] - 3*E[2, 1] + E[3]
sage: E[1,2,1].coproduct()
E[] # E[1, 2, 1] + E[1] # E[2, 1] + E[1, 2] # E[1] + E[1, 2, 1] # E[]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> E = QSym.E()
```

(continues on next page)

(continued from previous page)

```
>>> M = QSym.M()
>>> E(M[Integer(2),Integer(2)])
E[2, 2] - E[4]
>>> s = SymmetricFunctions(QQ).s()
>>> E(s[Integer(3),Integer(2)])
5*E[1, 1, 1, 1, 1] - 2*E[1, 1, 1, 2] - 2*E[1, 1, 2, 1]
 - 2*E[1, 2, 1, 1] + E[1, 2, 2] - 2*E[2, 1, 1, 1]
 + E[2, 1, 2] + E[2, 2, 1]
>>> (Integer(1) + E[Integer(1)])**Integer(3)
E[] + 3*E[1] + 6*E[1, 1] + 6*E[1, 1, 1] - 3*E[1, 2]
 - 3*E[2] - 3*E[2, 1] + E[3]
>>> E[Integer(1),Integer(2),Integer(1)].coproduct()
E[] # E[1, 2, 1] + E[1] # E[2, 1] + E[1, 2] # E[1] + E[1, 2, 1] # E[]
```

The following is an alias for this basis:

```
sage: QSym.Essential()
Quasisymmetric functions over the Rational Field in the Essential basis
```

```
>>> from sage.all import *
>>> QSym.Essential()
Quasisymmetric functions over the Rational Field in the Essential basis
```

antipode_on_basis(*compo*)

Return the result of the antipode applied to a quasi-symmetric Essential basis element.

INPUT:

- `compo` – composition

OUTPUT:

- The result of the antipode applied to the composition `compo`, expressed in the Essential basis.

EXAMPLES:

```
sage: E = QuasiSymmetricFunctions(QQ).E()
sage: E.antipode_on_basis(Composition([2,1]))
E[1, 2] - E[3]
sage: E.antipode_on_basis(Composition([]))
E[]
```

```
>>> from sage.all import *
>>> E = QuasiSymmetricFunctions(QQ).E()
>>> E.antipode_on_basis(Composition([Integer(2),Integer(1)]))
E[1, 2] - E[3]
>>> E.antipode_on_basis(Composition([]))
E[]
```

coproduct_on_basis(*compo*)

Return the coproduct of a Essential basis element.

Combinatorial rule: deconcatenation.

INPUT:

- `compo` – composition

OUTPUT:

- The coproduct applied to the Essential quasi-symmetric function indexed by `compo`, expressed in the Essential basis.

EXAMPLES:

```
sage: E = QuasiSymmetricFunctions(QQ).Essential()
sage: E[4,2,3].coproduct()
E[] # E[4, 2, 3] + E[4] # E[2, 3] + E[4, 2] # E[3] + E[4, 2, 3] # E[]
sage: E.coproduct_on_basis(Composition([]))
E[] # E[]
```

```
>>> from sage.all import *
>>> E = QuasiSymmetricFunctions(QQ).Essential()
>>> E[Integer(4),Integer(2),Integer(3)].coproduct()
E[] # E[4, 2, 3] + E[4] # E[2, 3] + E[4, 2] # E[3] + E[4, 2, 3] # E[]
>>> E.coproduct_on_basis(Composition([]))
E[] # E[]
```

product_on_basis(I, J)

The product on Essential basis elements.

The product of the basis elements indexed by two compositions I and J is the sum of the basis elements indexed by compositions K in the stuffle product (also called the overlapping shuffle product) of I and J with a coefficient of $(-1)^{\ell(I)+\ell(J)-\ell(K)}$, where $\ell(C)$ is the length of the composition C.

INPUT:

- `I`, `J` – compositions

OUTPUT:

- The product of the Essential quasi-symmetric functions indexed by `I` and `J`, expressed in the Essential basis.

EXAMPLES:

```
sage: E = QuasiSymmetricFunctions(QQ).E()
sage: c1 = Composition([2])
sage: c2 = Composition([1,3])
sage: E.product_on_basis(c1, c2)
E[1, 2, 3] + E[1, 3, 2] - E[1, 5] + E[2, 1, 3] - E[3, 3]
sage: E.product_on_basis(c1, Composition([]))
E[2]
sage: E.product_on_basis(c1, Composition([3]))
E[2, 3] + E[3, 2] - E[5]
```

```
>>> from sage.all import *
>>> E = QuasiSymmetricFunctions(QQ).E()
>>> c1 = Composition([Integer(2)])
>>> c2 = Composition([Integer(1),Integer(3)])
>>> E.product_on_basis(c1, c2)
E[1, 2, 3] + E[1, 3, 2] - E[1, 5] + E[2, 1, 3] - E[3, 3]
>>> E.product_on_basis(c1, Composition([]))
E[2]
>>> E.product_on_basis(c1, Composition([Integer(3)]))
E[2, 3] + E[3, 2] - E[5]
```

F

alias of *Fundamental*

class Fundamental(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of quasi-symmetric functions in the Fundamental basis.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(M[2,2])
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,2])
F[1, 2, 2] + F[1, 3, 1] + F[2, 2, 1] + F[2, 3] + F[3, 2]
sage: (1+F[1])^3
F[] + 3*F[1] + 3*F[1, 1] + F[1, 1, 1] + 2*F[1, 2] + 3*F[2] + 2*F[2, 1] + F[3]
sage: F[1,2,1].coproduct()
F[] # F[1, 2, 1] + F[1] # F[2, 1] + F[1, 1] # F[1, 1] + F[1, 2] # F[1] + F[1,␣
↪2, 1] # F[]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> F = QSym.F()
>>> M = QSym.M()
>>> F(M[Integer(2),Integer(2)])
F[1, 1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
>>> s = SymmetricFunctions(QQ).s()
>>> F(s[Integer(3),Integer(2)])
F[1, 2, 2] + F[1, 3, 1] + F[2, 2, 1] + F[2, 3] + F[3, 2]
>>> (Integer(1)+F[Integer(1)])**Integer(3)
F[] + 3*F[1] + 3*F[1, 1] + F[1, 1, 1] + 2*F[1, 2] + 3*F[2] + 2*F[2, 1] + F[3]
>>> F[Integer(1),Integer(2),Integer(1)].coproduct()
F[] # F[1, 2, 1] + F[1] # F[2, 1] + F[1, 1] # F[1, 1] + F[1, 2] # F[1] + F[1,␣
↪2, 1] # F[]
```

The following is an alias for this basis:

```
sage: QSym.Fundamental()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

```
>>> from sage.all import *
>>> QSym.Fundamental()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

class Element

Bases: IndexedFreeModuleElement

internal_coproduct()

Return the inner coproduct of `self` in the Fundamental basis.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the R-algebra of quasi-symmetric functions) is an R-algebra homomorphism $\Delta^{\times}$ from the R-algebra of quasi-symmetric functions to the tensor square (over R) of quasi-symmetric functions. It can be defined in the following two ways:

1. If I is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the nonzero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is I. If A is a $(0, I)$-matrix, then $\mathrm{row}(A)$ will denote the vector of row sums of A (regarded as a composition), and $\mathrm{column}(A)$ will denote the vector of column sums of A (regarded as a composition).

   For every composition I, the internal coproduct $\Delta^{\times}(M_I)$ of the I-th monomial quasisymmetric function M_I is the sum

   $$\sum_{A \text{ is a } (0,I)\text{-matrix}} M_{\mathrm{row}(A)} \otimes M_{\mathrm{column}(A)}.$$

   See Section 11.39 of [HazWitt1].
2. For every permutation w, let $C(w)$ denote the descent composition of w. Then, for any composition I of size n, the internal coproduct $\Delta^{\times}(F_I)$ of the I-th fundamental quasisymmetric function F_I is the sum

   $$\sum_{\substack{\sigma \in S_n, \\ \tau \in S_n, \\ \tau\sigma = \pi}} F_{C(\sigma)} \otimes F_{C(\tau)},$$

   where π is any permutation in S_n having descent composition I and where permutations act from the left and multiply accordingly, so $\tau\sigma$ means first applying σ and then τ. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the R-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method *kronecker_coproduct()* is a synonym of this one.

EXAMPLES:

Let us compute the internal coproduct of M_{21} (which is short for $M_{[2,1]}$). The $(0, [2, 1])$-matrices are

$$\begin{bmatrix} 2 & 1 \end{bmatrix}, \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$$

so

$$\Delta^{\times}(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
M[2, 1] # M[1, 2] + M[2, 1] # M[2, 1] + M[2, 1] # M[3] + M[3] # M[2, 1]
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(ZZ).M()
>>> a = M([Integer(2),Integer(1)])
>>> a.internal_coproduct()
M[2, 1] # M[1, 2] + M[2, 1] # M[2, 1] + M[2, 1] # M[3] + M[3] # M[2, 1]
```

Some examples on the Fundamental basis:

```
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
F[1, 1] # F[2] + F[2] # F[1, 1]
sage: F([2]).internal_coproduct()
F[1, 1] # F[1, 1] + F[2] # F[2]
sage: F([3]).internal_coproduct()
F[1, 1, 1] # F[1, 1, 1] + F[1, 2] # F[1, 2] + F[1, 2] # F[2, 1]
 + F[2, 1] # F[1, 2] + F[2, 1] # F[2, 1] + F[3] # F[3]
sage: F([1,2]).internal_coproduct()
F[1, 1, 1] # F[1, 2] + F[1, 2] # F[2, 1] + F[1, 2] # F[3]
 + F[2, 1] # F[1, 1, 1] + F[2, 1] # F[2, 1] + F[3] # F[1, 2]
```

```
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(ZZ).F()
>>> F([Integer(1),Integer(1)]).internal_coproduct()
F[1, 1] # F[2] + F[2] # F[1, 1]
>>> F([Integer(2)]).internal_coproduct()
F[1, 1] # F[1, 1] + F[2] # F[2]
>>> F([Integer(3)]).internal_coproduct()
F[1, 1, 1] # F[1, 1, 1] + F[1, 2] # F[1, 2] + F[1, 2] # F[2, 1]
 + F[2, 1] # F[1, 2] + F[2, 1] # F[2, 1] + F[3] # F[3]
>>> F([Integer(1),Integer(2)]).internal_coproduct()
F[1, 1, 1] # F[1, 2] + F[1, 2] # F[2, 1] + F[1, 2] # F[3]
 + F[2, 1] # F[1, 1, 1] + F[2, 1] # F[2, 1] + F[3] # F[1, 2]
```

kronecker_coproduct()

alias of *internal_coproduct()*.

star_involution()

Return the image of the quasisymmetric function `self` under the star involution.

The star involution is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the monomial quasisymmetric function M_I to M_{I^r}. Here, if I is a composition, we denote by I^r the reversed composition of I. Denoting by f^* the image of an element $f \in QSym$ under the star involution, it can be shown that every composition I satisfies

$$(M_I)^* = M_{I^r}, \quad (F_I)^* = F_{I^r},$$

where F_I denotes the fundamental quasisymmetric function corresponding to the composition I. The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of $QSym$. It also is an automorphism of the graded vector space $QSym$, and is the identity on the subspace Sym of $QSym$. It is adjoint to the star involution on $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by ρ in [LMvW13], section 3.6.

See also

star involution on QSym, *star involution on NCSF*.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,1].star_involution()
F[1, 3]
sage: F[5,3].star_involution()
F[3, 5]
sage: (F[9,1] - F[6,2] + 2*F[6,4] - 3*F[3] + 4*F[[]]).star_involution()
4*F[] + F[1, 9] - F[2, 6] - 3*F[3] + 2*F[4, 6]
sage: (F[3,3] - 2*F[2]).star_involution()
-2*F[2] + F[3, 3]
sage: F([4,2]).star_involution()
F[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> F = QSym.F()
>>> F[Integer(3),Integer(1)].star_involution()
F[1, 3]
>>> F[Integer(5),Integer(3)].star_involution()
F[3, 5]
>>> (F[Integer(9),Integer(1)] - F[Integer(6),Integer(2)] +␣
↪Integer(2)*F[Integer(6),Integer(4)] - Integer(3)*F[Integer(3)] +␣
↪Integer(4)*F[[]]).star_involution()
4*F[] + F[1, 9] - F[2, 6] - 3*F[3] + 2*F[4, 6]
>>> (F[Integer(3),Integer(3)] - Integer(2)*F[Integer(2)]).star_
↪involution()
-2*F[2] + F[3, 3]
>>> F([Integer(4),Integer(2)]).star_involution()
F[2, 4]
>>> dI = QSym.dI()
>>> dI([Integer(1),Integer(2)]).star_involution()
-dI[1, 2] + dI[2, 1]
>>> dI.zero().star_involution()
0
```

Eulerian(*n*, *j*, *k=None*)

Return the Eulerian (quasi)symmetric function $Q_{n,j}$ (with n either an integer or a partition) defined in [SW2010] in terms of the fundamental quasisymmetric functions. Or, if the optional argument `k` is specified, return the function $Q_{n,j,k}$ defined ibidem.

If n and j are nonnegative integers, then the Eulerian quasisymmetric function $Q_{n,j}$ is defined as

$$Q_{n,j} := \sum_{\sigma} F_{\mathrm{Dex}(\sigma)},$$

where we sum over all permutations $\sigma \in S_n$ such that the number of excedances of σ is j, and where $\mathrm{Dex}(\sigma)$ is a composition of n defined as follows: Let S be the set of all $i \in \{1, 2, \ldots, n-1\}$ such that either $\sigma_i > \sigma_{i+1} > i+1$ or $i \geq \sigma_i > \sigma_{i+1}$ or $\sigma_{i+1} > i+1 > \sigma_i$. Then, $\mathrm{Dex}(\sigma)$ is set to be the composition of n whose descent set is S.

Here, an excedance of a permutation $\sigma \in S_n$ means an element $i \in \{1, 2, \ldots, n-1\}$ satisfying $\sigma_i > i$.

Similarly we can define a quasisymmetric function $Q_{\lambda,j}$ for every partition λ and every nonnegative integer j. This differs from $Q_{n,j}$ only in that the sum is restricted to all permutations $\sigma \in S_n$ whose cycle type is λ (where $n = |\lambda|$, and where we still require the number of excedances to be j). The method at hand allows computing these functions by passing λ as the `n` parameter.

Analogously we can define a quasisymmetric function $Q_{n,j,k}$ for any nonnegative integers n, j and k by restricting the sum to all permutations $\sigma \in S_n$ that have exactly k fixed points (and j excedances). This can be obtained by specifying the optional `k` argument in this method.

All three versions of Eulerian quasisymmetric functions ($Q_{n,j}$, $Q_{\lambda,j}$ and $Q_{n,j,k}$) are actually symmetric functions. See *Eulerian()*.

INPUT:

- `n` – the nonnegative integer n or a partition
- `j` – the number of excedances
- `k` – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.Eulerian(3, 1)
F[1, 2] + F[2, 1] + 2*F[3]
sage: F.Eulerian(4, 2)
F[1, 2, 1] + 2*F[1, 3] + 3*F[2, 2] + 2*F[3, 1] + 3*F[4]
sage: F.Eulerian(5, 2)
F[1, 1, 2, 1] + F[1, 1, 3] + F[1, 2, 1, 1] + 7*F[1, 2, 2] + 6*F[1, 3, 1]␣
↪+ 6*F[1, 4] + 2*F[2, 1, 2] + 7*F[2, 2, 1] + 11*F[2, 3] + F[3, 1, 1] +␣

0
```

antipode_on_basis(*compo*)

Return the antipode to a Fundamental quasi-symmetric basis element.

INPUT:

- `compo` – composition

OUTPUT:

- The result of the antipode applied to the quasi-symmetric Fundamental basis element indexed by `compo`.

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.antipode_on_basis(Composition([2,1]))
-F[2, 1]
```

```
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(QQ).F()
>>> F.antipode_on_basis(Composition([Integer(2),Integer(1)]))
-F[2, 1]
```

coproduct_on_basis(*compo*)

Return the coproduct to a Fundamental quasi-symmetric basis element.

Combinatorial rule: quasi-deconcatenation.

INPUT:

- `compo` – composition

OUTPUT:

- The application of the coproduct to the Fundamental quasi-symmetric function indexed by the composition `compo`.

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[4].coproduct()
F[] # F[4] + F[1] # F[3] + F[2] # F[2] + F[3] # F[1] + F[4] # F[]
sage: F[2,1,3].coproduct()
F[] # F[2, 1, 3] + F[1] # F[1, 1, 3] + F[2] # F[1, 3] + F[2, 1] # F[3] +␣
↪F[2, 1, 1] # F[2] + F[2, 1, 2] # F[1] + F[2, 1, 3] # F[]
```

```
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> F[Integer(4)].coproduct()
F[] # F[4] + F[1] # F[3] + F[2] # F[2] + F[3] # F[1] + F[4] # F[]
>>> F[Integer(2),Integer(1),Integer(3)].coproduct()
F[] # F[2, 1, 3] + F[1] # F[1, 1, 3] + F[2] # F[1, 3] + F[2, 1] # F[3] +␣
↪F[2, 1, 1] # F[2] + F[2, 1, 2] # F[1] + F[2, 1, 3] # F[]
```

dual()

Return the dual basis to the Fundamental basis. This is the ribbon basis of the non-commutative symmetric functions.

OUTPUT: the ribbon basis of the non-commutative symmetric functions

EXAMPLES:

```
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon␣
↪basis
```

```
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(QQ).F()
>>> F.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon␣
↪basis
```

class HazewinkelLambda(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hazewinkel lambda basis of the quasi-symmetric functions.

This basis goes back to [Haz2004], albeit it is indexed in a different way here. It is a multiplicative basis in a weak sense of this word (the product of any two basis elements is a basis element, but of course not the one obtained by concatenating the indexing compositions).

In [Haz2004], Hazewinkel showed that the **k**-algebra QSym is a polynomial algebra. (The proof is correct but rests upon an unproven claim that the lexicographically largest term of the n-th shuffle power of a Lyndon word is the n-fold concatenation of this Lyndon word with itself, occurring $n!$ times in that shuffle power. But this can be deduced from Section 2 of [Rad1979]. See also Chapter 6 of [GriRei18], specifically Theorem 6.5.13, for a complete proof.) More precisely, he showed that QSym is generated, as a free commutative **k**-algebra, by the elements $\lambda^n(M_I)$, where n ranges over the positive integers, and I ranges over all compositions which are Lyndon words and whose entries have gcd 1. Here, λ^n denotes the n-th lambda operation as explained in *lambda_of_monomial()*.

Thus, products of these generators form a **k**-module basis of QSym. We index this basis by compositions here. More precisely, we define the Hazewinkel lambda basis $(\mathrm{HWL}_I)_I$ (with I ranging over all compositions) as follows:

Let I be a composition. Let $I = I_1 I_2 \ldots I_k$ be the Chen-Fox-Lyndon factorization of I (see *lyndon_factorization()*). For every $j \in \{1, 2, \ldots, k\}$, let g_j be the gcd of the entries of the Lyndon word I_j, and let J_j be the result of dividing the entries of I_j by this gcd. Then, HWL_I is defined to be $\prod_{j=1}^{k} \lambda^{g_j}(M_{J_j})$.

Todo

The conversion from the M basis to the HWL basis is currently implemented in the naive way (inverting the base-change matrix in the other direction). This matrix is not triangular (not even after any permutations of the bases), and there could very well be a faster method (the one given by Hazewinkel?).

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: HWL = QSym.HazewinkelLambda()
sage: M = QSym.M()
sage: M(HWL([2]))
M[1, 1]
sage: M(HWL([1,1]))
2*M[1, 1] + M[2]
sage: M(HWL([1,2]))
M[1, 2]
sage: M(HWL([2,1]))
3*M[1, 1, 1] + M[1, 2] + M[2, 1]
sage: M(HWL(Composition([])))
M[]
sage: HWL(M([1,1]))
HWL[2]
sage: HWL(M(Composition([2])))
HWL[1, 1] - 2*HWL[2]
sage: HWL(M([1]))
HWL[1]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> HWL = QSym.HazewinkelLambda()
>>> M = QSym.M()
>>> M(HWL([Integer(2)]))
M[1, 1]
>>> M(HWL([Integer(1),Integer(1)]))
2*M[1, 1] + M[2]
>>> M(HWL([Integer(1),Integer(2)]))
M[1, 2]
>>> M(HWL([Integer(2),Integer(1)]))
3*M[1, 1, 1] + M[1, 2] + M[2, 1]
>>> M(HWL(Composition([])))
M[]
>>> HWL(M([Integer(1),Integer(1)]))
HWL[2]
>>> HWL(M(Composition([Integer(2)])))
HWL[1, 1] - 2*HWL[2]
>>> HWL(M([Integer(1)]))
HWL[1]
```

product_on_basis(*I*, *J*)

The product on Hazewinkel Lambda basis elements.

The product of the basis elements indexed by two compositions I and J is the basis element obtained by concatenating the Lyndon factorizations of the words I and J, then reordering the Lyndon factors in nonincreasing order, and finally concatenating them in this order (giving a new composition).

INPUT:

- I, J – compositions

OUTPUT:

- The product of the Hazewinkel Lambda quasi-symmetric functions indexed by I and J, expressed in the Hazewinkel Lambda basis.

EXAMPLES:

```
sage: HWL = QuasiSymmetricFunctions(QQ).HazewinkelLambda()
sage: c1 = Composition([1, 2, 1])
sage: c2 = Composition([2, 1, 3, 2])
sage: HWL.product_on_basis(c1, c2)
HWL[2, 1, 3, 2, 1, 2, 1]
sage: HWL.product_on_basis(c1, Composition([]))
HWL[1, 2, 1]
sage: HWL.product_on_basis(Composition([]), Composition([]))
HWL[]
```

```
>>> from sage.all import *
>>> HWL = QuasiSymmetricFunctions(QQ).HazewinkelLambda()
>>> c1 = Composition([Integer(1), Integer(2), Integer(1)])
>>> c2 = Composition([Integer(2), Integer(1), Integer(3), Integer(2)])
>>> HWL.product_on_basis(c1, c2)
HWL[2, 1, 3, 2, 1, 2, 1]
>>> HWL.product_on_basis(c1, Composition([]))
HWL[1, 2, 1]
>>> HWL.product_on_basis(Composition([]), Composition([]))
HWL[]
```

M

alias of *Monomial*

class Monomial(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of quasi-symmetric function in the Monomial basis.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M(F[2,2])
M[1, 1, 1, 1] + M[1, 1, 2] + M[2, 1, 1] + M[2, 2]
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3,1,1])
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: (1+M[1])^3
M[] + 3*M[1] + 6*M[1, 1] + 6*M[1, 1, 1] + 3*M[1, 2] + 3*M[2] + 3*M[2, 1] +␣
```

(continues on next page)

(continued from previous page)

```
↪M[3]
sage: M[1,2,1].coproduct()
M[] # M[1, 2, 1] + M[1] # M[2, 1] + M[1, 2] # M[1] + M[1, 2, 1] # M[]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> M = QSym.M()
>>> F = QSym.F()
>>> M(F[Integer(2),Integer(2)])
M[1, 1, 1, 1] + M[1, 1, 2] + M[2, 1, 1] + M[2, 2]
>>> m = SymmetricFunctions(QQ).m()
>>> M(m[Integer(3),Integer(1),Integer(1)])
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
>>> (Integer(1)+M[Integer(1)])**Integer(3)
M[] + 3*M[1] + 6*M[1, 1] + 6*M[1, 1, 1] + 3*M[1, 2] + 3*M[2] + 3*M[2, 1] +␣
↪M[3]
>>> M[Integer(1),Integer(2),Integer(1)].coproduct()
M[] # M[1, 2, 1] + M[1] # M[2, 1] + M[1, 2] # M[1] + M[1, 2, 1] # M[]
```

The following is an alias for this basis:

```
sage: QSym.Monomial()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

```
>>> from sage.all import *
>>> QSym.Monomial()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

class Element

Bases: `IndexedFreeModuleElement`

Element methods of the `Monomial` basis of `QuasiSymmetricFunctions`.

expand(*n*, *alphabet='x'*)

Expand the quasi-symmetric function written in the monomial basis in n variables.

INPUT:

- `n` – integer
- `alphabet` – string (default: `'x'`)

OUTPUT: the quasi-symmetric function `self` expressed in the n variables described by `alphabet`

Todo

accept an *alphabet* as input

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M[4,2].expand(3)
x0^4*x1^2 + x0^4*x2^2 + x1^4*x2^2
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> M[Integer(4),Integer(2)].expand(Integer(3))
x0^4*x1^2 + x0^4*x2^2 + x1^4*x2^2
```

One can use a different set of variables by using the optional argument `alphabet`:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M[2,1,1].expand(4,alphabet='y')
y0^2*y1*y2 + y0^2*y1*y3 + y0^2*y2*y3 + y1^2*y2*y3
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> M[Integer(2),Integer(1),Integer(1)].expand(Integer(4),alphabet='y')
y0^2*y1*y2 + y0^2*y1*y3 + y0^2*y2*y3 + y1^2*y2*y3
```

is_symmetric()

Determine if a quasi-symmetric function, written in the Monomial basis, is symmetric.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

OUTPUT:

- `True` if `self` is an element of the symmetric functions and `False` otherwise.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.Monomial()
sage: (M[3,2] + M[2,3] + M[4,1]).is_symmetric()
False
sage: (M[3,2] + M[2,3]).is_symmetric()
True
sage: (M[1,2,1] + M[1,1,2]).is_symmetric()
False
sage: (M[1,2,1] + M[1,1,2] + M[2,1,1]).is_symmetric()
True
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> M = QSym.Monomial()
>>> (M[Integer(3),Integer(2)] + M[Integer(2),Integer(3)] +␣
↪M[Integer(4),Integer(1)]).is_symmetric()
False
>>> (M[Integer(3),Integer(2)] + M[Integer(2),Integer(3)]).is_
↪symmetric()
True
>>> (M[Integer(1),Integer(2),Integer(1)] + M[Integer(1),Integer(1),
↪Integer(2)]).is_symmetric()
False
>>> (M[Integer(1),Integer(2),Integer(1)] + M[Integer(1),Integer(1),
↪Integer(2)] + M[Integer(2),Integer(1),Integer(1)]).is_symmetric()
True
```

psi_involution()

Return the image of the quasisymmetric function `self` under the involution ψ.

The involution ψ is defined as the linear map $QSym \to QSym$ which, for every composition I, sends the fundamental quasisymmetric function F_I to F_{I^c}, where I^c denotes the complement of the composition I. The map ψ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution ψ of $QSym$ is adjoint to the involution ψ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution ψ has been denoted by ψ in [LMvW13], section 3.6.

See also

psi involution on QSym, *psi involution on NCSF*, *star involution on QSym*.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].psi_involution()
-M[3, 2] - M[5]
sage: M[3,1].psi_involution()
M[3, 1] + M[4]
sage: M[3,1,1].psi_involution()
M[3, 1, 1] + M[3, 2] + M[4, 1] + M[5]
sage: M[1,1,1].psi_involution()
M[1, 1, 1] + M[1, 2] + M[2, 1] + M[3]
sage: M[[]].psi_involution()
M[]
sage: M(0).psi_involution()
0
sage: (2*M[[]] - M[3,1] + 4*M[2]).psi_involution()
2*M[] - 4*M[2] - M[3, 1] - M[4]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> M = QSym.M()
>>> M[Integer(3),Integer(2)].psi_involution()
-M[3, 2] - M[5]
>>> M[Integer(3),Integer(1)].psi_involution()
M[3, 1] + M[4]
>>> M[Integer(3),Integer(1),Integer(1)].psi_involution()
M[3, 1, 1] + M[3, 2] + M[4, 1] + M[5]
>>> M[Integer(1),Integer(1),Integer(1)].psi_involution()
M[1, 1, 1] + M[1, 2] + M[2, 1] + M[3]
>>> M[[]].psi_involution()
M[]
>>> M(Integer(0)).psi_involution()
0
>>> (Integer(2)*M[[]] - M[Integer(3),Integer(1)] +␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(4)*M[Integer(2)]).psi_involution()
2*M[] - 4*M[2] - M[3, 1] - M[4]
```

This particular implementation is tailored to the monomial basis. It is semantically equivalent to the generic implementation it overshadows:

```
sage: F = QSym.F()
sage: all( F(M[I].psi_involution()) == F(M[I]).psi_involution()
....:      for I in Compositions(3) )
True

sage: F = QSym.F()
sage: all( F(M[I].psi_involution()) == F(M[I]).psi_involution()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> F = QSym.F()
>>> all( F(M[I].psi_involution()) == F(M[I]).psi_involution()
...      for I in Compositions(Integer(3)) )
True

>>> F = QSym.F()
>>> all( F(M[I].psi_involution()) == F(M[I]).psi_involution()
...      for I in Compositions(Integer(4)) )
True
```

to_symmetric_function()

Take a quasi-symmetric function, expressed in the monomial basis, and return its symmetric realization, when possible, expressed in the monomial basis of symmetric functions.

OUTPUT:

- If `self` is a symmetric function, then the expansion in the monomial basis of the symmetric functions is returned. Otherwise an error is raised.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.Monomial()
sage: (M[3,2] + M[2,3] + M[4,1]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: M[2, 3] + M[3, 2] + M[4, 1] is not a symmetric function
sage: (M[3,2] + M[2,3] + 2*M[4,1] + 2*M[1,4]).to_symmetric_function()
m[3, 2] + 2*m[4, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3,1,1]).to_symmetric_function()
m[3, 1, 1]
sage: (M(m[2,1])*M(m[2,1])).to_symmetric_function()-m[2,1]*m[2,1]
0
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
```

(continues on next page)

(continued from previous page)

```
>>> M = QSym.Monomial()
>>> (M[Integer(3),Integer(2)] + M[Integer(2),Integer(3)] +␣
↪M[Integer(4),Integer(1)]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: M[2, 3] + M[3, 2] + M[4, 1] is not a symmetric function
>>> (M[Integer(3),Integer(2)] + M[Integer(2),Integer(3)] +␣
↪Integer(2)*M[Integer(4),Integer(1)] + Integer(2)*M[Integer(1),
↪Integer(4)]).to_symmetric_function()
m[3, 2] + 2*m[4, 1]
>>> m = SymmetricFunctions(QQ).m()
>>> M(m[Integer(3),Integer(1),Integer(1)]).to_symmetric_function()
m[3, 1, 1]
>>> (M(m[Integer(2),Integer(1)])*M(m[Integer(2),Integer(1)])).to_
↪symmetric_function()-m[Integer(2),Integer(1)]*m[Integer(2),
↪Integer(1)]
0
```

antipode_on_basis(*compo*)

Return the result of the antipode applied to a quasi-symmetric Monomial basis element.

INPUT:

- `compo` – composition

OUTPUT:

- The result of the antipode applied to the composition `compo`, expressed in the Monomial basis.

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.antipode_on_basis(Composition([2,1]))
M[1, 2] + M[3]
sage: M.antipode_on_basis(Composition([]))
M[]
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).M()
>>> M.antipode_on_basis(Composition([Integer(2),Integer(1)]))
M[1, 2] + M[3]
>>> M.antipode_on_basis(Composition([]))
M[]
```

coproduct_on_basis(*compo*)

Return the coproduct of a Monomial basis element.

Combinatorial rule: deconcatenation.

INPUT:

- `compo` – composition

OUTPUT:

- The coproduct applied to the Monomial quasi-symmetric function indexed by `compo`, expressed in the Monomial basis.

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M[4,2,3].coproduct()
M[] # M[4, 2, 3] + M[4] # M[2, 3] + M[4, 2] # M[3] + M[4, 2, 3] # M[]
sage: M.coproduct_on_basis(Composition([]))
M[] # M[]
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> M[Integer(4),Integer(2),Integer(3)].coproduct()
M[] # M[4, 2, 3] + M[4] # M[2, 3] + M[4, 2] # M[3] + M[4, 2, 3] # M[]
>>> M.coproduct_on_basis(Composition([]))
M[] # M[]
```

dual()

Return the dual basis to the Monomial basis. This is the complete basis of the non-commutative symmetric functions.

OUTPUT: the complete basis of the non-commutative symmetric functions

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.dual()
Non-Commutative Symmetric Functions over the Rational Field in the␣
↪Complete basis
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).M()
>>> M.dual()
Non-Commutative Symmetric Functions over the Rational Field in the␣
↪Complete basis
```

lambda_of_monomial(I, n)

Return the image of the monomial quasi-symmetric function M_I under the lambda-map λ^n, expanded in the monomial basis.

The ring of quasi-symmetric functions over the integers, $\mathrm{QSym}_{\mathbf{Z}}$ (and more generally, the ring of quasi-symmetric functions over any binomial ring) becomes a λ-ring (with the λ-structure inherited from the ring of formal power series, so that $\lambda^i(x_j)$ is x_j if $i = 1$ and 0 if $i > 1$).

The Adams operations of this λ-ring are the Adams endomorphisms $\mathbf{f}_n$ (see *adams_operator()* for their definition). Using these endomorphisms, the λ-operations can be explicitly computed via the formula

$$\exp\left(-\sum_{n=1}^{\infty}\frac{1}{n}\mathbf{f}_n(x)t^n\right) = \sum_{j=0}^{\infty}(-1)^j\lambda^j(x)t^j$$

in the ring of formal power series in a variable t over the ring of quasi-symmetric functions. In particular, every composition $I = (I_1, I_2, \cdots, I_\ell)$ satisfies

$$\exp\left(-\sum_{n=1}^{\infty}\frac{1}{n}M_{(nI_1,nI_2,\cdots,nI_\ell)}t^n\right) = \sum_{j=0}^{\infty}(-1)^j\lambda^j(M_I)t^j$$

(corrected version of Remark 2.4 in [Haz2004]).

The quasi-symmetric functions $\lambda^i(M_I)$ with n ranging over the positive integers and I ranging over the reduced Lyndon compositions (i. e., compositions which are Lyndon words and have the gcd of their entries equal to 1) form a set of free polynomial generators for QSym. See [GriRei18], Chapter 6, for the proof, and [Haz2004] for a major part of it.

INPUT:

- `I` – composition
- `n` – nonnegative integer

OUTPUT:

The quasi-symmetric function $\lambda^n(M_I)$, expanded in the monomial basis over the ground ring of `self`.

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(CyclotomicField()).Monomial()
sage: M.lambda_of_monomial([1, 2], 2)
2*M[1, 1, 2, 2] + M[1, 1, 4] + M[1, 2, 1, 2] + M[1, 3, 2] + M[2, 2, 2]
sage: M.lambda_of_monomial([1, 1], 2)
3*M[1, 1, 1, 1] + M[1, 1, 2] + M[1, 2, 1] + M[2, 1, 1]
sage: M = QuasiSymmetricFunctions(Integers(19)).Monomial()
sage: M.lambda_of_monomial([1, 2], 3)
6*M[1, 1, 1, 2, 2, 2] + 3*M[1, 1, 1, 2, 4] + 3*M[1, 1, 1, 4, 2]
+ M[1, 1, 1, 6] + 4*M[1, 1, 2, 1, 2, 2] + 2*M[1, 1, 2, 1, 4]
+ 2*M[1, 1, 2, 2, 1, 2] + 2*M[1, 1, 2, 3, 2] + 4*M[1, 1, 3, 2, 2]
+ 2*M[1, 1, 3, 4] + M[1, 1, 4, 1, 2] + M[1, 1, 5, 2]
+ 2*M[1, 2, 1, 1, 2, 2] + M[1, 2, 1, 1, 4] + M[1, 2, 1, 2, 1, 2]
+ M[1, 2, 1, 3, 2] + 4*M[1, 2, 2, 2, 2] + M[1, 2, 2, 4] + M[1, 2, 4, 2]
+ 2*M[1, 3, 1, 2, 2] + M[1, 3, 1, 4] + M[1, 3, 2, 1, 2] + M[1, 3, 3, 2]
+ M[1, 4, 2, 2] + 3*M[2, 1, 2, 2, 2] + M[2, 1, 2, 4] + M[2, 1, 4, 2]
+ 2*M[2, 2, 1, 2, 2] + M[2, 2, 1, 4] + M[2, 2, 2, 1, 2] + M[2, 2, 3, 2]
+ 2*M[2, 3, 2, 2] + M[2, 3, 4] + M[3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(CyclotomicField()).Monomial()
>>> M.lambda_of_monomial([Integer(1), Integer(2)], Integer(2))
2*M[1, 1, 2, 2] + M[1, 1, 4] + M[1, 2, 1, 2] + M[1, 3, 2] + M[2, 2, 2]
>>> M.lambda_of_monomial([Integer(1), Integer(1)], Integer(2))
3*M[1, 1, 1, 1] + M[1, 1, 2] + M[1, 2, 1] + M[2, 1, 1]
>>> M = QuasiSymmetricFunctions(Integers(Integer(19))).Monomial()
>>> M.lambda_of_monomial([Integer(1), Integer(2)], Integer(3))
6*M[1, 1, 1, 2, 2, 2] + 3*M[1, 1, 1, 2, 4] + 3*M[1, 1, 1, 4, 2]
+ M[1, 1, 1, 6] + 4*M[1, 1, 2, 1, 2, 2] + 2*M[1, 1, 2, 1, 4]
+ 2*M[1, 1, 2, 2, 1, 2] + 2*M[1, 1, 2, 3, 2] + 4*M[1, 1, 3, 2, 2]
+ 2*M[1, 1, 3, 4] + M[1, 1, 4, 1, 2] + M[1, 1, 5, 2]
+ 2*M[1, 2, 1, 1, 2, 2] + M[1, 2, 1, 1, 4] + M[1, 2, 1, 2, 1, 2]
+ M[1, 2, 1, 3, 2] + 4*M[1, 2, 2, 2, 2] + M[1, 2, 2, 4] + M[1, 2, 4, 2]
+ 2*M[1, 3, 1, 2, 2] + M[1, 3, 1, 4] + M[1, 3, 2, 1, 2] + M[1, 3, 3, 2]
+ M[1, 4, 2, 2] + 3*M[2, 1, 2, 2, 2] + M[2, 1, 2, 4] + M[2, 1, 4, 2]
+ 2*M[2, 2, 1, 2, 2] + M[2, 2, 1, 4] + M[2, 2, 2, 1, 2] + M[2, 2, 3, 2]
+ 2*M[2, 3, 2, 2] + M[2, 3, 4] + M[3, 2, 2, 2]
```

The map λ^0 sends everything to 1:

```
sage: M = QuasiSymmetricFunctions(ZZ).Monomial()
sage: all( M.lambda_of_monomial(I, 0) == M.one()
```

(continues on next page)

(continued from previous page)

```
....:       for I in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(ZZ).Monomial()
>>> all( M.lambda_of_monomial(I, Integer(0)) == M.one()
...       for I in Compositions(Integer(3)) )
True
```

The map λ^1 is the identity map:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I)
....:       for I in Compositions(3) )
True
sage: M = QuasiSymmetricFunctions(Integers(5)).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I)
....:       for I in Compositions(3) )
True
sage: M = QuasiSymmetricFunctions(ZZ).Monomial()
sage: all( M.lambda_of_monomial(I, 1) == M(I)
....:       for I in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> all( M.lambda_of_monomial(I, Integer(1)) == M(I)
...       for I in Compositions(Integer(3)) )
True
>>> M = QuasiSymmetricFunctions(Integers(Integer(5))).Monomial()
>>> all( M.lambda_of_monomial(I, Integer(1)) == M(I)
...       for I in Compositions(Integer(3)) )
True
>>> M = QuasiSymmetricFunctions(ZZ).Monomial()
>>> all( M.lambda_of_monomial(I, Integer(1)) == M(I)
...       for I in Compositions(Integer(3)) )
True
```

product_on_basis(I, J)

The product on Monomial basis elements.

The product of the basis elements indexed by two compositions I and J is the sum of the basis elements indexed by compositions in the stuffle product (also called the overlapping shuffle product) of I and J.

INPUT:

- I, J – compositions

OUTPUT:

- The product of the Monomial quasi-symmetric functions indexed by I and J, expressed in the Monomial basis.

EXAMPLES:

```
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: c1 = Composition([2])
```

(continues on next page)

(continued from previous page)

```
sage: c2 = Composition([1,3])
sage: M.product_on_basis(c1, c2)
M[1, 2, 3] + M[1, 3, 2] + M[1, 5] + M[2, 1, 3] + M[3, 3]
sage: M.product_on_basis(c1, Composition([]))
M[2]
```

```
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> c1 = Composition([Integer(2)])
>>> c2 = Composition([Integer(1),Integer(3)])
>>> M.product_on_basis(c1, c2)
M[1, 2, 3] + M[1, 3, 2] + M[1, 5] + M[2, 1, 3] + M[3, 3]
>>> M.product_on_basis(c1, Composition([]))
M[2]
```

QS

alias of *Quasisymmetric_Schur*

class Quasisymmetric_Schur(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of quasi-symmetric function in the Quasisymmetric Schur basis.

The basis of Quasisymmetric Schur functions is defined in [QSCHUR] and in Definition 5.1.1 of [LMvW13]. Don't mistake them for the completely unrelated quasi-Schur functions of [NCSF1]!

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QS = QSym.QS()
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(QS[1,2])
F[1, 2]
sage: M(QS[1,2])
M[1, 1, 1] + M[1, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: QS(s[2,1,1])
QS[1, 1, 2] + QS[1, 2, 1] + QS[2, 1, 1]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QS = QSym.QS()
>>> F = QSym.F()
>>> M = QSym.M()
>>> F(QS[Integer(1),Integer(2)])
F[1, 2]
>>> M(QS[Integer(1),Integer(2)])
M[1, 1, 1] + M[1, 2]
>>> s = SymmetricFunctions(QQ).s()
>>> QS(s[Integer(2),Integer(1),Integer(1)])
QS[1, 1, 2] + QS[1, 2, 1] + QS[2, 1, 1]
```

dual()

The dual basis to the Quasisymmetric Schur basis.

The dual basis to the Quasisymmetric Schur basis is implemented as dual.

OUTPUT:

- the dual Quasisymmetric Schur basis of the non-commutative symmetric functions

EXAMPLES:

```
sage: QS = QuasiSymmetricFunctions(QQ).Quasisymmetric_Schur()
sage: QS.dual()
Non-Commutative Symmetric Functions over the Rational Field
 in the dual Quasisymmetric-Schur basis
```

```
>>> from sage.all import *
>>> QS = QuasiSymmetricFunctions(QQ).Quasisymmetric_Schur()
>>> QS.dual()
Non-Commutative Symmetric Functions over the Rational Field
 in the dual Quasisymmetric-Schur basis
```

YQS

alias of *Young_Quasisymmetric_Schur*

class Young_Quasisymmetric_Schur(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of quasi-symmetric functions in the Young Quasisymmetric Schur basis.

The basis of Young Quasisymmetric Schur functions is from Definition 5.2.1 of [LMvW13].

This basis is related to the Quasisymmetric Schur basis `QS` by `QS(alpha.reversed()) == YQS(alpha).star_involution()`.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: YQS = QSym.YQS()
sage: F = QSym.F()
sage: QS = QSym.QS()
sage: F(YQS[1,2])
F[1, 2]
sage: all(QS(al.reversed())==YQS(al).star_involution() for al in␣
↪Compositions(5))
True
sage: s = SymmetricFunctions(QQ).s()
sage: YQS(s[2,1,1])
YQS[1, 1, 2] + YQS[1, 2, 1] + YQS[2, 1, 1]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> YQS = QSym.YQS()
>>> F = QSym.F()
>>> QS = QSym.QS()
>>> F(YQS[Integer(1),Integer(2)])
F[1, 2]
>>> all(QS(al.reversed())==YQS(al).star_involution() for al in␣
```

(continues on next page)

(continued from previous page)

```
↪Compositions(Integer(5)))
True
>>> s = SymmetricFunctions(QQ).s()
>>> YQS(s[Integer(2),Integer(1),Integer(1)])
YQS[1, 1, 2] + YQS[1, 2, 1] + YQS[2, 1, 1]
```

a_realization()

Return the realization of the Monomial basis of the ring of quasi-symmetric functions.

OUTPUT: the Monomial basis of quasi-symmetric functions

EXAMPLES:

```
sage: QuasiSymmetricFunctions(QQ).a_realization()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

```
>>> from sage.all import *
>>> QuasiSymmetricFunctions(QQ).a_realization()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

dI

alias of *dualImmaculate*

dual()

Return the dual Hopf algebra of the quasi-symmetric functions, which is the non-commutative symmetric functions.

OUTPUT: the non-commutative symmetric functions

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.dual()
Non-Commutative Symmetric Functions over the Rational Field
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QSym.dual()
Non-Commutative Symmetric Functions over the Rational Field
```

class dualImmaculate(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The dual immaculate basis of the quasi-symmetric functions.

This basis first appears in [BBSSZ2012].

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dI()
sage: dI([1,3,2])*dI([1])  # long time (6s on sage.math, 2013)
dI[1, 1, 3, 2] + dI[2, 3, 2]
sage: dI([1,3])*dI([1,1])
dI[1, 1, 1, 3] + dI[1, 1, 4] + dI[1, 2, 3] - dI[1, 3, 2] - dI[1, 4, 1] - dI[1,
```

(continues on next page)

(continued from previous page)

```
↪ 5] + dI[2, 3, 1] + dI[2, 4]

F[2, 1, 3]
```

from_polynomial(*f*, *check=True*)

Return the quasi-symmetric function in the Monomial basis corresponding to the quasi-symmetric polynomial `f`.

INPUT:

- `f` – a polynomial in finitely many variables over the same base ring as `self`. It is assumed that this polynomial is quasi-symmetric.
- `check` – boolean (default: `True`); checks whether the polynomial is indeed quasi-symmetric

OUTPUT: quasi-symmetric function in the Monomial basis

EXAMPLES:

```
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.from_polynomial(f)
M[1]
```

```
>>> from sage.all import *
>>> P = PolynomialRing(QQ, 'x', Integer(3))
>>> x = P.gens()
>>> f = x[Integer(0)] + x[Integer(1)] + x[Integer(2)]
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QSym.from_polynomial(f)
M[1]
```

Beware of setting `check=False`:

```
sage: f = x[0] + 2*x[1] + x[2]
sage: QSym.from_polynomial(f, check=True)
Traceback (most recent call last):
...
ValueError: x0 + 2*x1 + x2 is not a quasi-symmetric polynomial
sage: QSym.from_polynomial(f, check=False)
M[1]
```

```
>>> from sage.all import *
>>> f = x[Integer(0)] + Integer(2)*x[Integer(1)] + x[Integer(2)]
>>> QSym.from_polynomial(f, check=True)
Traceback (most recent call last):
...
ValueError: x0 + 2*x1 + x2 is not a quasi-symmetric polynomial
>>> QSym.from_polynomial(f, check=False)
M[1]
```

To expand the quasi-symmetric function in a basis other than the Monomial basis, the following shorthands are provided:

```
sage: M = QSym.Monomial()
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: g = M.from_polynomial(f); g
M[2]
sage: F = QSym.Fundamental()
sage: F(g)
-F[1, 1] + F[2]
sage: F.from_polynomial(f)
-F[1, 1] + F[2]
```

```
>>> from sage.all import *
>>> M = QSym.Monomial()
>>> f =␣
↪x[Integer(0)]**Integer(2)+x[Integer(1)]**Integer(2)+x[Integer(2)]**Integer(2)
>>> g = M.from_polynomial(f); g
M[2]
>>> F = QSym.Fundamental()
>>> F(g)
-F[1, 1] + F[2]
>>> F.from_polynomial(f)
-F[1, 1] + F[2]
```

class phi(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of quasi-symmetric functions in the ϕ basis.

The ϕ basis is defined as a rescaled Hopf dual of the Φ basis of the non-commutative symmetric functions (see Section 3.1 of [BDHMN2017]), where the pairing is

$$(\phi_I, \Phi_J) = z_I \delta_{I,J},$$

where $z_I = 1^{m_1} m_1! 2^{m_2} m_2! \cdots$ with m_i being the multiplicity of i in the composition I. Therefore, we call these the *quasi-symmetric power sums of the second kind*.

Using the duality, we can directly define the ϕ basis by

$$\phi_I = \sum_{J \succ I} z_I / sp_{I,J} M_J,$$

where $sp_{I,J}$ is as defined in [NCSF].

The ϕ-basis is well-defined only when the base ring is a $\mathbf{Q}$-algebra.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: phi = QSym.phi(); phi
Quasisymmetric functions over the Rational Field in the phi basis
sage: phi.an_element()
2*phi[] + 2*phi[1] + 3*phi[1, 1]
sage: p = SymmetricFunctions(QQ).p()
sage: phi(p[2,2,1])
phi[1, 2, 2] + phi[2, 1, 2] + phi[2, 2, 1]
sage: all(sum(phi(list(al)) for al in Permutations(la))==phi(p(la)) for la in␣
↪Partitions(6))
True
sage: p = SymmetricFunctions(QQ).p()
sage: phi(p[3,2,2])
phi[2, 2, 3] + phi[2, 3, 2] + phi[3, 2, 2]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> phi = QSym.phi(); phi
Quasisymmetric functions over the Rational Field in the phi basis
>>> phi.an_element()
2*phi[] + 2*phi[1] + 3*phi[1, 1]
>>> p = SymmetricFunctions(QQ).p()
>>> phi(p[Integer(2),Integer(2),Integer(1)])
phi[1, 2, 2] + phi[2, 1, 2] + phi[2, 2, 1]
>>> all(sum(phi(list(al)) for al in Permutations(la))==phi(p(la)) for la in␣
↪Partitions(Integer(6)))
True
>>> p = SymmetricFunctions(QQ).p()
>>> phi(p[Integer(3),Integer(2),Integer(2)])
phi[2, 2, 3] + phi[2, 3, 2] + phi[3, 2, 2]
```

Checking the equivalent definition of ϕ_n:

```
sage: def test_phi(n):
....:     phi = QuasiSymmetricFunctions(QQ).phi()
....:     Phi = NonCommutativeSymmetricFunctions(QQ).Phi()
....:     M = matrix([[phi[I].duality_pairing(Phi[J])
....:                  for I in Compositions(n)]
....:                 for J in Compositions(n)])
....:     def z(J): return J.to_partition().centralizer_size()
....:     return M == matrix.diagonal([z(I) for I in Compositions(n)])
sage: all(test_phi(k) for k in range(1,5))
True
```

```
>>> from sage.all import *
>>> def test_phi(n):
...     phi = QuasiSymmetricFunctions(QQ).phi()
...     Phi = NonCommutativeSymmetricFunctions(QQ).Phi()
...     M = matrix([[phi[I].duality_pairing(Phi[J])
...                  for I in Compositions(n)]
...                 for J in Compositions(n)])
...     def z(J): return J.to_partition().centralizer_size()
...     return M == matrix.diagonal([z(I) for I in Compositions(n)])
>>> all(test_phi(k) for k in range(Integer(1),Integer(5)))
True
```

class psi(*QSym*)

Bases: *CombinatorialFreeModule*, BindableClass

The Hopf algebra of quasi-symmetric functions in the ψ basis.

The ψ basis is defined as a rescaled Hopf dual of the Ψ basis of the non-commutative symmetric functions (see Section 3.1 of [BDHMN2017]), where the pairing is

$$(\psi_I, \Psi_J) = z_I \delta_{I,J},$$

where $z_I = 1^{m_1} m_1! 2^{m_2} m_2! \cdots$ with m_i being the multiplicity of i in the composition I. Therefore, we call these the *quasi-symmetric power sums of the first kind*.

Using the duality, we can directly define the ψ basis by

$$\psi_I = \sum_{J \succ I} z_I / \pi_{I,J} M_J,$$

where $\pi_{I,J}$ is as defined in [NCSF].

The ψ-basis is well-defined only when the base ring is a $\mathbf{Q}$-algebra.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: psi = QSym.psi(); psi
Quasisymmetric functions over the Rational Field in the psi basis
sage: psi.an_element()
2*psi[] + 2*psi[1] + 3*psi[1, 1]
sage: p = SymmetricFunctions(QQ).p()
sage: psi(p[2,2,1])
psi[1, 2, 2] + psi[2, 1, 2] + psi[2, 2, 1]
sage: all(sum(psi(list(al)) for al in Permutations(la))==psi(p(la)) for la in␣
```

(continues on next page)

(continued from previous page)

```
↪Partitions(6))
True
sage: p = SymmetricFunctions(QQ).p()
sage: psi(p[3,2,2])
psi[2, 2, 3] + psi[2, 3, 2] + psi[3, 2, 2]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> psi = QSym.psi(); psi
Quasisymmetric functions over the Rational Field in the psi basis
>>> psi.an_element()
2*psi[] + 2*psi[1] + 3*psi[1, 1]
>>> p = SymmetricFunctions(QQ).p()
>>> psi(p[Integer(2),Integer(2),Integer(1)])
psi[1, 2, 2] + psi[2, 1, 2] + psi[2, 2, 1]
>>> all(sum(psi(list(al)) for al in Permutations(la))==psi(p(la)) for la in␣
↪Partitions(Integer(6)))
True
>>> p = SymmetricFunctions(QQ).p()
>>> psi(p[Integer(3),Integer(2),Integer(2)])
psi[2, 2, 3] + psi[2, 3, 2] + psi[3, 2, 2]
```

Checking the equivalent definition of ψ_n:

```
sage: def test_psi(n):
....:     psi = QuasiSymmetricFunctions(QQ).psi()
....:     Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
....:     M = matrix([[psi[I].duality_pairing(Psi[J])
....:                  for I in Compositions(n)]
....:                 for J in Compositions(n)])
....:     def z(J): return J.to_partition().centralizer_size()
....:     return M == matrix.diagonal([z(I) for I in Compositions(n)])
sage: all(test_psi(k) for k in range(1,5))
True
```

```
>>> from sage.all import *
>>> def test_psi(n):
...     psi = QuasiSymmetricFunctions(QQ).psi()
...     Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
...     M = matrix([[psi[I].duality_pairing(Psi[J])
...                  for I in Compositions(n)]
...                 for J in Compositions(n)])
...     def z(J): return J.to_partition().centralizer_size()
...     return M == matrix.diagonal([z(I) for I in Compositions(n)])
>>> all(test_psi(k) for k in range(Integer(1),Integer(5)))
True
```

4.1.9 sage.combinat.ncsym

Bases for NCSym

AUTHORS:

- Travis Scrimshaw (08-04-2013): initial version

class sage.combinat.ncsym.bases.**MultiplicativeNCSymBases**(*parent_with_realization*)

Bases: Category_realization_of_parent

Category of multiplicative bases of symmetric functions in non-commuting variables.

A multiplicative basis is one for which $\mathbf{b}_A \mathbf{b}_B = \mathbf{b}_{A|B}$ where $A|B$ is the *pipe()* operation on set partitions.

EXAMPLES:

```
sage: from sage.combinat.ncsym.bases import MultiplicativeNCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: MultiplicativeNCSymBases(NCSym)
Category of multiplicative bases of symmetric functions in non-commuting␣
↪variables over the Rational Field
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsym.bases import MultiplicativeNCSymBases
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> MultiplicativeNCSymBases(NCSym)
Category of multiplicative bases of symmetric functions in non-commuting␣
↪variables over the Rational Field
```

class ElementMethods

Bases: object

class ParentMethods

Bases: object

product_on_basis(*A*, *B*)

The product on basis elements.

The product on a multiplicative basis is given by $\mathbf{b}_A \cdot \mathbf{b}_B = \mathbf{b}_{A|B}$.

The bases $\{\mathbf{e}, \mathbf{h}, \mathbf{x}, \mathbf{cp}, \mathbf{p}, \mathbf{chi}, \mathbf{rho}\}$ are all multiplicative.

INPUT:

- A, B – set partitions

OUTPUT: an element in the basis self

EXAMPLES:

```
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: chi = SymmetricFunctionsNonCommutingVariables(QQ).chi()
sage: rho = SymmetricFunctionsNonCommutingVariables(QQ).rho()
sage: A = SetPartition([[1], [2, 3]])
sage: B = SetPartition([[1], [3], [2,4]])
sage: e.product_on_basis(A, B)
```

True
```

super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT: list of categories

class sage.combinat.ncsym.bases.**NCSymBases**(*parent_with_realization*)

Bases: Category_realization_of_parent

Category of bases of symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: from sage.combinat.ncsym.bases import NCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: NCSymBases(NCSym)
Category of bases of symmetric functions in non-commuting variables over the␣
↪Rational Field
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsym.bases import NCSymBases
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> NCSymBases(NCSym)
Category of bases of symmetric functions in non-commuting variables over the␣
↪Rational Field
```

class ElementMethods

Bases: object

expand(*n*, *alphabet='x'*)

Expand the symmetric function into n non-commuting variables in an alphabet, which by default is 'x'.

This computation is completed by coercing the element self into the monomial basis and computing the expansion in the alphabet there.

INPUT:

- n – the number of variables in the expansion
- alphabet – (default: 'x') the alphabet in which self is to be expanded

OUTPUT:

- an expansion of self into the n non-commuting variables specified by alphabet

EXAMPLES:

```
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].expand(3)
2*x0^3 + x0^2*x1 + x0^2*x2 + 2*x0*x1*x0 + x0*x1^2 + x0*x1*x2 + 2*x0*x2*x0
 + x0*x2*x1 + x0*x2^2 + x1*x0^2 + 2*x1*x0*x1 + x1*x0*x2 + x1^2*x0 + 2*x1^3
 + x1^2*x2 + x1*x2*x0 + 2*x1*x2*x1 + x1*x2^2 + x2*x0^2 + x2*x0*x1 +␣
↪2*x2*x0*x2
```

(continues on next page)

(continued from previous page)

```
 + x2*x1*x0 + x2*x1^2 + 2*x2*x1*x2 + x2^2*x0 + x2^2*x1 + 2*x2^3
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1,3],[2]].expand(3)
-x0^2*x1 - x0^2*x2 - x0*x1^2 - x0*x1*x2 - x0*x2*x1 - x0*x2^2 - x1*x0^2
 - x1*x0*x2 - x1^2*x0 - x1^2*x2 - x1*x2*x0 - x1*x2^2 - x2*x0^2 - x2*x0*x1
 - x2*x1*x0 - x2*x1^2 - x2^2*x0 - x2^2*x1
```

```
>>> from sage.all import *
>>> h = SymmetricFunctionsNonCommutingVariables(QQ).h()
>>> h[[Integer(1),Integer(3)],[Integer(2)]].expand(Integer(3))
2*x0^3 + x0^2*x1 + x0^2*x2 + 2*x0*x1*x0 + x0*x1^2 + x0*x1*x2 + 2*x0*x2*x0
 + x0*x2*x1 + x0*x2^2 + x1*x0^2 + 2*x1*x0*x1 + x1*x0*x2 + x1^2*x0 + 2*x1^3
 + x1^2*x2 + x1*x2*x0 + 2*x1*x2*x1 + x1*x2^2 + x2*x0^2 + x2*x0*x1 +␣
↪2*x2*x0*x2
 + x2*x1*x0 + x2*x1^2 + 2*x2*x1*x2 + x2^2*x0 + x2^2*x1 + 2*x2^3
>>> x = SymmetricFunctionsNonCommutingVariables(QQ).x()
>>> x[[Integer(1),Integer(3)],[Integer(2)]].expand(Integer(3))
-x0^2*x1 - x0^2*x2 - x0*x1^2 - x0*x1*x2 - x0*x2*x1 - x0*x2^2 - x1*x0^2
 - x1*x0*x2 - x1^2*x0 - x1^2*x2 - x1*x2*x0 - x1*x2^2 - x2*x0^2 - x2*x0*x1
 - x2*x1*x0 - x2*x1^2 - x2^2*x0 - x2^2*x1
```

internal_coproduct()

Return the internal coproduct of `self`.

The internal coproduct is defined on the power sum basis as

$$\mathbf{p}_A \mapsto \mathbf{p}_A \otimes \mathbf{p}_A$$

and the map is extended linearly.

OUTPUT: an element of the tensor square of the basis of `self`

EXAMPLES:

```
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1,3],[2]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 3}, {2}} + x{{1, 3}, {2}} # x{{1}, {2}, {3}}
 + x{{1, 3}, {2}} # x{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> x = SymmetricFunctionsNonCommutingVariables(QQ).x()
>>> x[[Integer(1),Integer(3)],[Integer(2)]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 3}, {2}} + x{{1, 3}, {2}} # x{{1}, {2}, {3}}
 + x{{1, 3}, {2}} # x{{1, 3}, {2}}
```

omega()

Return the involution ω applied to `self`.

The involution ω is defined by

$$\mathbf{e}_A \mapsto \mathbf{h}_A$$

and the result is extended linearly.

OUTPUT: an element in the same basis as `self`

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]].omega()
-2*m{{1, 2, 3}} - m{{1, 3}, {2}}
sage: p = NCSym.p()
sage: p[[1,3],[2]].omega()
-p{{1, 3}, {2}}
sage: cp = NCSym.cp()
sage: cp[[1,3],[2]].omega()
-2*cp{{1, 2, 3}} - cp{{1, 3}, {2}}
sage: x = NCSym.x()
sage: x[[1,3],[2]].omega()
-2*x{{1}, {2}, {3}} - x{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> m[[Integer(1),Integer(3)],[Integer(2)]].omega()
-2*m{{1, 2, 3}} - m{{1, 3}, {2}}
>>> p = NCSym.p()
>>> p[[Integer(1),Integer(3)],[Integer(2)]].omega()
-p{{1, 3}, {2}}
>>> cp = NCSym.cp()
>>> cp[[Integer(1),Integer(3)],[Integer(2)]].omega()
-2*cp{{1, 2, 3}} - cp{{1, 3}, {2}}
>>> x = NCSym.x()
>>> x[[Integer(1),Integer(3)],[Integer(2)]].omega()
-2*x{{1}, {2}, {3}} - x{{1, 3}, {2}}
```

to_symmetric_function()

Compute the projection of an element of symmetric function in non-commuting variables to the symmetric functions.

The projection of a monomial symmetric function in non-commuting variables indexed by the set partition `A` is defined as

$$\mathbf{m}_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts and $n_i(\mu)$ is the multiplicity of i in μ. For other bases this map is extended linearly.

OUTPUT: an element of the symmetric functions in the monomial basis

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: cp = NCSym.cp()
sage: x = NCSym.x()
sage: cp[[1,3],[2]].to_symmetric_function()
m[2, 1]
sage: x[[1,3],[2]].to_symmetric_function()
```

(continues on next page)

(continued from previous page)

```
-6*m[1, 1, 1] - 2*m[2, 1]
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
sage: p[[1,3],[2]].to_symmetric_function()
p[2, 1]
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> e = NCSym.e()
>>> h = NCSym.h()
>>> p = NCSym.p()
>>> cp = NCSym.cp()
>>> x = NCSym.x()
>>> cp[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
m[2, 1]
>>> x[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
-6*m[1, 1, 1] - 2*m[2, 1]
>>> e[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
2*e[2, 1]
>>> h[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
2*h[2, 1]
>>> p[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
p[2, 1]
```

to_wqsym()

Return the image of `self` under the canonical inclusion map $NCSym \to WQSym$.

The canonical inclusion map $NCSym \to WQSym$ is an injective homomorphism of algebras. It sends a basis element $\mathbf{m}_A$ of $NCSym$ to the sum of basis elements $\mathbf{M}_P$ of $WQSym$, where P ranges over all ordered set partitions that become A when the ordering is forgotten. This map is denoted by θ in [BZ05] (17).

See also

WordQuasiSymmetricFunctions for a definition of $WQSym$.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: cp = NCSym.cp()
sage: x = NCSym.x()
sage: m = NCSym.m()
sage: m[[1,3],[2]].to_wqsym()
M[{1, 3}, {2}] + M[{2}, {1, 3}]
sage: x[[1,3],[2]].to_wqsym()
-M[{1}, {2}, {3}] - M[{1}, {2, 3}] - M[{1}, {3}, {2}]
```

(continues on next page)

(continued from previous page)

```
 - M[{1, 2}, {3}] - M[{2}, {1}, {3}] - M[{2}, {3}, {1}]
 - M[{2, 3}, {1}] - M[{3}, {1}, {2}] - M[{3}, {1, 2}]
 - M[{3}, {2}, {1}]
sage: (4*p[[1,3],[2]]-p[[1]]).to_wqsym()
-M[{1}] + 4*M[{1, 2, 3}] + 4*M[{1, 3}, {2}] + 4*M[{2}, {1, 3}]
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> e = NCSym.e()
>>> h = NCSym.h()
>>> p = NCSym.p()
>>> cp = NCSym.cp()
>>> x = NCSym.x()
>>> m = NCSym.m()
>>> m[[Integer(1),Integer(3)],[Integer(2)]].to_wqsym()
M[{1, 3}, {2}] + M[{2}, {1, 3}]
>>> x[[Integer(1),Integer(3)],[Integer(2)]].to_wqsym()
-M[{1}, {2}, {3}] - M[{1}, {2, 3}] - M[{1}, {3}, {2}]
 - M[{1, 2}, {3}] - M[{2}, {1}, {3}] - M[{2}, {3}, {1}]
 - M[{2, 3}, {1}] - M[{3}, {1}, {2}] - M[{3}, {1, 2}]
 - M[{3}, {2}, {1}]
>>> (Integer(4)*p[[Integer(1),Integer(3)],[Integer(2)]]-p[[Integer(1)]]).
↪to_wqsym()
-M[{1}] + 4*M[{1, 2, 3}] + 4*M[{1, 3}, {2}] + 4*M[{2}, {1, 3}]
```

class ParentMethods

Bases: object

from_symmetric_function(*f*)

Return the image of the symmetric function `f` in `self`.

This is performed by converting to the monomial basis and extending the method *sum_of_partitions()* linearly. This is a linear map from the symmetric functions to the symmetric functions in non-commuting variables that does not preserve the product or coproduct structure of the Hopf algebra.

See also

to_symmetric_function()

INPUT:

- `f` – a symmetric function

OUTPUT: an element of `self`

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: Sym = SymmetricFunctions(QQ)
sage: e = NCSym.e()
sage: elem = Sym.e()
sage: elt = e.from_symmetric_function(elem[2,1,1]); elt
1/12*e{{1}, {2}, {3, 4}} + 1/12*e{{1}, {2, 3}, {4}} + 1/12*e{{1}, {2, 4},
↪{3}}
```

(continues on next page)

(continued from previous page)

```
 + 1/12*e{{1, 2}, {3}, {4}} + 1/12*e{{1, 3}, {2}, {4}} + 1/12*e{{1, 4},
↪{2}, {3}}
sage: elem(elt.to_symmetric_function())
e[2, 1, 1]
sage: e.from_symmetric_function(elem[4])
1/24*e{{1, 2, 3, 4}}
sage: p = NCSym.p()
sage: pow = Sym.p()
sage: elt = p.from_symmetric_function(pow[2,1,1]); elt
1/6*p{{1}, {2}, {3, 4}} + 1/6*p{{1}, {2, 3}, {4}} + 1/6*p{{1}, {2, 4}, {3}
↪}
 + 1/6*p{{1, 2}, {3}, {4}} + 1/6*p{{1, 3}, {2}, {4}} + 1/6*p{{1, 4}, {2},
↪{3}}
sage: pow(elt.to_symmetric_function())
p[2, 1, 1]
sage: p.from_symmetric_function(pow[4])
p{{1, 2, 3, 4}}
sage: h = NCSym.h()
sage: comp = Sym.complete()
sage: elt = h.from_symmetric_function(comp[2,1,1]); elt
1/12*h{{1}, {2}, {3, 4}} + 1/12*h{{1}, {2, 3}, {4}} + 1/12*h{{1}, {2, 4},
↪{3}}
 + 1/12*h{{1, 2}, {3}, {4}} + 1/12*h{{1, 3}, {2}, {4}} + 1/12*h{{1, 4},
↪{2}, {3}}
sage: comp(elt.to_symmetric_function())
h[2, 1, 1]

>>> elt = p.from_symmetric_function(pow[Integer(2),Integer(1),
↪Integer(1)]); elt
1/6*p{{1}, {2}, {3, 4}} + 1/6*p{{1}, {2, 3}, {4}} + 1/6*p{{1}, {2, 4}, {3}
↪}
 + 1/6*p{{1, 2}, {3}, {4}} + 1/6*p{{1, 3}, {2}, {4}} + 1/6*p{{1, 4}, {2},
↪{3}}
```

(continues on next page)

(continued from previous page)

```
>>> pow(elt.to_symmetric_function())
p[2, 1, 1]
>>> p.from_symmetric_function(pow[Integer(4)])
p{{1, 2, 3, 4}}
>>> h = NCSym.h()
>>> comp = Sym.complete()
>>> elt = h.from_symmetric_function(comp[Integer(2),Integer(1),
↪Integer(1)]); elt
1/12*h{{1}, {2}, {3, 4}} + 1/12*h{{1}, {2, 3}, {4}} + 1/12*h{{1}, {2, 4},
↪{3}}
 + 1/12*h{{1, 2}, {3}, {4}} + 1/12*h{{1, 3}, {2}, {4}} + 1/12*h{{1, 4},
↪{2}, {3}}
>>> comp(elt.to_symmetric_function())
h[2, 1, 1]
>>> h.from_symmetric_function(comp[Integer(4)])
1/24*h{{1, 2, 3, 4}}
```

internal_coproduct()

Compute the internal coproduct of `self`.

If *internal_coproduct_on_basis()* is available, construct the internal coproduct morphism from `self` to `self` ⊗ `self` by extending it by linearity. Otherwise, this uses *internal_coproduct_by_coercion()*, if available.

OUTPUT: an element of the tensor squared of `self`

EXAMPLES:

```
sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
sage: cp.internal_coproduct(cp[[1,3],[2]] - 2*cp[[1]])
-2*cp{{1}} # cp{{1}} + cp{{1, 2, 3}} # cp{{1, 3}, {2}} + cp{{1, 3}, {2}}
↪# cp{{1, 2, 3}}
 + cp{{1, 3}, {2}} # cp{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
>>> cp.internal_coproduct(cp[[Integer(1),Integer(3)],[Integer(2)]] -␣
↪Integer(2)*cp[[Integer(1)]])
-2*cp{{1}} # cp{{1}} + cp{{1, 2, 3}} # cp{{1, 3}, {2}} + cp{{1, 3}, {2}}
↪# cp{{1, 2, 3}}
 + cp{{1, 3}, {2}} # cp{{1, 3}, {2}}
```

internal_coproduct_by_coercion(*x*)

Return the internal coproduct by coercing the element to the powersum basis.

INPUT:

- `x` – an element of `self`

OUTPUT: an element of the tensor squared of `self`

EXAMPLES:

```
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].internal_coproduct() # indirect doctest
2*h{{1}, {2}, {3}} # h{{1}, {2}, {3}} - h{{1}, {2}, {3}} # h{{1, 3}, {2}}
 - h{{1, 3}, {2}} # h{{1}, {2}, {3}} + h{{1, 3}, {2}} # h{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> h = SymmetricFunctionsNonCommutingVariables(QQ).h()
>>> h[[Integer(1),Integer(3)],[Integer(2)]].internal_coproduct() #␣
↪indirect doctest
2*h{{1}, {2}, {3}} # h{{1}, {2}, {3}} - h{{1}, {2}, {3}} # h{{1, 3}, {2}}
 - h{{1, 3}, {2}} # h{{1}, {2}, {3}} + h{{1, 3}, {2}} # h{{1, 3}, {2}}
```

internal_coproduct_on_basis(*i*)

The internal coproduct of the algebra on the basis (optional).

INPUT:

- `i` – the indices of an element of the basis of `self`

OUTPUT: an element of the tensor squared of `self`

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.internal_coproduct_on_basis(SetPartition([[1,2]]))
m{{1, 2}} # m{{1, 2}}
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).m()
>>> m.internal_coproduct_on_basis(SetPartition([[Integer(1),Integer(2)]]))
m{{1, 2}} # m{{1, 2}}
```

primitive(*A*, *i=1*)

Return the primitive associated to `A` in `self`.

See also

primitive()

INPUT:

- `A` – set partition
- `i` – positive integer

OUTPUT: an element of `self`

EXAMPLES:

```
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: elt = e.primitive(SetPartition([[1,3],[2]])); elt
e{{1, 2}, {3}} - e{{1, 3}, {2}}
sage: elt.coproduct()
e{} # e{{1, 2}, {3}} - e{} # e{{1, 3}, {2}} + e{{1, 2}, {3}} # e{} - e{{1,
↪ 3}, {2}} # e{}
```

```
>>> from sage.all import *
>>> e = SymmetricFunctionsNonCommutingVariables(QQ).e()
>>> elt = e.primitive(SetPartition([[Integer(1),Integer(3)],
↪[Integer(2)]])); elt
e{{1, 2}, {3}} - e{{1, 3}, {2}}
>>> elt.coproduct()
```

(continues on next page)

(continued from previous page)

```
e{} # e{{1, 2}, {3}} - e{} # e{{1, 3}, {2}} + e{{1, 2}, {3}} # e{} - e{{1,
↪ 3}, {2}} # e{}
```

super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT: list of categories

class sage.combinat.ncsym.bases.**NCSymBasis_abstract**(*R*, *basis_keys=None*, *element_class=None*, *category=None*, *prefix=None*, *names=None*, ***kwds*)

Bases: *CombinatorialFreeModule*, BindableClass

Abstract base class for a basis of $NCSym$ or its dual.

class sage.combinat.ncsym.bases.**NCSymDualBases**(*parent_with_realization*)

Bases: Category_realization_of_parent

Category of bases of dual symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: from sage.combinat.ncsym.bases import NCSymDualBases
sage: DNCSym = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymDualBases(DNCSym)
Category of bases of dual symmetric functions in non-commuting variables over the␣
↪Rational Field
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsym.bases import NCSymDualBases
>>> DNCSym = SymmetricFunctionsNonCommutingVariables(QQ).dual()
>>> NCSymDualBases(DNCSym)
Category of bases of dual symmetric functions in non-commuting variables over the␣
↪Rational Field
```

super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT: list of categories

class sage.combinat.ncsym.bases.**NCSymOrNCSymDualBases**(*parent_with_realization*)

Bases: Category_realization_of_parent

Base category for the category of bases of symmetric functions in non-commuting variables or its Hopf dual for the common code.

class ElementMethods

Bases: object

duality_pairing(*other*)

Compute the pairing between `self` and an element `other` of the dual.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
```

(continues on next page)

(continued from previous page)

```
sage: w = m.dual_basis()
sage: elt = m[[1,3],[2]] - 3*m[[1,2],[3]]
sage: elt.duality_pairing(w[[1,3],[2]])
1
sage: elt.duality_pairing(w[[1,2],[3]])
-3
sage: elt.duality_pairing(w[[1,2]])
0
sage: e = NCSym.e()
sage: w[[1,3],[2]].duality_pairing(e[[1,3],[2]])
0
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> w = m.dual_basis()
>>> elt = m[[Integer(1),Integer(3)],[Integer(2)]] -␣
↪Integer(3)*m[[Integer(1),Integer(2)],[Integer(3)]]
>>> elt.duality_pairing(w[[Integer(1),Integer(3)],[Integer(2)]])
1
>>> elt.duality_pairing(w[[Integer(1),Integer(2)],[Integer(3)]])
-3
>>> elt.duality_pairing(w[[Integer(1),Integer(2)]])
0
>>> e = NCSym.e()
>>> w[[Integer(1),Integer(3)],[Integer(2)]].duality_pairing(e[[Integer(1),
↪Integer(3)],[Integer(2)]])
0
```

class ParentMethods

Bases: object

counit_on_basis(*A*)

The counit is defined by sending all elements of positive degree to zero.

INPUT:

- A – set partition

OUTPUT: either the 0 or the 1 of the base ring of self

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: m.counit_on_basis(SetPartition([]))
1
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: w.counit_on_basis(SetPartition([]))
1
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).m()
>>> m.counit_on_basis(SetPartition([[Integer(1),Integer(3)],␣
↪[Integer(2)]]))
0
>>> m.counit_on_basis(SetPartition([]))
1
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> w.counit_on_basis(SetPartition([[Integer(1),Integer(3)],␣
↪[Integer(2)]]))
0
>>> w.counit_on_basis(SetPartition([]))
1
```

duality_pairing(*x*, *y*)

Compute the pairing between an element of `self` and an element of the dual.

Carry out this computation by converting `x` to the **m** basis and `y` to the **w** basis.

INPUT:

- `x` – an element of symmetric functions in non-commuting variables
- `y` – an element of the dual of symmetric functions in non-commuting variables

OUTPUT: an element of the base ring of `self`

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: w = NCSym.m().dual_basis()
sage: matrix([[h(A).duality_pairing(w(B)) for A in SetPartitions(3)] for␣
↪B in SetPartitions(3)])
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
[2 1 1 2 1]
[1 1 1 1 1]
sage: (h[[1,2],[3]] + 3*h[[1,3],[2]]).duality_pairing(2*w[[1,3],[2]] +␣
↪w[[1,2,3]] + 2*w[[1,2],[3]])
32
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> h = NCSym.h()
>>> w = NCSym.m().dual_basis()
>>> matrix([[h(A).duality_pairing(w(B)) for A in␣
↪SetPartitions(Integer(3))] for B in SetPartitions(Integer(3))])
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
[2 1 1 2 1]
[1 1 1 1 1]
>>> (h[[Integer(1),Integer(2)],[Integer(3)]] + Integer(3)*h[[Integer(1),
↪Integer(3)],[Integer(2)]]).duality_pairing(Integer(2)*w[[Integer(1),
↪Integer(3)],[Integer(2)]] + w[[Integer(1),Integer(2),Integer(3)]] +␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(2)*w[[Integer(1),Integer(2)],[Integer(3)]])
32
```

duality_pairing_matrix(*basis*, *degree*)

The matrix of scalar products between elements of $NCSym$ and elements of $NCSym^*$.

INPUT:

- `basis` – a basis of the dual Hopf algebra
- `degree` – nonnegative integer

OUTPUT:

The matrix of scalar products between the basis `self` and the basis `basis` in the dual Hopf algebra of degree `degree`.

EXAMPLES:

The matrix between the **m** basis and the **w** basis:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = NCSym.dual().w()
sage: m.duality_pairing_matrix(w, 3)
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> w = NCSym.dual().w()
>>> m.duality_pairing_matrix(w, Integer(3))
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

Similarly for some of the other basis of $NCSym$ and the **w** basis:

```
sage: e = NCSym.e()
sage: e.duality_pairing_matrix(w, 3)
[0 0 0 0 1]
[0 0 1 1 1]
[0 1 0 1 1]
[0 1 1 0 1]
[1 1 1 1 1]
sage: p = NCSym.p()
sage: p.duality_pairing_matrix(w, 3)
[1 0 0 0 0]
[1 1 0 0 0]
[1 0 1 0 0]
[1 0 0 1 0]
```

(continues on next page)

(continued from previous page)

```
[1 1 1 1 1]
sage: cp = NCSym.cp()
sage: cp.duality_pairing_matrix(w, 3)
[1 0 0 0 0]
[1 1 0 0 0]
[0 0 1 0 0]
[1 0 0 1 0]
[1 1 1 1 1]
sage: x = NCSym.x()
sage: w.duality_pairing_matrix(x, 3)
[ 0  0  0  0  1]
[ 1  0 -1 -1  1]
[ 1 -1  0 -1  1]
[ 1 -1 -1  0  1]
[ 2 -1 -1 -1  1]
```

```
>>> from sage.all import *
>>> e = NCSym.e()
>>> e.duality_pairing_matrix(w, Integer(3))
[0 0 0 0 1]
[0 0 1 1 1]
[0 1 0 1 1]
[0 1 1 0 1]
[1 1 1 1 1]
>>> p = NCSym.p()
>>> p.duality_pairing_matrix(w, Integer(3))
[1 0 0 0 0]
[1 1 0 0 0]
[1 0 1 0 0]
[1 0 0 1 0]
[1 1 1 1 1]
>>> cp = NCSym.cp()
>>> cp.duality_pairing_matrix(w, Integer(3))
[1 0 0 0 0]
[1 1 0 0 0]
[0 0 1 0 0]
[1 0 0 1 0]
[1 1 1 1 1]
>>> x = NCSym.x()
>>> w.duality_pairing_matrix(x, Integer(3))
[ 0  0  0  0  1]
[ 1  0 -1 -1  1]
[ 1 -1  0 -1  1]
[ 1 -1 -1  0  1]
[ 2 -1 -1 -1  1]
```

A base case test:

```
sage: m.duality_pairing_matrix(w, 0)
[1]
```

```
>>> from sage.all import *
>>> m.duality_pairing_matrix(w, Integer(0))
[1]
```

one_basis()

Return the index of the basis element containing 1.

OUTPUT: the empty set partition

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.one_basis()
{}
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.one_basis()
{}
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).m()
>>> m.one_basis()
{}
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> w.one_basis()
{}
```

super_categories()

Return the super categories of bases of (the Hopf dual of) the symmetric functions in non-commuting variables.

OUTPUT: list of categories

Dual symmetric functions in non-commuting variables

AUTHORS:

class sage.combinat.ncsym.dual.**SymmetricFunctionsNonCommutingVariablesDual**(R)

Bases: UniqueRepresentation, Parent

The Hopf dual to the symmetric functions in non-commuting variables.

See Section 2.3 of [BZ05] for a study.

a_realization()

Return the realization of the **w** basis of self.

EXAMPLES:

```
sage: SymmetricFunctionsNonCommutingVariables(QQ).dual().a_realization()
Dual symmetric functions in non-commuting variables over the Rational Field␣
↪in the w basis
```

```
>>> from sage.all import *
>>> SymmetricFunctionsNonCommutingVariables(QQ).dual().a_realization()
```

(continues on next page)

(continued from previous page)

```
Dual symmetric functions in non-commuting variables over the Rational Field␣
↪in the w basis
```

dual()

Return the dual Hopf algebra of the dual symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymD.dual()
Symmetric functions in non-commuting variables over the Rational Field
```

```
>>> from sage.all import *
>>> NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
>>> NCSymD.dual()
Symmetric functions in non-commuting variables over the Rational Field
```

class w(*NCSymD*)

Bases: *NCSymBasis_abstract*

The dual Hopf algebra of symmetric functions in non-commuting variables in the **w** basis.

EXAMPLES:

```
sage: NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: w = NCSymD.w()
```

```
>>> from sage.all import *
>>> NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
>>> w = NCSymD.w()
```

We have the embedding χ^* of Sym into $NCSym^*$ available as a coercion:

```
sage: h = SymmetricFunctions(QQ).h()
sage: w(h[2,1])
w{{1}, {2, 3}} + w{{1, 2}, {3}} + w{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> w(h[Integer(2),Integer(1)])
w{{1}, {2, 3}} + w{{1, 2}, {3}} + w{{1, 3}, {2}}
```

Similarly we can pull back when we are in the image of χ^*:

```
sage: elt = 3*(w[[1],[2,3]] + w[[1,2],[3]] + w[[1,3],[2]])
sage: h(elt)
3*h[2, 1]
```

```
>>> from sage.all import *
>>> elt = Integer(3)*(w[[Integer(1)],[Integer(2),Integer(3)]] + w[[Integer(1),
↪Integer(2)],[Integer(3)]] + w[[Integer(1),Integer(3)],[Integer(2)]])
>>> h(elt)
3*h[2, 1]
```

class Element

Bases: IndexedFreeModuleElement

An element in the **w** basis.

expand(*n*, *letter='x'*)

Expand `self` written in the **w** basis in n^2 commuting variables which satisfy the relation $x_{ij}x_{ik} = 0$ for all i, j, and k.

The expansion of an element of the **w** basis is given by equations (26) and (55) in [HNT06].

INPUT:
- `n` – integer
- `letter` – string (default: `'x'`)

OUTPUT:
- The symmetric function of `self` expressed in the `n*n` non-commuting variables described by `letter`.

REFERENCES:

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1,3],[2]].expand(4)
x02*x11*x20 + x03*x11*x30 + x03*x22*x30 + x13*x22*x31
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> w[[Integer(1),Integer(3)],[Integer(2)]].expand(Integer(4))
x02*x11*x20 + x03*x11*x30 + x03*x22*x30 + x13*x22*x31
```

One can use a different set of variable by using the optional argument `letter`:

```
sage: w[[1,3],[2]].expand(3, letter='y')
y02*y11*y20
```

```
>>> from sage.all import *
>>> w[[Integer(1),Integer(3)],[Integer(2)]].expand(Integer(3), letter=
↪'y')
y02*y11*y20
```

is_symmetric()

Determine if a $NCSym^*$ function, expressed in the **w** basis, is symmetric.

A function f in the **w** basis is a symmetric function if it is in the image of χ^*. That is to say we have

$$f = \sum_{\lambda} c_\lambda \prod_i m_i(\lambda)! \sum_{\lambda(A)=\lambda} \mathbf{w}_A$$

where the second sum is over all set partitions A whose shape $\lambda(A)$ is equal to λ and $m_i(\mu)$ is the multiplicity of i in the partition μ.

OUTPUT:
- `True` if $\lambda(A) = \lambda(B)$ implies the coefficients of $\mathbf{w}_A$ and $\mathbf{w}_B$ are equal, `False` otherwise

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1])
sage: elt.is_symmetric()
True
sage: elt -= 3*w.sum_of_partitions([1,1])
sage: elt.is_symmetric()
True
sage: w = SymmetricFunctionsNonCommutingVariables(ZZ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.is_symmetric()
False
sage: elt = w[[1,3],[2]]
sage: elt.is_symmetric()
False
sage: elt = w[[1],[2,3]] + w[[1,2],[3]] + 2*w[[1,3],[2]]
sage: elt.is_symmetric()
False
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> elt = w.sum_of_partitions([Integer(2),Integer(1),Integer(1)])
>>> elt.is_symmetric()
True
>>> elt -= Integer(3)*w.sum_of_partitions([Integer(1),Integer(1)])
>>> elt.is_symmetric()
True
>>> w = SymmetricFunctionsNonCommutingVariables(ZZ).dual().w()
>>> elt = w.sum_of_partitions([Integer(2),Integer(1),Integer(1)]) /␣
↪Integer(2)
>>> elt.is_symmetric()
False
>>> elt = w[[Integer(1),Integer(3)],[Integer(2)]]
>>> elt.is_symmetric()
False
>>> elt = w[[Integer(1)],[Integer(2),Integer(3)]] + w[[Integer(1),
↪Integer(2)],[Integer(3)]] + Integer(2)*w[[Integer(1),Integer(3)],
↪[Integer(2)]]
>>> elt.is_symmetric()
False
```

to_symmetric_function()

Take a function in the **w** basis, and return its symmetric realization, when possible, expressed in the homogeneous basis of symmetric functions.

OUTPUT:

- If `self` is a symmetric function, then the expansion in the homogeneous basis of the symmetric functions is returned. Otherwise an error is raised.

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w[[1],[2,3]] + w[[1,2],[3]] + w[[1,3],[2]]
sage: elt.to_symmetric_function()
h[2, 1]
```

(continues on next page)

(continued from previous page)

```
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.to_symmetric_function()
1/2*h[2, 1, 1]
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> elt = w[[Integer(1)],[Integer(2),Integer(3)]] + w[[Integer(1),
↪Integer(2)],[Integer(3)]] + w[[Integer(1),Integer(3)],[Integer(2)]]
>>> elt.to_symmetric_function()
h[2, 1]
>>> elt = w.sum_of_partitions([Integer(2),Integer(1),Integer(1)]) /␣
↪Integer(2)
>>> elt.to_symmetric_function()
1/2*h[2, 1, 1]
```

antipode_on_basis(*A*)

Return the antipode applied to the basis element indexed by `A`.

INPUT:

- `A` – set partition

OUTPUT: an element in the basis `self`

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.antipode_on_basis(SetPartition([[1],[2,3]]))
-3*w{{1}, {2}, {3}} + w{{1, 2}, {3}} + w{{1, 3}, {2}}
sage: F = w[[1,3],[5],[2,4]].coproduct()
sage: F.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> w.antipode_on_basis(SetPartition([[Integer(1)],[Integer(2),
↪Integer(3)]]))
-3*w{{1}, {2}, {3}} + w{{1, 2}, {3}} + w{{1, 3}, {2}}
>>> F = w[[Integer(1),Integer(3)],[Integer(5)],[Integer(2),Integer(4)]].
↪coproduct()
>>> F.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

coproduct_on_basis(*A*)

Return the coproduct of a **w** basis element.

The coproduct on the basis element $\mathbf{w}_A$ is the sum over tensor product terms $\mathbf{w}_B \otimes \mathbf{w}_C$ where B is the restriction of A to $\{1, 2, \ldots, k\}$ and C is the restriction of A to $\{k+1, k+2, \ldots, n\}$.

INPUT:

- `A` – set partition

OUTPUT:

- The coproduct applied to the **w** dual symmetric function in non-commuting variables indexed by `A` expressed in the **w** basis.

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1], [2,3]].coproduct()
w{} # w{{1}, {2, 3}} + w{{1}} # w{{1, 2}}
 + w{{1}, {2}} # w{{1}} + w{{1}, {2, 3}} # w{}
sage: w.coproduct_on_basis(SetPartition([]))
w{} # w{}
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> w[[Integer(1)], [Integer(2),Integer(3)]].coproduct()
w{} # w{{1}, {2, 3}} + w{{1}} # w{{1, 2}}
 + w{{1}, {2}} # w{{1}} + w{{1}, {2, 3}} # w{}
>>> w.coproduct_on_basis(SetPartition([]))
w{} # w{}
```

dual_basis()

Return the dual basis to the **w** basis.

The dual basis to the **w** basis is the monomial basis of the symmetric functions in non-commuting variables.

OUTPUT: the monomial basis of the symmetric functions in non-commuting variables

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.dual_basis()
Symmetric functions in non-commuting variables over the Rational Field in␣
↪the monomial basis
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> w.dual_basis()
Symmetric functions in non-commuting variables over the Rational Field in␣
↪the monomial basis
```

duality_pairing(x, y)

Compute the pairing between an element of `self` and an element of the dual.

INPUT:

- `x` – an element of the dual of symmetric functions in non-commuting variables
- `y` – an element of the symmetric functions in non-commuting variables

OUTPUT: an element of the base ring of `self`

EXAMPLES:

```
sage: DNCSym = SymmetricFunctionsNonCommutingVariablesDual(QQ)
sage: w = DNCSym.w()
sage: m = w.dual_basis()
sage: matrix([[w(A).duality_pairing(m(B)) for A in SetPartitions(3)] for␣
↪B in SetPartitions(3)])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
```

(continues on next page)

(continued from previous page)

```
[0 0 0 1 0]
[0 0 0 0 1]
sage: (w[[1,2],[3]] + 3*w[[1,3],[2]]).duality_pairing(2*m[[1,3],[2]] +␣
↪m[[1,2,3]] + 2*m[[1,2],[3]])
8
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: matrix([[w(A).duality_pairing(h(B)) for A in SetPartitions(3)] for␣
↪B in SetPartitions(3)])
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
[2 1 1 2 1]
[1 1 1 1 1]
sage: (2*w[[1,3],[2]] + w[[1,2,3]] + 2*w[[1,2],[3]]).duality_pairing(h[[1,
↪2],[3]] + 3*h[[1,3],[2]])
32
```

```
>>> from sage.all import *
>>> DNCSym = SymmetricFunctionsNonCommutingVariablesDual(QQ)
>>> w = DNCSym.w()
>>> m = w.dual_basis()
>>> matrix([[w(A).duality_pairing(m(B)) for A in␣
↪SetPartitions(Integer(3))] for B in SetPartitions(Integer(3))])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
>>> (w[[Integer(1),Integer(2)],[Integer(3)]] + Integer(3)*w[[Integer(1),
↪Integer(3)],[Integer(2)]]).duality_pairing(Integer(2)*m[[Integer(1),
↪Integer(3)],[Integer(2)]] + m[[Integer(1),Integer(2),Integer(3)]] +␣
↪Integer(2)*m[[Integer(1),Integer(2)],[Integer(3)]])
8
>>> h = SymmetricFunctionsNonCommutingVariables(QQ).h()
>>> matrix([[w(A).duality_pairing(h(B)) for A in␣
↪SetPartitions(Integer(3))] for B in SetPartitions(Integer(3))])
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
[2 1 1 2 1]
[1 1 1 1 1]
>>> (Integer(2)*w[[Integer(1),Integer(3)],[Integer(2)]] + w[[Integer(1),
↪Integer(2),Integer(3)]] + Integer(2)*w[[Integer(1),Integer(2)],
↪[Integer(3)]]).duality_pairing(h[[Integer(1),Integer(2)],[Integer(3)]]␣
↪+ Integer(3)*h[[Integer(1),Integer(3)],[Integer(2)]])
32
```

product_on_basis(*A*, *B*)

The product on **w** basis elements.

The product on the **w** is the dual to the coproduct on the **m** basis. On the basis **w** it is defined as

$$\mathbf{w}_A \mathbf{w}_B = \sum_{S \subseteq [n]} \mathbf{w}_{A\uparrow_S \cup B\uparrow_{S^c}}$$

where the sum is over all possible subsets S of $[n]$ such that $|S| = |A|$ with a term indexed the union of $A\uparrow_S$ and $B\uparrow_{S^c}$. The notation $A\uparrow_S$ represents the unique set partition of the set S such that the standardization is A. This product is commutative.

INPUT:

- `A`, `B` – set partitions

OUTPUT: an element of the **w** basis

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1, 2, 3]])
sage: w.product_on_basis(A, B)
w{{1}, {2, 3}, {4, 5, 6}} + w{{1}, {2, 3, 4}, {5, 6}}
 + w{{1}, {2, 3, 5}, {4, 6}} + w{{1}, {2, 3, 6}, {4, 5}}
 + w{{1}, {2, 4}, {3, 5, 6}} + w{{1}, {2, 4, 5}, {3, 6}}
 + w{{1}, {2, 4, 6}, {3, 5}} + w{{1}, {2, 5}, {3, 4, 6}}
 + w{{1}, {2, 5, 6}, {3, 4}} + w{{1}, {2, 6}, {3, 4, 5}}
 + w{{1, 2, 3}, {4}, {5, 6}} + w{{1, 2, 4}, {3}, {5, 6}}
 + w{{1, 2, 5}, {3}, {4, 6}} + w{{1, 2, 6}, {3}, {4, 5}}
 + w{{1, 3, 4}, {2}, {5, 6}} + w{{1, 3, 5}, {2}, {4, 6}}
 + w{{1, 3, 6}, {2}, {4, 5}} + w{{1, 4, 5}, {2}, {3, 6}}
 + w{{1, 4, 6}, {2}, {3, 5}} + w{{1, 5, 6}, {2}, {3, 4}}
sage: B = SetPartition([[1], [2]])
sage: w.product_on_basis(A, B)
3*w{{1}, {2}, {3}, {4, 5}} + 2*w{{1}, {2}, {3, 4}, {5}}
 + 2*w{{1}, {2}, {3, 5}, {4}} + w{{1}, {2, 3}, {4}, {5}}
 + w{{1}, {2, 4}, {3}, {5}} + w{{1}, {2, 5}, {3}, {4}}
sage: w.product_on_basis(A, SetPartition([]))
w{{1}, {2, 3}}
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(3)]])
>>> B = SetPartition([[Integer(1), Integer(2), Integer(3)]])
>>> w.product_on_basis(A, B)
w{{1}, {2, 3}, {4, 5, 6}} + w{{1}, {2, 3, 4}, {5, 6}}
 + w{{1}, {2, 3, 5}, {4, 6}} + w{{1}, {2, 3, 6}, {4, 5}}
 + w{{1}, {2, 4}, {3, 5, 6}} + w{{1}, {2, 4, 5}, {3, 6}}
 + w{{1}, {2, 4, 6}, {3, 5}} + w{{1}, {2, 5}, {3, 4, 6}}
 + w{{1}, {2, 5, 6}, {3, 4}} + w{{1}, {2, 6}, {3, 4, 5}}
 + w{{1, 2, 3}, {4}, {5, 6}} + w{{1, 2, 4}, {3}, {5, 6}}
 + w{{1, 2, 5}, {3}, {4, 6}} + w{{1, 2, 6}, {3}, {4, 5}}
 + w{{1, 3, 4}, {2}, {5, 6}} + w{{1, 3, 5}, {2}, {4, 6}}
 + w{{1, 3, 6}, {2}, {4, 5}} + w{{1, 4, 5}, {2}, {3, 6}}
 + w{{1, 4, 6}, {2}, {3, 5}} + w{{1, 5, 6}, {2}, {3, 4}}
>>> B = SetPartition([[Integer(1)], [Integer(2)]])
>>> w.product_on_basis(A, B)
3*w{{1}, {2}, {3}, {4, 5}} + 2*w{{1}, {2}, {3, 4}, {5}}
```

(continues on next page)

(continued from previous page)

```
 + 2*w{{1}, {2}, {3, 5}, {4}} + w{{1}, {2, 3}, {4}, {5}}
 + w{{1}, {2, 4}, {3}, {5}} + w{{1}, {2, 5}, {3}, {4}}
>>> w.product_on_basis(A, SetPartition([]))
w{{1}, {2, 3}}
```

sum_of_partitions(*la*)

Return the sum over all sets partitions whose shape is `la`, scaled by $\prod_i m_i!$ where m_i is the multiplicity of i in `la`.

INPUT:

- `la` – integer partition

OUTPUT: an element of `self`

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.sum_of_partitions([2,1,1])
2*w{{1}, {2}, {3, 4}} + 2*w{{1}, {2, 3}, {4}} + 2*w{{1}, {2, 4}, {3}}
 + 2*w{{1, 2}, {3}, {4}} + 2*w{{1, 3}, {2}, {4}} + 2*w{{1, 4}, {2}, {3}}
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> w.sum_of_partitions([Integer(2),Integer(1),Integer(1)])
2*w{{1}, {2}, {3, 4}} + 2*w{{1}, {2, 3}, {4}} + 2*w{{1}, {2, 4}, {3}}
 + 2*w{{1, 2}, {3}, {4}} + 2*w{{1, 3}, {2}, {4}} + 2*w{{1, 4}, {2}, {3}}
```

to_symmetric_function()

The preimage of χ^* in the **w** basis.

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.to_symmetric_function
Generic morphism:
  From: Dual symmetric functions in non-commuting variables over the␣
↪Rational Field in the w basis
  To:   Symmetric Functions over Rational Field in the homogeneous basis
```

```
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> w.to_symmetric_function
Generic morphism:
  From: Dual symmetric functions in non-commuting variables over the␣
↪Rational Field in the w basis
  To:   Symmetric Functions over Rational Field in the homogeneous basis
```

class sage.combinat.ncsym.ncsym.**SymmetricFunctionsNonCommutingVariables**(R)

Bases: UniqueRepresentation, Parent

Symmetric functions in non-commutative variables.

The ring of symmetric functions in non-commutative variables, which is not to be confused with the *non-commutative symmetric functions*, is the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in $R\langle\langle x_1, x_2, x_3, \ldots\rangle\rangle$ of bounded degree) which are invariant with respect to the action of the symmetric group S_∞ on the indices of the indeterminates. It can be regarded as a direct limit over all $n \to \infty$ of rings of S_n-invariant polynomials in n non-commuting variables (that is, S_n-invariant elements of $R\langle x_1, x_2, \ldots, x_n\rangle$).

This ring is implemented as a Hopf algebra whose basis elements are indexed by set partitions.

Let $A = \{A_1, A_2, \ldots, A_r\}$ be a set partition of the integers $[k] := \{1, 2, \ldots, k\}$. This partition A determines an equivalence relation $\sim_A$ on $[k]$, which has $c \sim_A d$ if and only if c and d are in the same part A_j of A. The monomial basis element $\mathbf{m}_A$ indexed by A is the sum of monomials $x_{i_1} x_{i_2} \cdots x_{i_k}$ such that $i_c = i_d$ if and only if $c \sim_A d$.

The k-th graded component of the ring of symmetric functions in non-commutative variables has its dimension equal to the number of set partitions of $[k]$. (If we work, instead, with finitely many – say, n – variables, then its dimension is equal to the number of set partitions of $[k]$ where the number of parts is at most n.)

Note

All set partitions are considered standard (i.e., set partitions of $[n]$ for some n) unless otherwise stated.

REFERENCES:

EXAMPLES:

We begin by first creating the ring of $NCSym$ and the bases that are analogues of the usual symmetric functions:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: m
Symmetric functions in non-commuting variables over the Rational Field in the␣
↪monomial basis
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> e = NCSym.e()
>>> h = NCSym.h()
>>> p = NCSym.p()
>>> m
Symmetric functions in non-commuting variables over the Rational Field in the␣
↪monomial basis
```

The basis is indexed by set partitions, so we create a few elements and convert them between these bases:

```
sage: elt = m(SetPartition([[1,3],[2]])) - 2*m(SetPartition([[1],[2]])); elt
-2*m{{1}, {2}} + m{{1, 3}, {2}}
sage: e(elt)
1/2*e{{1}, {2, 3}} - 2*e{{1, 2}} + 1/2*e{{1, 2}, {3}} - 1/2*e{{1, 2, 3}} - 1/2*e{
↪{1, 3}, {2}}
sage: h(elt)
-4*h{{1}, {2}} - 2*h{{1}, {2}, {3}} + 1/2*h{{1}, {2, 3}} + 2*h{{1, 2}}
 + 1/2*h{{1, 2}, {3}} - 1/2*h{{1, 2, 3}} + 3/2*h{{1, 3}, {2}}
sage: p(elt)
-2*p{{1}, {2}} + 2*p{{1, 2}} - p{{1, 2, 3}} + p{{1, 3}, {2}}
sage: m(p(elt))
-2*m{{1}, {2}} + m{{1, 3}, {2}}

sage: elt = p(SetPartition([[1,3],[2]])) - 4*p(SetPartition([[1],[2]])) + 2; elt
2*p{} - 4*p{{1}, {2}} + p{{1, 3}, {2}}
sage: e(elt)
2*e{} - 4*e{{1}, {2}} + e{{1}, {2}, {3}} - e{{1, 3}, {2}}
sage: m(elt)
2*m{} - 4*m{{1}, {2}} - 4*m{{1, 2}} + m{{1, 2, 3}} + m{{1, 3}, {2}}
sage: h(elt)
2*h{} - 4*h{{1}, {2}} - h{{1}, {2}, {3}} + h{{1, 3}, {2}}
sage: p(m(elt))
2*p{} - 4*p{{1}, {2}} + p{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> elt = m(SetPartition([[Integer(1),Integer(3)],[Integer(2)]])) -␣
↪Integer(2)*m(SetPartition([[Integer(1)],[Integer(2)]])); elt
-2*m{{1}, {2}} + m{{1, 3}, {2}}
>>> e(elt)
1/2*e{{1}, {2, 3}} - 2*e{{1, 2}} + 1/2*e{{1, 2}, {3}} - 1/2*e{{1, 2, 3}} - 1/2*e{
↪{1, 3}, {2}}
>>> h(elt)
-4*h{{1}, {2}} - 2*h{{1}, {2}, {3}} + 1/2*h{{1}, {2, 3}} + 2*h{{1, 2}}
 + 1/2*h{{1, 2}, {3}} - 1/2*h{{1, 2, 3}} + 3/2*h{{1, 3}, {2}}
>>> p(elt)
-2*p{{1}, {2}} + 2*p{{1, 2}} - p{{1, 2, 3}} + p{{1, 3}, {2}}
>>> m(p(elt))
-2*m{{1}, {2}} + m{{1, 3}, {2}}

>>> elt = p(SetPartition([[Integer(1),Integer(3)],[Integer(2)]])) -␣
↪Integer(4)*p(SetPartition([[Integer(1)],[Integer(2)]])) + Integer(2); elt
2*p{} - 4*p{{1}, {2}} + p{{1, 3}, {2}}
>>> e(elt)
2*e{} - 4*e{{1}, {2}} + e{{1}, {2}, {3}} - e{{1, 3}, {2}}
>>> m(elt)
2*m{} - 4*m{{1}, {2}} - 4*m{{1, 2}} + m{{1, 2, 3}} + m{{1, 3}, {2}}
>>> h(elt)
2*h{} - 4*h{{1}, {2}} - h{{1}, {2}, {3}} + h{{1, 3}, {2}}
>>> p(m(elt))
2*p{} - 4*p{{1}, {2}} + p{{1, 3}, {2}}
```

There is also a shorthand for creating elements. We note that we must use `p[[]]` to create the empty set partition

due to python's syntax.

```
sage: eltm = m[[1,3],[2]] - 3*m[[1],[2]]; eltm
-3*m{{1}, {2}} + m{{1, 3}, {2}}
sage: elte = e[[1,3],[2]]; elte
e{{1, 3}, {2}}
sage: elth = h[[1,3],[2,4]]; elth
h{{1, 3}, {2, 4}}
sage: eltp = p[[1,3],[2,4]] + 2*p[[1]] - 4*p[[]]; eltp
-4*p{} + 2*p{{1}} + p{{1, 3}, {2, 4}}
```

```
>>> from sage.all import *
>>> eltm = m[[Integer(1),Integer(3)],[Integer(2)]] - Integer(3)*m[[Integer(1)],
↪[Integer(2)]]; eltm
-3*m{{1}, {2}} + m{{1, 3}, {2}}
>>> elte = e[[Integer(1),Integer(3)],[Integer(2)]]; elte
e{{1, 3}, {2}}
>>> elth = h[[Integer(1),Integer(3)],[Integer(2),Integer(4)]]; elth
h{{1, 3}, {2, 4}}
>>> eltp = p[[Integer(1),Integer(3)],[Integer(2),Integer(4)]] +␣
↪Integer(2)*p[[Integer(1)]] - Integer(4)*p[[]]; eltp
-4*p{} + 2*p{{1}} + p{{1, 3}, {2, 4}}
```

There is also a natural projection to the usual symmetric functions by letting the variables commute. This projection map preserves the product and coproduct structure. We check that Theorem 2.1 of [RS06] holds:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sm = Sym.m()
sage: Se = Sym.e()
sage: Sh = Sym.h()
sage: Sp = Sym.p()
sage: eltm.to_symmetric_function()
-6*m[1, 1] + m[2, 1]
sage: Sm(p(eltm).to_symmetric_function())
-6*m[1, 1] + m[2, 1]
sage: elte.to_symmetric_function()
2*e[2, 1]
sage: Se(h(elte).to_symmetric_function())
2*e[2, 1]
sage: elth.to_symmetric_function()
4*h[2, 2]
sage: Sh(m(elth).to_symmetric_function())
4*h[2, 2]
sage: eltp.to_symmetric_function()
-4*p[] + 2*p[1] + p[2, 2]
sage: Sp(e(eltp).to_symmetric_function())
-4*p[] + 2*p[1] + p[2, 2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Sm = Sym.m()
>>> Se = Sym.e()
>>> Sh = Sym.h()
```

(continues on next page)

(continued from previous page)

```
>>> Sp = Sym.p()
>>> eltm.to_symmetric_function()
-6*m[1, 1] + m[2, 1]
>>> Sm(p(eltm).to_symmetric_function())
-6*m[1, 1] + m[2, 1]
>>> elte.to_symmetric_function()
2*e[2, 1]
>>> Se(h(elte).to_symmetric_function())
2*e[2, 1]
>>> elth.to_symmetric_function()
4*h[2, 2]
>>> Sh(m(elth).to_symmetric_function())
4*h[2, 2]
>>> eltp.to_symmetric_function()
-4*p[] + 2*p[1] + p[2, 2]
>>> Sp(e(eltp).to_symmetric_function())
-4*p[] + 2*p[1] + p[2, 2]
```

a_realization()

Return the realization of the powersum basis of `self`.

OUTPUT: the powersum basis of symmetric functions in non-commuting variables

EXAMPLES:

```
sage: SymmetricFunctionsNonCommutingVariables(QQ).a_realization()
Symmetric functions in non-commuting variables over the Rational Field in the␣
↪powersum basis
```

```
>>> from sage.all import *
>>> SymmetricFunctionsNonCommutingVariables(QQ).a_realization()
Symmetric functions in non-commuting variables over the Rational Field in the␣
↪powersum basis
```

chi

alias of *supercharacter*

class coarse_powersum(*NCSym*)

Bases: *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the **cp** basis.

This basis was defined in [BZ05] as

$$\mathbf{cp}_A = \sum_{A \leq_* B} \mathbf{m}_B,$$

where we sum over all strict coarsenings of the set partition A. An alternative description of this basis was given in [BT13] as

$$\mathbf{cp}_A = \sum_{A \subseteq B} \mathbf{m}_B,$$

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition A.

> **Note**
>
> In [BZ05], this basis was denoted by **q**. In [BT13], this basis was called the powersum basis and denoted by p. However it is a coarser basis than the usual powersum basis in the sense that it does not yield the usual powersum basis of the symmetric function under the natural map of letting the variables commute.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: cp = NCSym.cp()
sage: cp[[1,3],[2,4]]*cp[[1,2,3]]
cp{{1, 3}, {2, 4}, {5, 6, 7}}
sage: cp[[1,2],[3]].internal_coproduct()
cp{{1, 2}, {3}} # cp{{1, 2}, {3}}
sage: ps = SymmetricFunctions(NCSym.base_ring()).p()
sage: ps(cp[[1,3],[2]].to_symmetric_function())
p[2, 1] - p[3]
sage: ps(cp[[1,2],[3]].to_symmetric_function())
p[2, 1]
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> cp = NCSym.cp()
>>> cp[[Integer(1),Integer(3)],[Integer(2),Integer(4)]]*cp[[Integer(1),
...Integer(2),Integer(3)]]
cp{{1, 3}, {2, 4}, {5, 6, 7}}
>>> cp[[Integer(1),Integer(2)],[Integer(3)]].internal_coproduct()
cp{{1, 2}, {3}} # cp{{1, 2}, {3}}
>>> ps = SymmetricFunctions(NCSym.base_ring()).p()
>>> ps(cp[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function())
p[2, 1] - p[3]
>>> ps(cp[[Integer(1),Integer(2)],[Integer(3)]].to_symmetric_function())
p[2, 1]
```

cp

alias of *coarse_powersum*

class deformed_coarse_powersum(*NCSym*, *q=2*)

Bases: *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the ρ basis.

This basis was defined in [BT13] as a q-deformation of the **cp** basis:

$$\rho_A = \sum_{A \subseteq B} \frac{1}{q^{\mathrm{nst}_{B-A}^{A}}} \mathbf{m}_B,$$

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition A.

INPUT:

- `q` – (default: `2`) the parameter q

EXAMPLES:

```
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)
```

```
>>> from sage.all import *
>>> R = QQ['q'].fraction_field()
>>> q = R.gen()
>>> NCSym = SymmetricFunctionsNonCommutingVariables(R)
>>> rho = NCSym.rho(q)
```

We construct Example 3.1 in [BT13]:

```
sage: rnode = lambda A: sorted([a[1] for a in A.arcs()], reverse=True)
sage: dimv = lambda A: sorted([a[1]-a[0] for a in A.arcs()], reverse=True)
sage: lst = list(SetPartitions(4))
sage: S = sorted(lst, key=lambda A: (dimv(A), rnode(A)))
sage: m = NCSym.m()
sage: matrix([[m(rho[A])[B] for B in S] for A in S])
[  1   1   1   1   1   1   1   1   1   1   1   1   1   1   1]
[  0   1   0   0   1   1   0   1   0   0   1   0   0   0   0]
[  0   0   1   0   1   0   1   1   0   0   0   0   0   0   1]
[  0   0   0   1   0   1   1   1   0   0   0   1   0   0   0]
[  0   0   0   0   1   0   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   1   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   1   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   0   0   1   0   0   1   1   0   0]
[  0   0   0   0   0   0   0   0   0   1   1   0   1   0   0]
[  0   0   0   0   0   0   0   0   0   0   1   0   0   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   1   0   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   0   1   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   0   0   1 1/q]
[  0   0   0   0   0   0   0   0   0   0   0   0   0   0   1]
```

```
>>> from sage.all import *
>>> rnode = lambda A: sorted([a[Integer(1)] for a in A.arcs()], reverse=True)
>>> dimv = lambda A: sorted([a[Integer(1)]-a[Integer(0)] for a in A.arcs()],␣
↪reverse=True)
>>> lst = list(SetPartitions(Integer(4)))
>>> S = sorted(lst, key=lambda A: (dimv(A), rnode(A)))
>>> m = NCSym.m()
>>> matrix([[m(rho[A])[B] for B in S] for A in S])
[  1   1   1   1   1   1   1   1   1   1   1   1   1   1   1]
[  0   1   0   0   1   1   0   1   0   0   1   0   0   0   0]
[  0   0   1   0   1   0   1   1   0   0   0   0   0   0   1]
[  0   0   0   1   0   1   1   1   0   0   0   1   0   0   0]
[  0   0   0   0   1   0   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   1   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   1   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   0   1   0   0   0   0   0   0   0]
[  0   0   0   0   0   0   0   0   1   0   0   1   1   0   0]
```

(continues on next page)

(continued from previous page)

```
[  0   0   0   0   0   0   0   0   0   1   1   0   1   0   0]
[  0   0   0   0   0   0   0   0   0   0   1   0   0   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   1   0   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   0   1   0   0]
[  0   0   0   0   0   0   0   0   0   0   0   0   0   1 1/q]
[  0   0   0   0   0   0   0   0   0   0   0   0   0   0   1]
```

q()

Return the deformation parameter q of `self`.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: rho = NCSym.rho(5)
sage: rho.q()
5

sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)
sage: rho.q() == q
True
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> rho = NCSym.rho(Integer(5))
>>> rho.q()
5

>>> R = QQ['q'].fraction_field()
>>> q = R.gen()
>>> NCSym = SymmetricFunctionsNonCommutingVariables(R)
>>> rho = NCSym.rho(q)
>>> rho.q() == q
True
```

dual()

Return the dual Hopf algebra of the symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: SymmetricFunctionsNonCommutingVariables(QQ).dual()
Dual symmetric functions in non-commuting variables over the Rational Field
```

```
>>> from sage.all import *
>>> SymmetricFunctionsNonCommutingVariables(QQ).dual()
Dual symmetric functions in non-commuting variables over the Rational Field
```

e

alias of *elementary*

class elementary(*NCSym*)

Bases: *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the elementary basis.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> e = NCSym.e()
```

class Element

Bases: IndexedFreeModuleElement

An element in the elementary basis of $NCSym$.

omega()

Return the involution ω applied to `self`.

The involution ω on $NCSym$ is defined by $\omega(\mathbf{e}_A) = \mathbf{h}_A$.

OUTPUT: an element in the basis `self`

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: elt = e[[1,3],[2]].omega(); elt
2*e{{1}, {2}, {3}} - e{{1, 3}, {2}}
sage: elt.omega()
e{{1, 3}, {2}}
sage: h(elt)
h{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> e = NCSym.e()
>>> h = NCSym.h()
>>> elt = e[[Integer(1),Integer(3)],[Integer(2)]].omega(); elt
2*e{{1}, {2}, {3}} - e{{1, 3}, {2}}
>>> elt.omega()
e{{1, 3}, {2}}
>>> h(elt)
h{{1, 3}, {2}}
```

to_symmetric_function()

The projection of `self` to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the **e** basis, and return the projection of expressed in the elementary basis of symmetric functions.

The map $\chi\colon NCSym \to Sym$ is given by

$$\mathbf{e}_A \mapsto e_{\lambda(A)} \prod_i \lambda(A)_i!$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts.

OUTPUT: an element of the symmetric functions in the elementary basis

EXAMPLES:

```
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: e[[1],[3],[2]].to_symmetric_function()
e[1, 1, 1]
```

```
>>> from sage.all import *
>>> e = SymmetricFunctionsNonCommutingVariables(QQ).e()
>>> e[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
2*e[2, 1]
>>> e[[Integer(1)],[Integer(3)],[Integer(2)]].to_symmetric_function()
e[1, 1, 1]
```

h

alias of *homogeneous*

class homogeneous(*NCSym*)

Bases: *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the homogeneous basis.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: h[[1,3],[2,4]]*h[[1,2,3]]
h{{1, 3}, {2, 4}, {5, 6, 7}}
sage: h[[1,2]].coproduct()
h{} # h{{1, 2}} + 2*h{{1}} # h{{1}} + h{{1, 2}} # h{}
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> h = NCSym.h()
>>> h[[Integer(1),Integer(3)],[Integer(2),Integer(4)]]*h[[Integer(1),
↪Integer(2),Integer(3)]]
h{{1, 3}, {2, 4}, {5, 6, 7}}
>>> h[[Integer(1),Integer(2)]].coproduct()
h{} # h{{1, 2}} + 2*h{{1}} # h{{1}} + h{{1, 2}} # h{}
```

class Element

Bases: IndexedFreeModuleElement

An element in the homogeneous basis of $NCSym$.

omega()

Return the involution ω applied to `self`.

The involution ω on $NCSym$ is defined by $\omega(\mathbf{h}_A) = \mathbf{e}_A$.

OUTPUT: an element in the basis `self`

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: e = NCSym.e()
sage: elt = h[[1,3],[2]].omega(); elt
2*h{{1}, {2}, {3}} - h{{1, 3}, {2}}
sage: elt.omega()
h{{1, 3}, {2}}
sage: e(elt)
e{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> h = NCSym.h()
>>> e = NCSym.e()
>>> elt = h[[Integer(1),Integer(3)],[Integer(2)]].omega(); elt
2*h{{1}, {2}, {3}} - h{{1, 3}, {2}}
>>> elt.omega()
h{{1, 3}, {2}}
>>> e(elt)
e{{1, 3}, {2}}
```

to_symmetric_function()

The projection of `self` to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the **h** basis, and return the projection of expressed in the complete basis of symmetric functions.

The map $\chi\colon NCSym \to Sym$ is given by

$$\mathbf{h}_A \mapsto h_{\lambda(A)} \prod_i \lambda(A)_i!$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts.

OUTPUT: an element of the symmetric functions in the complete basis

EXAMPLES:

```
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
sage: h[[1],[3],[2]].to_symmetric_function()
h[1, 1, 1]
```

```
>>> from sage.all import *
>>> h = SymmetricFunctionsNonCommutingVariables(QQ).h()
>>> h[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
2*h[2, 1]
>>> h[[Integer(1)],[Integer(3)],[Integer(2)]].to_symmetric_function()
h[1, 1, 1]
```

m

alias of *monomial*

class monomial(*NCSym*)

Bases: *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the monomial basis.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]]*m[[1,2]]
m{{1, 3}, {2}, {4, 5}} + m{{1, 3}, {2, 4, 5}} + m{{1, 3, 4, 5}, {2}}
sage: m[[1,3],[2]].coproduct()
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1,
 3}, {2}} # m{}
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> m[[Integer(1),Integer(3)],[Integer(2)]]*m[[Integer(1),Integer(2)]]
m{{1, 3}, {2}, {4, 5}} + m{{1, 3}, {2, 4, 5}} + m{{1, 3, 4, 5}, {2}}
>>> m[[Integer(1),Integer(3)],[Integer(2)]].coproduct()
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1,
 3}, {2}} # m{}
```

class Element

Bases: IndexedFreeModuleElement

An element in the monomial basis of $NCSym$.

expand(*n*, *alphabet='x'*)

Expand `self` written in the monomial basis in n non-commuting variables.

INPUT:

- `n` – integer
- `alphabet` – string (default: `'x'`)

OUTPUT:

- The symmetric function of `self` expressed in the `n` non-commuting variables described by `alphabet`.

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1,3],[2]].expand(4)
x0*x1*x0 + x0*x2*x0 + x0*x3*x0 + x1*x0*x1 + x1*x2*x1 + x1*x3*x1
 + x2*x0*x2 + x2*x1*x2 + x2*x3*x2 + x3*x0*x3 + x3*x1*x3 + x3*x2*x3
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
>>> m[[Integer(1),Integer(3)],[Integer(2)]].expand(Integer(4))
x0*x1*x0 + x0*x2*x0 + x0*x3*x0 + x1*x0*x1 + x1*x2*x1 + x1*x3*x1
 + x2*x0*x2 + x2*x1*x2 + x2*x3*x2 + x3*x0*x3 + x3*x1*x3 + x3*x2*x3
```

One can use a different set of variables by using the optional argument `alphabet`:

```
sage: m[[1],[2,3]].expand(3,alphabet='y')
y0*y1^2 + y0*y2^2 + y1*y0^2 + y1*y2^2 + y2*y0^2 + y2*y1^2
```

```
>>> from sage.all import *
>>> m[[Integer(1)],[Integer(2),Integer(3)]].expand(Integer(3),alphabet=
↪'y')
y0*y1^2 + y0*y2^2 + y1*y0^2 + y1*y2^2 + y2*y0^2 + y2*y1^2
```

to_symmetric_function()

The projection of `self` to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the **m** basis, and return the projection of expressed in the monomial basis of symmetric functions.

The map $\chi\colon NCSym \to Sym$ is defined by

$$\mathbf{m}_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts and $n_i(\mu)$ is the multiplicity of i in μ.

OUTPUT: an element of the symmetric functions in the monomial basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1,3],[2]].to_symmetric_function()
m[2, 1]
sage: m[[1],[3],[2]].to_symmetric_function()
6*m[1, 1, 1]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
>>> m[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
m[2, 1]
>>> m[[Integer(1)],[Integer(3)],[Integer(2)]].to_symmetric_function()
6*m[1, 1, 1]
```

coproduct_on_basis(A)

Return the coproduct of a monomial basis element.

INPUT:

- `A` – set partition

OUTPUT:

- The coproduct applied to the monomial symmetric function in non-commuting variables indexed by `A` expressed in the monomial basis.

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1, 3], [2]].coproduct()
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1, 3},
↪ {2}} # m{}
sage: m.coproduct_on_basis(SetPartition([]))
m{} # m{}
sage: m.coproduct_on_basis(SetPartition([[1,2,3]]))
m{} # m{{1, 2, 3}} + m{{1, 2, 3}} # m{}
sage: m[[1,5],[2,4],[3,7],[6]].coproduct()
```

(continues on next page)

(continued from previous page)

```
m{} # m{{1, 5}, {2, 4}, {3, 7}, {6}} + m{{1}} # m{{1, 5}, {2, 4}, {3, 6}}
 + 2*m{{1, 2}} # m{{1, 3}, {2, 5}, {4}} + m{{1, 2}} # m{{1, 4}, {2, 3},
↪{5}}
 + 2*m{{1, 2}, {3}} # m{{1, 3}, {2, 4}} + m{{1, 3}, {2}} # m{{1, 4}, {2,␣
↪3}}
 + 2*m{{1, 3}, {2, 4}} # m{{1, 2}, {3}} + 2*m{{1, 3}, {2, 5}, {4}} # m{{1,
↪ 2}}
 + m{{1, 4}, {2, 3}} # m{{1, 3}, {2}} + m{{1, 4}, {2, 3}, {5}} # m{{1, 2}}
 + m{{1, 5}, {2, 4}, {3, 6}} # m{{1}} + m{{1, 5}, {2, 4}, {3, 7}, {6}} # m
↪{}
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
>>> m[[Integer(1), Integer(3)], [Integer(2)]].coproduct()
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1, 3},
↪ {2}} # m{}
>>> m.coproduct_on_basis(SetPartition([]))
m{} # m{}
>>> m.coproduct_on_basis(SetPartition([[Integer(1),Integer(2),
↪Integer(3)]]))
m{} # m{{1, 2, 3}} + m{{1, 2, 3}} # m{}
>>> m[[Integer(1),Integer(5)],[Integer(2),Integer(4)],[Integer(3),
↪Integer(7)],[Integer(6)]].coproduct()
m{} # m{{1, 5}, {2, 4}, {3, 7}, {6}} + m{{1}} # m{{1, 5}, {2, 4}, {3, 6}}
 + 2*m{{1, 2}} # m{{1, 3}, {2, 5}, {4}} + m{{1, 2}} # m{{1, 4}, {2, 3},
↪{5}}
 + 2*m{{1, 2}, {3}} # m{{1, 3}, {2, 4}} + m{{1, 3}, {2}} # m{{1, 4}, {2,␣
↪3}}
 + 2*m{{1, 3}, {2, 4}} # m{{1, 2}, {3}} + 2*m{{1, 3}, {2, 5}, {4}} # m{{1,
↪ 2}}
 + m{{1, 4}, {2, 3}} # m{{1, 3}, {2}} + m{{1, 4}, {2, 3}, {5}} # m{{1, 2}}
 + m{{1, 5}, {2, 4}, {3, 6}} # m{{1}} + m{{1, 5}, {2, 4}, {3, 7}, {6}} # m
↪{}
```

dual_basis()

Return the dual basis to the monomial basis.

OUTPUT: the **w** basis of the dual Hopf algebra

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.dual_basis()
Dual symmetric functions in non-commuting variables over the Rational␣
↪Field in the w basis
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).m()
>>> m.dual_basis()
Dual symmetric functions in non-commuting variables over the Rational␣
↪Field in the w basis
```

duality_pairing(x, y)

Compute the pairing between an element of `self` and an element of the dual.

INPUT:

- `x` – an element of symmetric functions in non-commuting variables
- `y` – an element of the dual of symmetric functions in non-commuting variables

OUTPUT: an element of the base ring of `self`

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = m.dual_basis()
sage: matrix([[m(A).duality_pairing(w(B)) for A in SetPartitions(3)] for␣
↪B in SetPartitions(3)])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: (m[[1,2],[3]] + 3*m[[1,3],[2]]).duality_pairing(2*w[[1,3],[2]] +␣
↪w[[1,2,3]] + 2*w[[1,2],[3]])
8
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> w = m.dual_basis()
>>> matrix([[m(A).duality_pairing(w(B)) for A in␣
↪SetPartitions(Integer(3))] for B in SetPartitions(Integer(3))])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
>>> (m[[Integer(1),Integer(2)],[Integer(3)]] + Integer(3)*m[[Integer(1),
↪Integer(3)],[Integer(2)]]).duality_pairing(Integer(2)*w[[Integer(1),
↪Integer(3)],[Integer(2)]] + w[[Integer(1),Integer(2),Integer(3)]] +␣
↪Integer(2)*w[[Integer(1),Integer(2)],[Integer(3)]])
8
```

from_symmetric_function(*f*)

Return the image of the symmetric function `f` in `self`.

This is performed by converting to the monomial basis and extending the method *sum_of_partitions()* linearly. This is a linear map from the symmetric functions to the symmetric functions in non-commuting variables that does not preserve the product or coproduct structure of the Hopf algebra.

See also

to_symmetric_function()

INPUT:

- `f` – an element of the symmetric functions

OUTPUT: an element of the **m** basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: mon = SymmetricFunctions(QQ).m()
sage: elt = m.from_symmetric_function(mon[2,1,1]); elt
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4},
↪{3}}
 + 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4},
↪{2}, {3}}
sage: elt.to_symmetric_function()
m[2, 1, 1]
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: elm = SymmetricFunctions(QQ).e()
sage: e(m.from_symmetric_function(elm[4]))
1/24*e{{1, 2, 3, 4}}
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: hom = SymmetricFunctions(QQ).h()
sage: h(m.from_symmetric_function(hom[4]))
1/24*h{{1, 2, 3, 4}}
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: pow = SymmetricFunctions(QQ).p()
sage: p(m.from_symmetric_function(pow[4]))
p{{1, 2, 3, 4}}
sage: p(m.from_symmetric_function(pow[2,1]))
1/3*p{{1}, {2, 3}} + 1/3*p{{1, 2}, {3}} + 1/3*p{{1, 3}, {2}}
sage: p([[1,2]])*p([[1]])
p{{1, 2}, {3}}
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).m()
>>> mon = SymmetricFunctions(QQ).m()
>>> elt = m.from_symmetric_function(mon[Integer(2),Integer(1),
↪Integer(1)]); elt
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4},
↪{3}}
 + 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4},
↪{2}, {3}}
>>> elt.to_symmetric_function()
m[2, 1, 1]
>>> e = SymmetricFunctionsNonCommutingVariables(QQ).e()
>>> elm = SymmetricFunctions(QQ).e()
>>> e(m.from_symmetric_function(elm[Integer(4)]))
1/24*e{{1, 2, 3, 4}}
>>> h = SymmetricFunctionsNonCommutingVariables(QQ).h()
>>> hom = SymmetricFunctions(QQ).h()
>>> h(m.from_symmetric_function(hom[Integer(4)]))
1/24*h{{1, 2, 3, 4}}
>>> p = SymmetricFunctionsNonCommutingVariables(QQ).p()
>>> pow = SymmetricFunctions(QQ).p()
>>> p(m.from_symmetric_function(pow[Integer(4)]))
p{{1, 2, 3, 4}}
>>> p(m.from_symmetric_function(pow[Integer(2),Integer(1)]))
```

(continues on next page)

(continued from previous page)

```
1/3*p{{1}, {2, 3}} + 1/3*p{{1, 2}, {3}} + 1/3*p{{1, 3}, {2}}
>>> p([[Integer(1),Integer(2)]])*p([[Integer(1)]])
p{{1, 2}, {3}}
```

Check that $\chi \circ \widetilde{\chi}$ is the identity on Sym:

```
sage: all(m.from_symmetric_function(pow(la)).to_symmetric_function() ==␣
↪pow(la)
....:     for la in Partitions(4))
True
```

```
>>> from sage.all import *
>>> all(m.from_symmetric_function(pow(la)).to_symmetric_function() ==␣
↪pow(la)
...     for la in Partitions(Integer(4)))
True
```

internal_coproduct_on_basis(A)

Return the internal coproduct of a monomial basis element.

The internal coproduct is defined by

$$\Delta^{\odot}(\mathbf{m}_A) = \sum_{B \wedge C = A} \mathbf{m}_B \otimes \mathbf{m}_C$$

where we sum over all pairs of set partitions B and C whose infimum is A.

INPUT:

- `A` – set partition

OUTPUT: an element of the tensor square of the **m** basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m.internal_coproduct_on_basis(SetPartition([[1,3],[2]]))
m{{1, 2, 3}} # m{{1, 3}, {2}} + m{{1, 3}, {2}} # m{{1, 2, 3}} + m{{1, 3},
↪{2}} # m{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
>>> m.internal_coproduct_on_basis(SetPartition([[Integer(1),Integer(3)],
↪[Integer(2)]]))
m{{1, 2, 3}} # m{{1, 3}, {2}} + m{{1, 3}, {2}} # m{{1, 2, 3}} + m{{1, 3},
↪{2}} # m{{1, 3}, {2}}
```

product_on_basis(A, B)

The product on monomial basis elements.

The product of the basis elements indexed by two set partitions A and B is the sum of the basis elements indexed by set partitions C such that $C \wedge ([n]|[k]) = A|B$ where $n = |A|$ and $k = |B|$. Here $A \wedge B$ is the infimum of A and B and $A|B$ is the *SetPartition.pipe()* operation. Equivalently we can describe all C as matchings between the parts of A and B where if $a \in A$ is matched with $b \in B$, we take $a \cup b$ instead of a and b in C.

INPUT:

- A, B – set partitions

OUTPUT: an element of the **m** basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1], [3], [2,4]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5, 7}, {6}} + m{{1}, {2, 3, 4}, {5, 7}, {6}}
 + m{{1}, {2, 3, 5, 7}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5, 7}}
 + m{{1, 4}, {2, 3}, {5, 7}, {6}} + m{{1, 4}, {2, 3, 5, 7}, {6}}
 + m{{1, 4}, {2, 3, 6}, {5, 7}} + m{{1, 5, 7}, {2, 3}, {4}, {6}}
 + m{{1, 5, 7}, {2, 3, 4}, {6}} + m{{1, 5, 7}, {2, 3, 6}, {4}}
 + m{{1, 6}, {2, 3}, {4}, {5, 7}} + m{{1, 6}, {2, 3, 4}, {5, 7}}
 + m{{1, 6}, {2, 3, 5, 7}, {4}}
sage: B = SetPartition([[1], [2]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5}} + m{{1}, {2, 3, 4}, {5}}
 + m{{1}, {2, 3, 5}, {4}} + m{{1, 4}, {2, 3}, {5}} + m{{1, 4}, {2, 3, 5}}
 + m{{1, 5}, {2, 3}, {4}} + m{{1, 5}, {2, 3, 4}}
sage: m.product_on_basis(A, SetPartition([]))
m{{1}, {2, 3}}
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(3)]])
>>> B = SetPartition([[Integer(1)], [Integer(3)], [Integer(2),
↪Integer(4)]])
>>> m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5, 7}, {6}} + m{{1}, {2, 3, 4}, {5, 7}, {6}}
 + m{{1}, {2, 3, 5, 7}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5, 7}}
 + m{{1, 4}, {2, 3}, {5, 7}, {6}} + m{{1, 4}, {2, 3, 5, 7}, {6}}
 + m{{1, 4}, {2, 3, 6}, {5, 7}} + m{{1, 5, 7}, {2, 3}, {4}, {6}}
 + m{{1, 5, 7}, {2, 3, 4}, {6}} + m{{1, 5, 7}, {2, 3, 6}, {4}}
 + m{{1, 6}, {2, 3}, {4}, {5, 7}} + m{{1, 6}, {2, 3, 4}, {5, 7}}
 + m{{1, 6}, {2, 3, 5, 7}, {4}}
>>> B = SetPartition([[Integer(1)], [Integer(2)]])
>>> m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5}} + m{{1}, {2, 3, 4}, {5}}
 + m{{1}, {2, 3, 5}, {4}} + m{{1, 4}, {2, 3}, {5}} + m{{1, 4}, {2, 3, 5}}
 + m{{1, 5}, {2, 3}, {4}} + m{{1, 5}, {2, 3, 4}}
>>> m.product_on_basis(A, SetPartition([]))
m{{1}, {2, 3}}
```

sum_of_partitions(*la*)

Return the sum over all set partitions whose shape is `la` with a fixed coefficient C defined below.

Fix a partition λ, we define $\lambda! := \prod_i \lambda_i!$ and $\lambda^! := \prod_i m_i!$. Recall that $|\lambda| = \sum_i \lambda_i$ and m_i is the number of parts of length i of λ. Thus we defined the coefficient as

$$C := \frac{\lambda!\lambda^!}{|\lambda|!}.$$

Hence we can define a lift $\widetilde{\chi}$ from Sym to $NCSym$ by

$$m_\lambda \mapsto C \sum_A \mathbf{m}_A$$

where the sum is over all set partitions whose shape is λ.

INPUT:

- `la` – integer partition

OUTPUT: an element of the **m** basis

EXAMPLES:

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.sum_of_partitions(Partition([2,1,1]))
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4},
↪{3}}
 + 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4},
↪{2}, {3}}
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).m()
>>> m.sum_of_partitions(Partition([Integer(2),Integer(1),Integer(1)]))
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4},
↪{3}}
 + 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4},
↪{2}, {3}}
```

p

alias of *powersum*

class powersum(*NCSym*)

Bases: *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the powersum basis.

The powersum basis is given by

$$\mathbf{p}_A = \sum_{A \leq B} \mathbf{m}_B,$$

where we sum over all coarsenings of the set partition A. If we allow our variables to commute, then $\mathbf{p}_A$ goes to the usual powersum symmetric function p_λ whose (integer) partition λ is the shape of A.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: p = NCSym.p()

sage: x = p.an_element()**2; x
4*p{} + 8*p{{1}} + 4*p{{1}, {2}} + 6*p{{1}, {2, 3}}
 + 12*p{{1, 2}} + 6*p{{1, 2}, {3}} + 9*p{{1, 2}, {3, 4}}
sage: x.to_symmetric_function()
4*p[] + 8*p[1] + 4*p[1, 1] + 12*p[2] + 12*p[2, 1] + 9*p[2, 2]
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> p = NCSym.p()

>>> x = p.an_element()**Integer(2); x
4*p{} + 8*p{{1}} + 4*p{{1}, {2}} + 6*p{{1}, {2, 3}}
 + 12*p{{1, 2}} + 6*p{{1, 2}, {3}} + 9*p{{1, 2}, {3, 4}}
>>> x.to_symmetric_function()
4*p[] + 8*p[1] + 4*p[1, 1] + 12*p[2] + 12*p[2, 1] + 9*p[2, 2]
```

class Element

Bases: IndexedFreeModuleElement

An element in the powersum basis of $NCSym$.

to_symmetric_function()

The projection of `self` to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the **p** basis, and return the projection of expressed in the powersum basis of symmetric functions.

The map $\chi\colon NCSym \to Sym$ is given by

$$\mathbf{p}_A \mapsto p_{\lambda(A)}$$

where $\lambda(A)$ is the partition associated with A by taking the sizes of the parts.

OUTPUT: an element of symmetric functions in the power sum basis

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: p[[1,3],[2]].to_symmetric_function()
p[2, 1]
sage: p[[1],[3],[2]].to_symmetric_function()
p[1, 1, 1]
```

```
>>> from sage.all import *
>>> p = SymmetricFunctionsNonCommutingVariables(QQ).p()
>>> p[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
p[2, 1]
>>> p[[Integer(1)],[Integer(3)],[Integer(2)]].to_symmetric_function()
p[1, 1, 1]
```

antipode_on_basis(A)

Return the result of the antipode applied to a powersum basis element.

Let A be a set partition. The antipode given in [LM2011] is

$$S(\mathbf{p}_A) = \sum_{\gamma} (-1)^{\ell(\gamma)} \mathbf{p}_{\gamma[A]}$$

where we sum over all ordered set partitions (i.e. set compositions) of $[\ell(A)]$ and

$$\gamma[A] = A^{\downarrow}_{\gamma_1} | \cdots | A^{\downarrow}_{\gamma_{\ell(A)}}$$

is the action of γ on A defined in *SetPartition.ordered_set_partition_action()*.

INPUT:

- A – set partition

OUTPUT: an element in the basis self

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.antipode_on_basis(SetPartition([[1], [2,3]]))
p{{1, 2}, {3}}
sage: p.antipode_on_basis(SetPartition([]))
p{}
sage: F = p[[1,3],[5],[2,4]].coproduct()
sage: F.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

```
>>> from sage.all import *
>>> p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
>>> p.antipode_on_basis(SetPartition([[Integer(1)], [Integer(2),
↪Integer(3)]]))
p{{1, 2}, {3}}
>>> p.antipode_on_basis(SetPartition([]))
p{}
>>> F = p[[Integer(1),Integer(3)],[Integer(5)],[Integer(2),Integer(4)]].
↪coproduct()
>>> F.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

coproduct_on_basis(*A*)

Return the coproduct of a monomial basis element.

INPUT:

- A – set partition

OUTPUT:

- The coproduct applied to the monomial symmetric function in non-commuting variables indexed by A expressed in the monomial basis.

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p[[1, 3], [2]].coproduct()
p{} # p{{1, 3}, {2}} + p{{1}} # p{{1, 2}} + p{{1, 2}} # p{{1}} + p{{1, 3},
↪ {2}} # p{}
sage: p.coproduct_on_basis(SetPartition([[1]]))
p{} # p{{1}} + p{{1}} # p{}
sage: p.coproduct_on_basis(SetPartition([]))
p{} # p{}
```

```
>>> from sage.all import *
>>> p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
>>> p[[Integer(1), Integer(3)], [Integer(2)]].coproduct()
p{} # p{{1, 3}, {2}} + p{{1}} # p{{1, 2}} + p{{1, 2}} # p{{1}} + p{{1, 3},
↪ {2}} # p{}
>>> p.coproduct_on_basis(SetPartition([[Integer(1)]]))
p{} # p{{1}} + p{{1}} # p{}
>>> p.coproduct_on_basis(SetPartition([]))
p{} # p{}
```

internal_coproduct_on_basis(*A*)

Return the internal coproduct of a powersum basis element.

The internal coproduct is defined by

$$\Delta^{\odot}(\mathbf{p}_A) = \mathbf{p}_A \otimes \mathbf{p}_A$$

INPUT:

- `A` – set partition

OUTPUT: an element of the tensor square of `self`

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.internal_coproduct_on_basis(SetPartition([[1,3],[2]]))
p{{1, 3}, {2}} # p{{1, 3}, {2}}
```

```
>>> from sage.all import *
>>> p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
>>> p.internal_coproduct_on_basis(SetPartition([[Integer(1),Integer(3)],
↪[Integer(2)]]))
p{{1, 3}, {2}} # p{{1, 3}, {2}}
```

primitive(*A*, *i=1*)

Return the primitive associated to `A` in `self`.

Fix some $i \in S$. Let A be an atomic set partition of S, then the primitive $p(A)$ given in [LM2011] is

$$p(A) = \sum_{\gamma} (-1)^{\ell(\gamma)-1} \mathbf{p}_{\gamma[A]}$$

where we sum over all ordered set partitions of $[\ell(A)]$ such that $i \in \gamma_1$ and $\gamma[A]$ is the action of γ on A defined in *SetPartition.ordered_set_partition_action()*. If A is not atomic, then $p(A) = 0$.

See also

SetPartition.is_atomic()

INPUT:

- `A` – set partition
- `i` – (default: 1) index in the base set for `A` specifying which set of primitives this belongs to

OUTPUT: an element in the basis `self`

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: elt = p.primitive(SetPartition([[1,3], [2]])); elt
-p{{1, 2}, {3}} + p{{1, 3}, {2}}
sage: elt.coproduct()
-p{} # p{{1, 2}, {3}} + p{} # p{{1, 3}, {2}} - p{{1, 2}, {3}} # p{} + p{
↪{1, 3}, {2}} # p{}
sage: p.primitive(SetPartition([[1], [2,3]]))
0
sage: p.primitive(SetPartition([]))
p{}
```

```
>>> from sage.all import *
>>> p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
>>> elt = p.primitive(SetPartition([[Integer(1),Integer(3)],␣
↪[Integer(2)]])); elt
-p{{1, 2}, {3}} + p{{1, 3}, {2}}
>>> elt.coproduct()
-p{} # p{{1, 2}, {3}} + p{} # p{{1, 3}, {2}} - p{{1, 2}, {3}} # p{} + p{
↪{1, 3}, {2}} # p{}
>>> p.primitive(SetPartition([[Integer(1)], [Integer(2),Integer(3)]]))
0
>>> p.primitive(SetPartition([]))
p{}
```

rho

alias of *deformed_coarse_powersum*

class supercharacter(*NCSym*, *q=2*)

Bases: *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the supercharacter χ basis.

This basis was defined in [BT13] as a q-deformation of the supercharacter basis.

$$\chi_A = \sum_B \chi_A(B)\mathbf{m}_B,$$

where we sum over all set partitions A and $\chi_A(B)$ is the evaluation of the supercharacter χ_A on the superclass μ_B.

Note

The supercharacters considered in [BT13] are coarser than those considered by Aguiar et. al.

INPUT:

- `q` – (default: `2`) the parameter q

EXAMPLES:

```
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: chi = NCSym.chi(q)
sage: chi[[1,3],[2]]*chi[[1,2]]
chi{{1, 3}, {2}, {4, 5}}
sage: chi[[1,3],[2]].coproduct()
chi{} # chi{{1, 3}, {2}} + (2*q-2)*chi{{1}} # chi{{1}, {2}} +
 (3*q-2)*chi{{1}} # chi{{1, 2}} + (2*q-2)*chi{{1}, {2}} # chi{{1}} +
 (3*q-2)*chi{{1, 2}} # chi{{1}} + chi{{1, 3}, {2}} # chi{}
sage: chi2 = NCSym.chi()
sage: chi(chi2[[1,2],[3]])
((-q+2)/q)*chi{{1}, {2}, {3}} + 2/q*chi{{1, 2}, {3}}
sage: chi2
Symmetric functions in non-commuting variables over the Fraction Field
```

(continues on next page)

(continued from previous page)

```
 of Univariate Polynomial Ring in q over Rational Field in the
 supercharacter basis with parameter q=2
```

```
>>> from sage.all import *
>>> R = QQ['q'].fraction_field()
>>> q = R.gen()
>>> NCSym = SymmetricFunctionsNonCommutingVariables(R)
>>> chi = NCSym.chi(q)
>>> chi[[Integer(1),Integer(3)],[Integer(2)]]*chi[[Integer(1),Integer(2)]]
chi{{1, 3}, {2}, {4, 5}}
>>> chi[[Integer(1),Integer(3)],[Integer(2)]].coproduct()
chi{} # chi{{1, 3}, {2}} + (2*q-2)*chi{{1}} # chi{{1}, {2}} +
 (3*q-2)*chi{{1}} # chi{{1, 2}} + (2*q-2)*chi{{1}, {2}} # chi{{1}} +
 (3*q-2)*chi{{1, 2}} # chi{{1}} + chi{{1, 3}, {2}} # chi{}
>>> chi2 = NCSym.chi()
>>> chi(chi2[[Integer(1),Integer(2)],[Integer(3)]])
((-q+2)/q)*chi{{1}, {2}, {3}} + 2/q*chi{{1, 2}, {3}}
>>> chi2
Symmetric functions in non-commuting variables over the Fraction Field
 of Univariate Polynomial Ring in q over Rational Field in the
 supercharacter basis with parameter q=2
```

q()

Return the deformation parameter q of `self`.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: chi = NCSym.chi(5)
sage: chi.q()
5

sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: chi = NCSym.chi(q)
sage: chi.q() == q
True
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> chi = NCSym.chi(Integer(5))
>>> chi.q()
5

>>> R = QQ['q'].fraction_field()
>>> q = R.gen()
>>> NCSym = SymmetricFunctionsNonCommutingVariables(R)
>>> chi = NCSym.chi(q)
>>> chi.q() == q
True
```

x

alias of *x_basis*

class x_basis(*NCSym*)

Bases: *NCSymBasis_abstract*

The Hopf algebra of symmetric functions in non-commuting variables in the **x** basis.

This basis is defined in [BHRZ06] by the formula:

$$\mathbf{x}_A = \sum_{B \leq A} \mu(B, A) \mathbf{p}_B$$

and has the following properties:

$$\mathbf{x}_A \mathbf{x}_B = \mathbf{x}_{A|B}, \qquad \Delta^{\odot}(\mathbf{x}_C) = \sum_{A \vee B = C} \mathbf{x}_A \otimes \mathbf{x}_B.$$

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: x = NCSym.x()
sage: x[[1,3],[2,4]]*x[[1,2,3]]
x{{1, 3}, {2, 4}, {5, 6, 7}}
sage: x[[1,2],[3]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 2}, {3}} + x{{1, 2}, {3}} # x{{1}, {2}, {3}} +
 x{{1, 2}, {3}} # x{{1, 2}, {3}}
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> x = NCSym.x()
>>> x[[Integer(1),Integer(3)],[Integer(2),Integer(4)]]*x[[Integer(1),
 ↪Integer(2),Integer(3)]]
x{{1, 3}, {2, 4}, {5, 6, 7}}
>>> x[[Integer(1),Integer(2)],[Integer(3)]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 2}, {3}} + x{{1, 2}, {3}} # x{{1}, {2}, {3}} +
 x{{1, 2}, {3}} # x{{1, 2}, {3}}
```

sage.combinat.ncsym.ncsym.**matchings**(*A*, *B*)

Iterate through all matchings of the sets A and B.

EXAMPLES:

```
sage: from sage.combinat.ncsym.ncsym import matchings
sage: list(matchings([1, 2, 3], [-1, -2]))
[[[1], [2], [3], [-1], [-2]],
 [[1], [2], [3, -1], [-2]],
 [[1], [2], [3, -2], [-1]],
 [[1], [2, -1], [3], [-2]],
 [[1], [2, -1], [3, -2]],
 [[1], [2, -2], [3], [-1]],
 [[1], [2, -2], [3, -1]],
 [[1, -1], [2], [3], [-2]],
 [[1, -1], [2], [3, -2]],
 [[1, -1], [2, -2], [3]],
 [[1, -2], [2], [3], [-1]],
```

(continues on next page)

(continued from previous page)

```
 [[1, -2], [2], [3, -1]],
 [[1, -2], [2, -1], [3]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsym.ncsym import matchings
>>> list(matchings([Integer(1), Integer(2), Integer(3)], [-Integer(1), -
↪Integer(2)]))
[[[1], [2], [3], [-1], [-2]],
 [[1], [2], [3, -1], [-2]],
 [[1], [2], [3, -2], [-1]],
 [[1], [2, -1], [3], [-2]],
 [[1], [2, -1], [3, -2]],
 [[1], [2, -2], [3], [-1]],
 [[1], [2, -2], [3, -1]],
 [[1, -1], [2], [3], [-2]],
 [[1, -1], [2], [3, -2]],
 [[1, -1], [2, -2], [3]],
 [[1, -2], [2], [3], [-1]],
 [[1, -2], [2], [3, -1]],
 [[1, -2], [2, -1], [3]]]
```

sage.combinat.ncsym.ncsym.**nesting**(*la*, *nu*)

Return the nesting number of `la` inside of `nu`.

If we consider a set partition A as a set of arcs $i - j$ where i and j are in the same part of A. Define

$$\mathrm{nst}_\lambda^\nu = \#\{i < j < k < l \mid i - l \in \nu, j - k \in \lambda\},$$

and this corresponds to the number of arcs of λ strictly contained inside of ν.

EXAMPLES:

```
sage: from sage.combinat.ncsym.ncsym import nesting
sage: nu = SetPartition([[1,4], [2], [3]])
sage: mu = SetPartition([[1,4], [2,3]])
sage: nesting(set(mu).difference(nu), nu)
1

sage: A = SetPartition([[1], [2,5], [3,4]])
sage: B = SetPartition([[1,3,4], [2,5]])
sage: nesting(A, B)
1
sage: nesting(B, A)
1
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsym.ncsym import nesting
>>> nu = SetPartition([[Integer(1),Integer(4)], [Integer(2)], [Integer(3)]])
>>> mu = SetPartition([[Integer(1),Integer(4)], [Integer(2),Integer(3)]])
>>> nesting(set(mu).difference(nu), nu)
1

>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(5)], [Integer(3),
```

(continues on next page)

(continued from previous page)

```
↪Integer(4)]])
>>> B = SetPartition([[Integer(1),Integer(3),Integer(4)], [Integer(2),
↪Integer(5)]])
>>> nesting(A, B)
1
>>> nesting(B, A)
1
```

```
sage: lst = list(SetPartitions(4))
sage: d = {}
sage: for i, nu in enumerate(lst):
....:     for mu in nu.coarsenings():
....:         if set(nu.arcs()).issubset(mu.arcs()):
....:             d[i, lst.index(mu)] = nesting(set(mu).difference(nu), nu)
sage: matrix(d)

4.1.10 sage.combinat.path_tableaux

Catalog of path tableaux

The `path_tableaux` object may be used to access examples of various path tableau objects currently implemented in Sage. Using tab-completion on this object is an easy way to discover and quickly create the path tableaux that are available (as listed here).

Let `<tab>` indicate pressing the `Tab` key. So begin by typing `path_tableaux.<tab>` to the see the currently implemented path tableaux.

Dyck paths

This is an implementation of the abstract base class *sage.combinat.path_tableaux.path_tableau.PathTableau*. This is the simplest implementation of a path tableau and is included to provide a convenient test case and for pedagogical purposes.

In this implementation we have sequences of nonnegative integers. These are required to be the heights Dyck words (except that we do not require the sequence to start or end at height zero). These are in bijection with skew standard tableaux with at most two rows. Sequences which start and end at height zero are in bijection with noncrossing perfect matchings.

AUTHORS:

- Bruce Westbury (2018): initial version

class sage.combinat.path_tableaux.dyck_path.**DyckPath**(*parent*, *ot*, *check=True*)

Bases: *PathTableau*

An instance is the sequence of nonnegative integers given by the heights of a Dyck word.

INPUT:

- a sequence of nonnegative integers
- a two row standard skew tableau
- a Dyck word
- a noncrossing perfect matching

EXAMPLES:

```
sage: path_tableaux.DyckPath([0,1,2,1,0])
[0, 1, 2, 1, 0]

sage: w = DyckWord([1,1,0,0])
sage: path_tableaux.DyckPath(w)
[0, 1, 2, 1, 0]

sage: p = PerfectMatching([(1,2), (3,4)])
sage: path_tableaux.DyckPath(p)
[0, 1, 0, 1, 0]

sage: t = Tableau([[1,2,4],[3,5,6]])
sage: path_tableaux.DyckPath(t)
[0, 1, 2, 1, 2, 1, 0]

sage: st = SkewTableau([[None, 1,4],[2,3]])
sage: path_tableaux.DyckPath(st)
[1, 2, 1, 0, 1]
```

```
>>> from sage.all import *
>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1),
↪Integer(0)])
[0, 1, 2, 1, 0]

>>> w = DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)])
>>> path_tableaux.DyckPath(w)
[0, 1, 2, 1, 0]

>>> p = PerfectMatching([(Integer(1),Integer(2)), (Integer(3),Integer(4))])
>>> path_tableaux.DyckPath(p)
[0, 1, 0, 1, 0]

>>> t = Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3),Integer(5),
↪Integer(6)]])
>>> path_tableaux.DyckPath(t)
[0, 1, 2, 1, 2, 1, 0]

>>> st = SkewTableau([[None, Integer(1),Integer(4)],[Integer(2),Integer(3)]])
>>> path_tableaux.DyckPath(st)
[1, 2, 1, 0, 1]
```

Here we illustrate the slogan that promotion = rotation:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]

sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 3), (1, 2), (4, 5)]

sage: t = t.promotion()
sage: t.to_perfect_matching()
```

(continues on next page)

(continued from previous page)

```
[(0, 1), (2, 5), (3, 4)]

sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]

>>> t = t.promotion()
>>> t.to_perfect_matching()
[(0, 3), (1, 2), (4, 5)]

>>> t = t.promotion()
>>> t.to_perfect_matching()
[(0, 1), (2, 5), (3, 4)]

>>> t = t.promotion()
>>> t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
```

check()

Check that `self` is a valid path.

EXAMPLES:

```
sage: path_tableaux.DyckPath([0,1,0,-1,0]) # indirect doctest
Traceback (most recent call last):
...
ValueError: [0, 1, 0, -1, 0] has a negative entry

sage: path_tableaux.DyckPath([0,1,3,1,0]) # indirect doctest
Traceback (most recent call last):
...
ValueError: [0, 1, 3, 1, 0] is not a Dyck path
```

```
>>> from sage.all import *
>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(0),-Integer(1),
↪Integer(0)]) # indirect doctest
Traceback (most recent call last):
...
ValueError: [0, 1, 0, -1, 0] has a negative entry

>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(3),Integer(1),
↪Integer(0)]) # indirect doctest
Traceback (most recent call last):
...
ValueError: [0, 1, 3, 1, 0] is not a Dyck path
```

descents()

Return the descent set of `self`.

EXAMPLES:

```
sage: path_tableaux.DyckPath([0,1,2,1,2,1,0,1,0]).descents()
{3, 6}
```

```
>>> from sage.all import *
>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1),
↪Integer(2),Integer(1),Integer(0),Integer(1),Integer(0)]).descents()
{3, 6}
```

is_skew()

Return `True` if `self` is skew and `False` if not.

EXAMPLES:

```
sage: path_tableaux.DyckPath([0,1,2,1]).is_skew()
False

sage: path_tableaux.DyckPath([1,0,1,2,1]).is_skew()
True
```

```
>>> from sage.all import *
>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1)]).is_
↪skew()
False

>>> path_tableaux.DyckPath([Integer(1),Integer(0),Integer(1),Integer(2),
↪Integer(1)]).is_skew()
True
```

local_rule(i)

This has input a list of objects. This method first takes the list of objects of length three consisting of the $(i-1)$-st, i-th and $(i+1)$-term and applies the rule. It then replaces the i-th object by the object returned by the rule.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.local_rule(3)
[0, 1, 2, 1, 2, 1, 0]
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.local_rule(Integer(3))
[0, 1, 2, 1, 2, 1, 0]
```

to_DyckWord()

Convert `self` to a Dyck word.

EXAMPLES:

```
sage: c = path_tableaux.DyckPath([0,1,2,1,0])
sage: c.to_DyckWord()
[1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> c = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1),
↪Integer(0)])
>>> c.to_DyckWord()
[1, 1, 0, 0]
```

to_perfect_matching()

Return the perfect matching associated to `self`.

EXAMPLES:

```
sage: path_tableaux.DyckPath([0,1,2,1,2,1,0,1,0]).to_perfect_matching()
[(0, 5), (1, 2), (3, 4), (6, 7)]
```

```
>>> from sage.all import *
>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1),
↪Integer(2),Integer(1),Integer(0),Integer(1),Integer(0)]).to_perfect_
↪matching()
[(0, 5), (1, 2), (3, 4), (6, 7)]
```

to_tableau()

Return the skew tableau associated to `self`.

EXAMPLES:

```
sage: T = path_tableaux.DyckPath([0,1,2,3,2,3])
sage: T.to_tableau()
[[1, 2, 3, 5], [4]]

sage: U = path_tableaux.DyckPath([2,3,2,3])
sage: U.to_tableau()
[[None, None, 1, 3], [2]]
```

```
>>> from sage.all import *
>>> T = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(3)])
>>> T.to_tableau()
[[1, 2, 3, 5], [4]]

>>> U = path_tableaux.DyckPath([Integer(2),Integer(3),Integer(2),Integer(3)])
>>> U.to_tableau()
[[None, None, 1, 3], [2]]
```

to_word()

Return the word in the alphabet $\{0, 1\}$ associated to `self`.

EXAMPLES:

```
sage: path_tableaux.DyckPath([1,0,1,2,1]).to_word()
[0, 1, 1, 0]
```

```
>>> from sage.all import *
>>> path_tableaux.DyckPath([Integer(1),Integer(0),Integer(1),Integer(2),
↪Integer(1)]).to_word()
[0, 1, 1, 0]
```

class sage.combinat.path_tableaux.dyck_path.**DyckPaths**

Bases: *PathTableaux*

The parent class for DyckPath.

Element

alias of *DyckPath*

Frieze patterns

This implements the original frieze patterns due to Conway and Coxeter. Such a frieze pattern is considered as a sequence of nonnegative integers following [CoCo1] and [CoCo2] using *sage.combinat.path_tableaux.path_tableau*.

AUTHORS:

- Bruce Westbury (2019): initial version

class sage.combinat.path_tableaux.frieze.**FriezePattern**

Bases: *PathTableau*

A frieze pattern.

We encode a frieze pattern as a sequence in a fixed ground field.

INPUT:

- `fp` – a sequence of elements of `field`
- `field` – (default: `QQ`) the ground field

EXAMPLES:

```
sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: path_tableaux.CylindricalDiagram(t)

```

change_ring(*R*)

Return `self` as a frieze pattern with coefficients in `R`.

This assumes that there is a canonical coerce map from the base ring of `self` to `R`.

EXAMPLES:

```
sage: fp = path_tableaux.FriezePattern([1,2,7,5,3,7,4,1])
sage: fp.change_ring(RealField())                                               #␣
↪needs sage.rings.real_mpfr
[0.000000000000000, 1.00000000000000, ...
 4.00000000000000, 1.00000000000000, 0.000000000000000]
sage: fp.change_ring(GF(7))
Traceback (most recent call last):
...
TypeError: no base extension defined
```

```
>>> from sage.all import *
>>> fp = path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(7),
↪Integer(5),Integer(3),Integer(7),Integer(4),Integer(1)])
>>> fp.change_ring(RealField())                                                 #␣

TypeError: no base extension defined
```

check()

Check that `self` is a valid frieze pattern.

is_integral()

Return `True` if all entries of the frieze pattern are positive integers.

EXAMPLES:

```
sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).is_integral()
True

sage: path_tableaux.FriezePattern([1,3,4,5,1]).is_integral()
False
```

```
>>> from sage.all import *
>>> path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(7),Integer(5),
↪Integer(3),Integer(7),Integer(4),Integer(1)]).is_integral()
True

>>> path_tableaux.FriezePattern([Integer(1),Integer(3),Integer(4),Integer(5),
↪Integer(1)]).is_integral()
False
```

is_positive()

Return `True` if all elements of `self` are positive.

This implies that all entries of `CylindricalDiagram(self)` are positive.

Warning

There are orders on all fields. These may not be ordered fields as they may not be compatible with the field operations. This method is intended to be used with ordered fields only.

EXAMPLES:

```
sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).is_positive()
True

sage: path_tableaux.FriezePattern([1,-3,4,5,1]).is_positive()
False

sage: x = polygen(ZZ, 'x')
sage: K.<sqrt3> = NumberField(x^2 - 3)                                  #␣
↪needs sage.rings.number_field
sage: path_tableaux.FriezePattern([1,sqrt3,1], K).is_positive()         #␣
↪needs sage.rings.number_field
True
```

```
>>> from sage.all import *
>>> path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(7),Integer(5),
↪Integer(3),Integer(7),Integer(4),Integer(1)]).is_positive()
True

>>> path_tableaux.FriezePattern([Integer(1),-Integer(3),Integer(4),Integer(5),
↪Integer(1)]).is_positive()
False

>>> x = polygen(ZZ, 'x')
>>> K = NumberField(x**Integer(2) - Integer(3), names=('sqrt3',)); (sqrt3,) =␣
↪K._first_ngens(1)# needs sage.rings.number_field
>>> path_tableaux.FriezePattern([Integer(1),sqrt3,Integer(1)], K).is_
↪positive()              # needs sage.rings.number_field
True
```

is_skew()

Return `True` if `self` is skew and `False` if not.

EXAMPLES:

```
sage: path_tableaux.FriezePattern([1,2,1,2,3,1]).is_skew()
False

sage: path_tableaux.FriezePattern([2,2,1,2,3,1]).is_skew()
True
```

```
>>> from sage.all import *
>>> path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(3),Integer(1)]).is_skew()
False

>>> path_tableaux.FriezePattern([Integer(2),Integer(2),Integer(1),Integer(2),
↪Integer(3),Integer(1)]).is_skew()
True
```

local_rule(i)

Return the i-th local rule on `self`.

This interprets `self` as a list of objects. This method first takes the list of objects of length three consisting of the $(i-1)$-st, i-th and $(i+1)$-term and applies the rule. It then replaces the i-th object by the object returned by the rule.

EXAMPLES:

```
sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: t.local_rule(3)
[1, 2, 5, 2, 3, 1]

sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: t.local_rule(0)
Traceback (most recent call last):
...
ValueError: 0 is not a valid integer
```

```
>>> from sage.all import *
>>> t = path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(1),
↪Integer(2),Integer(3),Integer(1)])
>>> t.local_rule(Integer(3))
[1, 2, 5, 2, 3, 1]

>>> t = path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(1),
↪Integer(2),Integer(3),Integer(1)])
>>> t.local_rule(Integer(0))
Traceback (most recent call last):
...
ValueError: 0 is not a valid integer
```

plot(*model='UHP'*)

Plot the frieze as an ideal hyperbolic polygon.

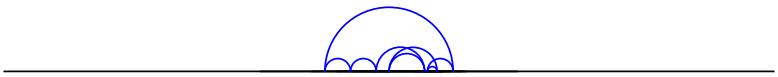
This is only defined up to isometry of the hyperbolic plane.

We are identifying the boundary of the hyperbolic plane with the real projective line.

The option `model` must be one of

- `'UHP'` – (default) for the upper half plane model
- `'PD'` – for the Poincare disk model
- `'KM'` – for the Klein model

The hyperboloid model is not an option as this does not implement boundary points.



EXAMPLES:

```
sage: # needs sage.plot sage.symbolic
sage: t = path_tableaux.FriezePattern([1,2,7,5,3,7,4,1])
sage: t.plot()
Graphics object consisting of 18 graphics primitives
```

(continues on next page)

(continued from previous page)

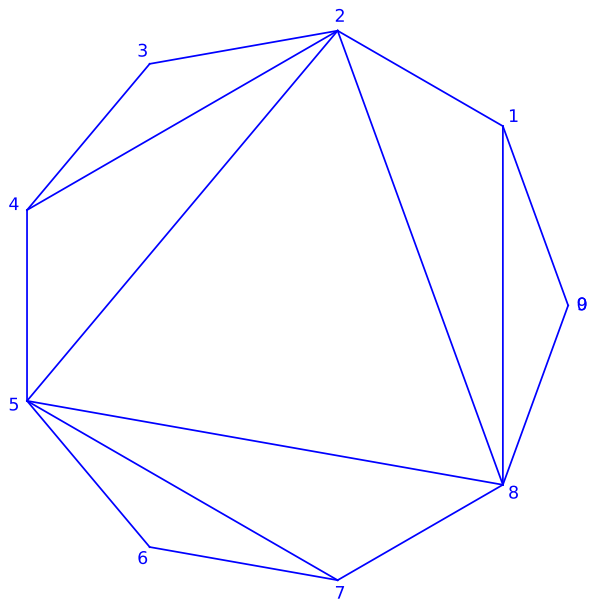
```
sage: t.plot(model='UHP')
Graphics object consisting of 18 graphics primitives
sage: t.plot(model='PD')
Traceback (most recent call last):
...
TypeError: '>' not supported between instances of 'NotANumber' and 'Pi'
sage: t.plot(model='KM')
Graphics object consisting of 18 graphics primitives
```

```
>>> from sage.all import *
>>> # needs sage.plot sage.symbolic
>>> t = path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(7),
↪Integer(5),Integer(3),Integer(7),Integer(4),Integer(1)])
>>> t.plot()
Graphics object consisting of 18 graphics primitives
>>> t.plot(model='UHP')
Graphics object consisting of 18 graphics primitives
>>> t.plot(model='PD')
Traceback (most recent call last):
...
TypeError: '>' not supported between instances of 'NotANumber' and 'Pi'
>>> t.plot(model='KM')
Graphics object consisting of 18 graphics primitives
```

triangulation()

Plot a regular polygon with some diagonals.

If `self` is positive and integral then this will be a triangulation.



EXAMPLES:

```
sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).triangulation()        #␣
↪needs sage.plot sage.symbolic
```

(continues on next page)

(continued from previous page)

```
Graphics object consisting of 25 graphics primitives

sage: path_tableaux.FriezePattern([1,2,1/7,5,3]).triangulation()            #␣
↪needs sage.plot sage.symbolic
Graphics object consisting of 12 graphics primitives

sage: x = polygen(ZZ, 'x')
sage: K.<sqrt2> = NumberField(x^2 - 2)                                      #␣
↪needs sage.rings.number_field
sage: path_tableaux.FriezePattern([1,sqrt2,1,sqrt2,3,2*sqrt2,5,3*sqrt2,1],  #␣
↪needs sage.plot sage.rings.number_field sage.symbolic
....:                               field=K).triangulation()
Graphics object consisting of 24 graphics primitives
```

```
>>> from sage.all import *
>>> path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(7),Integer(5),
↪Integer(3),Integer(7),Integer(4),Integer(1)]).triangulation()        #␣
↪needs sage.plot sage.symbolic
Graphics object consisting of 25 graphics primitives

>>> path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(1)/Integer(7),
↪Integer(5),Integer(3)]).triangulation()            # needs sage.plot sage.
↪symbolic
Graphics object consisting of 12 graphics primitives

>>> x = polygen(ZZ, 'x')
>>> K = NumberField(x**Integer(2) - Integer(2), names=('sqrt2',)); (sqrt2,) =␣
↪K._first_ngens(1)# needs sage.rings.number_field
>>> path_tableaux.FriezePattern([Integer(1),sqrt2,Integer(1),sqrt2,Integer(3),
↪Integer(2)*sqrt2,Integer(5),Integer(3)*sqrt2,Integer(1)],  # needs sage.
↪plot sage.rings.number_field sage.symbolic
...                               field=K).triangulation()
Graphics object consisting of 24 graphics primitives
```

width()

Return the width of `self`.

If the first and last terms of `self` are 1 then this is the length of `self` plus two and otherwise is undefined.

EXAMPLES:

```
sage: path_tableaux.FriezePattern([1,2,1,2,3,1]).width()
8

sage: path_tableaux.FriezePattern([1,2,1,2,3,4]).width() is None
True
```

```
>>> from sage.all import *
>>> path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(3),Integer(1)]).width()
```

(continues on next page)

(continued from previous page)

```
8

>>> path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(3),Integer(4)]).width() is None
True
```

class sage.combinat.path_tableaux.frieze.**FriezePatterns**(*field*)

Bases: *PathTableaux*

The set of all frieze patterns.

EXAMPLES:

```
sage: P = path_tableaux.FriezePatterns(QQ)
sage: fp = P((1, 1, 1))
sage: fp
[1]
sage: path_tableaux.CylindricalDiagram(fp)
[1, 1, 1]
[ , 1, 2, 1]
[ ,  , 1, 1, 1]
```

```
>>> from sage.all import *
>>> P = path_tableaux.FriezePatterns(QQ)
>>> fp = P((Integer(1), Integer(1), Integer(1)))
>>> fp
[1]
>>> path_tableaux.CylindricalDiagram(fp)
[1, 1, 1]
[ , 1, 2, 1]
[ ,  , 1, 1, 1]
```

- *Semistandard tableaux*

Path tableaux

This is an abstract base class for using local rules to construct rectification and the action of the cactus group [Wes2017].

This is a construction of the Henriques-Kamnitzer construction of the action of the cactus group on tensor powers of a crystal. This is also a generalisation of the Fomin growth rules, which are a version of the operations on standard tableaux which were previously constructed using jeu de taquin.

The basic operations are rectification, evacuation and promotion. Rectification of standard skew tableaux agrees with the rectification by jeu de taquin as does evacuation. Promotion agrees with promotion by jeu de taquin on rectangular tableaux but in general they are different.

class sage.combinat.path_tableaux.path_tableau.**CylindricalDiagram**(*T*)

Bases: SageObject

Cylindrical growth diagrams.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 3, 2, 1, 0]
[ , 0, 1, 2, 1, 0, 1, 0]
[ ,  , 0, 1, 0, 1, 2, 1, 0]
[ ,  ,  , 0, 1, 2, 3, 2, 1, 0]
[ ,  ,  ,  , 0, 1, 2, 1, 0, 1, 0]
[ ,  ,  ,  ,  , 0, 1, 0, 1, 2, 1, 0]
[ ,  ,  ,  ,  ,  , 0, 1, 2, 3, 2, 1, 0]
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 3, 2, 1, 0]
[ , 0, 1, 2, 1, 0, 1, 0]
[ ,  , 0, 1, 0, 1, 2, 1, 0]
[ ,  ,  , 0, 1, 2, 3, 2, 1, 0]
[ ,  ,  ,  , 0, 1, 2, 1, 0, 1, 0]
[ ,  ,  ,  ,  , 0, 1, 0, 1, 2, 1, 0]
[ ,  ,  ,  ,  ,  , 0, 1, 2, 3, 2, 1, 0]
```

pp()

A pretty print utility method.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: path_tableaux.CylindricalDiagram(t).pp()
0 1 2 3 2 1 0
  0 1 2 1 0 1 0
    0 1 0 1 2 1 0
      0 1 2 3 2 1 0
        0 1 2 1 0 1 0
          0 1 0 1 2 1 0
            0 1 2 3 2 1 0

sage: t = path_tableaux.FriezePattern([1,3,4,5,1])
sage: path_tableaux.CylindricalDiagram(t).pp()
  0   1   3   4   5   1   0
    0   1 5/3 7/3 2/3   1   0
```

(continues on next page)

(continued from previous page)

```
          0   1   2   1   3   1   0
              0   1   1   4 5/3   1   0
                  0   1   5 7/3   2   1   0
                      0   1 2/3   1   1   1   0
                          0   1   3   4   5   1   0
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> path_tableaux.CylindricalDiagram(t).pp()
0 1 2 3 2 1 0
  0 1 2 1 0 1 0
    0 1 0 1 2 1 0
      0 1 2 3 2 1 0
        0 1 2 1 0 1 0
          0 1 0 1 2 1 0
            0 1 2 3 2 1 0

>>> t = path_tableaux.FriezePattern([Integer(1),Integer(3),Integer(4),
↪Integer(5),Integer(1)])
>>> path_tableaux.CylindricalDiagram(t).pp()
  0   1   3   4   5   1   0
      0   1 5/3 7/3 2/3   1   0
          0   1   2   1   3   1   0
              0   1   1   4 5/3   1   0
                  0   1   5 7/3   2   1   0
                      0   1 2/3   1   1   1   0
                          0   1   3   4   5   1   0
```

class sage.combinat.path_tableaux.path_tableau.**PathTableau**

Bases: ClonableArray

This is the abstract base class for a path tableau.

cactus(i, j)

Return the action of the generator $s_{i,j}$ of the cactus group on `self`.

INPUT:

- `i` – positive integer
- `j` – positive integer weakly greater than i

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.cactus(1,5)
[0, 1, 0, 1, 2, 1, 0]

sage: t.cactus(1,6)
[0, 1, 2, 1, 0, 1, 0]

sage: t.cactus(1,7) == t.evacuation()
True
```

(continues on next page)

(continued from previous page)

```
sage: t.cactus(1,7).cactus(1,6) == t.promotion()
True
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.cactus(Integer(1),Integer(5))
[0, 1, 0, 1, 2, 1, 0]

>>> t.cactus(Integer(1),Integer(6))
[0, 1, 2, 1, 0, 1, 0]

>>> t.cactus(Integer(1),Integer(7)) == t.evacuation()
True
>>> t.cactus(Integer(1),Integer(7)).cactus(Integer(1),Integer(6)) == t.
↪promotion()
True
```

commutor(*other*, *verbose=False*)

Return the commutor of `self` with `other`.

If `verbose=True` then the function will print the rectangle.

EXAMPLES:

```
sage: t1 = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t2 = path_tableaux.DyckPath([0,1,2,1,0])
sage: t1.commutor(t2)
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
sage: t1.commutor(t2,verbose=True)
[0, 1, 2, 1, 0]
[1, 2, 3, 2, 1]
[2, 3, 4, 3, 2]
[3, 4, 5, 4, 3]
[2, 3, 4, 3, 2]
[1, 2, 3, 2, 1]
[0, 1, 2, 1, 0]
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
```

```
>>> from sage.all import *
>>> t1 = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t2 = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1),
↪Integer(0)])
>>> t1.commutor(t2)
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
>>> t1.commutor(t2,verbose=True)
[0, 1, 2, 1, 0]
[1, 2, 3, 2, 1]
[2, 3, 4, 3, 2]
[3, 4, 5, 4, 3]
[2, 3, 4, 3, 2]
```

(continues on next page)

(continued from previous page)

```
[1, 2, 3, 2, 1]
[0, 1, 2, 1, 0]
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
```

dual_equivalence_graph()

Return the graph with vertices the orbit of `self` and edges given by the action of the cactus group generators.

In most implementations the generators $s_{i,i+1}$ will act as the identity operators. The usual dual equivalence graphs are given by replacing the label $i, i+2$ by i and removing edges with other labels.

EXAMPLES:

```
sage: s = path_tableaux.DyckPath([0,1,2,3,2,3,2,1,0])
sage: s.dual_equivalence_graph().adjacency_matrix()                             #␣
↪needs sage.graphs sage.modules
[0 1 1 1 0 1 0 1 1 0 0 0 0 0]
[1 0 1 1 1 1 1 0 1 0 0 1 1 0]
[1 1 0 1 1 1 0 1 0 1 1 1 0 0]
[1 1 1 0 1 0 1 1 1 1 0 1 1 0]

 ([0, 1, 2, 1, 0, 1, 0], [0, 1, 2, 3, 2, 1, 0], '3,7'),
 ([0, 1, 2, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0], '3,6')]
```

evacuation()

Return the evacuation operator applied to `self`.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.evacuation()
[0, 1, 2, 3, 2, 1, 0]
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.evacuation()
[0, 1, 2, 3, 2, 1, 0]
```

final_shape()

Return the final shape of `self`.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.final_shape()
0
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.final_shape()
0
```

initial_shape()

Return the initial shape of `self`.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.initial_shape()
0
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.initial_shape()
0
```

local_rule(i)

This is the abstract local rule defined in any coboundary category.

This has input a list of objects. This method first takes the list of objects of length three consisting of the $(i-1)$-st, i-th and $(i+1)$-term and applies the rule. It then replaces the i-th object by the object returned by the rule.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.local_rule(3)
[0, 1, 2, 1, 2, 1, 0]
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.local_rule(Integer(3))
[0, 1, 2, 1, 2, 1, 0]
```

orbit()

Return the orbit of `self` under the action of the cactus group.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.orbit()
{[0, 1, 0, 1, 0, 1, 0],
 [0, 1, 0, 1, 2, 1, 0],
 [0, 1, 2, 1, 0, 1, 0],
 [0, 1, 2, 1, 2, 1, 0],
 [0, 1, 2, 3, 2, 1, 0]}
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.orbit()
{[0, 1, 0, 1, 0, 1, 0],
 [0, 1, 0, 1, 2, 1, 0],
 [0, 1, 2, 1, 0, 1, 0],
```

(continues on next page)

(continued from previous page)

```
 [0, 1, 2, 1, 2, 1, 0],
 [0, 1, 2, 3, 2, 1, 0]}
```

promotion()

Return the promotion operator applied to `self`.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.promotion()
[0, 1, 2, 1, 0, 1, 0]
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.promotion()
[0, 1, 2, 1, 0, 1, 0]
```

size()

Return the size or length of `self`.

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.size()
7
```

```
>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(2),Integer(1),Integer(0)])
>>> t.size()
7
```

class sage.combinat.path_tableaux.path_tableau.**PathTableaux**

Bases: `UniqueRepresentation`, `Parent`

The abstract parent class for PathTableau.

Semistandard tableaux

This is an implementation of the abstract base class *sage.combinat.path_tableaux.path_tableau.PathTableau*.

This implementation is for semistandard tableaux, represented as a chain of partitions (essentially, the Gelfand-Tsetlin pattern). This generalises the jeu de taquin operations of rectification, promotion, evacuation from standard tableaux to semistandard tableaux. The local rule is the Bender-Knuth involution.

EXAMPLES:

```
sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1],
....:                                             [3,3,2,1], [4,3,3,1,0]])
sage: pt.promotion()
[(), (2,), (3, 1), (3, 2, 1), (4, 3, 1, 0), (4, 3, 3, 1, 0)]
sage: pt.evacuation()
```

(continues on next page)

(continued from previous page)

```
[(), (2,), (4, 0), (4, 2, 0), (4, 3, 1, 0), (4, 3, 3, 1, 0)]

sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1],
....:                                             [3,3,2,1], [9/2,3,3,1,0]])
sage: pt.promotion()
[(), (2,), (3, 1), (3, 2, 1), (9/2, 3, 1, 0), (9/2, 3, 3, 1, 0)]
sage: pt.evacuation()
[(), (5/2,), (9/2, 0), (9/2, 2, 0), (9/2, 3, 1, 0), (9/2, 3, 3, 1, 0)]

sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [4,2], [5,4,1]])
sage: path_tableaux.CylindricalDiagram(pt)
[       (),      (3,),    (4, 2), (5, 4, 1)]
[         ,        (),      (3,),    (5, 2), (5, 4, 1)]
[         ,          ,        (),      (4,),    (4, 3), (5, 4, 1)]
[         ,          ,          ,        (),      (3,),    (5, 1), (5, 4, 1)]

sage: pt2 = path_tableaux.SemistandardPathTableau([[3,2], [3,3,1],
....:                                              [3,3,2,1], [4,3,3,1,0]])

AUTHORS:

- Bruce Westbury (2020): initial version

class sage.combinat.path_tableaux.semistandard.**SemistandardPathTableau**(*parent*, *st*, *check=True*)

Bases: *PathTableau*

An instance is a sequence of lists. Usually the entries will be nonnegative integers in which case this is the chain of partitions of a (skew) semistandard tableau. In general the entries are elements of an ordered abelian group; each list is weakly decreasing and successive lists are interleaved.

INPUT:

Can be any of the following

- a sequence of partitions
- a sequence of lists/tuples
- a semistandard tableau
- a semistandard skew tableau
- a Gelfand-Tsetlin pattern

EXAMPLES:

```
sage: path_tableaux.SemistandardPathTableau([[], [2], [2,1]])
[(), (2,), (2, 1)]

sage: gt = GelfandTsetlinPattern([[2,1], [2]])
sage: path_tableaux.SemistandardPathTableau(gt)
[(), (2,), (2, 1)]

sage: st = SemistandardTableau([[1,1], [2]])
sage: path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

sage: st = SkewTableau([[1,1], [2]])
sage: path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

sage: st = SkewTableau([[None,1,1], [2]])
sage: path_tableaux.SemistandardPathTableau(st)
[(1,), (3, 0), (3, 1, 0)]

sage: path_tableaux.SemistandardPathTableau([[], [5/2], [7/2,2]])
[(), (5/2,), (7/2, 2)]

sage: path_tableaux.SemistandardPathTableau([[], [2.5], [3.5,2]])
[(), (2.50000000000000,), (3.50000000000000, 2)]
```

```
>>> from sage.all import *
>>> path_tableaux.SemistandardPathTableau([[], [Integer(2)], [Integer(2),
↪Integer(1)]])
[(), (2,), (2, 1)]

>>> gt = GelfandTsetlinPattern([[Integer(2),Integer(1)], [Integer(2)]])
>>> path_tableaux.SemistandardPathTableau(gt)
[(), (2,), (2, 1)]

>>> st = SemistandardTableau([[Integer(1),Integer(1)], [Integer(2)]])
>>> path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

>>> st = SkewTableau([[Integer(1),Integer(1)], [Integer(2)]])
>>> path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

>>> st = SkewTableau([[None,Integer(1),Integer(1)], [Integer(2)]])
>>> path_tableaux.SemistandardPathTableau(st)
```

(continues on next page)

(continued from previous page)

```
[(1,), (3, 0), (3, 1, 0)]

>>> path_tableaux.SemistandardPathTableau([[], [Integer(5)/Integer(2)],␣
↪[Integer(7)/Integer(2),Integer(2)]])
[(), (5/2,), (7/2, 2)]

>>> path_tableaux.SemistandardPathTableau([[], [RealNumber('2.5')], [RealNumber(
↪'3.5'),Integer(2)]])
[(), (2.50000000000000,), (3.50000000000000, 2)]
```

check()

Check that `self` is a valid path.

EXAMPLES:

```
sage: path_tableaux.SemistandardPathTableau([[], [3], [2,2]])       #␣
↪indirect doctest
Traceback (most recent call last):
...
ValueError: [(), (3,), (2, 2)] does not satisfy
the required inequalities in row 1

sage: path_tableaux.SemistandardPathTableau([[], [3/2], [2,5/2]])   #␣
↪indirect doctest
Traceback (most recent call last):
...
ValueError: [(), (3/2,), (2, 5/2)] does not satisfy
the required inequalities in row 1
```

```
>>> from sage.all import *
>>> path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(2),
↪Integer(2)]])       # indirect doctest
Traceback (most recent call last):
...
ValueError: [(), (3,), (2, 2)] does not satisfy
the required inequalities in row 1

>>> path_tableaux.SemistandardPathTableau([[], [Integer(3)/Integer(2)],␣
↪[Integer(2),Integer(5)/Integer(2)]])   # indirect doctest
Traceback (most recent call last):
...
ValueError: [(), (3/2,), (2, 5/2)] does not satisfy
the required inequalities in row 1
```

is_integral()

Return `True` if all entries are nonnegative integers.

EXAMPLES:

```
sage: path_tableaux.SemistandardPathTableau([[], [3], [3,2]]).is_integral()
True
sage: path_tableaux.SemistandardPathTableau([[], [5/2], [7/2,2]]).is_
↪integral()
```

(continues on next page)

(continued from previous page)

```
False
sage: path_tableaux.SemistandardPathTableau([[], [3], [3,-2]]).is_integral()
False
```

```
>>> from sage.all import *
>>> path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
↪Integer(2)]]).is_integral()
True
>>> path_tableaux.SemistandardPathTableau([[], [Integer(5)/Integer(2)],␣
↪[Integer(7)/Integer(2),Integer(2)]]).is_integral()
False
>>> path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),-
↪Integer(2)]]).is_integral()
False
```

is_skew()

Return `True` if `self` is skew.

EXAMPLES:

```
sage: path_tableaux.SemistandardPathTableau([[], [2]]).is_skew()
False
sage: path_tableaux.SemistandardPathTableau([[2,1]]).is_skew()
True
```

```
>>> from sage.all import *
>>> path_tableaux.SemistandardPathTableau([[], [Integer(2)]]).is_skew()
False
>>> path_tableaux.SemistandardPathTableau([[Integer(2),Integer(1)]]).is_skew()
True
```

local_rule(i)

This is the Bender-Knuth involution.

This is implemented by toggling the entries of the i-th list. The allowed range for `i` is `0 < i < len(self)-1` so any row except the first and last can be changed.

EXAMPLES:

```
sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2],
....:                                             [3,3,1], [3,3,2,1]])
sage: pt.local_rule(1)
[(), (2,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]
sage: pt.local_rule(2)
[(), (3,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]
sage: pt.local_rule(3)
[(), (3,), (3, 2), (3, 2, 2), (3, 3, 2, 1)]
```

```
>>> from sage.all import *
>>> pt = path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
↪Integer(2)],
...                                             [Integer(3),Integer(3),
↪Integer(1)], [Integer(3),Integer(3),Integer(2),Integer(1)]])
```

(continues on next page)

(continued from previous page)

```
>>> pt.local_rule(Integer(1))
[(), (2,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]
>>> pt.local_rule(Integer(2))
[(), (3,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]
>>> pt.local_rule(Integer(3))
[(), (3,), (3, 2), (3, 2, 2), (3, 3, 2, 1)]
```

rectify(*inner=None*, *verbose=False*)

Rectify `self`.

This gives the usual rectification of a skew standard tableau and gives a generalisation to skew semistandard tableaux. The usual construction uses jeu de taquin but here we use the Bender-Knuth involutions.

EXAMPLES:

```
sage: st = SkewTableau([[None, None, None, 4], [None, None, 1, 6],
....:                   [None, None, 5], [2, 3]])
sage: path_tableaux.SemistandardPathTableau(st).rectify()
[(), (1,), (1, 1), (2, 1, 0), (3, 1, 0, 0), (3, 2, 0, 0, 0), (4, 2, 0, 0, 0,␣
↪0)]
sage: path_tableaux.SemistandardPathTableau(st).rectify(verbose=True)
[[(3, 2, 2), (3, 3, 2, 0), (3, 3, 2, 1, 0), (3, 3, 2, 2, 0, 0),
  (4, 3, 2, 2, 0, 0, 0), (4, 3, 3, 2, 0, 0, 0, 0), (4, 4, 3, 2, 0, 0, 0, 0,␣
↪0)],
 [(3, 2), (3, 3, 0), (3, 3, 1, 0), (3, 3, 2, 0, 0), (4, 3, 2, 0, 0, 0),
  (4, 3, 3, 0, 0, 0, 0), (4, 4, 3, 0, 0, 0, 0, 0)],
 [(3,), (3, 1), (3, 1, 1), (3, 2, 1, 0), (4, 2, 1, 0, 0), (4, 3, 1, 0, 0, 0),
  (4, 4, 1, 0, 0, 0, 0)],
 [(), (1,), (1, 1), (2, 1, 0), (3, 1, 0, 0), (3, 2, 0, 0, 0), (4, 2, 0, 0, 0,␣
↪0)]]
```

```
>>> from sage.all import *
>>> st = SkewTableau([[None, None, None, Integer(4)], [None, None, Integer(1),
↪ Integer(6)],
...                   [None, None, Integer(5)], [Integer(2), Integer(3)]])
>>> path_tableaux.SemistandardPathTableau(st).rectify()
[(), (1,), (1, 1), (2, 1, 0), (3, 1, 0, 0), (3, 2, 0, 0, 0), (4, 2, 0, 0, 0,␣
↪0)]
>>> path_tableaux.SemistandardPathTableau(st).rectify(verbose=True)
[[(3, 2, 2), (3, 3, 2, 0), (3, 3, 2, 1, 0), (3, 3, 2, 2, 0, 0),
  (4, 3, 2, 2, 0, 0, 0), (4, 3, 3, 2, 0, 0, 0, 0), (4, 4, 3, 2, 0, 0, 0, 0,␣
↪0)],
 [(3, 2), (3, 3, 0), (3, 3, 1, 0), (3, 3, 2, 0, 0), (4, 3, 2, 0, 0, 0),
  (4, 3, 3, 0, 0, 0, 0), (4, 4, 3, 0, 0, 0, 0, 0)],
 [(3,), (3, 1), (3, 1, 1), (3, 2, 1, 0), (4, 2, 1, 0, 0), (4, 3, 1, 0, 0, 0),
  (4, 4, 1, 0, 0, 0, 0)],
 [(), (1,), (1, 1), (2, 1, 0), (3, 1, 0, 0), (3, 2, 0, 0, 0), (4, 2, 0, 0, 0,␣
↪0)]]
```

size()

Return the size or length of `self`.

EXAMPLES:

```
sage: path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1], [3,3,2,
↪1]]).size()
5
```

```
>>> from sage.all import *
>>> path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
↪Integer(2)], [Integer(3),Integer(3),Integer(1)], [Integer(3),Integer(3),
↪Integer(2),Integer(1)]]).size()
5
```

to_pattern()

Convert `self` to a Gelfand-Tsetlin pattern.

EXAMPLES:

```
sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1],
....:                                             [3,3,2,1], [4,3,3,1]])
sage: pt.to_pattern()
[[4, 3, 3, 1, 0], [3, 3, 2, 1], [3, 3, 1], [3, 2], [3]]
```

```
>>> from sage.all import *
>>> pt = path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
↪Integer(2)], [Integer(3),Integer(3),Integer(1)],
...                                             [Integer(3),Integer(3),
↪Integer(2),Integer(1)], [Integer(4),Integer(3),Integer(3),Integer(1)]])
>>> pt.to_pattern()
[[4, 3, 3, 1, 0], [3, 3, 2, 1], [3, 3, 1], [3, 2], [3]]
```

to_tableau()

Convert `self` to a *SemistandardTableau*.

The elements of *SemistandardSkewTableaux* are not implemented as a separate class, so this returns a *SkewTableau*

EXAMPLES:

```
sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1],
....:                                             [3,3,2,1], [4,3,3,1,0]])
sage: pt.to_tableau()
[[1, 1, 1, 5], [2, 2, 3], [3, 4, 5], [4]]
```

```
>>> from sage.all import *
>>> pt = path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
↪Integer(2)], [Integer(3),Integer(3),Integer(1)],
...                                             [Integer(3),Integer(3),
↪Integer(2),Integer(1)], [Integer(4),Integer(3),Integer(3),Integer(1),
↪Integer(0)]])
>>> pt.to_tableau()
[[1, 1, 1, 5], [2, 2, 3], [3, 4, 5], [4]]
```

class sage.combinat.path_tableaux.semistandard.**SemistandardPathTableaux**

Bases: *PathTableaux*

The parent class for *SemistandardPathTableau*.

Element

alias of *SemistandardPathTableau*

4.1.11 sage.combinat.posets

Bubble and Shuffle lattices

Shuffle lattices were defined by Greene in [Gre1988].

Bubble lattices were introduced by McConville and Mühle in [MacCM2022].

The Bubble lattice $B_{m,n}$ and the Shuffle lattice $S_{m,n}$ share the same underlying set, namely all shuffles of two subwords of the two words $X = (x_1, x_2, \ldots, x_m)$ and $Y = (y_1, y_2, \ldots, y_n)$.

Note

In the implementation here, the underlying set is the set of all shuffles of subsets of $\{-m, \ldots, -1\}$ with subsets of $\{1, \ldots, n\}$.

sage.combinat.posets.bubble_shuffle.**BubblePoset**(*m*, *n*)

Return the Bubble lattice $B_{m,n}$.

Bubble lattices were introduced by McConville and Mühle in [MacCM2022].

The Bubble lattice $B_{m,n}$ and the Shuffle lattice $S_{m,n}$ share the same underlying set, namely all shuffles of two subwords of the two words $X = (x_1, x_2, \ldots, x_m)$ and $Y = (y_1, y_2, \ldots, y_n)$.

The Bubble poset is an extension of the Shuffle poset, by adding the exchange of adjacent letters from X and Y, from xy to yx.

See also

ShufflePoset(), *sage.combinat.posets.bubble_shuffle.noncrossing_bipartite_complex()*

EXAMPLES:

```
sage: P = posets.BubblePoset(2,1); P
Finite lattice containing 12 elements
sage: P.zeta_polynomial()
1/40*q^5 + 7/24*q^4 + 23/24*q^3 - 7/24*q^2 + 1/60*q
```

```
>>> from sage.all import *
>>> P = posets.BubblePoset(Integer(2),Integer(1)); P
Finite lattice containing 12 elements
>>> P.zeta_polynomial()
1/40*q^5 + 7/24*q^4 + 23/24*q^3 - 7/24*q^2 + 1/60*q
```

sage.combinat.posets.bubble_shuffle.**ShufflePoset**(*m*, *n*)

Return the Shuffle lattice $S_{m,n}$.

Shuffle lattices were defined by Greene in [Gre1988].

The Bubble lattice $B_{m,n}$ and the Shuffle lattice $S_{m,n}$ share the same underlying set, namely all shuffles of two subwords of the two words $X = (x_1, x_2, \ldots, x_m)$ and $Y = (y_1, y_2, \ldots, y_n)$.

The partial order in the Shuffle poset is defined by either inserting a letter from Y or deleting a letter from X.

See also

BubblePoset()

EXAMPLES:

```
sage: P = posets.ShufflePoset(2,1); P
Finite lattice containing 12 elements
sage: P.zeta_polynomial()
2*q^3 - q^2
```

```
>>> from sage.all import *
>>> P = posets.ShufflePoset(Integer(2),Integer(1)); P
Finite lattice containing 12 elements
>>> P.zeta_polynomial()
2*q^3 - q^2
```

sage.combinat.posets.bubble_shuffle.**bubble_cardinality**(*m*, *n*)

Return the cardinality of the Bubble lattice $B_{m,n}$.

We have

$$|B_{m,n}| = \sum_{i=0}^{m} \sum_{j=0}^{n} \binom{i+j}{j} \binom{m}{i} \binom{n}{j}.$$

This is also the cardinality of the Shuffle lattice $S_{m,n}$.

INPUT:

- `m` – integer
- `n` – integer

EXAMPLES:

```
sage: from sage.combinat.posets.bubble_shuffle import bubble_cardinality
sage: bubble_cardinality(2,1)
12
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.bubble_shuffle import bubble_cardinality
>>> bubble_cardinality(Integer(2),Integer(1))
12
```

sage.combinat.posets.bubble_shuffle.**bubble_coverings**(*m*, *n*, *mot*, *transpose=True*)

Return generating relations of the Bubble lattice $B_{m,n}$.

Note that these relations include the cover relations, but not only them.

This can also produce covers in the Shuffle lattice $S_{m,n}$.

INPUT:

- `m` – integer
- `n` – integer
- `mot` – element of $B_{m,n}$ as a tuple

- `transpose` – boolean (default: `True`) whether to return covers in the Bubble lattice or in the Shuffle lattice

EXAMPLES:

```
sage: from sage.combinat.posets.bubble_shuffle import bubble_coverings
sage: list(bubble_coverings(2, 1, (-2, 1)))
[(1,), (1, -2)]
sage: list(bubble_coverings(2, 1, (-2, 1), False))
[(1,)]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.bubble_shuffle import bubble_coverings
>>> list(bubble_coverings(Integer(2), Integer(1), (-Integer(2), Integer(1))))
[(1,), (1, -2)]
>>> list(bubble_coverings(Integer(2), Integer(1), (-Integer(2), Integer(1)),␣
↪False))
[(1,)]
```

sage.combinat.posets.bubble_shuffle.**bubble_set**(m, n)

Return the underlying set of the Bubble lattice $B_{m,n}$.

This is the set of all shuffles of subsets of $\{-m, \ldots, -1\}$ with subsets of $\{1, \ldots, n\}$.

This is also the underlying set of the Shuffle lattice $S_{m,n}$.

INPUT:

- `m` – integer
- `n` – integer

EXAMPLES:

```
sage: from sage.combinat.posets.bubble_shuffle import bubble_set
sage: list(bubble_set(2,1))
[(),
 (1,),
 (-1,),
 (-1, 1),
 (1, -1),
 (-2,),
 (-2, 1),
 (1, -2),
 (-1, -2),
 (-1, -2, 1),
 (1, -1, -2),
 (-1, 1, -2)]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.bubble_shuffle import bubble_set
>>> list(bubble_set(Integer(2),Integer(1)))
[(),
 (1,),
 (-1,),
 (-1, 1),
 (1, -1),
```

(continues on next page)

(continued from previous page)

```
 (-2,),
 (-2, 1),
 (1, -2),
 (-1, -2),
 (-1, -2, 1),
 (1, -1, -2),
 (-1, 1, -2)]
```

sage.combinat.posets.bubble_shuffle.**noncrossing_bipartite_complex**(*m*, *n*)

Return a simplicial complex related to the Bubble lattice $B_{m,n}$.

This is a pure spherical simplicial complex, whose flip graph is isomorphic to the Hasse diagram of $B_{m,n}$.

See also

BubblePoset()

EXAMPLES:

```
sage: C = simplicial_complexes.NoncrossingBipartiteComplex(2,1)
sage: H = C.flip_graph()
sage: P = posets.BubblePoset(2,1)
sage: H.is_isomorphic(P.hasse_diagram().to_undirected())
True
```

```
>>> from sage.all import *
>>> C = simplicial_complexes.NoncrossingBipartiteComplex(Integer(2),Integer(1))
>>> H = C.flip_graph()
>>> P = posets.BubblePoset(Integer(2),Integer(1))
>>> H.is_isomorphic(P.hasse_diagram().to_undirected())
True
```

Cartesian products of posets

AUTHORS:

- Daniel Krenn (2015)

class sage.combinat.posets.cartesian_product.**CartesianProductPoset**(*sets*, *category*, *order=None*, ***kwargs*)

Bases: CartesianProduct

A class implementing Cartesian products of posets (and elements thereof). Compared to CartesianProduct you are able to specify an order for comparison of the elements.

INPUT:

- sets – tuple of parents
- category – a subcategory of Sets().CartesianProducts() & Posets()
- order – string or function specifying an order less or equal; it can be one of the following:
  - 'native' – elements are ordered by their native ordering, i.e., the order the wrapped elements (tuples) provide

- `'lex'` – elements are ordered lexicographically
- `'product'` – an element is less or equal to another element, if less or equal is true for all its components (Cartesian projections)
- a function which performs the comparison $\leq$; it takes two input arguments and outputs a boolean

Other keyword arguments (`kwargs`) are passed to the constructor of `CartesianProduct`.

EXAMPLES:

```
sage: P = Poset((srange(3), lambda left, right: left <= right))
sage: Cl = cartesian_product((P, P), order='lex')
sage: Cl((1, 1)) <= Cl((2, 0))
True
sage: Cp = cartesian_product((P, P), order='product')
sage: Cp((1, 1)) <= Cp((2, 0))
False
sage: def le_sum(left, right):
....:     return (sum(left) < sum(right) or
....:             sum(left) == sum(right) and left[0] <= right[0])
sage: Cs = cartesian_product((P, P), order=le_sum)
sage: Cs((1, 1)) <= Cs((2, 0))
True
```

```
>>> from sage.all import *
>>> P = Poset((srange(Integer(3)), lambda left, right: left <= right))
>>> Cl = cartesian_product((P, P), order='lex')
>>> Cl((Integer(1), Integer(1))) <= Cl((Integer(2), Integer(0)))
True
>>> Cp = cartesian_product((P, P), order='product')
>>> Cp((Integer(1), Integer(1))) <= Cp((Integer(2), Integer(0)))
False
>>> def le_sum(left, right):
...     return (sum(left) < sum(right) or
...             sum(left) == sum(right) and left[Integer(0)] <= right[Integer(0)])
>>> Cs = cartesian_product((P, P), order=le_sum)
>>> Cs((Integer(1), Integer(1))) <= Cs((Integer(2), Integer(0)))
True
```

See also

`CartesianProduct`

class Element

Bases: `Element`

le(*left*, *right*)

Test whether `left` is less than or equal to `right`.

INPUT:

- `left` – an element
- `right` – an element

OUTPUT: boolean

> **Note**
>
> This method uses the order defined on creation of this Cartesian product. See *CartesianProduct-Poset*.

EXAMPLES:

```
sage: P = posets.ChainPoset(10)
sage: def le_sum(left, right):
....:     return (sum(left) < sum(right) or
....:             sum(left) == sum(right) and left[0] <= right[0])
sage: C = cartesian_product((P, P), order=le_sum)
sage: C.le(C((1, 6)), C((6, 1)))
True
sage: C.le(C((6, 1)), C((1, 6)))
False
sage: C.le(C((1, 6)), C((6, 6)))
True
sage: C.le(C((6, 6)), C((1, 6)))
False
```

```
>>> from sage.all import *
>>> P = posets.ChainPoset(Integer(10))
>>> def le_sum(left, right):
...     return (sum(left) < sum(right) or
...             sum(left) == sum(right) and left[Integer(0)] <=␣
↪right[Integer(0)])
>>> C = cartesian_product((P, P), order=le_sum)
>>> C.le(C((Integer(1), Integer(6))), C((Integer(6), Integer(1))))
True
>>> C.le(C((Integer(6), Integer(1))), C((Integer(1), Integer(6))))
False
>>> C.le(C((Integer(1), Integer(6))), C((Integer(6), Integer(6))))
True
>>> C.le(C((Integer(6), Integer(6))), C((Integer(1), Integer(6))))
False
```

le_lex(*left*, *right*)

Test whether `left` is lexicographically smaller or equal to `right`.

INPUT:

- `left` – an element
- `right` – an element

OUTPUT: boolean

EXAMPLES:

```
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='lex')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
....:     for b in T:
```

(continues on next page)

(continued from previous page)

```
....:         assert Q.le(a, b) == (a <= b)
....:         print('%s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

```
>>> from sage.all import *
>>> P = Poset((srange(Integer(2)), lambda left, right: left <= right))
>>> Q = cartesian_product((P, P), order='lex')
>>> T = [Q((Integer(0), Integer(0))), Q((Integer(1), Integer(1))),␣
↪Q((Integer(0), Integer(1))), Q((Integer(1), Integer(0)))]
>>> for a in T:
...     for b in T:
...         assert Q.le(a, b) == (a <= b)
...         print('%s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

le_native(*left*, *right*)

Test whether `left` is smaller or equal to `right` in the order provided by the elements themselves.

INPUT:

- `left` – an element
- `right` – an element

OUTPUT: boolean

EXAMPLES:

```
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='native')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
....:     for b in T:
....:         assert Q.le(a, b) == (a <= b)
....:         print('%s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

```
>>> from sage.all import *
>>> P = Poset((srange(Integer(2)), lambda left, right: left <= right))
>>> Q = cartesian_product((P, P), order='native')
>>> T = [Q((Integer(0), Integer(0))), Q((Integer(1), Integer(1))),␣
↪Q((Integer(0), Integer(1))), Q((Integer(1), Integer(0)))]
>>> for a in T:
...     for b in T:
...         assert Q.le(a, b) == (a <= b)
...         print('%s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

le_product(*left*, *right*)

Test whether `left` is component-wise smaller or equal to `right`.

INPUT:

- `left` – an element
- `right` – an element

OUTPUT: boolean

The comparison is `True` if the result of the comparison in each component is `True`.

EXAMPLES:

```
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='product')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
....:     for b in T:
....:         assert Q.le(a, b) == (a <= b)
....:         print('%s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = False
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

```
>>> from sage.all import *
>>> P = Poset((srange(Integer(2)), lambda left, right: left <= right))
>>> Q = cartesian_product((P, P), order='product')
>>> T = [Q((Integer(0), Integer(0))), Q((Integer(1), Integer(1))),␣
↪Q((Integer(0), Integer(1))), Q((Integer(1), Integer(0)))]
>>> for a in T:
...     for b in T:
...         assert Q.le(a, b) == (a <= b)
...         print('%s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
```

(continues on next page)

(continued from previous page)

```
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = False
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

Catalog of posets and lattices

Some common posets can be accessed through the `posets.<tab>` object:

```
sage: posets.PentagonPoset()
Finite lattice containing 5 elements
```

```
>>> from sage.all import *
>>> posets.PentagonPoset()
Finite lattice containing 5 elements
```

Moreover, the set of all posets of order n is represented by `Posets(n)`:

```
sage: Posets(5)
Posets containing 5 elements
```

```
>>> from sage.all import *
>>> Posets(Integer(5))
Posets containing 5 elements
```

The infinite set of all posets can be used to find minimal examples:

```
sage: for P in Posets():
....:     if not P.is_series_parallel():
....:         break
sage: P
Finite poset containing 4 elements
```

```
>>> from sage.all import *
>>> for P in Posets():
...     if not P.is_series_parallel():
...         break
>>> P
Finite poset containing 4 elements
```

Catalog of common posets:

AltNuTamariLattice()	Return the alt ν-Tamari lattice.
AntichainPoset()	Return an antichain on n elements.
BooleanLattice()	Return the Boolean lattice on 2^n elements.
BubblePoset()	Return the Bubble lattice for (m, n).
ChainPoset()	Return a chain on n elements.

continues on next page

Table 4 – continued from previous page

ChuteMoveLattice()	Return the chute move lattice on polyominoes.
Crown()	Return the crown poset on $2n$ elements.
DexterSemilattice()	Return the Dexter semilattice.
DiamondPoset()	Return the lattice of rank two on n elements.
DivisorLattice()	Return the divisor lattice of an integer.
DoubleTailedDiamond()	Return the double tailed diamond poset on $2n + 2$ elements.
HochschildLattice()	Return the Hochschild lattice for n.
IntegerCompositions()	Return the poset of integer compositions of n.
IntegerPartitions()	Return the poset of integer partitions of `n`.
IntegerPartitionsDominanceOrder()	Return the lattice of integer partitions of the integer n ordered by dominance.
MobilePoset()	Return the mobile poset formed by the $ribbon$ with $hangers$ below and an $anchor$ above.
NoncrossingPartitions()	Return the poset of noncrossing partitions of a finite Coxeter group `W`.
NuTamariLattice()	Return the ν-Tamari lattice.
PentagonPoset()	Return the Pentagon poset.
PermutationPattern()	Return the Permutation pattern poset.
PermutationPatternInterval()	Return an interval in the Permutation pattern poset.
PermutationPatternOccurrenceInterval()	Return the occurrence poset for a pair of comparable elements in the Permutation pattern poset.
PowerPoset()	Return a power poset.
ProductOfChains()	Return a product of chain posets.
RandomLattice()	Return a random lattice on n elements.
RandomPoset()	Return a random poset on n elements.
RibbonPoset()	Return a ribbon on n elements with descents at $descents$.
RestrictedIntegerPartitions()	Return the poset of integer partitions of n, ordered by restricted refinement.
Sashes()	Return the lattice of sashes of n.
SetPartitions()	Return the poset of set partitions of the set $\{1, \ldots, n\}$.
ShardPoset()	Return the shard intersection order.
ShufflePoset()	Return the Shuffle lattice for (m, n).
SSTPoset()	Return the poset on semistandard tableaux of shape s and largest entry f that is ordered by componentwise comparison.
StandardExample()	Return the standard example of a poset with dimension n.
SymmetricGroupAbsoluteOrderPoset()	The poset of permutations with respect to absolute order.
SymmetricGroupBruhatIntervalPoset()	The poset of permutations with respect to Bruhat order.
SymmetricGroupBruhatOrderPoset()	The poset of permutations with respect to Bruhat order.
SymmetricGroupWeakOrderPoset()	The poset of permutations of $\{1, 2, \ldots, n\}$ with respect to the weak order.
TamariLattice()	Return the Tamari lattice.
TetrahedralPoset()	Return the Tetrahedral poset with $n - 1$ layers based on the input colors.
UpDownPoset()	Return the up-down poset on n elements.
YoungDiagramPoset()	Return the poset of cells in the Young diagram of a partition.
YoungsLattice()	Return Young's Lattice up to rank n.
YoungsLatticePrincipalOrderIdeal()	Return the principal order ideal of the partition lam in Young's Lattice.
YoungFibonacci()	Return the Young-Fibonacci lattice up to rank n.

Other available posets:

face_lattice()	Return the face lattice of a polyhedron.
face_lattice()	Return the face lattice of a combinatorial polyhedron.

Constructions

class sage.combinat.posets.poset_examples.**Posets**

Bases: object

A collection of posets and lattices.

EXAMPLES:

```
sage: posets.BooleanLattice(3)
Finite lattice containing 8 elements
sage: posets.ChainPoset(3)
Finite lattice containing 3 elements
sage: posets.NuTamariLattice([1, 0, 1, 0])
Finite lattice containing 2 elements
sage: posets.AltNuTamariLattice('01001', [0, 0])
Finite lattice containing 7 elements
sage: posets.RandomPoset(17,.15)
Finite poset containing 17 elements
```

```
>>> from sage.all import *
>>> posets.BooleanLattice(Integer(3))
Finite lattice containing 8 elements
>>> posets.ChainPoset(Integer(3))
Finite lattice containing 3 elements
>>> posets.NuTamariLattice([Integer(1), Integer(0), Integer(1), Integer(0)])
Finite lattice containing 2 elements
>>> posets.AltNuTamariLattice('01001', [Integer(0), Integer(0)])
Finite lattice containing 7 elements
>>> posets.RandomPoset(Integer(17),RealNumber('.15'))
Finite poset containing 17 elements
```

The category of all posets:

```
sage: Posets()
Category of posets
```

```
>>> from sage.all import *
>>> Posets()
Category of posets
```

The enumerated set of all posets on 3 elements, up to an isomorphism:

```
sage: Posets(3)
Posets containing 3 elements
```

```
>>> from sage.all import *
>>> Posets(Integer(3))
Posets containing 3 elements
```

See also

Posets, FinitePosets, *Poset()*

static AltNuTamariLattice(*nu*, *delta=None*)

Return the (δ, ν)-Tamari lattice (or alt ν-Tamari lattice).

For more information, see [CC2023].

The path ν is a path of North steps (represented as 1 s) and East steps (represented as 0 s).

The vector $\delta = (\delta_1, \ldots, \delta_n)$ is an increment vector with respect to the path ν, that is to say $\delta_i \leq \nu_i$, where ν_i is the number of 0 s following the i-th 1 of ν. If not provided, δ is set by default to produce the classical ν-Tamari lattice.

INPUT:

- ν – list of 0s and 1s or a string of 0s and 1s
- δ – list of nonnegative integers

OUTPUT: a finite lattice

EXAMPLES:

```
sage: from sage.combinat.nu_tamari_lattice import AltNuTamariLattice,␣
↪NuTamariLattice
sage: AltNuTamariLattice('01001', [0, 0])
Finite lattice containing 7 elements
sage: AltNuTamariLattice('01001', [1, 0])
Finite lattice containing 7 elements
sage: AltNuTamariLattice('01001') == AltNuTamariLattice('01001', [2, 0])
True
sage: nu = '00100100101'; P = AltNuTamariLattice(nu); Q = NuTamariLattice(nu);
↪ P.is_isomorphic(Q)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.nu_tamari_lattice import AltNuTamariLattice,␣
↪NuTamariLattice
>>> AltNuTamariLattice('01001', [Integer(0), Integer(0)])
Finite lattice containing 7 elements
>>> AltNuTamariLattice('01001', [Integer(1), Integer(0)])
Finite lattice containing 7 elements
>>> AltNuTamariLattice('01001') == AltNuTamariLattice('01001', [Integer(2),␣
↪Integer(0)])
True
>>> nu = '00100100101'; P = AltNuTamariLattice(nu); Q = NuTamariLattice(nu);␣
↪P.is_isomorphic(Q)
True
```

REFERENCES:

- [PRV2017]
- [CC2023]

static AntichainPoset(*n*, *facade=None*)

Return an antichain (a poset with no comparable elements) containing n elements.

INPUT:

- `n` – integer; number of elements
- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor

EXAMPLES:

```
sage: A = posets.AntichainPoset(6); A
Finite poset containing 6 elements
```

```
>>> from sage.all import *
>>> A = posets.AntichainPoset(Integer(6)); A
Finite poset containing 6 elements
```

static BooleanLattice(*n*, *facade=None*, *use_subsets=False*)

Return the Boolean lattice containing 2^n elements.

- `n` – integer; number of elements will be 2^n
- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor
- `use_subsets` – boolean (default: `False`); if `True`, then label the elements by subsets of $\{1, 2, \ldots, n\}$; otherwise label the elements by $0, 1, 2, \ldots, 2^n - 1$

EXAMPLES:

```
sage: posets.BooleanLattice(5)
Finite lattice containing 32 elements

sage: sorted(posets.BooleanLattice(2))
[0, 1, 2, 3]
sage: sorted(posets.BooleanLattice(2, use_subsets=True), key=list)
[{}, {1}, {1, 2}, {2}]
```

```
>>> from sage.all import *
>>> posets.BooleanLattice(Integer(5))
Finite lattice containing 32 elements

>>> sorted(posets.BooleanLattice(Integer(2)))
[0, 1, 2, 3]
>>> sorted(posets.BooleanLattice(Integer(2), use_subsets=True), key=list)
[{}, {1}, {1, 2}, {2}]
```

static BubblePoset(*m*, *n*)

Return the Bubble lattice $B_{m,n}$.

Bubble lattices were introduced by McConville and Mühle in [MacCM2022].

The Bubble lattice $B_{m,n}$ and the Shuffle lattice $S_{m,n}$ share the same underlying set, namely all shuffles of two subwords of the two words $X = (x_1, x_2, \ldots, x_m)$ and $Y = (y_1, y_2, \ldots, y_n)$.

The Bubble poset is an extension of the Shuffle poset, by adding the exchange of adjacent letters from X and Y, from xy to yx.

See also

ShufflePoset(), *sage.combinat.posets.bubble_shuffle.noncrossing_bipartite_complex()*

EXAMPLES:

```
sage: P = posets.BubblePoset(2,1); P
Finite lattice containing 12 elements
sage: P.zeta_polynomial()
1/40*q^5 + 7/24*q^4 + 23/24*q^3 - 7/24*q^2 + 1/60*q
```

```
>>> from sage.all import *
>>> P = posets.BubblePoset(Integer(2),Integer(1)); P
Finite lattice containing 12 elements
>>> P.zeta_polynomial()
1/40*q^5 + 7/24*q^4 + 23/24*q^3 - 7/24*q^2 + 1/60*q
```

static ChainPoset(*n*, *facade=None*)

Return a chain (a totally ordered poset) containing n elements.

- `n` – integer; number of elements
- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor

EXAMPLES:

```
sage: C = posets.ChainPoset(6); C
Finite lattice containing 6 elements
sage: C.linear_extension()
[0, 1, 2, 3, 4, 5]
```

```
>>> from sage.all import *
>>> C = posets.ChainPoset(Integer(6)); C
Finite lattice containing 6 elements
>>> C.linear_extension()
[0, 1, 2, 3, 4, 5]
```

static ChuteMoveLattice(*M*, *n=None*)

Return the chute move lattice.

INPUT:

- `M` – a permutation, or an L-convex polyomino
- `n` – a positive integer, if `M` is a polyomino, or `None`

EXAMPLES:

```
sage: from sage.combinat.posets.chute_move import intervals_to_polyomino
sage: M = intervals_to_polyomino([(1,4),(1,3),(1,2),(1,1)])
sage: L = posets.ChuteMoveLattice(M, 1); L
Finite lattice containing 5 elements

sage: from sage.combinat.tamari_lattices import GeneralizedTamariLattice
sage: b = 4; m = 2; T = GeneralizedTamariLattice(m*b+1,b,m=2)
sage: C = posets.ChuteMoveLattice(Permutation([1,8,6,4,2,3,5,7]))
sage: C.is_isomorphic(T)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.chute_move import intervals_to_polyomino
>>> M = intervals_to_polyomino([(Integer(1),Integer(4)),(Integer(1),
...Integer(3)),(Integer(1),Integer(2)),(Integer(1),Integer(1))])
>>> L = posets.ChuteMoveLattice(M, Integer(1)); L
Finite lattice containing 5 elements

>>> from sage.combinat.tamari_lattices import GeneralizedTamariLattice
>>> b = Integer(4); m = Integer(2); T =␣
...GeneralizedTamariLattice(m*b+Integer(1),b,m=Integer(2))
>>> C = posets.ChuteMoveLattice(Permutation([Integer(1),Integer(8),Integer(6),
...Integer(4),Integer(2),Integer(3),Integer(5),Integer(7)]))
>>> C.is_isomorphic(T)
True
```

static CoxeterGroupAbsoluteOrderPoset(*W*, *use_reduced_words=True*)

Return the poset of elements of a Coxeter group with respect to absolute order.

INPUT:

- `W` – a Coxeter group
- `use_reduced_words` – boolean (default: `True`); if `True`, then the elements are labeled by their lexicographically minimal reduced word

EXAMPLES:

```
sage: W = CoxeterGroup(['B', 3])                                    #␣
...needs sage.groups
sage: posets.CoxeterGroupAbsoluteOrderPoset(W)                      #␣
...needs sage.groups
Finite poset containing 48 elements

sage: W = WeylGroup(['B', 2], prefix='s')                           #␣
...needs sage.groups
sage: posets.CoxeterGroupAbsoluteOrderPoset(W, False)               #␣
...needs sage.groups
Finite poset containing 8 elements
```

```
>>> from sage.all import *
>>> W = CoxeterGroup(['B', Integer(3)])                                 ␣
...     # needs sage.groups
>>> posets.CoxeterGroupAbsoluteOrderPoset(W)                          #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.groups
Finite poset containing 48 elements

>>> W = WeylGroup(['B', Integer(2)], prefix='s')                              ␣
↪     # needs sage.groups
>>> posets.CoxeterGroupAbsoluteOrderPoset(W, False)                          #␣
↪needs sage.groups
Finite poset containing 8 elements
```

static Crown(*n*, *facade=None*)

Return the crown poset of $2n$ elements.

In this poset every element i for $0 \leq i \leq n-1$ is covered by elements $i+n$ and $i+n+1$, except that $n-1$ is covered by n and $n+1$.

INPUT:

- `n` – number of elements, an integer at least 2
- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor

EXAMPLES:

```
sage: posets.Crown(3)
Finite poset containing 6 elements
```

```
>>> from sage.all import *
>>> posets.Crown(Integer(3))
Finite poset containing 6 elements
```

static DexterSemilattice(*n*)

Return the n-th Dexter meet-semilattice.

INPUT:

- `n` – nonnegative integer (the index)

OUTPUT: a finite meet-semilattice

The elements of the semilattice are *Dyck paths* in the $(n+1 \times n)$-rectangle.

EXAMPLES:

```
sage: posets.DexterSemilattice(3)
Finite meet-semilattice containing 5 elements

sage: P = posets.DexterSemilattice(4); P
Finite meet-semilattice containing 14 elements
sage: len(P.maximal_chains())
15
sage: len(P.maximal_elements())
4
sage: P.chain_polynomial()
q^5 + 19*q^4 + 47*q^3 + 42*q^2 + 14*q + 1
```

```
>>> from sage.all import *
>>> posets.DexterSemilattice(Integer(3))
Finite meet-semilattice containing 5 elements

>>> P = posets.DexterSemilattice(Integer(4)); P
Finite meet-semilattice containing 14 elements
>>> len(P.maximal_chains())
15
>>> len(P.maximal_elements())
4
>>> P.chain_polynomial()
q^5 + 19*q^4 + 47*q^3 + 42*q^2 + 14*q + 1
```

REFERENCES:

- [Cha18]

static DiamondPoset(*n*, *facade=None*)

Return the lattice of rank two containing `n` elements.

INPUT:

- `n` – number of elements, an integer at least 3
- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor

EXAMPLES:

```
sage: posets.DiamondPoset(7)
Finite lattice containing 7 elements
```

```
>>> from sage.all import *
>>> posets.DiamondPoset(Integer(7))
Finite lattice containing 7 elements
```

static DivisorLattice(*n*, *facade=None*)

Return the divisor lattice of an integer.

Elements of the lattice are divisors of n, and we have $x \leq y$ in the lattice if x divides y.

INPUT:

- `n` – integer
- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor

EXAMPLES:

```
sage: P = posets.DivisorLattice(12)
sage: sorted(P.cover_relations())
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]

sage: P = posets.DivisorLattice(10, facade=False)
sage: P(2) < P(5)
False
```

```
>>> from sage.all import *
>>> P = posets.DivisorLattice(Integer(12))
>>> sorted(P.cover_relations())
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]

>>> P = posets.DivisorLattice(Integer(10), facade=False)
>>> P(Integer(2)) < P(Integer(5))
False
```

static DoubleTailedDiamond(*n*)

Return a double-tailed diamond of $2n + 2$ elements.

INPUT:

- `n` – positive integer

EXAMPLES:

```
sage: P = posets.DoubleTailedDiamond(2); P
Finite d-complete poset containing 6 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [2, 4], [3, 5], [4, 5], [5, 6]]
```

```
>>> from sage.all import *
>>> P = posets.DoubleTailedDiamond(Integer(2)); P
Finite d-complete poset containing 6 elements
>>> P.cover_relations()
[[1, 2], [2, 3], [2, 4], [3, 5], [4, 5], [5, 6]]
```

static HessenbergPoset(*H*)

Return the poset associated to a Hessenberg function `H`.

A *Hessenberg function* (of length n) is a function $H : \{1, \ldots, n\} \to \{1, \ldots, n\}$ such that $\max(i, H(i-1)) \leq H(i) \leq n$ for all i (where $H(0) = 0$ by convention). The corresponding poset is given by $i < j$ (in the poset) if and only if $H(i) < j$ (as integers). These posets correspond to the natural unit interval order posets.

INPUT:

- `H` – list of the Hessenberg function values (without $H(0)$)

EXAMPLES:

```
sage: P = posets.HessenbergPoset([2, 3, 5, 5, 5]); P
Finite poset containing 5 elements
sage: P.cover_relations()
[[2, 4], [2, 5], [1, 3], [1, 4], [1, 5]]
```

```
>>> from sage.all import *
>>> P = posets.HessenbergPoset([Integer(2), Integer(3), Integer(5),␣
↪Integer(5), Integer(5)]); P
Finite poset containing 5 elements
>>> P.cover_relations()
[[2, 4], [2, 5], [1, 3], [1, 4], [1, 5]]
```

static HochschildLattice(*n*)

Return the Hochschild lattice H_n.

See *hochschild_lattice()* for details.

static IntegerCompositions(*n*)

Return the poset of integer compositions of the integer n.

A composition of a positive integer n is a list of positive integers that sum to n. The order is reverse refinement: $p = [p_1, p_2, ..., p_l] \leq q = [q_1, q_2, ..., q_m]$ if q consists of an integer composition of p_1, followed by an integer composition of p_2, and so on.

EXAMPLES:

```
sage: P = posets.IntegerCompositions(7); P
Finite poset containing 64 elements
sage: len(P.cover_relations())
192
```

```
>>> from sage.all import *
>>> P = posets.IntegerCompositions(Integer(7)); P
Finite poset containing 64 elements
>>> len(P.cover_relations())
192
```

static IntegerPartitions(*n*)

Return the poset of integer partitions of the integer n.

A partition of a positive integer n is a non-increasing list of positive integers that sum to n. If p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two parts of p (and sorting, if necessary).

EXAMPLES:

```
sage: P = posets.IntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
28
```

```
>>> from sage.all import *
>>> P = posets.IntegerPartitions(Integer(7)); P
Finite poset containing 15 elements
>>> len(P.cover_relations())
28
```

static IntegerPartitionsDominanceOrder(*n*)

Return the lattice of integer partitions of the integer n ordered by dominance.

That is, if $p = (p_1, \ldots, p_i)$ and $q = (q_1, \ldots, q_j)$ are integer partitions of n, then $p \geq q$ if and only if $p_1 + \cdots + p_k \geq q_1 + \cdots + q_k$ for all k.

INPUT:

- n – positive integer

EXAMPLES:

```
sage: P = posets.IntegerPartitionsDominanceOrder(6); P
Finite lattice containing 11 elements
sage: P.cover_relations()
```

(continues on next page)

(continued from previous page)

```
[[[1, 1, 1, 1, 1, 1], [2, 1, 1, 1, 1]],
 [[2, 1, 1, 1, 1], [2, 2, 1, 1]],
 [[2, 2, 1, 1], [2, 2, 2]],
 [[2, 2, 1, 1], [3, 1, 1, 1]],
 [[2, 2, 2], [3, 2, 1]],
 [[3, 1, 1, 1], [3, 2, 1]],
 [[3, 2, 1], [3, 3]],
 [[3, 2, 1], [4, 1, 1]],
 [[3, 3], [4, 2]],
 [[4, 1, 1], [4, 2]],
 [[4, 2], [5, 1]],
 [[5, 1], [6]]]
```

```
>>> from sage.all import *
>>> P = posets.IntegerPartitionsDominanceOrder(Integer(6)); P
Finite lattice containing 11 elements
>>> P.cover_relations()
[[[1, 1, 1, 1, 1, 1], [2, 1, 1, 1, 1]],
 [[2, 1, 1, 1, 1], [2, 2, 1, 1]],
 [[2, 2, 1, 1], [2, 2, 2]],
 [[2, 2, 1, 1], [3, 1, 1, 1]],
 [[2, 2, 2], [3, 2, 1]],
 [[3, 1, 1, 1], [3, 2, 1]],
 [[3, 2, 1], [3, 3]],
 [[3, 2, 1], [4, 1, 1]],
 [[3, 3], [4, 2]],
 [[4, 1, 1], [4, 2]],
 [[4, 2], [5, 1]],
 [[5, 1], [6]]]
```

static MobilePoset(*ribbon*, *hangers*, *anchor=None*)

Return a mobile poset with the ribbon `ribbon` and with hanging d-complete posets specified in `hangers` and a d-complete poset attached above, specified in `anchor`.

INPUT:

- `ribbon` – a finite poset that is a ribbon
- `hangers` – dictionary mapping an element on the ribbon to a list of d-complete posets that it covers
- `anchor` – (optional) a `tuple` (`ribbon_elmt`, `anchor_elmt`, `anchor_poset`), where `anchor_elmt` covers `ribbon_elmt`, and `anchor_elmt` is an acyclic element of `anchor_poset`

EXAMPLES:

```
sage: R = Posets.RibbonPoset(5, [1,2])
sage: H = Poset([[5, 6, 7], [(5, 6), (6,7)]])
sage: M = Posets.MobilePoset(R, {3: [H]})
sage: len(M.cover_relations())
7

sage: P = posets.MobilePoset(posets.RibbonPoset(7, [1,3]),
....:          {1: [posets.YoungDiagramPoset([3, 2], dual=True)],
....:           3: [posets.DoubleTailedDiamond(6)]},
```

(continues on next page)

(continued from previous page)

```
....:          anchor=(4, 2, posets.ChainPoset(6)))
sage: len(P.cover_relations())
33
```

```
>>> from sage.all import *
>>> R = Posets.RibbonPoset(Integer(5), [Integer(1),Integer(2)])
>>> H = Poset([[Integer(5), Integer(6), Integer(7)], [(Integer(5),␣
↪Integer(6)), (Integer(6),Integer(7))]])
>>> M = Posets.MobilePoset(R, {Integer(3): [H]})
>>> len(M.cover_relations())
7

>>> P = posets.MobilePoset(posets.RibbonPoset(Integer(7), [Integer(1),
↪Integer(3)]),
...          {Integer(1): [posets.YoungDiagramPoset([Integer(3), Integer(2)],␣
↪dual=True)],
...           Integer(3): [posets.DoubleTailedDiamond(Integer(6))]},
...          anchor=(Integer(4), Integer(2), posets.ChainPoset(Integer(6))))
>>> len(P.cover_relations())
33
```

static NoncrossingPartitions(*W*)

Return the lattice of noncrossing partitions.

INPUT:

- `W` – a finite Coxeter group or a Weyl group

EXAMPLES:

```
sage: W = CoxeterGroup(['A', 3])                                        #␣
↪needs sage.groups
sage: posets.NoncrossingPartitions(W)                                   #␣
↪needs sage.groups
Finite lattice containing 14 elements

sage: W = WeylGroup(['B', 2], prefix='s')                               #␣
↪needs sage.groups
sage: posets.NoncrossingPartitions(W)                                   #␣
↪needs sage.groups
Finite lattice containing 6 elements
```

```
>>> from sage.all import *
>>> W = CoxeterGroup(['A', Integer(3)])                                  ␣
↪     # needs sage.groups
>>> posets.NoncrossingPartitions(W)                                    #␣
↪needs sage.groups
Finite lattice containing 14 elements

>>> W = WeylGroup(['B', Integer(2)], prefix='s')                         ␣
↪     # needs sage.groups
>>> posets.NoncrossingPartitions(W)                                    #␣
↪needs sage.groups
```

(continues on next page)

(continued from previous page)

```
Finite lattice containing 6 elements
```

static NuTamariLattice(*nu*)

Return the ν-Tamari lattice.

INPUT:

- ν – list of 0s and 1s or a string of 0s and 1s

OUTPUT: a finite lattice

The elements of the lattice are *nu-Dyck paths* weakly above ν.

The usual Tamari lattice is the special case where $\nu = (NE)^h$ where h is the height.

Other special cases give the m-Tamari lattices studied in [BMFPR].

EXAMPLES:

```
sage: from sage.combinat.nu_tamari_lattice import NuTamariLattice
sage: NuTamariLattice([1,0,1,0,0,1,0])
Finite lattice containing 7 elements
sage: NuTamariLattice([1,0,1,0,1,0])
Finite lattice containing 5 elements
sage: NuTamariLattice([1,0,1,0,1,0,1,0])
Finite lattice containing 14 elements
sage: NuTamariLattice([1,0,1,0,1,0,0,0,1])
Finite lattice containing 24 elements
```

```
>>> from sage.all import *
>>> from sage.combinat.nu_tamari_lattice import NuTamariLattice
>>> NuTamariLattice([Integer(1),Integer(0),Integer(1),Integer(0),Integer(0),
↪Integer(1),Integer(0)])
Finite lattice containing 7 elements
>>> NuTamariLattice([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0)])
Finite lattice containing 5 elements
>>> NuTamariLattice([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(1),Integer(0)])
Finite lattice containing 14 elements
>>> NuTamariLattice([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(0),Integer(0),Integer(0),Integer(1)])
Finite lattice containing 24 elements
```

static PentagonPoset(*facade=None*)

Return the Pentagon poset.

INPUT:

- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor

EXAMPLES:

```
sage: P = posets.PentagonPoset(); P
Finite lattice containing 5 elements
```

(continues on next page)

(continued from previous page)

```
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset(); P
Finite lattice containing 5 elements
>>> P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
```

static PermutationPattern(*n*)

Return the poset of permutations under pattern containment up to rank n.

INPUT:

- `n` – positive integer

A permutation $u = u_1 \cdots u_n$ contains the pattern $v = v_1 \cdots v_m$ if there is a (not necessarily consecutive) subsequence of u of length m whose entries have the same relative order as v.

See Wikipedia article Permutation_pattern.

EXAMPLES:

```
sage: P4 = posets.PermutationPattern(4); P4
Finite poset containing 33 elements
sage: sorted(P4.lower_covers(Permutation([2,4,1,3])))
[[1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]
```

```
>>> from sage.all import *
>>> P4 = posets.PermutationPattern(Integer(4)); P4
Finite poset containing 33 elements
>>> sorted(P4.lower_covers(Permutation([Integer(2),Integer(4),Integer(1),
↪Integer(3)])))
[[1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]
```

See also

has_pattern()

static PermutationPatternInterval(*bottom*, *top*)

Return the poset consisting of an interval in the poset of permutations under pattern containment between `bottom` and `top`.

INPUT:

- `bottom`, `top` – permutations where `top` contains `bottom` as a pattern

A permutation $u = u_1 \cdots u_n$ contains the pattern $v = v_1 \cdots v_m$ if there is a (not necessarily consecutive) subsequence of u of length m whose entries have the same relative order as v.

See Wikipedia article Permutation_pattern.

EXAMPLES:

```
sage: t = Permutation([2,3,1])
sage: b = Permutation([4,6,2,3,5,1])
sage: R = posets.PermutationPatternInterval(t, b); R
Finite poset containing 14 elements
sage: R.moebius_function(R.bottom(),R.top())
-4
```

```
>>> from sage.all import *
>>> t = Permutation([Integer(2),Integer(3),Integer(1)])
>>> b = Permutation([Integer(4),Integer(6),Integer(2),Integer(3),Integer(5),
↪Integer(1)])
>>> R = posets.PermutationPatternInterval(t, b); R
Finite poset containing 14 elements
>>> R.moebius_function(R.bottom(),R.top())
-4
```

See also

has_pattern(), *PermutationPattern()*

static PermutationPatternOccurrenceInterval(*bottom*, *top*, *pos*)

Return the poset consisting of an interval in the poset of permutations under pattern containment between `bottom` and `top`, where a specified instance of `bottom` in `top` must be maintained.

INPUT:

- **bottom, top – permutations where top contains** `bottom` as a pattern
- **pos – list of indices indicating a distinguished copy of** `bottom` inside `top` (indexed starting at 0)

For further information (and picture illustrating included example), see [ST2010] .

See Wikipedia article Permutation_pattern.

EXAMPLES:

```
sage: t = Permutation([3,2,1])
sage: b = Permutation([6,3,4,5,2,1])
sage: A = posets.PermutationPatternOccurrenceInterval(t, b, (0,2,4)); A
Finite poset containing 8 elements
```

```
>>> from sage.all import *
>>> t = Permutation([Integer(3),Integer(2),Integer(1)])
>>> b = Permutation([Integer(6),Integer(3),Integer(4),Integer(5),Integer(2),
↪Integer(1)])
>>> A = posets.PermutationPatternOccurrenceInterval(t, b, (Integer(0),
↪Integer(2),Integer(4))); A
Finite poset containing 8 elements
```

> **See also**
>
> *has_pattern()*, *PermutationPattern()*, *PermutationPatternInterval()*

static PowerPoset(*n*)

Return the power poset on n element posets.

Elements of the power poset are all posets on the set $\{0, 1, \ldots, n-1\}$ ordered by extension. That is, the antichain of n elements is the bottom and $P_a \leq P_b$ in the power poset if P_b is an extension of P_a.

These were studied in [Bru1994].

EXAMPLES:

```
sage: P3 = posets.PowerPoset(3); P3
Finite meet-semilattice containing 19 elements
sage: all(P.is_chain() for P in P3.maximal_elements())
True
```

```
>>> from sage.all import *
>>> P3 = posets.PowerPoset(Integer(3)); P3
Finite meet-semilattice containing 19 elements
>>> all(P.is_chain() for P in P3.maximal_elements())
True
```

static ProductOfChains(*chain_lengths*, *facade=None*)

Return a product of chains.

- `chain_lengths` – list of nonnegative integers; number of elements in each chain
- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor

EXAMPLES:

```
sage: P = posets.ProductOfChains([2, 2]); P
Finite lattice containing 4 elements
sage: P.linear_extension()
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: P.upper_covers((0,0))
[(0, 1), (1, 0)]
sage: P.lower_covers((1,1))
[(0, 1), (1, 0)]
```

```
>>> from sage.all import *
>>> P = posets.ProductOfChains([Integer(2), Integer(2)]); P
Finite lattice containing 4 elements
>>> P.linear_extension()
[(0, 0), (0, 1), (1, 0), (1, 1)]
>>> P.upper_covers((Integer(0),Integer(0)))
[(0, 1), (1, 0)]
>>> P.lower_covers((Integer(1),Integer(1)))
[(0, 1), (1, 0)]
```

static RandomLattice(*n*, *p*, *properties=None*)

Return a random lattice on `n` elements.

INPUT:

- `n` – number of elements, a nonnegative integer
- `p` – a probability, a positive real number less than one
- `properties` – list of properties for the lattice. Currently implemented:
  - `None`, no restrictions for lattices to create
  - `'planar'`, the lattice has an upward planar drawing
  - `'dismantlable'` (implicated by `'planar'`)
  - `'distributive'` (implicated by `'stone'`)
  - `'stone'`

OUTPUT:

A lattice on n elements. When `properties` is `None`, the probability p roughly measures number of covering relations of the lattice. To create interesting examples, make the probability a little below one, for example 0.9.

Currently parameter `p` has no effect only when `properties` is not `None`.

Note

Results are reproducible in same Sage version only. Underlying algorithm may change in future versions.

EXAMPLES:

```
sage: set_random_seed(0)  # Results are reproducible
sage: L = posets.RandomLattice(8, 0.995); L
Finite lattice containing 8 elements
sage: L.cover_relations()
[[3, 5],
 [3, 7],
 [3, 0],
 [5, 6],
 [5, 4],
 [5, 1],
 [6, 2],
 [7, 4],
 [4, 2],
 [1, 2],
 [0, 2]]
sage: L = posets.RandomLattice(10, 0, properties=['dismantlable'])
sage: L.is_dismantlable()
True
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))  # Results are reproducible
>>> L = posets.RandomLattice(Integer(8), RealNumber('0.995')); L
Finite lattice containing 8 elements
```

(continues on next page)

(continued from previous page)

```
>>> L.cover_relations()
[[3, 5],
 [3, 7],
 [3, 0],
 [5, 6],
 [5, 4],
 [5, 1],
 [6, 2],
 [7, 4],
 [4, 2],
 [1, 2],
 [0, 2]]
>>> L = posets.RandomLattice(Integer(10), Integer(0), properties=[
↪'dismantlable'])
>>> L.is_dismantlable()
True
```

See also

RandomPoset()

static RandomPoset(n, p)

Generate a random poset on `n` elements according to a probability `p`.

INPUT:

- `n` – number of elements, a nonnegative integer
- `p` – a probability, a real number between 0 and 1 (inclusive)

OUTPUT:

A poset on n elements. The probability p roughly measures width/height of the output: $p = 0$ always generates an antichain, $p = 1$ will return a chain. To create interesting examples, keep the probability small, perhaps on the order of $1/n$.

EXAMPLES:

```
sage: set_random_seed(0)  # Results are reproducible
sage: P = posets.RandomPoset(5, 0.3)
sage: P.cover_relations()
[[3, 2], [2, 5], [1, 5]]
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))  # Results are reproducible
>>> P = posets.RandomPoset(Integer(5), RealNumber('0.3'))
>>> P.cover_relations()
[[3, 2], [2, 5], [1, 5]]
```

See also

RandomLattice()

static RestrictedIntegerPartitions(*n*)

Return the poset of integer partitions of the integer n ordered by restricted refinement.

That is, if p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two distinct parts of p (and sorting, if necessary).

EXAMPLES:

```
sage: P = posets.RestrictedIntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
17
```

```
>>> from sage.all import *
>>> P = posets.RestrictedIntegerPartitions(Integer(7)); P
Finite poset containing 15 elements
>>> len(P.cover_relations())
17
```

static RibbonPoset(*n*, *descents*)

Return a ribbon poset on `n` vertices with descents at `descents`.

INPUT:

- `n` – the number of vertices
- `descents` – an iterable; the indices on the ribbon where $y > x$

EXAMPLES:

```
sage: R = Posets.RibbonPoset(5, [1,2])
sage: sorted(R.cover_relations())
[[0, 1], [2, 1], [3, 2], [3, 4]]
```

```
>>> from sage.all import *
>>> R = Posets.RibbonPoset(Integer(5), [Integer(1),Integer(2)])
>>> sorted(R.cover_relations())
[[0, 1], [2, 1], [3, 2], [3, 4]]
```

static SSTPoset(*s*, *f=None*)

The lattice poset on semistandard tableaux of shape `s` and largest entry `f` that is ordered by componentwise comparison of the entries.

INPUT:

- `s` – shape of the tableaux
- `f` – integer (default: `None`); the maximum fill number. By default (`None`), the method uses the number of cells in the shape.

Note

This is a basic implementation and most certainly not the most efficient.

EXAMPLES:

```
sage: posets.SSTPoset([2,1])
Finite lattice containing 8 elements

sage: posets.SSTPoset([2,1],4)
Finite lattice containing 20 elements

sage: posets.SSTPoset([2,1],2).cover_relations()
[[[1, 1], [2]], [[1, 2], [2]]]

sage: posets.SSTPoset([3,2]).bottom()       # long time (6s on sage.math,␣
↪2012)
[[1, 1, 1], [2, 2]]

sage: posets.SSTPoset([3,2],4).maximal_elements()
[[3, 3, 4], [4, 4]]]
```

```
>>> from sage.all import *
>>> posets.SSTPoset([Integer(2),Integer(1)])
Finite lattice containing 8 elements

>>> posets.SSTPoset([Integer(2),Integer(1)],Integer(4))
Finite lattice containing 20 elements

>>> posets.SSTPoset([Integer(2),Integer(1)],Integer(2)).cover_relations()
[[[1, 1], [2]], [[1, 2], [2]]]

>>> posets.SSTPoset([Integer(3),Integer(2)]).bottom()       # long time (6s␣
↪on sage.math, 2012)
[[1, 1, 1], [2, 2]]

>>> posets.SSTPoset([Integer(3),Integer(2)],Integer(4)).maximal_elements()
[[3, 3, 4], [4, 4]]]
```

static Sashes(n)

Return the lattice of sashes of length `n`.

See *lattice_of_sashes()* for details.

static SetPartitions(n)

Return the lattice of set partitions of the set $\{1, \ldots, n\}$ ordered by refinement.

INPUT:

- `n` – positive integer

EXAMPLES:

```
sage: posets.SetPartitions(4)
Finite lattice containing 15 elements
```

```
>>> from sage.all import *
>>> posets.SetPartitions(Integer(4))
Finite lattice containing 15 elements
```

static ShardPoset(n)

Return the shard intersection order on permutations of size n.

See *shard_poset()* for details.

static ShufflePoset(m, n)

Return the Shuffle lattice $S_{m,n}$.

Shuffle lattices were defined by Greene in [Gre1988].

The Bubble lattice $B_{m,n}$ and the Shuffle lattice $S_{m,n}$ share the same underlying set, namely all shuffles of two subwords of the two words $X = (x_1, x_2, \ldots, x_m)$ and $Y = (y_1, y_2, \ldots, y_n)$.

The partial order in the Shuffle poset is defined by either inserting a letter from Y or deleting a letter from X.

See also

BubblePoset()

EXAMPLES:

```
sage: P = posets.ShufflePoset(2,1); P
Finite lattice containing 12 elements
sage: P.zeta_polynomial()
2*q^3 - q^2
```

```
>>> from sage.all import *
>>> P = posets.ShufflePoset(Integer(2),Integer(1)); P
Finite lattice containing 12 elements
>>> P.zeta_polynomial()
2*q^3 - q^2
```

static StandardExample(*n*, *facade=None*)

Return the partially ordered set on $2n$ elements with dimension n.

Let P be the poset on $\{0, 1, 2, \ldots, 2n-1\}$ whose defining relations are that $i < j$ for every $0 \leq i < n \leq j < 2n$ except when $i + n = j$. The poset P is the so-called *standard example* of a poset with dimension n.

INPUT:

- `n` – integer ≥ 2; dimension of the constructed poset
- `facade` – boolean; whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the *Poset()* constructor

OUTPUT: the standard example of a poset of dimension n

EXAMPLES:

```
sage: A = posets.StandardExample(3); A
Finite poset containing 6 elements
sage: A.dimension()                                                    #␣
↪needs networkx
3
```

```
>>> from sage.all import *
>>> A = posets.StandardExample(Integer(3)); A
```

(continues on next page)

(continued from previous page)

```
Finite poset containing 6 elements
>>> A.dimension()                                                    #␣
↪needs networkx
3
```

REFERENCES:

- [Gar2015]
- [Ros1999]

static SymmetricGroupAbsoluteOrderPoset(*n*, *labels='permutations'*)

Return the poset of permutations with respect to absolute order.

INPUT:

- `n` – a positive integer
- `label` – (default: `'permutations'`) a label for the elements of the poset returned by the function; the options are
  - `'permutations'` – labels the elements by their one-line notation
  - `'reduced_words'` – labels the elements by the lexicographically minimal reduced word
  - `'cycles'` – labels the elements by their expression as a product of cycles

EXAMPLES:

```
sage: posets.SymmetricGroupAbsoluteOrderPoset(4)                      #␣
↪needs sage.groups
Finite poset containing 24 elements
sage: posets.SymmetricGroupAbsoluteOrderPoset(3, labels='cycles')     #␣
↪needs sage.groups
Finite poset containing 6 elements
sage: posets.SymmetricGroupAbsoluteOrderPoset(3, labels='reduced_words')  #␣
↪needs sage.groups
Finite poset containing 6 elements
```

```
>>> from sage.all import *
>>> posets.SymmetricGroupAbsoluteOrderPoset(Integer(4))                 ␣
↪     # needs sage.groups
Finite poset containing 24 elements
>>> posets.SymmetricGroupAbsoluteOrderPoset(Integer(3), labels='cycles')  ␣
↪     # needs sage.groups
Finite poset containing 6 elements
>>> posets.SymmetricGroupAbsoluteOrderPoset(Integer(3), labels='reduced_words
↪')     # needs sage.groups
Finite poset containing 6 elements
```

static SymmetricGroupBruhatIntervalPoset(*start*, *end*)

The poset of permutations with respect to Bruhat order.

INPUT:

- `start` – list permutation
- `end` – list permutation (same n, of course)

> **Note**
>
> Must have `start` <= `end`.

EXAMPLES:

Any interval is rank symmetric if and only if it avoids these permutations:

```
sage: P1 = posets.SymmetricGroupBruhatIntervalPoset([1,2,3,4], [3,4,1,2])
sage: P2 = posets.SymmetricGroupBruhatIntervalPoset([1,2,3,4], [4,2,3,1])
sage: ranks1 = [P1.rank(v) for v in P1]
sage: ranks2 = [P2.rank(v) for v in P2]
sage: [ranks1.count(i) for i in sorted(set(ranks1))]
[1, 3, 5, 4, 1]
sage: [ranks2.count(i) for i in sorted(set(ranks2))]
[1, 3, 5, 6, 4, 1]
```

```
>>> from sage.all import *
>>> P1 = posets.SymmetricGroupBruhatIntervalPoset([Integer(1),Integer(2),
↪Integer(3),Integer(4)], [Integer(3),Integer(4),Integer(1),Integer(2)])
>>> P2 = posets.SymmetricGroupBruhatIntervalPoset([Integer(1),Integer(2),
↪Integer(3),Integer(4)], [Integer(4),Integer(2),Integer(3),Integer(1)])
>>> ranks1 = [P1.rank(v) for v in P1]
>>> ranks2 = [P2.rank(v) for v in P2]
>>> [ranks1.count(i) for i in sorted(set(ranks1))]
[1, 3, 5, 4, 1]
>>> [ranks2.count(i) for i in sorted(set(ranks2))]
[1, 3, 5, 6, 4, 1]
```

static SymmetricGroupBruhatOrderPoset(*n*)

The poset of permutations with respect to Bruhat order.

EXAMPLES:

```
sage: posets.SymmetricGroupBruhatOrderPoset(4)
Finite poset containing 24 elements
```

```
>>> from sage.all import *
>>> posets.SymmetricGroupBruhatOrderPoset(Integer(4))
Finite poset containing 24 elements
```

static SymmetricGroupWeakOrderPoset(*n*, *labels='permutations'*, *side='right'*)

The poset of permutations of $\{1, 2, \ldots, n\}$ with respect to the weak order (also known as the permutohedron order, cf. *permutohedron_lequal()*).

The optional variable `labels` (default: `'permutations'`) determines the labelling of the elements if $n < 10$. The optional variable `side` (default: `'right'`) determines whether the right or the left permutohedron order is to be used.

EXAMPLES:

```
sage: posets.SymmetricGroupWeakOrderPoset(4)
Finite lattice containing 24 elements
```

```
>>> from sage.all import *
>>> posets.SymmetricGroupWeakOrderPoset(Integer(4))
Finite lattice containing 24 elements
```

static TamariLattice(*n*, *m=1*)

Return the n-th Tamari lattice.

Using the slope parameter m, one can also get the m-Tamari lattices.

INPUT:

- `n` – nonnegative integer (the index)
- `m` – nonnegative integer (the slope, default: 1)

OUTPUT: a finite lattice

In the usual case, the elements of the lattice are *Dyck paths* in the $(n+1 \times n)$-rectangle. For a general slope m, the elements are Dyck paths in the $(mn+1 \times n)$-rectangle.

See Tamari lattice for mathematical background.

EXAMPLES:

```
sage: posets.TamariLattice(3)
Finite lattice containing 5 elements

sage: posets.TamariLattice(3, 2)
Finite lattice containing 12 elements
```

```
>>> from sage.all import *
>>> posets.TamariLattice(Integer(3))
Finite lattice containing 5 elements

>>> posets.TamariLattice(Integer(3), Integer(2))
Finite lattice containing 12 elements
```

REFERENCES:

- [BMFPR2011]

static TetrahedralPoset(*n*, **colors*, ***labels*)

Return the tetrahedral poset based on the input colors.

This method will return the tetrahedral poset with $n-1$ layers and covering relations based on the input colors of 'green', 'red', 'orange', 'silver', 'yellow' and 'blue' as defined in [Striker2011]. For particular color choices, the order ideals of the resulting tetrahedral poset will be isomorphic to known combinatorial objects.

For example, for the colors 'blue', 'yellow', 'orange', and 'green', the order ideals will be in bijection with alternating sign matrices. For the colors 'yellow', 'orange', and 'green', the order ideals will be in bijection with semistandard Young tableaux of staircase shape. For the colors 'red', 'orange', 'green', and optionally 'yellow', the order ideals will be in bijection with totally symmetric self-complementary plane partitions in a $2n \times 2n \times 2n$ box.

INPUT:

- `n` – defines the number (n-1) of layers in the poset
- `colors` – the colors that define the covering relations of the poset; colors used are 'green', 'red', 'yellow', 'orange', 'silver', and 'blue'

- `labels` – keyword variable used to determine whether the poset is labeled with integers or tuples. To label with integers, the method should be called with `labels='integers'`. Otherwise, the labeling will default to tuples.

EXAMPLES:

```
sage: posets.TetrahedralPoset(4,'green','red','yellow','silver','blue','orange
↪')
Finite poset containing 10 elements

sage: posets.TetrahedralPoset(4,'green','red','yellow','silver','blue','orange
↪',
....:                         labels='integers')
Finite poset containing 10 elements

sage: A = AlternatingSignMatrices(3)
sage: p = A.lattice()
sage: ji = p.join_irreducibles_poset()
sage: tet = posets.TetrahedralPoset(3, 'green','yellow','blue','orange')
sage: ji.is_isomorphic(tet)
True
```

```
>>> from sage.all import *
>>> posets.TetrahedralPoset(Integer(4),'green','red','yellow','silver','blue',
↪'orange')
Finite poset containing 10 elements

>>> posets.TetrahedralPoset(Integer(4),'green','red','yellow','silver','blue',
↪'orange',
...                         labels='integers')
Finite poset containing 10 elements

>>> A = AlternatingSignMatrices(Integer(3))
>>> p = A.lattice()
>>> ji = p.join_irreducibles_poset()
>>> tet = posets.TetrahedralPoset(Integer(3), 'green','yellow','blue','orange
↪')
>>> ji.is_isomorphic(tet)
True
```

static UpDownPoset(*n*, *m=1*)

Return the up-down poset on n elements where every $(m+1)$ step is down and the rest are up.

The case where $m = 1$ is sometimes referred to as the zig-zag poset or the fence.

INPUT:

- `n` – nonnegative integer; number of elements in the poset
- `m` – nonnegative integer (default: 1); how frequently down steps occur

OUTPUT:

The partially ordered set on $\{0, 1, \ldots, n-1\}$ where i covers $i+1$ if m divides $i+1$, and $i+1$ covers i otherwise.

EXAMPLES:

```
sage: P = posets.UpDownPoset(7, 2); P
Finite poset containing 7 elements
sage: sorted(P.cover_relations())
[[0, 1], [1, 2], [3, 2], [3, 4], [4, 5], [6, 5]]
```

```
>>> from sage.all import *
>>> P = posets.UpDownPoset(Integer(7), Integer(2)); P
Finite poset containing 7 elements
>>> sorted(P.cover_relations())
[[0, 1], [1, 2], [3, 2], [3, 4], [4, 5], [6, 5]]
```

Fibonacci numbers as the number of antichains of a poset:

```
sage: [len(posets.UpDownPoset(n).antichains().list()) for n in range(6)]
[1, 2, 3, 5, 8, 13]
```

```
>>> from sage.all import *
>>> [len(posets.UpDownPoset(n).antichains().list()) for n in␣
↪range(Integer(6))]
[1, 2, 3, 5, 8, 13]
```

static YoungDiagramPoset(*lam*, *dual=False*)

Return the poset of cells in the Young diagram of a partition.

INPUT:

- `lam` – a partition
- `dual` – boolean (default: `False`); determines the orientation of the poset. If `True`, then it is a join semilattice, otherwise it is a meet semilattice.

EXAMPLES:

```
sage: P = posets.YoungDiagramPoset(Partition([2, 2])); P
Finite meet-semilattice containing 4 elements

sage: sorted(P.cover_relations())
[[(0, 0), (0, 1)], [(0, 0), (1, 0)], [(0, 1), (1, 1)], [(1, 0), (1, 1)]]

sage: posets.YoungDiagramPoset([3, 2], dual=True)
Finite join-semilattice containing 5 elements
```

```
>>> from sage.all import *
>>> P = posets.YoungDiagramPoset(Partition([Integer(2), Integer(2)])); P
Finite meet-semilattice containing 4 elements

>>> sorted(P.cover_relations())
[[(0, 0), (0, 1)], [(0, 0), (1, 0)], [(0, 1), (1, 1)], [(1, 0), (1, 1)]]

>>> posets.YoungDiagramPoset([Integer(3), Integer(2)], dual=True)
Finite join-semilattice containing 5 elements
```

static YoungFibonacci(n)

Return the Young-Fibonacci lattice up to rank n.

Elements of the (infinite) lattice are words with letters '1' and '2'. The covers of a word are the words with another '1' added somewhere not after the first occurrence of an existing '1' and, additionally, the words where the first '1' is replaced by a '2'. The lattice is truncated to have rank n.

See Wikipedia article Young-Fibonacci lattice.

EXAMPLES:

```
sage: Y5 = posets.YoungFibonacci(5); Y5
Finite meet-semilattice containing 20 elements
sage: sorted(Y5.upper_covers(Word('211')))
[word: 1211, word: 2111, word: 221]
```

```
>>> from sage.all import *
>>> Y5 = posets.YoungFibonacci(Integer(5)); Y5
Finite meet-semilattice containing 20 elements
>>> sorted(Y5.upper_covers(Word('211')))
[word: 1211, word: 2111, word: 221]
```

static YoungsLattice(n)

Return Young's Lattice up to rank n.

In other words, the poset of partitions of size less than or equal to n ordered by inclusion.

INPUT:

- `n` – positive integer

EXAMPLES:

```
sage: P = posets.YoungsLattice(3); P
Finite meet-semilattice containing 7 elements
sage: P.cover_relations()
[[[], [1]],
 [[1], [1, 1]],
 [[1], [2]],
 [[1, 1], [1, 1, 1]],
 [[1, 1], [2, 1]],
 [[2], [2, 1]],
 [[2], [3]]]
```

```
>>> from sage.all import *
>>> P = posets.YoungsLattice(Integer(3)); P
Finite meet-semilattice containing 7 elements
>>> P.cover_relations()
[[[], [1]],
 [[1], [1, 1]],
 [[1], [2]],
 [[1, 1], [1, 1, 1]],
 [[1, 1], [2, 1]],
 [[2], [2, 1]],
 [[2], [3]]]
```

static YoungsLatticePrincipalOrderIdeal(lam)

Return the principal order ideal of the partition lam in Young's Lattice.

INPUT:

- `lam` – a partition

EXAMPLES:

```
sage: P = posets.YoungsLatticePrincipalOrderIdeal(Partition([2,2]))
sage: P
Finite lattice containing 6 elements
sage: P.cover_relations()
[[[], [1]],
 [[1], [1, 1]],
 [[1], [2]],
 [[1, 1], [2, 1]],
 [[2], [2, 1]],
 [[2, 1], [2, 2]]]
```

```
>>> from sage.all import *
>>> P = posets.YoungsLatticePrincipalOrderIdeal(Partition([Integer(2),
↪Integer(2)]))
>>> P
Finite lattice containing 6 elements
>>> P.cover_relations()
[[[], [1]],
 [[1], [1, 1]],
 [[1], [2]],
 [[1, 1], [2, 1]],
 [[2], [2, 1]],
 [[2, 1], [2, 2]]]
```

sage = <module 'sage' from '/run/media/hsy/3000gb/sagemath/sage/src/sage/__init__.py'>

sage.combinat.posets.poset_examples.**check_int**(*n*, *minimum=0*)

Check that `n` is an integer at least equal to `minimum`.

This is a boilerplate function ensuring input safety.

INPUT:

- `n` – anything
- `minimum` – an optional integer (default: 0)

EXAMPLES:

```
sage: from sage.combinat.posets.poset_examples import check_int
sage: check_int(6, 3)
6
sage: check_int(6)
6

sage: check_int(-1)
Traceback (most recent call last):
...
ValueError: number of elements must be a nonnegative integer, not -1

sage: check_int(1, 3)
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: number of elements must be an integer at least 3, not 1

sage: check_int('junk')
Traceback (most recent call last):
...
ValueError: number of elements must be a nonnegative integer, not junk
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.poset_examples import check_int
>>> check_int(Integer(6), Integer(3))
6
>>> check_int(Integer(6))
6

>>> check_int(-Integer(1))
Traceback (most recent call last):
...
ValueError: number of elements must be a nonnegative integer, not -1

>>> check_int(Integer(1), Integer(3))
Traceback (most recent call last):
...
ValueError: number of elements must be an integer at least 3, not 1

>>> check_int('junk')
Traceback (most recent call last):
...
ValueError: number of elements must be a nonnegative integer, not junk
```

sage.combinat.posets.poset_examples.**posets**

alias of *Posets*

D-complete posets

AUTHORS:

- Stefan Grosser (06-2020): initial implementation

class sage.combinat.posets.d_complete.**DCompletePoset**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: *FiniteJoinSemilattice*

A d-complete poset.

D-complete posets are a class of posets introduced by Proctor in [Proc1999]. It includes common families such as shapes, shifted shapes, and rooted forests. Proctor showed in [PDynk1999] that d-complete posets have decompositions in *irreducible* posets, and showed in [Proc2014] that d-complete posets admit a hook-length formula (see Wikipedia article Hook_length_formula). A complete proof of the hook-length formula can be found in [KY2019].

EXAMPLES:

```
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Posets.DoubleTailedDiamond(2)
sage: TestSuite(P).run()
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.poset_examples import Posets
>>> P = Posets.DoubleTailedDiamond(Integer(2))
>>> TestSuite(P).run()
```

get_hook(*elmt*)

Return the hook length of the element `elmt`.

EXAMPLES:

```
sage: from sage.combinat.posets.d_complete import DCompletePoset
sage: P = DCompletePoset(DiGraph({0: [1], 1: [2]}))
sage: P.get_hook(1)
2
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.d_complete import DCompletePoset
>>> P = DCompletePoset(DiGraph({Integer(0): [Integer(1)], Integer(1):␣
↪[Integer(2)]}))
>>> P.get_hook(Integer(1))
2
```

get_hooks()

Return all the hook lengths as a dictionary.

EXAMPLES:

```
sage: from sage.combinat.posets.d_complete import DCompletePoset
sage: P = DCompletePoset(DiGraph({0: [1, 2], 1: [3], 2: [3], 3: []}))
sage: P.get_hooks()
{0: 1, 1: 2, 2: 2, 3: 3}
sage: from sage.combinat.posets.poset_examples import Posets
sage: YDP321 = Posets.YoungDiagramPoset(Partition([3,2,1]))
sage: P = DCompletePoset(YDP321._hasse_diagram.reverse())
sage: P.get_hooks()
{0: 5, 1: 3, 2: 1, 3: 3, 4: 1, 5: 1}
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.d_complete import DCompletePoset
>>> P = DCompletePoset(DiGraph({Integer(0): [Integer(1), Integer(2)],␣
↪Integer(1): [Integer(3)], Integer(2): [Integer(3)], Integer(3): []}))
>>> P.get_hooks()
{0: 1, 1: 2, 2: 2, 3: 3}
>>> from sage.combinat.posets.poset_examples import Posets
>>> YDP321 = Posets.YoungDiagramPoset(Partition([Integer(3),Integer(2),
↪Integer(1)]))
>>> P = DCompletePoset(YDP321._hasse_diagram.reverse())
>>> P.get_hooks()
{0: 5, 1: 3, 2: 1, 3: 3, 4: 1, 5: 1}
```

hook_product()

Return the hook product for the poset.

Elements of posets, lattices, semilattices, etc.

class sage.combinat.posets.elements.**JoinSemilatticeElement**(*poset*, *element*, *vertex*)

Bases: *PosetElement*

class sage.combinat.posets.elements.**LatticePosetElement**(*poset*, *element*, *vertex*)

Bases: *MeetSemilatticeElement*, *JoinSemilatticeElement*

class sage.combinat.posets.elements.**MeetSemilatticeElement**(*poset*, *element*, *vertex*)

Bases: *PosetElement*

class sage.combinat.posets.elements.**PosetElement**(*poset*, *element*, *vertex*)

Bases: Element

Establish the parent-child relationship between poset and element, where element is associated to the vertex vertex of the Hasse diagram of the poset.

INPUT:

- poset – a poset object
- element – any object
- vertex – a vertex of the Hasse diagram of the poset

Fast linear extension iterator

sage.combinat.posets.linear_extension_iterator.**linear_extension_iterator**(*D*)

Iterate over the linear extensions of the poset.

The list _le keeps track of the current linear extensions. The boolean variable is_plus keeps track of the "sign".

INPUT:

- D – the Hasse diagram of a poset

Warning

It is assumed that D is not modified while the linear extensions are generated.

EXAMPLES:

```
sage: from sage.combinat.posets.linear_extension_iterator import linear_extension_
↪iterator
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })._hasse_diagram
sage: list(linear_extension_iterator(D))                                    #␣
↪needs sage.modules
[[0, 1, 2, 3, 4],
 [0, 2, 1, 3, 4],
 [0, 2, 1, 4, 3],
 [0, 2, 4, 1, 3],
 [0, 1, 2, 4, 3]]

sage: D = posets.BooleanLattice(3)._hasse_diagram
```

(continues on next page)

(continued from previous page)

```
sage: len(list(linear_extension_iterator(D)))                                  #␣
↪needs sage.modules
48

sage: D = posets.AntichainPoset(9)._hasse_diagram
sage: len(list(linear_extension_iterator(D))) == factorial(9)    # long time,␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.linear_extension_iterator import linear_extension_
↪iterator
>>> D = Poset({ Integer(0):[Integer(1),Integer(2)], Integer(1):[Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)] })._hasse_diagram
>>> list(linear_extension_iterator(D))                                         #␣
↪needs sage.modules
[[0, 1, 2, 3, 4],
 [0, 2, 1, 3, 4],
 [0, 2, 1, 4, 3],
 [0, 2, 4, 1, 3],
 [0, 1, 2, 4, 3]]

>>> D = posets.BooleanLattice(Integer(3))._hasse_diagram
>>> len(list(linear_extension_iterator(D)))                                    #␣
↪needs sage.modules
48

>>> D = posets.AntichainPoset(Integer(9))._hasse_diagram
>>> len(list(linear_extension_iterator(D))) == factorial(Integer(9))    # long␣
↪time, needs sage.modules
True
```

Finite lattices and semilattices

This module implements finite (semi)lattices. It defines:

LatticePoset()	Construct a lattice.
MeetSemilattice()	Construct a meet semi-lattice.
JoinSemilattice()	Construct a join semi-lattice.
FiniteLatticePoset	A class for finite lattices.
FiniteMeetSemilattice	A class for finite meet semilattices.
FiniteJoinSemilattice	A class for finite join semilattices.

List of (semi)lattice methods

Meet and join

meet()	Return the meet of given elements.
join()	Return the join of given elements.
meet_matrix()	Return the matrix of meets of all elements of the meet semi-lattice.
join_matrix()	Return the matrix of joins of all elements of the join semi-lattice.

Properties of the lattice

is_distributive()	Return `True` if the lattice is distributive.
is_modular()	Return `True` if the lattice is modular.
is_lower_semimodular()	Return `True` if all elements with common upper cover have a common lower cover.
is_upper_semimodular()	Return `True` if all elements with common lower cover have a common upper cover.
is_semidistributive()	Return `True` if the lattice is both join- and meet-semidistributive.
is_join_semidistributive()	Return `True` if the lattice is join-semidistributive.
is_meet_semidistributive()	Return `True` if the lattice is meet-semidistributive.
is_join_distributive()	Return `True` if the lattice is join-distributive.
is_meet_distributive()	Return `True` if the lattice is meet-distributive.
is_atomic()	Return `True` if every element of the lattice can be written as a join of atoms.
is_coatomic()	Return `True` if every element of the lattice can be written as a meet of coatoms.
is_geometric()	Return `True` if the lattice is atomic and upper semimodular.
is_extremal()	Return `True` if the lattice is extremal.
is_complemented()	Return `True` if every element of the lattice has at least one complement.
is_sectionally_complemented()	Return `True` if every interval from the bottom is complemented.
is_cosectionally_complemented()	Return `True` if every interval to the top is complemented.
is_relatively_complemented()	Return `True` if every interval of the lattice is complemented.
is_pseudocomplemented()	Return `True` if every element of the lattice has a (meet-)pseudocomplement.
is_join_pseudocomplemented()	Return `True` if every element of the lattice has a join-pseudocomplement.
is_orthocomplemented()	Return `True` if the lattice has an orthocomplementation.
is_supersolvable()	Return `True` if the lattice is supersolvable.
is_planar()	Return `True` if the lattice has an upward planar drawing.
is_dismantlable()	Return `True` if the lattice is dismantlable.
is_interval_dismantlable()	Return `True` if the lattice is interval dismantlable.
is_left_modular()	Return `True` if the lattice is left_modular.
is_sublattice_dismantlable()	Return `True` if the lattice is sublattice dismantlable.
is_stone()	Return `True` if the lattice is a Stone lattice.
is_trim()	Return `True` if the lattice is a trim lattice.
is_vertically_decomposable()	Return `True` if the lattice is vertically decomposable.
is_simple()	Return `True` if the lattice has no nontrivial congruences.
is_isoform()	Return `True` if all congruences of the lattice consists of isoform blocks.
is_uniform()	Return `True` if all congruences of the lattice consists of equal-sized blocks.
is_regular()	Return `True` if all congruences of lattice are determined by any of the congruence blocks.
is_subdirectly_reducible()	Return `True` if the lattice is a sublattice of the product of smaller lattices.
is_constructible_by_doublings()	Return `True` if the lattice is constructible by doublings from the one-element lattice.

continues on next page

Table 5 – continued from previous page

breadth()	Return the breadth of the lattice.

Specific elements

atoms()	Return elements covering the bottom element.
coatoms()	Return elements covered by the top element.
double_irreducibles()	Return double irreducible elements.
join_primes()	Return the join prime elements.
meet_primes()	Return the meet prime elements.
complements()	Return the list of complements of an element, or the dictionary of complements for all elements.
pseudocomplement()	Return the pseudocomplement of an element.
is_modular_element()	Return `True` if given element is modular in the lattice.
is_left_modular_element()	Return `True` if given element is left modular in the lattice.
neutral_elements()	Return neutral elements of the lattice.
canonical_joinands()	Return the canonical joinands of an element.
canonical_meetands()	Return the canonical meetands of an element.

Sublattices

sublattice()	Return sublattice generated by list of elements.
submeetsemilattice()	Return meet-subsemilattice generated by list of elements.
subjoinsemilattice()	Return join-subsemilattice generated by list of elements.
is_sublattice()	Return `True` if the lattice is a sublattice of given lattice.
sublattices()	Return all sublattices of the lattice.
sublattices_lattice()	Return the lattice of sublattices.
isomorphic_sublattices_iterator()	Return an iterator over the sublattices isomorphic to given lattice.
maximal_sublattices()	Return maximal sublattices of the lattice.
frattini_sublattice()	Return the intersection of maximal sublattices of the lattice.
skeleton()	Return the skeleton of the lattice.
center()	Return the sublattice of complemented neutral elements.
vertical_decomposition()	Return the vertical decomposition of the lattice.

Miscellaneous

moebius_algebra()	Return the Möbius algebra of the lattice.
quantum_moebius_algebra()	Return the quantum Möbius algebra of the lattice.
vertical_composition()	Return ordinal sum of lattices with top/bottom element unified.
day_doubling()	Return the lattice with Alan Day's doubling construction of a subset.
adjunct()	Return the adjunct with other lattice.
subdirect_decomposition()	Return the subdirect decomposition of the lattice.
congruence()	Return the congruence generated by lists of elements.
quotient()	Return the quotient lattice by a congruence.
congruences_lattice()	Return the lattice of congruences.

class sage.combinat.posets.lattices.**FiniteJoinSemilattice**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: *FinitePoset*

We assume that the argument passed to FiniteJoinSemilattice is the poset of a join-semilattice (i.e. a poset with least upper bound for each pair of elements).

Element

alias of *JoinSemilatticeElement*

coatoms()

Return the list of co-atoms of this (semi)lattice.

A *co-atom* of a lattice is an element covered by the top element.

EXAMPLES:

```
sage: L = posets.DivisorLattice(60)
sage: sorted(L.coatoms())
[12, 20, 30]
```

```
>>> from sage.all import *
>>> L = posets.DivisorLattice(Integer(60))
>>> sorted(L.coatoms())
[12, 20, 30]
```

See also

- Dual function: *atoms()*

join(*x*, *y=None*)

Return the join of given elements in the lattice.

INPUT:

- x, y – two elements of the (semi)lattice OR
- x – list or tuple of elements

EXAMPLES:

```
sage: D = posets.DiamondPoset(5)
sage: D.join(1, 2)
4
sage: D.join(1, 1)
1
sage: D.join(1, 4)
4
sage: D.join(1, 0)
1
```

```
>>> from sage.all import *
>>> D = posets.DiamondPoset(Integer(5))
>>> D.join(Integer(1), Integer(2))
4
```

(continues on next page)

(continued from previous page)

```
>>> D.join(Integer(1), Integer(1))
1
>>> D.join(Integer(1), Integer(4))
4
>>> D.join(Integer(1), Integer(0))
1
```

Using list of elements as an argument. Join of empty list is the bottom element:

```
sage: B4=posets.BooleanLattice(4)
sage: B4.join([2,4,8])
14
sage: B4.join([])
0
```

```
>>> from sage.all import *
>>> B4=posets.BooleanLattice(Integer(4))
>>> B4.join([Integer(2),Integer(4),Integer(8)])
14
>>> B4.join([])
0
```

For non-facade lattices operator + works for join:

```
sage: L = posets.PentagonPoset(facade=False)
sage: L(1)+L(2)
4
```

```
>>> from sage.all import *
>>> L = posets.PentagonPoset(facade=False)
>>> L(Integer(1))+L(Integer(2))
4
```

See also

- Dual function: *meet()*

join_matrix()

Return a matrix whose `(i,j)` entry is `k`, where `self.linear_extension()[k]` is the join (least upper bound) of `self.linear_extension()[i]` and `self.linear_extension()[j]`.

EXAMPLES:

```
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade =␣
↪False)
sage: J = P.join_matrix(); J
[0 1 2 3 4 5 6 7]
[1 1 3 3 7 7 7 7]
[2 3 2 3 4 6 6 7]
[3 3 3 3 7 7 7 7]
```

(continues on next page)

(continued from previous page)

```
[4 7 4 7 4 7 7 7]
[5 7 6 7 7 5 6 7]
[6 7 6 7 7 6 6 7]
[7 7 7 7 7 7 7 7]
sage: J[P(4).vertex,P(3).vertex] == P(7).vertex
True
sage: J[P(5).vertex,P(2).vertex] == P(5).vertex
True
sage: J[P(5).vertex,P(2).vertex] == P(2).vertex
False
```

```
>>> from sage.all import *
>>> P = LatticePoset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],
↪[Integer(4),Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],
↪[Integer(7)],[]], facade = False)
>>> J = P.join_matrix(); J
[0 1 2 3 4 5 6 7]
[1 1 3 3 7 7 7 7]
[2 3 2 3 4 6 6 7]
[3 3 3 3 7 7 7 7]
[4 7 4 7 4 7 7 7]
[5 7 6 7 7 5 6 7]
[6 7 6 7 7 6 6 7]
[7 7 7 7 7 7 7 7]
>>> J[P(Integer(4)).vertex,P(Integer(3)).vertex] == P(Integer(7)).vertex
True
>>> J[P(Integer(5)).vertex,P(Integer(2)).vertex] == P(Integer(5)).vertex
True
>>> J[P(Integer(5)).vertex,P(Integer(2)).vertex] == P(Integer(2)).vertex
False
```

class sage.combinat.posets.lattices.**FiniteLatticePoset**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: *FiniteMeetSemilattice*, *FiniteJoinSemilattice*

We assume that the argument passed to FiniteLatticePoset is the poset of a lattice (i.e. a poset with greatest lower bound and least upper bound for each pair of elements).

Element

alias of *LatticePosetElement*

adjunct(*other*, *a*, *b*)

Return the adjunct of the lattice by `other` on the pair (a, b).

It is assumed that $a < b$ but b does not cover a.

The adjunct of a lattice K to L with respect to pair (a, b) of L is defined such that $x < y$ if

- $x, y \in K$ and $x < y$ in K,
- $x, y \in L$ and $x < y$ in L,
- $x \in L$, $y \in K$ and $x \leq a$ in L, or
- $x \in K$, $y \in L$ and $b \leq y$ in L.

Informally this can be seen as attaching the lattice K to L as a new block between a and b. Dismantlable lattices are exactly those that can be created from chains with this function.

Mathematically, it is only defined when L and K have no common element; here we force that by giving them different names in the resulting lattice.

EXAMPLES:

```
sage: Pnum = posets.PentagonPoset()
sage: Palp = Pnum.relabel(lambda x: chr(ord('a')+x))
sage: PP = Pnum.adjunct(Palp, 0, 3)
sage: PP.atoms()
[(0, 1), (0, 2), (1, 'a')]
sage: PP.coatoms()
[(0, 1), (0, 3)]
```

```
>>> from sage.all import *
>>> Pnum = posets.PentagonPoset()
>>> Palp = Pnum.relabel(lambda x: chr(ord('a')+x))
>>> PP = Pnum.adjunct(Palp, Integer(0), Integer(3))
>>> PP.atoms()
[(0, 1), (0, 2), (1, 'a')]
>>> PP.coatoms()
[(0, 1), (0, 3)]
```

breadth(*certificate=False*)

Return the breadth of the lattice.

The breadth of a lattice is the largest integer n such that any join of elements $x_1, x_2, \ldots, x_{n+1}$ is join of a proper subset of x_i.

This can be also characterized by subposets: a lattice of breadth at least n contains a subposet isomorphic to the Boolean lattice of 2^n elements.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return the pair (b, a) where b is the breadth and a is an antichain such that the join of a differs from the join of any proper subset of a. If `certificate=False` return just the breadth.

EXAMPLES:

```
sage: D10 = posets.DiamondPoset(10)
sage: D10.breadth()
2

sage: B3 = posets.BooleanLattice(3)
sage: B3.breadth()
3
sage: B3.breadth(certificate=True)
(3, [1, 2, 4])
```

```
>>> from sage.all import *
>>> D10 = posets.DiamondPoset(Integer(10))
>>> D10.breadth()
2

>>> B3 = posets.BooleanLattice(Integer(3))
>>> B3.breadth()
3
>>> B3.breadth(certificate=True)
(3, [1, 2, 4])
```

ALGORITHM:

For a lattice to have breadth at least n, it must have an n-element antichain A with join j. Element j must cover at least n elements. There must also be $n-2$ levels of elements between A and j. So we start by searching elements that could be our j and then just check possible antichains A.

Note

Prior to version 8.1 this function returned just an antichain with `certificate=True`.

canonical_joinands(e)

Return the canonical joinands of e.

The canonical joinands of an element e in the lattice L is the subset $S \subseteq L$ such that 1) the join of S is e, and 2) if the join of some other subset S' of is also e, then for every element $s \in S$ there is an element $s' \in S'$ such that $s \leq s'$.

Informally said this is the set of lowest possible elements with given join. It exists for every element if and only if the lattice is join-semidistributive. Canonical joinands are always join-irreducibles.

INPUT:

- `e` – an element of the lattice

OUTPUT: canonical joinands as a list, if it exists; if not, `None`

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5], 4: [6],
....:                   5: [7], 6: [7]})
sage: L.canonical_joinands(7)
[3, 4]

sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6],
....: 5: [6]})
sage: L.canonical_joinands(6) is None
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5)], Integer(3): [Integer(5)], Integer(4):␣
↪[Integer(6)],
...                    Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.canonical_joinands(Integer(7))
```

(continues on next page)

(continued from previous page)

```
[3, 4]

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5)], Integer(3): [Integer(6)], Integer(4):␣
↪[Integer(6)],
... Integer(5): [Integer(6)]})
>>> L.canonical_joinands(Integer(6)) is None
True
```

See also

canonical_meetands()

canonical_meetands(*e*)

Return the canonical meetands of e.

The canonical meetands of an element e in the lattice L is the subset $S \subseteq L$ such that 1) the meet of S is e, and 2) if the meet of some other subset S' of is also e, then for every element $s \in S$ there is an element $s' \in S'$ such that $s \geq s'$.

Informally said this is the set of greatest possible elements with given meet. It exists for every element if and only if the lattice is meet-semidistributive. Canonical meetands are always meet-irreducibles.

INPUT:

- `e` – an element of the lattice

OUTPUT: canonical meetands as a list, if it exists; if not, `None`

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5, 6], 4: [6],
....:                   5: [7], 6: [7]})
sage: L.canonical_meetands(1)
[5, 4]

sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6],
....: 5: [6]})
sage: L.canonical_meetands(1) is None
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4)], Integer(3): [Integer(5), Integer(6)], Integer(4):␣
↪[Integer(6)],
...                    Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.canonical_meetands(Integer(1))
[5, 4]

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5)], Integer(3): [Integer(6)], Integer(4):␣
↪[Integer(6)],
... Integer(5): [Integer(6)]})
```

(continues on next page)

(continued from previous page)

```
>>> L.canonical_meetands(Integer(1)) is None
True
```

See also

canonical_joinands()

center()

Return the center of the lattice.

An element of a lattice is *central* if it is neutral and has a complement. The subposet induced by central elements is a *center* of the lattice. Actually it is a Boolean lattice.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [8, 9, 7],
....:                   4: [5, 6], 5: [8, 10], 6: [10], 7: [13, 11],
....:                   8: [13, 12], 9: [11, 12], 10: [13],
....:                   11: [14], 12: [14], 13: [14]})
sage: C = L.center(); C
Finite lattice containing 4 elements
sage: C.cover_relations()
[[1, 2], [1, 12], [2, 14], [12, 14]]

sage: L = posets.DivisorLattice(60)
sage: sorted(L.center().list())
[1, 3, 4, 5, 12, 15, 20, 60]
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(6), Integer(7)], Integer(3): [Integer(8), Integer(9),␣
↪Integer(7)],
...                   Integer(4): [Integer(5), Integer(6)], Integer(5):␣
↪[Integer(8), Integer(10)], Integer(6): [Integer(10)], Integer(7):␣
↪[Integer(13), Integer(11)],
...                   Integer(8): [Integer(13), Integer(12)], Integer(9):␣
↪[Integer(11), Integer(12)], Integer(10): [Integer(13)],
...                   Integer(11): [Integer(14)], Integer(12): [Integer(14)],␣
↪Integer(13): [Integer(14)]})
>>> C = L.center(); C
Finite lattice containing 4 elements
>>> C.cover_relations()
[[1, 2], [1, 12], [2, 14], [12, 14]]

>>> L = posets.DivisorLattice(Integer(60))
>>> sorted(L.center().list())
[1, 3, 4, 5, 12, 15, 20, 60]
```

See also

neutral_elements(), *complements()*

complements(*element=None*)

Return the list of complements of an element in the lattice, or the dictionary of complements for all elements.

Elements x and y are complements if their meet and join are respectively the bottom and the top element of the lattice.

INPUT:

- `element` – an element of the lattice whose complement is returned. If `None` (default) then dictionary of complements for all elements having at least one complement is returned.

EXAMPLES:

```
sage: L = LatticePoset({0:['a','b','c'],'a':[1],'b':[1],'c':[1]})
sage: C = L.complements()
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(0):['a','b','c'],'a':[Integer(1)],'b
↪':[Integer(1)],'c':[Integer(1)]})
>>> C = L.complements()
```

Let us check that 'a' and 'b' are complements of each other:

```
sage: 'a' in C['b']
True
sage: 'b' in C['a']
True
```

```
>>> from sage.all import *
>>> 'a' in C['b']
True
>>> 'b' in C['a']
True
```

Full list of complements:

```
sage: L.complements() # random order
{0: [1], 1: [0], 'a': ['b', 'c'], 'b': ['c', 'a'], 'c': ['b', 'a']}

sage: L = LatticePoset({0:[1,2],1:[3],2:[3],3:[4]})
sage: L.complements() # random order
{0: [4], 4: [0]}
sage: L.complements(1)
[]
```

```
>>> from sage.all import *
>>> L.complements() # random order
{0: [1], 1: [0], 'a': ['b', 'c'], 'b': ['c', 'a'], 'c': ['b', 'a']}

>>> L = LatticePoset({Integer(0):[Integer(1),Integer(2)],
↪Integer(1):[Integer(3)],Integer(2):[Integer(3)],Integer(3):[Integer(4)]})
>>> L.complements() # random order
{0: [4], 4: [0]}
>>> L.complements(Integer(1))
[]
```

See also

is_complemented()

congruence(S)

Return the congruence generated by set of sets S.

A congruence of a lattice is an equivalence relation $\cong$ that is compatible with meet and join; i.e. if $a_1 \cong a_2$ and $b_1 \cong b_2$, then $(a_1$
$veeb_1) \cong (a_2$
$veeb_2)$ and $(a_1 \wedge b_1) \cong (a_2 \wedge b_2)$.

By the congruence generated by set of sets $\{S_1, \ldots, S_n\}$ we mean the least congruence $\cong$ such that for every $x, y \in S_i$ for some i we have $x \cong y$.

INPUT:

- `S` – list of lists; list of element blocks that the congruence will contain

OUTPUT:

Congruence of the lattice as a *sage.combinat.set_partition.SetPartition*.

EXAMPLES:

```
sage: # needs sage.combinat
sage: L = posets.DivisorLattice(12)
sage: cong = L.congruence([[1, 3]])
sage: sorted(sorted(c) for c in cong)
[[1, 3], [2, 6], [4, 12]]
sage: L.congruence([[1, 2], [6, 12]])
{{1, 2, 4}, {3, 6, 12}}

sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.congruence([[1, 2]])                                                #␣
↪needs sage.combinat
{{1, 2}, {3, 4}, {5}}

sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 4: [5], 5: [7, 8],
....:                   6: [8], 3: [9], 7: [10], 8: [10], 9:[10]})
sage: cong = L.congruence([[1, 2]])                                         #␣
↪needs sage.combinat
sage: cong[0]                                                               #␣
↪needs sage.combinat
frozenset({1, 2, 3, 4, 5, 6, 7, 8, 9, 10})
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> L = posets.DivisorLattice(Integer(12))
>>> cong = L.congruence([[Integer(1), Integer(3)]])
>>> sorted(sorted(c) for c in cong)
[[1, 3], [2, 6], [4, 12]]
>>> L.congruence([[Integer(1), Integer(2)], [Integer(6), Integer(12)]])
{{1, 2, 4}, {3, 6, 12}}
```

(continues on next page)

(continued from previous page)

```
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4)], Integer(3): [Integer(4)], Integer(4): [Integer(5)]})
>>> L.congruence([[Integer(1), Integer(2)]])                              ␣
↪              # needs sage.combinat
{{1, 2}, {3, 4}, {5}}

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5), Integer(6)], Integer(4): [Integer(5)], Integer(5):␣
↪[Integer(7), Integer(8)],
...                   Integer(6): [Integer(8)], Integer(3): [Integer(9)],␣
↪Integer(7): [Integer(10)], Integer(8): [Integer(10)],␣
↪Integer(9):[Integer(10)]})
>>> cong = L.congruence([[Integer(1), Integer(2)]])                       ␣
↪              # needs sage.combinat
>>> cong[Integer(0)]                                                      ␣
↪     # needs sage.combinat
frozenset({1, 2, 3, 4, 5, 6, 7, 8, 9, 10})
```

See also

quotient()

congruences_lattice(*labels='congruence'*)

Return the lattice of congruences.

A congruence of a lattice is a partition of elements to classes compatible with both meet- and join-operation; see *congruence()*. Elements of the *congruence lattice* are congruences ordered by refinement; i.e. if every class of a congruence Θ is contained in some class of Φ, then $\Theta \leq \Phi$ in the congruence lattice.

INPUT:

- `labels` – string; the type of elements in the resulting lattice

OUTPUT: a distributive lattice

- If `labels='congruence'`, then elements of the result will be congruences given as *sage.combinat.set_partition.SetPartition*.
- If `labels='integers'`, result is a lattice on integers isomorphic to the congruence lattice.

EXAMPLES:

```
sage: # needs sage.combinat
sage: N5 = posets.PentagonPoset()
sage: CL = N5.congruences_lattice(); CL
Finite lattice containing 5 elements
sage: CL.atoms()
[{{0}, {1}, {2, 3}, {4}}]
sage: CL.coatoms()
[{{0, 1}, {2, 3, 4}}, {{0, 2, 3}, {1, 4}}]

sage: C4 = posets.ChainPoset(4)
sage: CL = C4.congruences_lattice(labels='integer')                       #␣
↪needs sage.combinat
```

(continues on next page)

(continued from previous page)

```
sage: CL.is_isomorphic(posets.BooleanLattice(3))                              #␣
↪needs sage.combinat
True
```

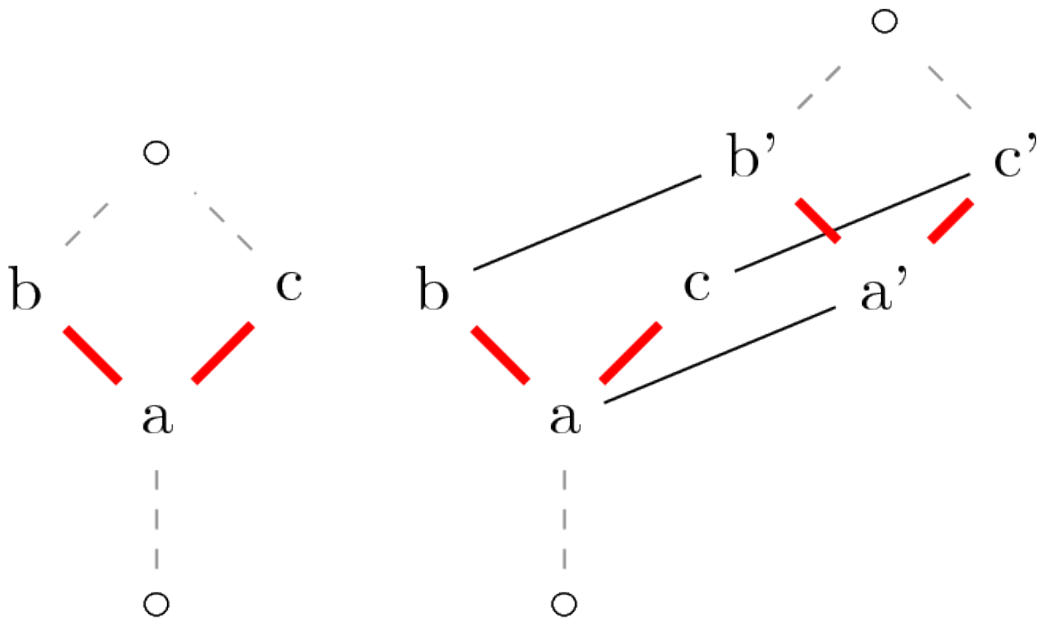
```
>>> from sage.all import *
>>> # needs sage.combinat
>>> N5 = posets.PentagonPoset()
>>> CL = N5.congruences_lattice(); CL
Finite lattice containing 5 elements
>>> CL.atoms()
[{{0}, {1}, {2, 3}, {4}}]
>>> CL.coatoms()
[{{0, 1}, {2, 3, 4}}, {{0, 2, 3}, {1, 4}}]

>>> C4 = posets.ChainPoset(Integer(4))
>>> CL = C4.congruences_lattice(labels='integer')                             #␣
↪needs sage.combinat
>>> CL.is_isomorphic(posets.BooleanLattice(Integer(3)))                        ␣
↪     # needs sage.combinat
True
```

day_doubling(S)

Return the lattice with Alan Day's doubling construction of subset S.

The subset S is assumed to be convex (i.e. if $a, c \in S$ and $a < b < c$ in the lattice, then $b \in S$) and connected (i.e. if $a, b \in S$ then there is a chain $a = e_1, e_2, \ldots, e_n = b$ such that e_i either covers or is covered by e_{i+1}).



Alan Day's doubling construction is a specific extension of the lattice. Here we formulate it in a format more suitable for computation.

Let L be a lattice and S a convex subset of it. The resulting lattice $L[S]$ has elements $(e, 0)$ for each $e \in L$

and $(e, 1)$ for each $e \in S$. If $x \leq y$ in L, then in the new lattice we have

- $(x, 0), (x, 1) \leq (y, 0), (y, 1)$
- $(x, 0) \leq (x, 1)$

INPUT:

- `S` – a subset of the lattice

EXAMPLES:

```
sage: L = LatticePoset({1: ['a', 'b', 2], 'a': ['c'], 'b': ['c', 'd'],
....:                   2: [3], 'c': [4], 'd': [4], 3: [4]})
sage: L2 = L.day_doubling(['a', 'b', 'c', 'd']); L2
Finite lattice containing 12 elements
sage: set(L2.upper_covers((1, 0))) == set([(2, 0), ('a', 0), ('b', 0)])
True
sage: set(L2.upper_covers(('b', 0))) == set([('d', 0), ('b', 1), ('c', 0)])
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): ['a', 'b', Integer(2)], 'a': ['c'], 'b': ['c
↪', 'd'],
...                   Integer(2): [Integer(3)], 'c': [Integer(4)], 'd':␣
↪[Integer(4)], Integer(3): [Integer(4)]})
>>> L2 = L.day_doubling(['a', 'b', 'c', 'd']); L2
Finite lattice containing 12 elements
>>> set(L2.upper_covers((Integer(1), Integer(0)))) == set([(Integer(2),␣
↪Integer(0)), ('a', Integer(0)), ('b', Integer(0))])
True
>>> set(L2.upper_covers(('b', Integer(0)))) == set([('d', Integer(0)), ('b',␣
↪Integer(1)), ('c', Integer(0))])
True
```

See also

is_constructible_by_doublings()

double_irreducibles()

Return the list of double irreducible elements of this lattice.

A *double irreducible* element of a lattice is an element covering and covered by exactly one element. In other words it is neither a meet nor a join of any elements.

EXAMPLES:

```
sage: L = posets.DivisorLattice(12)
sage: sorted(L.double_irreducibles())
[3, 4]

sage: L = posets.BooleanLattice(3)
sage: L.double_irreducibles()
[]
```

```
>>> from sage.all import *
>>> L = posets.DivisorLattice(Integer(12))
>>> sorted(L.double_irreducibles())
[3, 4]

>>> L = posets.BooleanLattice(Integer(3))
>>> L.double_irreducibles()
[]
```

See also

`meet_irreducibles()`, `join_irreducibles()`

feichtner_yuzvinsky_ring(*G*, *use_defining=False*, *base_ring=None*)

Return the Feichtner-Yuzvinsky ring of `self` and `G`.

Let R be a commutative ring, L a lattice, and $G \subseteq L$. The *Feichtner-Yuzvinsky ring* is the quotient of the polynomial ring $R[h_g \mid g \in G]$ by the ideal generated by

- h_a for every atom $a \in L \cap G$ and
- for every antichain A of the subposet G such that $g := \bigvee A \in G$ (with the join taken in L)

$$\prod_{a \in A} (h_g - h_a).$$

This was originally described for G such that (L, G) is a built lattice in the sense of [FY2004] (which has a geometric motivation), but this has been extended to G being an arbitrary subset.

This is not the original definition, which uses the nested subsets of G (see [FY2004] for the definition). However, the original construction, which we call the *defining* presentation and use the variables $\{x_g \mid g \in G\}$, can be recovered by setting $h_g = \sum_{g' \geq g} x_{g'}$ (where $g' \in G$).

INPUT:

- `G` – a subset of elements of `self`
- `use_defining` – boolean (default: `False`); whether or not to use the defining presentation in x_g
- `base_ring` – (default: $\mathbf{Q}$) the base ring

The order on the variables is equal to the ordering of the elements in `G`.

EXAMPLES:

```
sage: B2 = posets.BooleanLattice(2)
sage: FY = B2.feichtner_yuzvinsky_ring(B2[1:])
sage: FY
Quotient of Multivariate Polynomial Ring in h0, h1, h2 over Rational Field
 by the ideal (h0, h1, h0*h1 - h0*h2 - h1*h2 + h2^2)

sage: FY = B2.feichtner_yuzvinsky_ring(B2[1:], use_defining=True)
sage: FY
Quotient of Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
 by the ideal (x0 + x2, x1 + x2, x0*x1)
```

```
>>> from sage.all import *
>>> B2 = posets.BooleanLattice(Integer(2))
>>> FY = B2.feichtner_yuzvinsky_ring(B2[Integer(1):])
>>> FY
Quotient of Multivariate Polynomial Ring in h0, h1, h2 over Rational Field
 by the ideal (h0, h1, h0*h1 - h0*h2 - h1*h2 + h2^2)

>>> FY = B2.feichtner_yuzvinsky_ring(B2[Integer(1):], use_defining=True)
>>> FY
Quotient of Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
 by the ideal (x0 + x2, x1 + x2, x0*x1)
```

We reproduce the example from Section 5 of [Coron2023]:

```
sage: # needs sage.geometry.polyhedron
sage: H.<a,b,c,d> = HyperplaneArrangements(QQ)
sage: Arr = H(a-b, b-c, c-d, d-a)
sage: P = LatticePoset(Arr.intersection_poset())
sage: FY = P.feichtner_yuzvinsky_ring([P.top(),5,1,2,3,4])
sage: FY.defining_ideal().groebner_basis()                                    #␣
↪needs sage.libs.singular
[h0^2 - h0*h1, h1^2, h2, h3, h4, h5]
```

```
>>> from sage.all import *
>>> # needs sage.geometry.polyhedron
>>> H = HyperplaneArrangements(QQ, names=('a', 'b', 'c', 'd',)); (a, b, c, d,
↪) = H._first_ngens(4)
>>> Arr = H(a-b, b-c, c-d, d-a)
>>> P = LatticePoset(Arr.intersection_poset())
>>> FY = P.feichtner_yuzvinsky_ring([P.top(),Integer(5),Integer(1),Integer(2),
↪Integer(3),Integer(4)])
>>> FY.defining_ideal().groebner_basis()                                      #␣
↪needs sage.libs.singular
[h0^2 - h0*h1, h1^2, h2, h3, h4, h5]
```

frattini_sublattice()

Return the Frattini sublattice of the lattice.

The Frattini sublattice $\Phi(L)$ is the intersection of all proper maximal sublattices of L. It is also the set of "non-generators" - if the sublattice generated by set S of elements is whole lattice, then also $S \setminus \Phi(L)$ generates whole lattice.

EXAMPLES:

```
sage: L = LatticePoset(( [], [[1,2],[1,17],[1,8],[2,3],[2,22],
....:                         [2,5],[2,7],[17,22],[17,13],[8,7],
....:                         [8,13],[3,16],[3,9],[22,16],[22,18],
....:                         [22,10],[5,18],[5,14],[7,9],[7,14],
....:                         [7,10],[13,10],[16,6],[16,19],[9,19],
....:                         [18,6],[18,33],[14,33],[10,19],
....:                         [10,33],[6,4],[19,4],[33,4]] ))
sage: sorted(L.frattini_sublattice().list())
[1, 2, 4, 10, 19, 22, 33]
```

```
>>> from sage.all import *
>>> L = LatticePoset(( [], [[Integer(1),Integer(2)],[Integer(1),Integer(17)],
↪[Integer(1),Integer(8)],[Integer(2),Integer(3)],[Integer(2),Integer(22)],
...                          [Integer(2),Integer(5)],[Integer(2),Integer(7)],
↪[Integer(17),Integer(22)],[Integer(17),Integer(13)],[Integer(8),Integer(7)],
...                          [Integer(8),Integer(13)],[Integer(3),Integer(16)],
↪[Integer(3),Integer(9)],[Integer(22),Integer(16)],[Integer(22),Integer(18)],
...                          [Integer(22),Integer(10)],[Integer(5),
↪Integer(18)],[Integer(5),Integer(14)],[Integer(7),Integer(9)],[Integer(7),
↪Integer(14)],
...                          [Integer(7),Integer(10)],[Integer(13),
↪Integer(10)],[Integer(16),Integer(6)],[Integer(16),Integer(19)],[Integer(9),
↪Integer(19)],
...                          [Integer(18),Integer(6)],[Integer(18),
↪Integer(33)],[Integer(14),Integer(33)],[Integer(10),Integer(19)],
...                          [Integer(10),Integer(33)],[Integer(6),Integer(4)],
↪[Integer(19),Integer(4)],[Integer(33),Integer(4)]] ))
>>> sorted(L.frattini_sublattice().list())
[1, 2, 4, 10, 19, 22, 33]
```

is_atomic(*certificate=False*)

Return `True` if the lattice is atomic, and `False` otherwise.

A lattice is atomic if every element can be written as a join of atoms.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, e)`, where e is a join-irreducible element that is not an atom. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3:[5], 4:[6], 5:[6]})
sage: L.is_atomic()
True

sage: L = LatticePoset({0: [1, 2], 1: [3], 2: [3], 3:[4]})
sage: L.is_atomic()
False
sage: L.is_atomic(certificate=True)
(False, 4)
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5)], Integer(3):[Integer(5)], Integer(4):[Integer(6)],␣
↪Integer(5):[Integer(6)]})
>>> L.is_atomic()
True

>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3)], Integer(2): [Integer(3)], Integer(3):[Integer(4)]})
```

(continues on next page)

(continued from previous page)

```
>>> L.is_atomic()
False
>>> L.is_atomic(certificate=True)
(False, 4)
```

Note

See [EnumComb1], Section 3.3 for a discussion of atomic lattices.

See also

- Dual property: *is_coatomic()*
- Stronger properties: *is_sectionally_complemented()*
- Mutually exclusive properties: *is_vertically_decomposable()*

is_coatomic(*certificate=False*)

Return `True` if the lattice is coatomic, and `False` otherwise.

A lattice is coatomic if every element can be written as a meet of coatoms; i.e. if the dual of the lattice is atomic.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, e)`, where e is a meet-irreducible element that is not a coatom. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(3)
sage: L.is_coatomic()
True

sage: L = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4:[5]})
sage: L.is_coatomic()
False
sage: L.is_coatomic(certificate=True)
(False, 1)
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(3))
>>> L.is_coatomic()
True

>>> L = LatticePoset({Integer(1): [Integer(2)], Integer(2): [Integer(3),␣
↪Integer(4)], Integer(3): [Integer(5)], Integer(4):[Integer(5)]})
>>> L.is_coatomic()
```

(continues on next page)

(continued from previous page)

```
False
>>> L.is_coatomic(certificate=True)
(False, 1)
```

See also

- Dual property: *is_atomic()*
- Stronger properties: *is_cosectionally_complemented()*
- Mutually exclusive properties: *is_vertically_decomposable()*

is_complemented(*certificate=False*)

Return `True` if the lattice is complemented, and `False` otherwise.

A lattice is complemented if every element has at least one complement.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, e)`, where `e` is an element without a complement. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: L.is_complemented()
True

sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5], 4: [6],
....:                   5: [7], 6: [7]})
sage: L.is_complemented()
False
sage: L.is_complemented(certificate=True)
(False, 2)
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3)],␣
↪Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3):␣
↪[Integer(4)]})
>>> L.is_complemented()
True

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5)], Integer(4):␣
↪[Integer(6)],
...                    Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_complemented()
False
>>> L.is_complemented(certificate=True)
(False, 2)
```

- Stronger properties: *is_sectionally_complemented()*, *is_cosectionally_complemented()*, *is_orthocomplemented()*
- Other: *complements()*

is_congruence_uniform()

Return whether `self` is congruence uniform.

This is equivalent to being constructible by doubling intervals.

See also

is_constructible_by_doublings()

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.is_congruence_uniform()
True
sage: P = posets.DiamondPoset(5)
sage: P.is_congruence_uniform()
False
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.is_congruence_uniform()
True
>>> P = posets.DiamondPoset(Integer(5))
>>> P.is_congruence_uniform()
False
```

REFERENCES:

- [Day1979]

is_constructible_by_doublings(*type*)

Return `True` if the lattice is constructible by doublings, and `False` otherwise.

We call a lattice doubling constructible if it can be constructed from the one element lattice by a sequence of Alan Day's doubling constructions.

Lattices constructible by interval doubling are also called *bounded*. Lattices constructible by lower and upper pseudo-interval are called *lower bounded* and *upper bounded*. Lattices constructible by any convex set doubling are called *congruence normal*.

INPUT:

- `type` – string; can be one of the following:
  - `'interval'` – allow only doublings of an interval
  - `'lower'` – allow doublings of lower pseudo-interval; that is, a subset of the lattice with a unique minimal element

- `'upper'` – allow doublings of upper pseudo-interval; that is, a subset of the lattice with a unique maximal element
- `'convex'` – allow doubling of any convex set
- `'any'` – allow doubling of any set

EXAMPLES:

The pentagon can be constructed by doubling intervals; the 5-element diamond can not be constructed by any doublings:

```
sage: posets.PentagonPoset().is_constructible_by_doublings('interval')
True

sage: posets.DiamondPoset(5).is_constructible_by_doublings('any')           #␣
↪needs sage.combinat
False
```

```
>>> from sage.all import *
>>> posets.PentagonPoset().is_constructible_by_doublings('interval')
True

>>> posets.DiamondPoset(Integer(5)).is_constructible_by_doublings('any')     ␣
↪     # needs sage.combinat
False
```

After doubling both upper and lower pseudo-interval a lattice is constructible by convex subset doubling:

```
sage: L = posets.BooleanLattice(2)
sage: L = L.day_doubling([0, 1, 2])  # A lower pseudo-interval
sage: L.is_constructible_by_doublings('interval')
False
sage: L.is_constructible_by_doublings('lower')
True
sage: L = L.day_doubling([(3,0), (1,1), (2,1)])  # An upper pseudo-interval
sage: L.is_constructible_by_doublings('upper')
False
sage: L.is_constructible_by_doublings('convex')                             #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(2))
>>> L = L.day_doubling([Integer(0), Integer(1), Integer(2)])  # A lower␣
↪pseudo-interval
>>> L.is_constructible_by_doublings('interval')
False
>>> L.is_constructible_by_doublings('lower')
True
>>> L = L.day_doubling([(Integer(3),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(1))])  # An upper pseudo-interval
>>> L.is_constructible_by_doublings('upper')
False
>>> L.is_constructible_by_doublings('convex')                               #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat
True
```

An example of a lattice that can be constructed by doublings of a non-convex subsets:

```
sage: L = LatticePoset(DiGraph('OQC?a?@CO?G_C@?GA?O??_??@?BO?A_?G??C??_?@???
↪'))
sage: L.is_constructible_by_doublings('convex')
False
sage: L.is_constructible_by_doublings('any')
True
```

```
>>> from sage.all import *
>>> L = LatticePoset(DiGraph('OQC?a?@CO?G_C@?GA?O??_??@?BO?A_?G??C??_?@???'))
>>> L.is_constructible_by_doublings('convex')
False
>>> L.is_constructible_by_doublings('any')
True
```

See also

- Stronger properties: *is_distributive()* (doubling by interval), *is_join_semidistributive()* (doubling by lower pseudo-intervals), *is_meet_semidistributive()* (doubling by upper pseudo-intervals)
- Mutually exclusive properties: *is_simple()* (doubling by any set)
- Other: *day_doubling()*

ALGORITHM:

According to [HOLM2016] a lattice L is lower bounded if and only if $|\mathrm{Ji}(L)| = |\mathrm{Ji}(\mathrm{Con}\ L)|$, and so dually $|\mathrm{Mi}(L)| = |\mathrm{Mi}(\mathrm{Con}\ L)|$ in upper bounded lattices. The same reference gives a test for being constructible by convex or by any subset.

is_cosectionally_complemented(*certificate=False*)

Return `True` if the lattice is cosectionally complemented, and `False` otherwise.

A lattice is *cosectionally complemented* if all intervals to the top element interpreted as sublattices are complemented lattices.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not cosectionally complemented

OUTPUT:

- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (b, e))`, where b is an element so that in the sublattice from b to the top element has no complement for element e.

EXAMPLES:

The smallest sectionally but not cosectionally complemented lattice:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5], 4: [6], 5: [6]})
sage: L.is_sectionally_complemented(), L.is_cosectionally_complemented()
(True, False)
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5)], Integer(3): [Integer(5)], Integer(4):␣
↪[Integer(6)], Integer(5): [Integer(6)]})
>>> L.is_sectionally_complemented(), L.is_cosectionally_complemented()
(True, False)
```

A sectionally and cosectionally but not relatively complemented lattice:

```
sage: L = LatticePoset(DiGraph('MYi@O?P??D?OG?@?O_?C?Q??O?W?@??O??'))
sage: L.is_sectionally_complemented() and L.is_cosectionally_complemented()
True
sage: L.is_relatively_complemented()
False
```

```
>>> from sage.all import *
>>> L = LatticePoset(DiGraph('MYi@O?P??D?OG?@?O_?C?Q??O?W?@??O??'))
>>> L.is_sectionally_complemented() and L.is_cosectionally_complemented()
True
>>> L.is_relatively_complemented()
False
```

Getting a certificate:

```
sage: L = LatticePoset(DiGraph('HW?@D?Q?GE?G@??'))
sage: L.is_cosectionally_complemented(certificate=True)
(False, (2, 7))
```

```
>>> from sage.all import *
>>> L = LatticePoset(DiGraph('HW?@D?Q?GE?G@??'))
>>> L.is_cosectionally_complemented(certificate=True)
(False, (2, 7))
```

See also

- Dual property: *is_sectionally_complemented()*
- Weaker properties: *is_complemented()*, *is_coatomic()*, *is_regular()*
- Stronger properties: *is_relatively_complemented()*

is_dismantlable(*certificate=False*)

Return `True` if the lattice is dismantlable, and `False` otherwise.

An n-element lattice L_n is dismantlable if there is a sublattice chain $L_{n-1} \supset L_{n-2}, \supset \cdots, \supset L_0$ so that every L_i is a sublattice of L_{i+1} with one element less, and L_0 is the empty lattice. In other words, a dismantlable lattice can be reduced to empty lattice removing doubly irreducible element one by one.

INPUT:

- `certificate` – boolean; whether to return a certificate
  - If `certificate = False` (default), returns `True` or `False` accordingly.
  - If `certificate = True`, returns:
    * `(True, elms)` when the lattice is dismantlable, where `elms` is elements listed in a possible removing order.
    * `(False, crown)` when the lattice is not dismantlable, where `crown` is a subposet of $2k$ elements $a_1, \ldots, a_k, b_1, \ldots, b_k$ with covering relations $a_i \lessdot b_i$ and $a_i \lessdot b_{i+1}$ for $i \in [1, \ldots, k-1]$, and $a_k \lessdot b_1$.

EXAMPLES:

```
sage: DL12 = LatticePoset((divisors(12), attrcall("divides")))
sage: DL12.is_dismantlable()
True
sage: DL12.is_dismantlable(certificate=True)
(True, [4, 2, 1, 3, 6, 12])

sage: B3 = posets.BooleanLattice(3)
sage: B3.is_dismantlable()
False
sage: B3.is_dismantlable(certificate=True)
(False, Finite poset containing 6 elements)
```

```
>>> from sage.all import *
>>> DL12 = LatticePoset((divisors(Integer(12)), attrcall("divides")))
>>> DL12.is_dismantlable()
True
>>> DL12.is_dismantlable(certificate=True)
(True, [4, 2, 1, 3, 6, 12])

>>> B3 = posets.BooleanLattice(Integer(3))
>>> B3.is_dismantlable()
False
>>> B3.is_dismantlable(certificate=True)
(False, Finite poset containing 6 elements)
```

Every planar lattice is dismantlable. Converse is not true:

```
sage: L = LatticePoset( ([], [[0, 1], [0, 2], [0, 3], [0, 4],
....:                        [1, 7], [2, 6], [3, 5], [4, 5],
....:                        [4, 6], [4, 7], [5, 8], [6, 8],
....:                        [7, 8]]) )
sage: L.is_dismantlable()
True
sage: L.is_planar()
False
```

```
>>> from sage.all import *
>>> L = LatticePoset( ([], [[Integer(0), Integer(1)], [Integer(0),␣
↪Integer(2)], [Integer(0), Integer(3)], [Integer(0), Integer(4)],
...                        [Integer(1), Integer(7)], [Integer(2),␣
↪Integer(6)], [Integer(3), Integer(5)], [Integer(4), Integer(5)],
```

(continues on next page)

(continued from previous page)

```
...                          [Integer(4), Integer(6)], [Integer(4),␣
↪Integer(7)], [Integer(5), Integer(8)], [Integer(6), Integer(8)],
...                          [Integer(7), Integer(8)]]) )
>>> L.is_dismantlable()
True
>>> L.is_planar()
False
```

See also

- Stronger properties: *is_planar()*
- Weaker properties: *is_sublattice_dismantlable()*

is_distributive(*certificate=False*)

Return `True` if the lattice is distributive, and `False` otherwise.

A lattice $(L, \vee, \wedge)$ is distributive if meet distributes over join: $x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)$ for every $x, y, z \in L$ just like $x \cdot (y + z) = x \cdot y + x \cdot z$ in normal arithmetic. For duality in lattices it follows that then also join distributes over meet.

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (x, y, z))`, where x, y and z are elements of the lattice such that $x \wedge (y \vee z) \neq (x \wedge y) \vee (x \wedge z)$. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.is_distributive()
True
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [6], 4: [6], 5: [6]})
sage: L.is_distributive()
False
sage: L.is_distributive(certificate=True)
(False, (5, 3, 2))
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4)], Integer(3): [Integer(4)], Integer(4): [Integer(5)]})
>>> L.is_distributive()
True
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5)], Integer(3): [Integer(6)], Integer(4):␣
↪[Integer(6)], Integer(5): [Integer(6)]})
>>> L.is_distributive()
False
>>> L.is_distributive(certificate=True)
(False, (5, 3, 2))
```

See also

- Weaker properties: *is_modular()*, *is_semidistributive()*, *is_join_distributive()*, *is_meet_distributive()*, *is_subdirectly_reducible()*, *is_trim()*, *is_congruence_uniform()*, *is_extremal()*
- Stronger properties: *is_stone()*

is_extremal()

Return `True` if the lattice is extremal, and `False` otherwise.

A lattice is *extremal* if the number of join-irreducibles is equal to the number of meet-irreducibles and to the number of cover relations in the longest chains.

EXAMPLES:

```
sage: posets.PentagonPoset().is_extremal()
True

sage: P = LatticePoset(posets.SymmetricGroupWeakOrderPoset(3))
sage: P.is_extremal()
False
```

```
>>> from sage.all import *
>>> posets.PentagonPoset().is_extremal()
True

>>> P = LatticePoset(posets.SymmetricGroupWeakOrderPoset(Integer(3)))
>>> P.is_extremal()
False
```

See also

- Stronger properties: *is_distributive()*, *is_trim()*

REFERENCES:

- [Mark1992]

is_geometric()

Return `True` if the lattice is geometric, and `False` otherwise.

A lattice is geometric if it is both atomic and upper semimodular.

EXAMPLES:

Canonical example is the lattice of partitions of finite set ordered by refinement:

```
sage: L = posets.SetPartitions(4)                                    #␣
↪needs sage.combinat
sage: L.is_geometric()                                               #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> L = posets.SetPartitions(Integer(4))
↪     # needs sage.combinat
>>> L.is_geometric()
↪needs sage.combinat
True
```

Smallest example of geometric lattice that is not modular:

```
sage: L = LatticePoset(DiGraph('K]?@g@S?q?M?@?@?@?@?@?@??'))
sage: L.is_geometric()
True
sage: L.is_modular()
False
```

```
>>> from sage.all import *
>>> L = LatticePoset(DiGraph('K]?@g@S?q?M?@?@?@?@?@?@??'))
>>> L.is_geometric()
True
>>> L.is_modular()
False
```

Two non-examples:

```
sage: L = LatticePoset({1:[2, 3, 4], 2:[5, 6], 3:[5], 4:[6], 5:[7], 6:[7]})
sage: L.is_geometric()  # Graded, but not upper semimodular
False
sage: L = posets.ChainPoset(3)
sage: L.is_geometric()  # Modular, but not atomic
False
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1):[Integer(2), Integer(3), Integer(4)],
↪Integer(2):[Integer(5), Integer(6)], Integer(3):[Integer(5)],
↪Integer(4):[Integer(6)], Integer(5):[Integer(7)], Integer(6):[Integer(7)]})
>>> L.is_geometric()  # Graded, but not upper semimodular
False
>>> L = posets.ChainPoset(Integer(3))
>>> L.is_geometric()  # Modular, but not atomic
False
```

See also

- Weaker properties: *is_upper_semimodular()*, *is_relatively_complemented()*

is_interval_dismantlable(*certificate=False*)

Return `True` if the lattice is interval dismantlable, and `False` otherwise.

An interval dismantling is a subdivision of a lattice to a principal upper set and a principal lower set. A lattice is *interval dismantlable* if it can be decomposed into 1-element lattices by consecutive interval distmantlings.

A lattice is *minimally interval non-dismantlable* if it is not interval dismantlable, but all of its sublattices are interval dismantlable.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- if `certificate=False`, return only `True` or `False`
- if `certificate=True`, return either
  - `(True, list)` where `list` is a nested list showing the decomposition; for example `list[1][0]` is a lower part of upper part of the lattice when decomposed twice.
  - `(False, M)` where M is a minimally interval non-dismantlable sublattice of the lattice.

EXAMPLES:

```
sage: L1 = LatticePoset({1: [2, 3], 3: [4, 5], 2: [6], 4: [6], 5: [6]})
sage: L1.is_interval_dismantlable()
True

sage: L2 = LatticePoset({1: [2, 3, 4, 5], 2: [6], 3: [6], 4: [6],
....:                    5: [6, 7], 6: [8], 7: [9, 10], 8:[10], 9:[10]})
sage: L2.is_interval_dismantlable()
False
```

```
>>> from sage.all import *
>>> L1 = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(3):␣
↪[Integer(4), Integer(5)], Integer(2): [Integer(6)], Integer(4):␣
↪[Integer(6)], Integer(5): [Integer(6)]})
>>> L1.is_interval_dismantlable()
True

>>> L2 = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4),␣
↪Integer(5)], Integer(2): [Integer(6)], Integer(3): [Integer(6)],␣
↪Integer(4): [Integer(6)],
...                    Integer(5): [Integer(6), Integer(7)], Integer(6):␣
↪[Integer(8)], Integer(7): [Integer(9), Integer(10)],␣
↪Integer(8):[Integer(10)], Integer(9):[Integer(10)]})
>>> L2.is_interval_dismantlable()
False
```

To get certificates:

```
sage: L1.is_interval_dismantlable(certificate=True)
(True, [[[1], [2]], [[3], [5]], [[4], [6]]])
sage: L2.is_interval_dismantlable(certificate=True)
(False, Finite lattice containing 5 elements)
```

```
>>> from sage.all import *
>>> L1.is_interval_dismantlable(certificate=True)
(True, [[[1], [2]], [[3], [5]], [[4], [6]]])
>>> L2.is_interval_dismantlable(certificate=True)
(False, Finite lattice containing 5 elements)
```

- Weaker properties: *is_sublattice_dismantlable()*

is_isoform(*certificate=False*)

Return `True` if the lattice is isoform and `False` otherwise.

A congruence is *isoform* (or *isotype*) if all blocks are isomorphic sublattices. A lattice is isoform if it has only isoform congruences.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not isoform

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, C)`, where C is a non-isoform congruence as a *sage.combinat.set_partition.SetPartition*. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [6, 7],
....:                   4: [7], 5: [8], 6: [8], 7: [8]})
sage: L.is_isoform()                                                    #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(6), Integer(7)],
...                   Integer(4): [Integer(7)], Integer(5): [Integer(8)],␣
↪Integer(6): [Integer(8)], Integer(7): [Integer(8)]})
>>> L.is_isoform()                                                      #␣
↪needs sage.combinat
True
```

Every isoform lattice is (trivially) uniform, but the converse is not true:

```
sage: L = LatticePoset({1: [2, 3, 6], 2: [4, 5], 3: [5], 4: [9, 8],
....:                   5: [7, 8], 6: [9], 7: [10], 8: [10], 9: [10]})
sage: L.is_isoform(), L.is_uniform()                                    #␣
↪needs sage.combinat
(False, True)

sage: L.is_isoform(certificate=True)                                    #␣
↪needs sage.combinat
(False, {{1, 2, 4, 6, 9}, {3, 5, 7, 8, 10}})
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(6)],␣
↪Integer(2): [Integer(4), Integer(5)], Integer(3): [Integer(5)], Integer(4):␣
↪[Integer(9), Integer(8)],
```

(continues on next page)

(continued from previous page)

```
...                   Integer(5): [Integer(7), Integer(8)], Integer(6):␣
↪[Integer(9)], Integer(7): [Integer(10)], Integer(8): [Integer(10)],␣
↪Integer(9): [Integer(10)]})
>>> L.is_isoform(), L.is_uniform()                                    #␣
↪needs sage.combinat
(False, True)

>>> L.is_isoform(certificate=True)                                    #␣
↪needs sage.combinat
(False, {{1, 2, 4, 6, 9}, {3, 5, 7, 8, 10}})
```

See also

is_join_distributive(*certificate=False*)

Return `True` if the lattice is join-distributive and `False` otherwise.

A lattice is *join-distributive* if every interval from an element to the join of the element's upper covers is a distributive lattice. Actually this distributive sublattice is then a Boolean lattice.

They are also called as *Dilworth's lattices* and *upper locally distributive lattices*. They can be characterized in many other ways, see [Dil1940].

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, e)`, where e is an element such that the interval from e to the meet of upper covers of e is not distributive. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5, 7],
....:                   4: [6, 7], 5: [8, 9], 6: [9], 7: [9, 10],
....:                   8: [11], 9: [11], 10: [11]})
sage: L.is_join_distributive()
True

sage: L = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [6],
....:                   5: [7], 6: [7]})
sage: L.is_join_distributive()
False
sage: L.is_join_distributive(certificate=True)
(False, 2)
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5), Integer(7)],
...                    Integer(4): [Integer(6), Integer(7)], Integer(5):␣
↪[Integer(8), Integer(9)], Integer(6): [Integer(9)], Integer(7): [Integer(9),
↪ Integer(10)],
...                    Integer(8): [Integer(11)], Integer(9): [Integer(11)],␣
↪Integer(10): [Integer(11)]})
>>> L.is_join_distributive()
True

>>> L = LatticePoset({Integer(1): [Integer(2)], Integer(2): [Integer(3),␣
↪Integer(4)], Integer(3): [Integer(5)], Integer(4): [Integer(6)],
...                    Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_join_distributive()
False
>>> L.is_join_distributive(certificate=True)
(False, 2)
```

is_join_pseudocomplemented(*certificate=False*)

Return `True` if the lattice is join-pseudocomplemented, and `False` otherwise.

A lattice is join-pseudocomplemented if every element e has a join-pseudocomplement e', i.e. the least element such that the join of e and e' is the top element.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, e)`, where `e` is an element without a join-pseudocomplement. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7],
....:                   5: [6], 6: [7]})
sage: L.is_join_pseudocomplemented()
True

sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7],
....:                   5: [7], 6: [7]})
sage: L.is_join_pseudocomplemented()
False
sage: L.is_join_pseudocomplemented(certificate=True)
(False, 4)
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(5)], Integer(2):␣
↪[Integer(3), Integer(6)], Integer(3): [Integer(4)], Integer(4):␣
↪[Integer(7)],
...                    Integer(5): [Integer(6)], Integer(6): [Integer(7)]})
>>> L.is_join_pseudocomplemented()
True

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5), Integer(6)], Integer(3): [Integer(6)], Integer(4):␣
↪[Integer(7)],
...                    Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_join_pseudocomplemented()
False
>>> L.is_join_pseudocomplemented(certificate=True)
(False, 4)
```

See also

- Dual property: *is_pseudocomplemented()*
- Stronger properties: *is_join_semidistributive()*

is_join_semidistributive(*certificate=False*)

Return `True` if the lattice is join-semidistributive, and `False` otherwise.

A lattice is join-semidistributive if for all elements e, x, y in the lattice we have

$$e \vee x = e \vee y \implies e \vee x = e \vee (x \wedge y)$$

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (e, x, y))` such that $e \vee x = e \vee y$ but $e \vee x \neq e \vee (x \wedge y)$. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: T4 = posets.TamariLattice(4)
sage: T4.is_join_semidistributive()
True
sage: L = LatticePoset({1:[2, 3], 2:[4, 5], 3:[5, 6],
....:                   4:[7], 5:[7], 6:[7]})
sage: L.is_join_semidistributive()
False
sage: L.is_join_semidistributive(certificate=True)
(False, (5, 4, 6))
```

```
>>> from sage.all import *
>>> T4 = posets.TamariLattice(Integer(4))
>>> T4.is_join_semidistributive()
```

(continues on next page)

(continued from previous page)

```
True
>>> L = LatticePoset({Integer(1):[Integer(2), Integer(3)],␣
↪Integer(2):[Integer(4), Integer(5)], Integer(3):[Integer(5), Integer(6)],
...                   Integer(4):[Integer(7)], Integer(5):[Integer(7)],␣
↪Integer(6):[Integer(7)]})
>>> L.is_join_semidistributive()
False
>>> L.is_join_semidistributive(certificate=True)
(False, (5, 4, 6))
```

- Stronger properties: *is_semidistributive()*, *is_meet_distributive()*, *is_constructible_by_doublings()* (by lower pseudo-intervals)

is_left_modular(*H=None*, *certificate=False*)

Return whether `self` is a left-modular lattice.

INPUT:

- `H` – subset of elements; full `self` if no `H` is given
- `certificate` – boolean (default: `False`); whether to return a failure

OUTPUT:

if `certificate == True`, this returns either `(True, None)` or `(False, (y, x, z))` where the tuple (y, x, z) fails left-modularity.

if `certificate == False`, this returns `False` if any $x \in H$ fails to be left-modular and `True` otherwise.

ALGORITHM:

Given a lattice L and a subset of elements H, an element $x \in H$ is left-modular if for every $y, z \in L, y \leq z$ we have $(y \vee x) \wedge z = y \vee (x \wedge z)$.

See also

- Stronger properties: *is_trim()*
- *is_left_modular_element()*

EXAMPLES:

A lattice that is not left-modular:

```
sage: L = LatticePoset(([1,2,3,4,5],
....:     [[1,2],[1,3],[3,4],[4,5],[2,5]]))
sage: L.is_left_modular()
False
```

```
>>> from sage.all import *
>>> L = LatticePoset(([Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)],
...      [[Integer(1),Integer(2)],[Integer(1),Integer(3)],[Integer(3),
↪Integer(4)],[Integer(4),Integer(5)],[Integer(2),Integer(5)]]))
>>> L.is_left_modular()
False
```

A left-modular lattice:

```
sage: L = LatticePoset(([1,2,3,4,5,6],
....:      [[1,2],[1,3],[3,4],[4,5],[2,5],[2,6],[6,5],[2,4]]))
sage: L.is_left_modular()
True
```

```
>>> from sage.all import *
>>> L = LatticePoset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6)],
...      [[Integer(1),Integer(2)],[Integer(1),Integer(3)],[Integer(3),
↪Integer(4)],[Integer(4),Integer(5)],[Integer(2),Integer(5)],[Integer(2),
↪Integer(6)],[Integer(6),Integer(5)],[Integer(2),Integer(4)]]))
>>> L.is_left_modular()
True
```

is_left_modular_element(x)

Return `True` if `x` is a left modular element and `False` otherwise.

INPUT:

- `x` – an element of the lattice

An element x in a lattice L is *left modular* if

$$(y \vee x) \wedge z = y \vee (x \wedge z)$$

for every $y \leq z \in L$.

It is enough to check this condition on all cover relations $y < z$.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: [i for i in P if P.is_left_modular_element(i)]
[0, 2, 3, 4]
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> [i for i in P if P.is_left_modular_element(i)]
[0, 2, 3, 4]
```

See also

- Stronger properties: *is_modular_element()*
- *is_left_modular()*

is_lower_semimodular(*certificate=False*)

Return `True` if the lattice is lower semimodular and `False` otherwise.

A lattice is lower semimodular if any pair of elements with a common upper cover have also a common lower cover.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not lower semimodular

OUTPUT:

- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (a, b))`, where a and b are covered by their join but do no cover their meet.

See Wikipedia article Semimodular_lattice

EXAMPLES:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_lower_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_lower_semimodular()
False

sage: L = posets.ChainPoset(6)
sage: L.is_lower_semimodular()
True

sage: L = LatticePoset(DiGraph('IS?`?AAOE_@?C?_@??'))
sage: L.is_lower_semimodular(certificate=True)
(False, (4, 2))
```

```
>>> from sage.all import *
>>> L = posets.DiamondPoset(Integer(5))
>>> L.is_lower_semimodular()
True

>>> L = posets.PentagonPoset()
>>> L.is_lower_semimodular()
False

>>> L = posets.ChainPoset(Integer(6))
>>> L.is_lower_semimodular()
True

>>> L = LatticePoset(DiGraph('IS?`?AAOE_@?C?_@??'))
>>> L.is_lower_semimodular(certificate=True)
(False, (4, 2))
```

See also

- Dual property: *is_upper_semimodular()*
- Weaker properties: *is_graded()*
- Stronger properties: *is_modular()*, *is_meet_distributive()*

is_meet_distributive(*certificate=False*)

Return `True` if the lattice is meet-distributive and `False` otherwise.

A lattice is *meet-distributive* if every interval to an element from the meet of the element's lower covers is a distributive lattice. Actually this distributive sublattice is then a Boolean lattice.

They are also called as *lower locally distributive lattices*. They can be characterized in many other ways, see [Dil1940].

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, e)`, where e is an element such that the interval to e from the meet of lower covers of e is not distributive. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5, 6, 7],
....:                   4: [7], 5: [9, 8], 6: [10, 8], 7:
....:                   [9, 10], 8: [11], 9: [11], 10: [11]})
sage: L.is_meet_distributive()
True

sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6],
....:                   5: [6], 6: [7]})
sage: L.is_meet_distributive()
False
sage: L.is_meet_distributive(certificate=True)
(False, 6)
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5)], Integer(3): [Integer(5), Integer(6), Integer(7)],

is_meet_semidistributive(*certificate=False*)

Return `True` if the lattice is meet-semidistributive, and `False` otherwise.

A lattice is meet-semidistributive if for all elements e, x, y in the lattice we have

$$e \wedge x = e \wedge y \implies e \wedge x = e \wedge (x \vee y)$$

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (e, x, y))` such that $e \wedge x = e \wedge y$ but $e \wedge x \neq e \wedge (x \vee y)$. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1:[2, 3, 4], 2:[4, 5], 3:[5, 6],
....:                   4:[7], 5:[7], 6:[7]})
sage: L.is_meet_semidistributive()
True
sage: L_ = L.dual()
sage: L_.is_meet_semidistributive()
False
sage: L_.is_meet_semidistributive(certificate=True)
(False, (5, 4, 6))
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1):[Integer(2), Integer(3), Integer(4)],␣
↪Integer(2):[Integer(4), Integer(5)], Integer(3):[Integer(5), Integer(6)],
...                   Integer(4):[Integer(7)], Integer(5):[Integer(7)],␣
↪Integer(6):[Integer(7)]})
>>> L.is_meet_semidistributive()
True
>>> L_ = L.dual()
>>> L_.is_meet_semidistributive()
False
>>> L_.is_meet_semidistributive(certificate=True)
(False, (5, 4, 6))
```

See also

- Dual property: *is_join_semidistributive()*
- Weaker properties: *is_pseudocomplemented()*, *is_interval_dismantlable()*
- Stronger properties: *is_semidistributive()*, *is_join_distributive()*, *is_constructible_by_doublings()* (by upper pseudo-intervals)

is_modular(*L=None*, *certificate=False*)

Return `True` if the lattice is modular and `False` otherwise.

An element b of a lattice is *modular* if

$$x \vee (a \wedge b) = (x \vee a) \wedge b$$

for every element $x \leq b$ and a. A lattice is modular if every element is modular. There are other equivalent definitions, see Wikipedia article Modular_lattice.

With the parameter `L` this can be used to check that some subset of elements are all modular.

INPUT:

- `L` – (default: `None`) a list of elements to check being modular, if `L` is `None`, then this checks the entire lattice
- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (x, a, b))`, where a, b and x are elements of the lattice such that $x < b$ but $x \vee (a \wedge b) \neq (x \vee a) \wedge b$. If also L is given then b in the certificate will be an element of L. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_modular()
True

sage: L = posets.PentagonPoset()
sage: L.is_modular()
False

sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_modular(certificate=True)
(False, (2, 6, 4))
sage: [L.is_modular([x]) for x in L]
[True, True, False, True, True, False, True]
```

```
>>> from sage.all import *
>>> L = posets.DiamondPoset(Integer(5))
>>> L.is_modular()
True

>>> L = posets.PentagonPoset()
>>> L.is_modular()
```

(continues on next page)

(continued from previous page)

```
False

>>> L = LatticePoset({Integer(1):[Integer(2),Integer(3)],
↪Integer(2):[Integer(4),Integer(5)],Integer(3):[Integer(5),Integer(6)],
↪Integer(4):[Integer(7)],Integer(5):[Integer(7)],Integer(6):[Integer(7)]})
>>> L.is_modular(certificate=True)
(False, (2, 6, 4))
>>> [L.is_modular([x]) for x in L]
[True, True, False, True, True, False, True]
```

See also

- Weaker properties: *is_upper_semimodular()*, *is_lower_semimodular()*, *is_supersolvable()*
- Stronger properties: *is_distributive()*
- Other: *is_modular_element()*

is_modular_element(*x*)

Return `True` if `x` is a modular element and `False` otherwise.

INPUT:

- `x` – an element of the lattice

An element x in a lattice L is *modular* if $x \leq b$ implies

$$x \vee (a \wedge b) = (x \vee a) \wedge b$$

for every $a, b \in L$.

EXAMPLES:

```
sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_modular()
False
sage: [L.is_modular_element(x) for x in L]
[True, True, False, True, True, False, True]
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1):[Integer(2),Integer(3)],
↪Integer(2):[Integer(4),Integer(5)],Integer(3):[Integer(5),Integer(6)],
↪Integer(4):[Integer(7)],Integer(5):[Integer(7)],Integer(6):[Integer(7)]})
>>> L.is_modular()
False
>>> [L.is_modular_element(x) for x in L]
[True, True, False, True, True, False, True]
```

See also

- Weaker properties: *is_left_modular_element()*

- Other: *is_modular()* to check modularity for the full lattice or some set of elements

is_orthocomplemented(*unique=False*)

Return `True` if the lattice admits an orthocomplementation, and `False` otherwise.

An orthocomplementation of a lattice is a function defined for every element e and marked as $e^\perp$ such that 1) they are complements, i.e. $e \vee e^\perp$ is the top element and $e \wedge e^\perp$ is the bottom element, 2) it is involution, i.e. $(e^\perp)^\perp = e$, and 3) it is order-reversing, i.e. if $a < b$ then $b^\perp < a^\perp$.

INPUT:

- `unique` – boolean; if `True`, return `True` only if the lattice has exactly one orthocomplementation. If `False` (the default), return `True` when the lattice has at least one orthocomplementation.

EXAMPLES:

```
sage: D5 = posets.DiamondPoset(5)
sage: D5.is_orthocomplemented()
False

sage: D6 = posets.DiamondPoset(6)
sage: D6.is_orthocomplemented()                                             #␣
↪needs sage.groups
True
sage: D6.is_orthocomplemented(unique=True)                                  #␣
↪needs sage.groups
False

sage: hexagon = LatticePoset({0: [1, 2], 1: [3], 2: [4], 3:[5], 4: [5]})
sage: hexagon.is_orthocomplemented(unique=True)                             #␣
↪needs sage.groups
True
```

```
>>> from sage.all import *
>>> D5 = posets.DiamondPoset(Integer(5))
>>> D5.is_orthocomplemented()
False

>>> D6 = posets.DiamondPoset(Integer(6))
>>> D6.is_orthocomplemented()                                               #␣
↪needs sage.groups
True
>>> D6.is_orthocomplemented(unique=True)                                    #␣
↪needs sage.groups
False

>>> hexagon = LatticePoset({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3)], Integer(2): [Integer(4)], Integer(3):[Integer(5)],␣
↪Integer(4): [Integer(5)]})
>>> hexagon.is_orthocomplemented(unique=True)                               #␣
↪needs sage.groups
True
```

See also

- Weaker properties: *is_complemented()*, is_self_dual()

is_planar()

Return True if the lattice is *upward* planar, and False otherwise.

A lattice is upward planar if its Hasse diagram has a planar drawing in the $\mathbb{R}^2$ plane, in such a way that x is strictly below y (on the vertical axis) whenever $x < y$ in the lattice.

Note that the scientific literature on posets often omits "upward" and shortens it to "planar lattice" (e.g. [GW2014]), which can cause confusion with the notion of graph planarity in graph theory.

Note

Not all lattices which are planar – in the sense of graph planarity – admit such a planar drawing (see example below).

ALGORITHM:

Using the result from [Platt1976], this method returns its result by testing that the Hasse diagram of the lattice is planar (in the sense of graph theory) when an edge is added between the top and bottom elements.

EXAMPLES:

The Boolean lattice of 2^3 elements is not upward planar, even if its covering relations graph is planar:

```
sage: B3 = posets.BooleanLattice(3)
sage: B3.is_planar()
False
sage: G = B3.cover_relations_graph()
sage: G.is_planar()
True
```

```
>>> from sage.all import *
>>> B3 = posets.BooleanLattice(Integer(3))
>>> B3.is_planar()
False
>>> G = B3.cover_relations_graph()
>>> G.is_planar()
True
```

Ordinal product of planar lattices is obviously planar. Same does not apply to Cartesian products:

```
sage: P = posets.PentagonPoset()
sage: Pc = P.product(P)
sage: Po = P.ordinal_product(P)
sage: Pc.is_planar()
False
sage: Po.is_planar()
True
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> Pc = P.product(P)
>>> Po = P.ordinal_product(P)
>>> Pc.is_planar()
False
>>> Po.is_planar()
True
```

See also

- Weaker properties: *is_dismantlable()*

is_pseudocomplemented(*certificate=False*)

Return `True` if the lattice is pseudocomplemented, and `False` otherwise.

A lattice is (meet-)pseudocomplemented if every element e has a pseudocomplement $e^\star$, i.e. the greatest element such that the meet of e and $e^\star$ is the bottom element.

See Wikipedia article Pseudocomplement.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, e)`, where `e` is an element without a pseudocomplement. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7],
....:                   5: [6], 6: [7]})
sage: L.is_pseudocomplemented()
True

sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7],
....:                   5: [7], 6: [7]})
sage: L.is_pseudocomplemented()
False
sage: L.is_pseudocomplemented(certificate=True)
(False, 3)
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(5)], Integer(2):␣
↪[Integer(3), Integer(6)], Integer(3): [Integer(4)], Integer(4):␣
↪[Integer(7)],
...                    Integer(5): [Integer(6)], Integer(6): [Integer(7)]})
>>> L.is_pseudocomplemented()
True

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5), Integer(6)], Integer(3): [Integer(6)], Integer(4):␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(7)],
...                    Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_pseudocomplemented()
False
>>> L.is_pseudocomplemented(certificate=True)
(False, 3)
```

See also

- Dual property: *is_join_pseudocomplemented()*
- Stronger properties: *is_meet_semidistributive()*
- Other: *pseudocomplement()*.

ALGORITHM:

According to [Cha92] a lattice is pseudocomplemented if and only if every atom has a pseudocomplement. So we only check those.

is_regular(*certificate=False*)

Return `True` if the lattice is regular and `False` otherwise.

A congruence of a lattice is *regular* if it is generated by any of its parts. A lattice is regular if it has only regular congruences.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not regular

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (C, p))`, where C is a non-regular congruence as a *sage.combinat.set_partition.SetPartition* and p is a congruence class of C such that the congruence generated by p is not C. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [8, 7], 4: [6, 7],
....:                   5: [8], 6: [9], 7: [9], 8: [9]})
sage: L.is_regular()                                                    #␣
↪needs sage.combinat
True

sage: N5 = posets.PentagonPoset()
sage: N5.is_regular()                                                   #␣
↪needs sage.combinat
False
sage: N5.is_regular(certificate=True)                                   #␣
↪needs sage.combinat
(False, ({{0}, {1}, {2, 3}, {4}}, [0]))
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(8), Integer(7)],␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(4): [Integer(6), Integer(7)],
...                   Integer(5): [Integer(8)], Integer(6): [Integer(9)],␣
↪Integer(7): [Integer(9)], Integer(8): [Integer(9)]})
>>> L.is_regular()                                                    #␣
↪needs sage.combinat
True

>>> N5 = posets.PentagonPoset()
>>> N5.is_regular()                                                   #␣
↪needs sage.combinat
False
>>> N5.is_regular(certificate=True)                                   #␣
↪needs sage.combinat
(False, ({{0}, {1}, {2, 3}, {4}}, [0]))
```

- Mutually exclusive properties: *is_vertically_decomposable()*
- Other: *congruence()*

is_relatively_complemented(*certificate=False*)

Return `True` if the lattice is relatively complemented, and `False` otherwise.

A lattice is relatively complemented if every interval of it is a complemented lattice.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not relatively complemented

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (a, b, c))`, where b is the only element that covers a and is covered by c. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4, 8], 2: [5, 6], 3: [5, 7],
....:                   4: [6, 7], 5: [9], 6: [9], 7: [9], 8: [9]})
sage: L.is_relatively_complemented()
True

sage: L = posets.PentagonPoset()
sage: L.is_relatively_complemented()
False
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4),␣
↪Integer(8)], Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5),␣
↪Integer(7)],
```

(continues on next page)

(continued from previous page)

```
...                   Integer(4): [Integer(6), Integer(7)], Integer(5):␣
↪[Integer(9)], Integer(6): [Integer(9)], Integer(7): [Integer(9)],␣
↪Integer(8): [Integer(9)]})
>>> L.is_relatively_complemented()
True

>>> L = posets.PentagonPoset()
>>> L.is_relatively_complemented()
False
```

Relatively complemented lattice must be both atomic and coatomic. Implication to other direction does not hold:

```
sage: L = LatticePoset({0: [1, 2, 3, 4, 5], 1: [6, 7], 2: [6, 8],
....:                   3: [7, 8, 9], 4: [9, 11], 5: [9, 10],
....:                   6: [10, 11], 7: [12], 8: [12], 9: [12],
....:                   10: [12], 11: [12]})
sage: L.is_atomic() and L.is_coatomic()
True
sage: L.is_relatively_complemented()
False
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3),␣
↪Integer(4), Integer(5)], Integer(1): [Integer(6), Integer(7)], Integer(2):␣
↪[Integer(6), Integer(8)],
...                   Integer(3): [Integer(7), Integer(8), Integer(9)],␣
↪Integer(4): [Integer(9), Integer(11)], Integer(5): [Integer(9),␣
↪Integer(10)],
...                   Integer(6): [Integer(10), Integer(11)], Integer(7):␣
↪[Integer(12)], Integer(8): [Integer(12)], Integer(9): [Integer(12)],
...                   Integer(10): [Integer(12)], Integer(11): [Integer(12)]})
>>> L.is_atomic() and L.is_coatomic()
True
>>> L.is_relatively_complemented()
False
```

We can also get a non-complemented 3-element interval:

```
sage: L.is_relatively_complemented(certificate=True)
(False, (1, 6, 11))
```

```
>>> from sage.all import *
>>> L.is_relatively_complemented(certificate=True)
(False, (1, 6, 11))
```

See also

- Weaker properties: *is_sectionally_complemented()*, *is_cosectionally_complemented()*, *is_isoform()*

- Stronger properties: *is_geometric()*

is_sectionally_complemented(*certificate=False*)

Return `True` if the lattice is sectionally complemented, and `False` otherwise.

A lattice is sectionally complemented if all intervals from the bottom element interpreted as sublattices are complemented lattices.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not sectionally complemented

OUTPUT:

- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (t, e))`, where t is an element so that in the sublattice from the bottom element to t has no complement for element e.

EXAMPLES:

Smallest examples of a complemented but not sectionally complemented lattice and a sectionally complemented but not relatively complemented lattice:

```
sage: L = posets.PentagonPoset()
sage: L.is_complemented()
True
sage: L.is_sectionally_complemented()
False

sage: L = LatticePoset({0: [1, 2, 3], 1: [4], 2: [4], 3: [5], 4: [5]})
sage: L.is_sectionally_complemented()
True
sage: L.is_relatively_complemented()
False
```

```
>>> from sage.all import *
>>> L = posets.PentagonPoset()
>>> L.is_complemented()
True
>>> L.is_sectionally_complemented()
False

>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3)],␣
↪Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3):␣
↪[Integer(5)], Integer(4): [Integer(5)]})
>>> L.is_sectionally_complemented()
True
>>> L.is_relatively_complemented()
False
```

Getting a certificate:

```
sage: L = LatticePoset(DiGraph('HYOgC?C@?C?G@??'))
sage: L.is_sectionally_complemented(certificate=True)
(False, (6, 1))
```

```
>>> from sage.all import *
>>> L = LatticePoset(DiGraph('HYOgC?C@?C?G@??'))
>>> L.is_sectionally_complemented(certificate=True)
(False, (6, 1))
```

See also

- Dual property: *is_cosectionally_complemented()*
- Weaker properties: *is_complemented()*, *is_atomic()*, *is_regular()*
- Stronger properties: *is_relatively_complemented()*

is_semidistributive()

Return `True` if the lattice is both join- and meet-semidistributive, and `False` otherwise.

EXAMPLES:

Tamari lattices are typical examples of semidistributive but not distributive (and hence not modular) lattices:

```
sage: T4 = posets.TamariLattice(4)
sage: T4.is_semidistributive(), T4.is_distributive()
(True, False)
```

```
>>> from sage.all import *
>>> T4 = posets.TamariLattice(Integer(4))
>>> T4.is_semidistributive(), T4.is_distributive()
(True, False)
```

Smallest non-selfdual example:

```
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5], 4: [6], 5: [7], 6: [7]})
sage: L.is_semidistributive()
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5)], Integer(3): [Integer(5)], Integer(4):␣
↪[Integer(6)], Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_semidistributive()
True
```

The diamond is not semidistributive:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_semidistributive()
False
```

```
>>> from sage.all import *
>>> L = posets.DiamondPoset(Integer(5))
>>> L.is_semidistributive()
False
```

See also

- Weaker properties: *is_join_semidistributive()*, *is_meet_semidistributive()*
- Stronger properties: *is_distributive()*, *is_congruence_uniform()*

is_simple(*certificate=False*)

Return `True` if the lattice is simple and `False` otherwise.

A lattice is *simple* if it has no nontrivial congruences; in other words, for every two distinct elements a and b the principal congruence generated by (a, b) has only one component, i.e. the whole lattice.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not simple

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, c)`, where c is a nontrivial congruence as a *sage.combinat.set_partition.SetPartition*. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: # needs sage.combinat
sage: posets.DiamondPoset(5).is_simple()  # Smallest nontrivial example
True
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6], 5: [6]})
sage: L.is_simple()
False
sage: L.is_simple(certificate=True)
(False, {{1, 3}, {2, 4, 5, 6}})
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> posets.DiamondPoset(Integer(5)).is_simple()  # Smallest nontrivial example
True
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5)], Integer(3): [Integer(6)], Integer(4):␣
↪[Integer(6)], Integer(5): [Integer(6)]})
>>> L.is_simple()
False
>>> L.is_simple(certificate=True)
(False, {{1, 3}, {2, 4, 5, 6}})
```

Two more examples. First is a non-simple lattice without any 2-element congruences:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5], 4: [6, 7],
....:                   5: [8], 6: [8], 7: [8]})
sage: L.is_simple()                                                    #␣
↪needs sage.combinat
False
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6, 7], 4: [8],
....:                   5: [8], 6: [8], 7: [8]})
sage: L.is_simple()                                                    #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5)], Integer(3): [Integer(5)], Integer(4): [Integer(6),
↪ Integer(7)],
...                   Integer(5): [Integer(8)], Integer(6): [Integer(8)],␣
↪Integer(7): [Integer(8)]})
>>> L.is_simple()                                                          #␣
↪needs sage.combinat
False
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5)], Integer(3): [Integer(6), Integer(7)], Integer(4):␣
↪[Integer(8)],
...                   Integer(5): [Integer(8)], Integer(6): [Integer(8)],␣
↪Integer(7): [Integer(8)]})
>>> L.is_simple()                                                          #␣
↪needs sage.combinat
True
```

See also

- Weaker properties: *is_isoform()*
- Mutually exclusive properties: *is_constructible_by_doublings()* (by any set)
- Other: *congruence()*

is_stone(*certificate=False*)

Return `True` if the lattice is a Stone lattice, and `False` otherwise.

The lattice is expected to be distributive (and hence pseudocomplemented).

A pseudocomplemented lattice is a Stone lattice if

$$e^* \vee e^{**} = \top$$

for every element e of the lattice, where * is the pseudocomplement and $\top$ is the top element of the lattice.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, e)` such that $e^* \vee e^{**} \neq \top$. If `certificate=False` return `True` or `False`.

If the lattice is not distributive, the result is either `(False, None)` or `False`.

EXAMPLES:

Divisor lattices are canonical example:

```
sage: D72 = posets.DivisorLattice(72)
sage: D72.is_stone()
True
```

```
>>> from sage.all import *
>>> D72 = posets.DivisorLattice(Integer(72))
>>> D72.is_stone()
True
```

A non-example:

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.is_stone()
False
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4)], Integer(3): [Integer(4)], Integer(4): [Integer(5)]})
>>> L.is_stone()
False
```

See also

- Weaker properties: *is_distributive()*

is_subdirectly_reducible(*certificate=False*)

Return `True` if the lattice is subdirectly reducible.

A lattice M is a *subdirect product* of K and L if it is a sublattice of $K \times L$. Lattice M is *subdirectly reducible* if there exists such lattices K and L so that M is not a sublattice of either.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- if `certificate=False`, return only `True` or `False`
- if `certificate=True`, return either
  - `(True, (K, L))` such that the lattice is isomorphic to a sublattice of $K \times L$.
  - `(False, (a, b))`, where a and b are elements that are in the same congruence class for every nontrivial congruence of the lattice. Special case: If the lattice has zero or one element, return `(False, None)`.

EXAMPLES:

```
sage: N5 = posets.PentagonPoset()
sage: N5.is_subdirectly_reducible()                                             #␣
↪needs sage.combinat
False

sage: hex = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
```

(continues on next page)

(continued from previous page)

```
sage: hex.is_subdirectly_reducible()                                          #␣
↪needs sage.combinat
True

sage: hex.is_subdirectly_reducible(certificate=True)                          #␣
↪needs sage.combinat
(True,
 (Finite lattice containing 5 elements, Finite lattice containing 5 elements))

sage: N5.is_subdirectly_reducible(certificate=True)                           #␣
↪needs sage.combinat
(False, (2, 3))
sage: res, cert = hex.is_subdirectly_reducible(certificate=True)              #␣
↪needs sage.combinat
sage: cert[0].is_isomorphic(N5)                                               #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> N5 = posets.PentagonPoset()
>>> N5.is_subdirectly_reducible()                                             #␣
↪needs sage.combinat
False

>>> hex = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4)], Integer(3): [Integer(5)], Integer(4): [Integer(6)],␣
↪Integer(5): [Integer(6)]})
>>> hex.is_subdirectly_reducible()                                            #␣
↪needs sage.combinat
True

>>> hex.is_subdirectly_reducible(certificate=True)                            #␣
↪needs sage.combinat
(True,
 (Finite lattice containing 5 elements, Finite lattice containing 5 elements))

>>> N5.is_subdirectly_reducible(certificate=True)                             #␣
↪needs sage.combinat
(False, (2, 3))
>>> res, cert = hex.is_subdirectly_reducible(certificate=True)                #␣
↪needs sage.combinat
>>> cert[Integer(0)].is_isomorphic(N5)                                        ␣
↪     # needs sage.combinat
True
```

See also

- Stronger properties: *is_distributive()*, *is_vertically_decomposable()*
- Other: *subdirect_decomposition()*

is_sublattice(*other*)

Return `True` if the lattice is a sublattice of `other`, and `False` otherwise.

Lattice K is a sublattice of L if K is an (induced) subposet of L and closed under meet and join of L.

Note

This method does not check whether the lattice is a *isomorphic* (i.e., up to relabeling) sublattice of `other`, but only if `other` directly contains the lattice as an sublattice.

EXAMPLES:

A pentagon sublattice in a non-modular lattice:

```
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], 4: [7], 5: [7], 6:␣
↪[7]})
sage: N5 = LatticePoset({1: [2, 6], 2: [4], 4: [7], 6: [7]})
sage: N5.is_sublattice(L)
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5)], Integer(3): [Integer(5), Integer(6)], Integer(4):␣
↪[Integer(7)], Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> N5 = LatticePoset({Integer(1): [Integer(2), Integer(6)], Integer(2):␣
↪[Integer(4)], Integer(4): [Integer(7)], Integer(6): [Integer(7)]})
>>> N5.is_sublattice(L)
True
```

This pentagon is a subposet but not closed under join, hence not a sublattice:

```
sage: N5_ = LatticePoset({1: [2, 3], 2: [4], 3: [7], 4: [7]})
sage: N5_.is_induced_subposet(L)
True
sage: N5_.is_sublattice(L)
False
```

```
>>> from sage.all import *
>>> N5_ = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4)], Integer(3): [Integer(7)], Integer(4): [Integer(7)]})
>>> N5_.is_induced_subposet(L)
True
>>> N5_.is_sublattice(L)
False
```

See also

isomorphic_sublattices_iterator()

is_sublattice_dismantlable()

Return `True` if the lattice is sublattice dismantlable, and `False` otherwise.

A sublattice dismantling is a subdivision of a lattice into two non-empty sublattices. A lattice is *sublattice dismantlable* if it can be decomposed into 1-element lattices by consecutive sublattice dismantlings.

EXAMPLES:

The smallest non-example is this (and the dual):

```
sage: P = Poset({1: [11, 12, 13], 2: [11, 14, 15],
....:            3: [12, 14, 16], 4: [13, 15, 16]})
sage: L = LatticePoset(P.with_bounds())
sage: L.is_sublattice_dismantlable()
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1): [Integer(11), Integer(12), Integer(13)],␣
↪Integer(2): [Integer(11), Integer(14), Integer(15)],
...            Integer(3): [Integer(12), Integer(14), Integer(16)],␣
↪Integer(4): [Integer(13), Integer(15), Integer(16)]})
>>> L = LatticePoset(P.with_bounds())
>>> L.is_sublattice_dismantlable()
False
```

Here we adjoin a (double-irreducible-)dismantlable lattice as a part to an interval-dismantlable lattice:

```
sage: B3 = posets.BooleanLattice(3)
sage: N5 = posets.PentagonPoset()
sage: L = B3.adjunct(N5, 1, 7)
sage: L.is_dismantlable(), L.is_interval_dismantlable()
(False, False)
sage: L.is_sublattice_dismantlable()
True
```

```
>>> from sage.all import *
>>> B3 = posets.BooleanLattice(Integer(3))
>>> N5 = posets.PentagonPoset()
>>> L = B3.adjunct(N5, Integer(1), Integer(7))
>>> L.is_dismantlable(), L.is_interval_dismantlable()
(False, False)
>>> L.is_sublattice_dismantlable()
True
```

See also

- Stronger properties: *is_dismantlable()*, *is_interval_dismantlable()*

Todo

Add a certificate-option.

is_supersolvable(*certificate=False*)

Return `True` if the lattice is supersolvable, and `False` otherwise.

A lattice L is *supersolvable* if there exists a maximal chain C such that every $x \in C$ is a modular element in L. Equivalent definition is that the sublattice generated by C and any other chain is distributive.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(False, None)` or `(True, C)`, where `C` is a maximal chain of modular elements. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_supersolvable()
True

sage: L = posets.PentagonPoset()
sage: L.is_supersolvable()
False

sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_supersolvable()
True
sage: L.is_supersolvable(certificate=True)
(True, [1, 2, 5, 7])
sage: L.is_modular()
False

sage: L = LatticePoset({0: [1, 2, 3, 4], 1: [5, 6, 7],
....:                   2: [5, 8, 9], 3: [6, 8, 10], 4: [7, 9, 10],
....:                   5: [11], 6: [11], 7: [11], 8: [11],
....:                   9: [11], 10: [11]})
sage: L.is_supersolvable()
False
```

```
>>> from sage.all import *
>>> L = posets.DiamondPoset(Integer(5))
>>> L.is_supersolvable()
True

>>> L = posets.PentagonPoset()
>>> L.is_supersolvable()
False

>>> L = LatticePoset({Integer(1):[Integer(2),Integer(3)],
...Integer(2):[Integer(4),Integer(5)],Integer(3):[Integer(5),Integer(6)],
...Integer(4):[Integer(7)],Integer(5):[Integer(7)],Integer(6):[Integer(7)]})
>>> L.is_supersolvable()
True
>>> L.is_supersolvable(certificate=True)
(True, [1, 2, 5, 7])
>>> L.is_modular()
False
```

(continues on next page)

(continued from previous page)

```
>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3),␣
↪Integer(4)], Integer(1): [Integer(5), Integer(6), Integer(7)],
...                   Integer(2): [Integer(5), Integer(8), Integer(9)],␣
↪Integer(3): [Integer(6), Integer(8), Integer(10)], Integer(4): [Integer(7),␣
↪Integer(9), Integer(10)],
...                   Integer(5): [Integer(11)], Integer(6): [Integer(11)],␣
↪Integer(7): [Integer(11)], Integer(8): [Integer(11)],
...                   Integer(9): [Integer(11)], Integer(10): [Integer(11)]})
>>> L.is_supersolvable()
False
```

See also

- Weaker properties: *is_graded()*
- Stronger properties: *is_modular()*

is_trim(*certificate=False*)

Return whether a lattice is trim.

A lattice is trim if it is extremal and left modular.

This notion is defined in [Thom2006].

INPUT:

- `certificate` – boolean (default: `False`); whether to return instead a maximum chain of left modular elements

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.is_trim()
True

sage: Q = LatticePoset(posets.SymmetricGroupWeakOrderPoset(3))
sage: Q.is_trim()
False
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.is_trim()
True

>>> Q = LatticePoset(posets.SymmetricGroupWeakOrderPoset(Integer(3)))
>>> Q.is_trim()
False
```

- Weaker properties: *is_left_modular()*
- Stronger properties: *is_distributive()*

REFERENCES:

is_uniform(*certificate=False*)

Return `True` if the lattice is uniform and `False` otherwise.

A congruence is *uniform* if all blocks have equal number of elements. A lattice is uniform if it has only uniform congruences.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not uniform

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, C)`, where C is a non-uniform congruence as a *sage.combinat.set_partition.SetPartition*. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [5], 4: [5],
....:                   5: [9, 8], 6: [9], 7: [10], 8: [10], 9: [10]})
sage: L.is_uniform()                                                        #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(6), Integer(7)], Integer(3): [Integer(5)], Integer(4):␣
↪[Integer(5)],
...                    Integer(5): [Integer(9), Integer(8)], Integer(6):␣
↪[Integer(9)], Integer(7): [Integer(10)], Integer(8): [Integer(10)],␣
↪Integer(9): [Integer(10)]})
>>> L.is_uniform()                                                          #␣
↪needs sage.combinat
True
```

Every uniform lattice is regular, but the converse is not true:

```
sage: N6 = LatticePoset({1: [2, 3, 5], 2: [4], 3: [4], 5: [6], 4: [6]})
sage: N6.is_uniform(), N6.is_regular()
(False, True)

sage: N6.is_uniform(certificate=True)                                       #␣
↪needs sage.combinat
(False, {{1, 2, 3, 4}, {5, 6}})
```

```
>>> from sage.all import *
>>> N6 = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(5)],␣
↪Integer(2): [Integer(4)], Integer(3): [Integer(4)], Integer(5):␣
↪[Integer(6)], Integer(4): [Integer(6)]})
>>> N6.is_uniform(), N6.is_regular()
```

(continues on next page)

(continued from previous page)

```
(False, True)

>>> N6.is_uniform(certificate=True)                                    #␣
↪needs sage.combinat
(False, {{1, 2, 3, 4}, {5, 6}})
```

See also

- Weaker properties: *is_regular()*
- Stronger properties: *is_isoform()*
- Other: *congruence()*

is_upper_semimodular(*certificate=False*)

Return `True` if the lattice is upper semimodular and `False` otherwise.

A lattice is upper semimodular if any pair of elements with a common lower cover have also a common upper cover.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate if the lattice is not upper semimodular

OUTPUT:

- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (a, b))`, where a and b covers their meet but are not covered by their join.

See Wikipedia article Semimodular_lattice

EXAMPLES:

```
sage: L = posets.DiamondPoset(5)
sage: L.is_upper_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_upper_semimodular()
False

sage: L = LatticePoset(posets.IntegerPartitions(4))                 #␣
↪needs sage.combinat
sage: L.is_upper_semimodular()                                      #␣
↪needs sage.combinat
True

sage: L = LatticePoset({1:[2, 3, 4], 2: [5], 3:[5, 6], 4:[6], 5:[7], 6:[7]})
sage: L.is_upper_semimodular(certificate=True)
(False, (4, 2))
```

```
>>> from sage.all import *
>>> L = posets.DiamondPoset(Integer(5))
```

(continues on next page)

(continued from previous page)

```
>>> L.is_upper_semimodular()
True

>>> L = posets.PentagonPoset()
>>> L.is_upper_semimodular()
False

>>> L = LatticePoset(posets.IntegerPartitions(Integer(4)))                    ␣
↪     # needs sage.combinat
>>> L.is_upper_semimodular()                                                  #␣
↪needs sage.combinat
True

>>> L = LatticePoset({Integer(1):[Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5)], Integer(3):[Integer(5), Integer(6)],␣
↪Integer(4):[Integer(6)], Integer(5):[Integer(7)], Integer(6):[Integer(7)]})
>>> L.is_upper_semimodular(certificate=True)
(False, (4, 2))
```

- Weaker properties: *is_graded()*
- Stronger properties: *is_modular()*, *is_join_distributive()*, *is_geometric()*

is_vertically_decomposable(*certificate=False*)

Return `True` if the lattice is vertically decomposable, and `False` otherwise.

A lattice is vertically decomposable if it has an element that is comparable to all elements and is neither the bottom nor the top element.

Informally said, a lattice is vertically decomposable if it can be seen as two lattices "glued" by unifying the top element of first lattice to the bottom element of second one.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(False, None)` or `(True, e)`, where e is an element that is comparable to all other elements and is neither the bottom nor the top element. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: posets.TamariLattice(4).is_vertically_decomposable()
False
sage: L = LatticePoset( ([1, 2, 3, 6, 12, 18, 36],
....:     attrcall("divides")) )
sage: L.is_vertically_decomposable()
True
```

(continues on next page)

(continued from previous page)

```
sage: L.is_vertically_decomposable(certificate=True)
(True, 6)
```

```
>>> from sage.all import *
>>> posets.TamariLattice(Integer(4)).is_vertically_decomposable()
False
>>> L = LatticePoset( ([Integer(1), Integer(2), Integer(3), Integer(6),␣
↪Integer(12), Integer(18), Integer(36)],
...     attrcall("divides")) )
>>> L.is_vertically_decomposable()
True
>>> L.is_vertically_decomposable(certificate=True)
(True, 6)
```

See also

- Weaker properties: *is_subdirectly_reducible()*
- Mutually exclusive properties: *is_atomic()*, *is_coatomic()*, *is_regular()*
- Other: *vertical_decomposition()*

isomorphic_sublattices_iterator(*other*)

Return an iterator over the sublattices of the lattice isomorphic to `other`.

INPUT:

- `other` – a finite lattice

EXAMPLES:

A non-modular lattice contains a pentagon sublattice:

```
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], 4: [7], 5: [7], 6:␣
↪[7]})
sage: L.is_modular()
False
sage: N5 = posets.PentagonPoset()
sage: N5_in_L = next(L.isomorphic_sublattices_iterator(N5)); N5_in_L
Finite lattice containing 5 elements
sage: N5_in_L.list()
[1, 3, 6, 4, 7]
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4), Integer(5)], Integer(3): [Integer(5), Integer(6)], Integer(4):␣
↪[Integer(7)], Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_modular()
False
>>> N5 = posets.PentagonPoset()
>>> N5_in_L = next(L.isomorphic_sublattices_iterator(N5)); N5_in_L
Finite lattice containing 5 elements
```

(continues on next page)

(continued from previous page)

```
>>> N5_in_L.list()
[1, 3, 6, 4, 7]
```

A divisor lattice is modular, hence does not contain the pentagon as sublattice, even if it has the pentagon subposet:

```
sage: D12 = posets.DivisorLattice(12)
sage: D12.has_isomorphic_subposet(N5)
True
sage: list(D12.isomorphic_sublattices_iterator(N5))
[]
```

```
>>> from sage.all import *
>>> D12 = posets.DivisorLattice(Integer(12))
>>> D12.has_isomorphic_subposet(N5)
True
>>> list(D12.isomorphic_sublattices_iterator(N5))
[]
```

See also

sage.combinat.posets.posets.FinitePoset.isomorphic_subposets_iterator()

Warning

This function will return same sublattice as many times as there are automorphism on it. This is due to `subgraph_search_iterator()` returning labelled subgraphs.

join_primes()

Return the join-prime elements of the lattice.

An element x of a lattice L is *join-prime* if $x \leq a \vee b$ implies $x \leq a$ or $x \leq b$ for every $a, b \in L$.

These are also called *coprime* in some books. Every join-prime is join-irreducible; converse holds if and only if the lattice is distributive.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5],
....:                   4: [6], 5: [7], 6: [7]})
sage: L.join_primes()
[3, 4]

sage: D12 = posets.DivisorLattice(12)  # Distributive lattice
sage: D12.join_irreducibles() == D12.join_primes()
True
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5)],
```

(continues on next page)

(continued from previous page)

```
...                   Integer(4): [Integer(6)], Integer(5): [Integer(7)],␣
↪Integer(6): [Integer(7)]})
>>> L.join_primes()
[3, 4]

>>> D12 = posets.DivisorLattice(Integer(12))  # Distributive lattice
>>> D12.join_irreducibles() == D12.join_primes()
True
```

See also

- Dual function: *meet_primes()*
- Other: join_irreducibles()

maximal_sublattices()

Return maximal (proper) sublattices of the lattice.

EXAMPLES:

```
sage: L = LatticePoset(( [], [[1,2],[1,17],[1,8],[2,3],[2,22],
....:                         [2,5],[2,7],[17,22],[17,13],[8,7],
....:                         [8,13],[3,16],[3,9],[22,16],[22,18],
....:                         [22,10],[5,18],[5,14],[7,9],[7,14],
....:                         [7,10],[13,10],[16,6],[16,19],[9,19],
....:                         [18,6],[18,33],[14,33],[10,19],
....:                         [10,33],[6,4],[19,4],[33,4]] ))
sage: maxs = L.maximal_sublattices()
sage: len(maxs)
7
sage: sorted(maxs[0].list())
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 14, 16, 18, 19, 22, 33]
```

```
>>> from sage.all import *
>>> L = LatticePoset(( [], [[Integer(1),Integer(2)],[Integer(1),Integer(17)],
↪[Integer(1),Integer(8)],[Integer(2),Integer(3)],[Integer(2),Integer(22)],
...                         [Integer(2),Integer(5)],[Integer(2),Integer(7)],
↪[Integer(17),Integer(22)],[Integer(17),Integer(13)],[Integer(8),Integer(7)],
...                         [Integer(8),Integer(13)],[Integer(3),Integer(16)],
↪[Integer(3),Integer(9)],[Integer(22),Integer(16)],[Integer(22),Integer(18)],
...                         [Integer(22),Integer(10)],[Integer(5),
↪Integer(18)],[Integer(5),Integer(14)],[Integer(7),Integer(9)],[Integer(7),
↪Integer(14)],
...                         [Integer(7),Integer(10)],[Integer(13),
↪Integer(10)],[Integer(16),Integer(6)],[Integer(16),Integer(19)],[Integer(9),
↪Integer(19)],
...                         [Integer(18),Integer(6)],[Integer(18),
↪Integer(33)],[Integer(14),Integer(33)],[Integer(10),Integer(19)],
...                         [Integer(10),Integer(33)],[Integer(6),Integer(4)],
↪[Integer(19),Integer(4)],[Integer(33),Integer(4)]] ))
>>> maxs = L.maximal_sublattices()
```

(continues on next page)

(continued from previous page)

```
>>> len(maxs)
7
>>> sorted(maxs[Integer(0)].list())
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 14, 16, 18, 19, 22, 33]
```

meet_primes()

Return the meet-prime elements of the lattice.

An element x of a lattice L is *meet-prime* if $x \geq a \wedge b$ implies $x \geq a$ or $x \geq b$ for every $a, b \in L$.

These are also called just *prime* in some books. Every meet-prime is meet-irreducible; converse holds if and only if the lattice is distributive.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5],
....:                   4: [6], 5: [7], 6: [7]})
sage: L.meet_primes()
[6, 5]

sage: D12 = posets.DivisorLattice(12)
sage: sorted(D12.meet_primes())
[3, 4, 6]
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5)],
...                   Integer(4): [Integer(6)], Integer(5): [Integer(7)],␣
↪Integer(6): [Integer(7)]})
>>> L.meet_primes()
[6, 5]

>>> D12 = posets.DivisorLattice(Integer(12))
>>> sorted(D12.meet_primes())
[3, 4, 6]
```

See also

- Dual function: *join_primes()*
- Other: meet_irreducibles()

moebius_algebra(*R*)

Return the Möbius algebra of self over R.

OUTPUT: an instance of *sage.combinat.posets.moebius_algebra.MoebiusAlgebra*

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: L.moebius_algebra(QQ)
Moebius algebra of Finite lattice containing 16 elements over Rational Field
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> L.moebius_algebra(QQ)
Moebius algebra of Finite lattice containing 16 elements over Rational Field
```

neutral_elements()

Return the list of neutral elements of the lattice.

An element e of the lattice L is *neutral* if the sublattice generated by e, x and y is distributive for all $x, y \in L$. It can also be characterized as an element of intersection of maximal distributive sublattices.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3], 2: [6], 3: [4, 5, 6], 4: [8],
....:                   5: [7], 6: [7], 7: [8, 9], 8: [10], 9: [10]})
sage: L.neutral_elements()
[1, 3, 8, 10]
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(6)], Integer(3): [Integer(4), Integer(5), Integer(6)], Integer(4):␣
↪[Integer(8)],
...                    Integer(5): [Integer(7)], Integer(6): [Integer(7)],␣
↪Integer(7): [Integer(8), Integer(9)], Integer(8): [Integer(10)],␣
↪Integer(9): [Integer(10)]})
>>> L.neutral_elements()
[1, 3, 8, 10]
```

quantum_moebius_algebra(*q=None*)

Return the quantum Möbius algebra of `self` with parameter `q`.

INPUT:

- `q` – (optional) the deformation parameter q

OUTPUT: an instance of *sage.combinat.posets.moebius_algebra.QuantumMoebiusAlgebra*

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: L.quantum_moebius_algebra()
Quantum Moebius algebra of Finite lattice containing 16 elements
 with q=q over Univariate Laurent Polynomial Ring in q over Integer Ring
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> L.quantum_moebius_algebra()
Quantum Moebius algebra of Finite lattice containing 16 elements
 with q=q over Univariate Laurent Polynomial Ring in q over Integer Ring
```

quotient(*congruence*, *labels='tuple'*)

Return the quotient lattice by `congruence`.

Let L be a lattice and Θ be a congruence of L with congruence classes $\Theta_1, \Theta_2, \ldots$. The quotient lattice L/Θ is the lattice with elements $\{\Theta_1, \Theta_2, \ldots\}$ and meet and join given by the original lattice. Explicitly, if $e_1 \in \Theta_1$ and $e_2 \in \Theta_2$, such that $e_1 \vee e_2 \in \Theta_3$ then $\Theta_1 \vee \Theta_2 = \Theta_3$ in L/Θ and similarly for meets.

INPUT:

- `congruence` – list of lists; a congruence
- `labels` – string; the elements of the resulting lattice and can be one of the following:
  - `'tuple'` – elements are tuples of elements of the original lattice
  - `'lattice'` – elements are sublattices of the original lattice
  - `'integer'` – elements are labeled by integers

Warning

`congruence` is expected to be a valid congruence of the lattice. This is *not* checked.

EXAMPLES:

```
sage: # needs sage.combinat
sage: L = posets.PentagonPoset()
sage: c = L.congruence([[0, 1]])
sage: I = L.quotient(c); I
Finite lattice containing 2 elements
sage: I.top()
(2, 3, 4)
sage: I = L.quotient(c, labels='lattice')
sage: I.top()
Finite lattice containing 3 elements

sage: # needs sage.combinat
sage: B3 = posets.BooleanLattice(3)
sage: c = B3.congruence([[0,1]])
sage: B2 = B3.quotient(c, labels='integer')
sage: B2.is_isomorphic(posets.BooleanLattice(2))
True
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> L = posets.PentagonPoset()
>>> c = L.congruence([[Integer(0), Integer(1)]])
>>> I = L.quotient(c); I
Finite lattice containing 2 elements
>>> I.top()
(2, 3, 4)
>>> I = L.quotient(c, labels='lattice')
>>> I.top()
Finite lattice containing 3 elements

>>> # needs sage.combinat
>>> B3 = posets.BooleanLattice(Integer(3))
>>> c = B3.congruence([[Integer(0),Integer(1)]])
>>> B2 = B3.quotient(c, labels='integer')
>>> B2.is_isomorphic(posets.BooleanLattice(Integer(2)))
True
```

See also

congruence()

skeleton()

Return the skeleton of the lattice.

The lattice is expected to be pseudocomplemented.

The *skeleton* of a pseudocomplemented lattice L, where * is the pseudocomplementation operation, is the subposet induced by $\{e^* \mid e \in L\}$. Actually this poset is a Boolean lattice.

EXAMPLES:

```
sage: D12 = posets.DivisorLattice(12)
sage: S = D12.skeleton(); S
Finite lattice containing 4 elements
sage: S.cover_relations()
[[1, 3], [1, 4], [3, 12], [4, 12]]

sage: T4 = posets.TamariLattice(4)
sage: T4.skeleton().is_isomorphic(posets.BooleanLattice(3))
True
```

```
>>> from sage.all import *
>>> D12 = posets.DivisorLattice(Integer(12))
>>> S = D12.skeleton(); S
Finite lattice containing 4 elements
>>> S.cover_relations()
[[1, 3], [1, 4], [3, 12], [4, 12]]

>>> T4 = posets.TamariLattice(Integer(4))
>>> T4.skeleton().is_isomorphic(posets.BooleanLattice(Integer(3)))
True
```

See also

sage.combinat.posets.lattices.FiniteMeetSemilattice.pseudocomplement().

subdirect_decomposition()

Return the subdirect decomposition of the lattice.

The subdirect decomposition of a lattice L is the list of smaller lattices $L_1, \ldots, L_n$ such that L is a sublattice of $L_1 \times \ldots \times L_n$, none of L_i can be decomposed further and L is not a sublattice of any L_i. (Except when the list has only one element, i.e. when the lattice is subdirectly irreducible.)

EXAMPLES:

```
sage: posets.ChainPoset(3).subdirect_decomposition()                    #␣
↪needs sage.combinat
[Finite lattice containing 2 elements, Finite lattice containing 2 elements]

sage: # needs sage.combinat
```

(continues on next page)

(continued from previous page)

```
sage: L = LatticePoset({1: [2, 4], 2: [3], 3: [6, 7], 4: [5, 7],
....:                   5: [9, 8], 6: [9], 7: [9], 8: [10], 9: [10]})
sage: Ldecomp = L.subdirect_decomposition()
sage: [fac.cardinality() for fac in Ldecomp]
[2, 5, 7]
sage: Ldecomp[1].is_isomorphic(posets.PentagonPoset())
True
```

```
>>> from sage.all import *
>>> posets.ChainPoset(Integer(3)).subdirect_decomposition()
↪     # needs sage.combinat
[Finite lattice containing 2 elements, Finite lattice containing 2 elements]

>>> # needs sage.combinat
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(4)], Integer(2):
↪[Integer(3)], Integer(3): [Integer(6), Integer(7)], Integer(4): [Integer(5),
↪ Integer(7)],
...                    Integer(5): [Integer(9), Integer(8)], Integer(6):
↪[Integer(9)], Integer(7): [Integer(9)], Integer(8): [Integer(10)],
↪Integer(9): [Integer(10)]})
>>> Ldecomp = L.subdirect_decomposition()
>>> [fac.cardinality() for fac in Ldecomp]
[2, 5, 7]
>>> Ldecomp[Integer(1)].is_isomorphic(posets.PentagonPoset())
True
```

sublattice(*elms*, ***kwds*)

Return the smallest sublattice containing elements on the given list.

INPUT:

- `elms` – list of elements of the lattice

EXAMPLES:

```
sage: L = LatticePoset(([], [[1,2],[1,17],[1,8],[2,3],[2,22],[2,5],[2,7],[17,
↪22],[17,13],[8,7],[8,13],[3,16],[3,9],[22,16],[22,18],[22,10],[5,18],[5,14],
↪[7,9],[7,14],[7,10],[13,10],[16,6],[16,19],[9,19],[18,6],[18,33],[14,33],
↪[10,19],[10,33],[6,4],[19,4],[33,4]]))
sage: L.sublattice([14, 13, 22]).list()
[1, 2, 8, 7, 14, 17, 13, 22, 10, 33]

sage: L = posets.BooleanLattice(3)
sage: L.sublattice([3,5,6,7])
Finite lattice containing 8 elements
```

```
>>> from sage.all import *
>>> L = LatticePoset(([], [[Integer(1),Integer(2)],[Integer(1),Integer(17)],
↪[Integer(1),Integer(8)],[Integer(2),Integer(3)],[Integer(2),Integer(22)],
↪[Integer(2),Integer(5)],[Integer(2),Integer(7)],[Integer(17),Integer(22)],
↪[Integer(17),Integer(13)],[Integer(8),Integer(7)],[Integer(8),Integer(13)],
↪[Integer(3),Integer(16)],[Integer(3),Integer(9)],[Integer(22),Integer(16)],
↪[Integer(22),Integer(18)],[Integer(22),Integer(10)],[Integer(5),
```

(continues on next page)

(continued from previous page)

```
↪Integer(18)],[Integer(5),Integer(14)],[Integer(7),Integer(9)],[Integer(7),
↪Integer(14)],[Integer(7),Integer(10)],[Integer(13),Integer(10)],
↪[Integer(16),Integer(6)],[Integer(16),Integer(19)],[Integer(9),Integer(19)],
↪[Integer(18),Integer(6)],[Integer(18),Integer(33)],[Integer(14),
↪Integer(33)],[Integer(10),Integer(19)],[Integer(10),Integer(33)],
↪[Integer(6),Integer(4)],[Integer(19),Integer(4)],[Integer(33),Integer(4)]]))
>>> L.sublattice([Integer(14), Integer(13), Integer(22)]).list()
[1, 2, 8, 7, 14, 17, 13, 22, 10, 33]

>>> L = posets.BooleanLattice(Integer(3))
>>> L.sublattice([Integer(3),Integer(5),Integer(6),Integer(7)])
Finite lattice containing 8 elements
```

sublattices()

Return all sublattices of the lattice.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2:[5], 3:[5, 6], 4:[6],
....:                   5:[7], 6:[7]})
sage: sublats = L.sublattices(); len(sublats)
54
sage: sublats[3]
Finite lattice containing 4 elements
sage: sublats[3].list()
[1, 2, 3, 5]
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],␣
↪Integer(2):[Integer(5)], Integer(3):[Integer(5), Integer(6)],␣
↪Integer(4):[Integer(6)],
...                    Integer(5):[Integer(7)], Integer(6):[Integer(7)]})
>>> sublats = L.sublattices(); len(sublats)
54
>>> sublats[Integer(3)]
Finite lattice containing 4 elements
>>> sublats[Integer(3)].list()
[1, 2, 3, 5]
```

sublattices_lattice(*labels='lattice'*)

Return the lattice of sublattices.

Every element of the returned lattice is a sublattice and they are ordered by containment; that is, atoms are one-element lattices, coatoms are maximal sublattices of the original lattice and so on.

INPUT:

- `labels` – string; can be one of the following:
  - `'lattice'` (default) elements of the lattice will be lattices that correspond to sublattices of the original lattice
  - `'tuple'` – elements are tuples of elements of the sublattices of the original lattice
  - `'integer'` – elements are plain integers

EXAMPLES:

```
sage: D4 = posets.DiamondPoset(4)
sage: sll = D4.sublattices_lattice(labels='tuple')
sage: sll.coatoms()  # = maximal sublattices of the original lattice
[(0, 1, 3), (0, 2, 3)]

sage: L = posets.DivisorLattice(12)
sage: sll = L.sublattices_lattice()
sage: L.is_dismantlable() == (len(sll.atoms()) == sll.rank())
True
```

```
>>> from sage.all import *
>>> D4 = posets.DiamondPoset(Integer(4))
>>> sll = D4.sublattices_lattice(labels='tuple')
>>> sll.coatoms()  # = maximal sublattices of the original lattice
[(0, 1, 3), (0, 2, 3)]

>>> L = posets.DivisorLattice(Integer(12))
>>> sll = L.sublattices_lattice()
>>> L.is_dismantlable() == (len(sll.atoms()) == sll.rank())
True
```

vertical_composition(*other*, *labels='pairs'*)

Return the vertical composition of the lattice with `other`.

Let L and K be lattices and b_K the bottom element of K. The vertical composition of L and K is the ordinal sum of L and $K \setminus \{b_K\}$. Informally said this is lattices "glued" together with a common element.

Mathematically, it is only defined when L and K have no common element; here we force that by giving them different names in the resulting poset.

INPUT:

- `other` – a lattice
- `labels` – string (default: `'pairs'`); can be one of the following:
  - `'pairs'` – each element `v` in this poset will be named `(0, v)` and each element `u` in `other` will be named `(1, u)` in the result
  - `'integers'` – the elements of the result will be relabeled with consecutive integers

EXAMPLES:

```
sage: L = LatticePoset({'a': ['b', 'c'], 'b': ['d'], 'c': ['d']})
sage: K = LatticePoset({'e': ['f', 'g'], 'f': ['h'], 'g': ['h']})
sage: M = L.vertical_composition(K)
sage: M.list()
[(0, 'a'), (0, 'b'), (0, 'c'), (0, 'd'), (1, 'f'), (1, 'g'), (1, 'h')]
sage: M.upper_covers((0, 'd'))
[(1, 'f'), (1, 'g')]

sage: C2 = posets.ChainPoset(2)
sage: M3 = posets.DiamondPoset(5)
sage: L = C2.vertical_composition(M3, labels='integers')
```

(continues on next page)

(continued from previous page)

```
sage: L.cover_relations()
[[0, 1], [1, 2], [1, 3], [1, 4], [2, 5], [3, 5], [4, 5]]
```

```
>>> from sage.all import *
>>> L = LatticePoset({'a': ['b', 'c'], 'b': ['d'], 'c': ['d']})
>>> K = LatticePoset({'e': ['f', 'g'], 'f': ['h'], 'g': ['h']})
>>> M = L.vertical_composition(K)
>>> M.list()
[(0, 'a'), (0, 'b'), (0, 'c'), (0, 'd'), (1, 'f'), (1, 'g'), (1, 'h')]
>>> M.upper_covers((Integer(0), 'd'))
[(1, 'f'), (1, 'g')]

>>> C2 = posets.ChainPoset(Integer(2))
>>> M3 = posets.DiamondPoset(Integer(5))
>>> L = C2.vertical_composition(M3, labels='integers')
>>> L.cover_relations()
[[0, 1], [1, 2], [1, 3], [1, 4], [2, 5], [3, 5], [4, 5]]
```

See also

vertical_decomposition(), *sage.combinat.posets.posets.FinitePoset.ordinal_sum()*

vertical_decomposition(*elements_only=False*)

Return sublattices from the vertical decomposition of the lattice.

Let $d_1, \ldots, d_n$ be elements (excluding the top and bottom elements) comparable to every element of the lattice. Let b be the bottom element and t be the top element. This function returns either a list $d_1, \ldots, d_n$, or the list of intervals $[b, d_1], [d_1, d_2], \ldots, [d_{n-1}, d_n], [d_n, t]$ as lattices.

Informally said, this returns the lattice split into parts at every single-element "cutting point".

INPUT:

- `elements_only` – if `True`, return the list of decomposing elements as defined above; if `False` (the default), return the list of sublattices so that the lattice is a vertical composition of them.

EXAMPLES:

Number 6 is divided by 1, 2, and 3, and it divides 12, 18 and 36:

```
sage: L = LatticePoset( ([1, 2, 3, 6, 12, 18, 36],
....:     attrcall("divides")) )
sage: parts = L.vertical_decomposition()
sage: [lat.list() for lat in parts]
[[1, 2, 3, 6], [6, 12, 18, 36]]
sage: L.vertical_decomposition(elements_only=True)
[6]
```

```
>>> from sage.all import *
>>> L = LatticePoset( ([Integer(1), Integer(2), Integer(3), Integer(6),␣
↪Integer(12), Integer(18), Integer(36)],
...     attrcall("divides")) )
```

(continues on next page)

(continued from previous page)

```
>>> parts = L.vertical_decomposition()
>>> [lat.list() for lat in parts]
[[1, 2, 3, 6], [6, 12, 18, 36]]
>>> L.vertical_decomposition(elements_only=True)
[6]
```

See also

vertical_composition(), *is_vertically_decomposable()*

class sage.combinat.posets.lattices.**FiniteMeetSemilattice**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: *FinitePoset*

Note

We assume that the argument passed to MeetSemilattice is the poset of a meet-semilattice (i.e. a poset with greatest lower bound for each pair of elements).

Element

alias of *MeetSemilatticeElement*

atoms()

Return the list atoms of this (semi)lattice.

An *atom* of a lattice is an element covering the bottom element.

EXAMPLES:

```
sage: L = posets.DivisorLattice(60)
sage: sorted(L.atoms())
[2, 3, 5]
```

```
>>> from sage.all import *
>>> L = posets.DivisorLattice(Integer(60))
>>> sorted(L.atoms())
[2, 3, 5]
```

See also

- Dual function: *coatoms()*

meet(*x*, *y=None*)

Return the meet of given elements in the lattice.

INPUT:

- `x`, `y` – two elements of the (semi)lattice OR
- `x` – list or tuple of elements

EXAMPLES:

```
sage: D = posets.DiamondPoset(5)
sage: D.meet(1, 2)
0
sage: D.meet(1, 1)
1
sage: D.meet(1, 0)
0
sage: D.meet(1, 4)
1
```

```
>>> from sage.all import *
>>> D = posets.DiamondPoset(Integer(5))
>>> D.meet(Integer(1), Integer(2))
0
>>> D.meet(Integer(1), Integer(1))
1
>>> D.meet(Integer(1), Integer(0))
0
>>> D.meet(Integer(1), Integer(4))
1
```

Using list of elements as an argument. Meet of empty list is the bottom element:

```
sage: B4=posets.BooleanLattice(4)
sage: B4.meet([3,5,6])
0
sage: B4.meet([])
15
```

```
>>> from sage.all import *
>>> B4=posets.BooleanLattice(Integer(4))
>>> B4.meet([Integer(3),Integer(5),Integer(6)])
0
>>> B4.meet([])
15
```

For non-facade lattices operator `*` works for meet:

```
sage: L = posets.PentagonPoset(facade=False)
sage: L(1)*L(2)
0
```

```
>>> from sage.all import *
>>> L = posets.PentagonPoset(facade=False)
>>> L(Integer(1))*L(Integer(2))
0
```

See also

- Dual function: *join()*

meet_matrix()

Return a matrix whose `(i,j)` entry is `k`, where `self.linear_extension()[k]` is the meet (greatest lower bound) of `self.linear_extension()[i]` and `self.linear_extension()[j]`.

EXAMPLES:

```
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade =␣
↪False)
sage: M = P.meet_matrix(); M
[0 0 0 0 0 0 0 0]
[0 1 0 1 0 0 0 1]
[0 0 2 2 2 0 2 2]
[0 1 2 3 2 0 2 3]
[0 0 2 2 4 0 2 4]
[0 0 0 0 0 5 5 5]
[0 0 2 2 2 5 6 6]
[0 1 2 3 4 5 6 7]
sage: M[P(4).vertex,P(3).vertex] == P(0).vertex
True
sage: M[P(5).vertex,P(2).vertex] == P(2).vertex
True
sage: M[P(5).vertex,P(2).vertex] == P(5).vertex
False
```

```
>>> from sage.all import *
>>> P = LatticePoset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],
↪[Integer(4),Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],
↪[Integer(7)],[]], facade = False)
>>> M = P.meet_matrix(); M
[0 0 0 0 0 0 0 0]
[0 1 0 1 0 0 0 1]
[0 0 2 2 2 0 2 2]
[0 1 2 3 2 0 2 3]
[0 0 2 2 4 0 2 4]
[0 0 0 0 0 5 5 5]
[0 0 2 2 2 5 6 6]
[0 1 2 3 4 5 6 7]
>>> M[P(Integer(4)).vertex,P(Integer(3)).vertex] == P(Integer(0)).vertex
True
>>> M[P(Integer(5)).vertex,P(Integer(2)).vertex] == P(Integer(2)).vertex
True
>>> M[P(Integer(5)).vertex,P(Integer(2)).vertex] == P(Integer(5)).vertex
False
```

pseudocomplement(*element*)

Return the pseudocomplement of `element`, if it exists.

The (meet-)pseudocomplement is the greatest element whose meet with given element is the bottom element. I.e. in a meet-semilattice with bottom element $\hat{0}$ the pseudocomplement of an element e is the element $e^\star$ such that $e \wedge e^\star = \hat{0}$ and $e' \leq e^\star$ if $e \wedge e' = \hat{0}$.

See Wikipedia article Pseudocomplement.

INPUT:

- `element` – an element of the lattice

OUTPUT:

An element of the lattice or `None` if the pseudocomplement does not exist.

EXAMPLES:

The pseudocomplement's pseudocomplement is not always the original element:

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: L.pseudocomplement(2)
5
sage: L.pseudocomplement(5)
4
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):␣
↪[Integer(4)], Integer(3): [Integer(5)], Integer(4): [Integer(6)],␣
↪Integer(5): [Integer(6)]})
>>> L.pseudocomplement(Integer(2))
5
>>> L.pseudocomplement(Integer(5))
4
```

An element can have complements but no pseudocomplement, or vice versa:

```
sage: L = LatticePoset({0: [1, 2], 1: [3, 4, 5], 2: [5], 3: [6],
....:                   4: [6], 5: [6]})
sage: L.complements(1), L.pseudocomplement(1)
([], 2)
sage: L.complements(2), L.pseudocomplement(2)
([3, 4], None)
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3), Integer(4), Integer(5)], Integer(2): [Integer(5)], Integer(3):␣
↪[Integer(6)],
...                    Integer(4): [Integer(6)], Integer(5): [Integer(6)]})
>>> L.complements(Integer(1)), L.pseudocomplement(Integer(1))
([], 2)
>>> L.complements(Integer(2)), L.pseudocomplement(Integer(2))
([3, 4], None)
```

See also

is_pseudocomplemented()

subjoinsemilattice(*elms*, ***kwds*)

Return the smallest join-subsemilattice containing elements on the given list.

INPUT:

- `elms` – list of elements of the lattice

EXAMPLES:

```
sage: L = posets.DivisorLattice(1000)
sage: L_ = L.subjoinsemilattice([2, 25, 125]); L_
Finite join-semilattice containing 5 elements
sage: sorted(L_.list())
[2, 25, 50, 125, 250]
```

```
>>> from sage.all import *
>>> L = posets.DivisorLattice(Integer(1000))
>>> L_ = L.subjoinsemilattice([Integer(2), Integer(25), Integer(125)]); L_
Finite join-semilattice containing 5 elements
>>> sorted(L_.list())
[2, 25, 50, 125, 250]
```

See also

- Dual function: *submeetsemilattice()*

submeetsemilattice(*elms*, ***kwds*)

Return the smallest meet-subsemilattice containing elements on the given list.

INPUT:

- `elms` – list of elements of the lattice

EXAMPLES:

```
sage: L = posets.DivisorLattice(1000)
sage: L_ = L.submeetsemilattice([200, 250, 125]); L_
Finite meet-semilattice containing 5 elements
sage: L_.list()
[25, 50, 200, 125, 250]
```

```
>>> from sage.all import *
>>> L = posets.DivisorLattice(Integer(1000))
>>> L_ = L.submeetsemilattice([Integer(200), Integer(250), Integer(125)]); L_
Finite meet-semilattice containing 5 elements
>>> L_.list()
[25, 50, 200, 125, 250]
```

See also

- Dual function: *subjoinsemilattice()*

sage.combinat.posets.lattices.**JoinSemilattice**(*data=None*, **args*, ***options*)

Construct a join semi-lattice from various forms of input data.

INPUT:

- `data`, `*args`, `**options` – data and options that will be passed down to *Poset()* to construct a poset that is also a join semilattice

See also

Poset(), *MeetSemilattice()*, *LatticePoset()*

EXAMPLES:

Using data that defines a poset:

```
sage: JoinSemilattice([[1,2],[3],[3]])
Finite join-semilattice containing 3 elements

sage: JoinSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite join-semilattice containing 3 elements
```

```
>>> from sage.all import *
>>> JoinSemilattice([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]])
Finite join-semilattice containing 3 elements

>>> JoinSemilattice([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]], cover_
↪relations = True)
Finite join-semilattice containing 3 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: J = JoinSemilattice(P); J
Finite join-semilattice containing 3 elements
sage: type(J)
<class 'sage.combinat.posets.lattices.FiniteJoinSemilattice_with_category'>
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]])
>>> J = JoinSemilattice(P); J
Finite join-semilattice containing 3 elements
>>> type(J)
<class 'sage.combinat.posets.lattices.FiniteJoinSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: JoinSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
....:                  'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
...
LatticeError: no join for b and c
```

```
>>> from sage.all import *
>>> JoinSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
...                  'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
...
LatticeError: no join for b and c
```

sage.combinat.posets.lattices.**LatticePoset**(*data=None*, **args*, ***options*)

Construct a lattice from various forms of input data.

INPUT:

- `data`, `*args`, `**options` – data and options that will be passed down to *Poset()* to construct a poset that is also a lattice.

OUTPUT: an instance of *FiniteLatticePoset*

See also

Posets, FiniteLatticePosets, *JoinSemilattice()*, *MeetSemilattice()*

EXAMPLES:

Using data that defines a poset:

```
sage: LatticePoset([[1,2],[3],[3]])
Finite lattice containing 3 elements

sage: LatticePoset([[1,2],[3],[3]], cover_relations = True)
Finite lattice containing 3 elements
```

```
>>> from sage.all import *
>>> LatticePoset([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]])
Finite lattice containing 3 elements

>>> LatticePoset([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]], cover_
↪relations = True)
Finite lattice containing 3 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: L = LatticePoset(P); L
Finite lattice containing 3 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteLatticePoset_with_category'>
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]])
>>> L = LatticePoset(P); L
Finite lattice containing 3 elements
>>> type(L)
<class 'sage.combinat.posets.lattices.FiniteLatticePoset_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: LatticePoset((elms, rels))
Traceback (most recent call last):
...
ValueError: not a meet-semilattice: no bottom element
```

```
>>> from sage.all import *
>>> elms = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),Integer(6),
↪Integer(7)]
>>> rels = [[Integer(1),Integer(2)],[Integer(3),Integer(4)],[Integer(4),
↪Integer(5)],[Integer(2),Integer(5)]]
>>> LatticePoset((elms, rels))
Traceback (most recent call last):
...
ValueError: not a meet-semilattice: no bottom element
```

Creating a facade lattice:

```
sage: L = LatticePoset([[1,2],[3],[3]], facade = True)
sage: L.category()
Category of facade finite enumerated lattice posets
sage: parent(L[0])
Integer Ring
sage: TestSuite(L).run(skip = ['_test_an_element']) # is_parent_of is not yet␣
↪implemented
```

```
>>> from sage.all import *
>>> L = LatticePoset([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]], facade␣
↪= True)
>>> L.category()
Category of facade finite enumerated lattice posets
>>> parent(L[Integer(0)])
Integer Ring
>>> TestSuite(L).run(skip = ['_test_an_element']) # is_parent_of is not yet␣
↪implemented
```

sage.combinat.posets.lattices.**MeetSemilattice**(*data=None*, **args*, ***options*)

Construct a meet semi-lattice from various forms of input data.

INPUT:

- `data`, `*args`, `**options` – data and options that will be passed down to *Poset()* to construct a poset that is also a meet semilattice.

See also

Poset(), *JoinSemilattice()*, *LatticePoset()*

EXAMPLES:

Using data that defines a poset:

```
sage: MeetSemilattice([[1,2],[3],[3]])
Finite meet-semilattice containing 3 elements

sage: MeetSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite meet-semilattice containing 3 elements
```

```
>>> from sage.all import *
>>> MeetSemilattice([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]])
Finite meet-semilattice containing 3 elements

>>> MeetSemilattice([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]], cover_
↪relations = True)
Finite meet-semilattice containing 3 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: L = MeetSemilattice(P); L
Finite meet-semilattice containing 3 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice_with_category'>
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]])
>>> L = MeetSemilattice(P); L
Finite meet-semilattice containing 3 elements
>>> type(L)
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: MeetSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
....:                  'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
...
LatticeError: no meet for e and d
```

```
>>> from sage.all import *
>>> MeetSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
...                  'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
...
LatticeError: no meet for e and d
```

Finite posets

This module implements finite partially ordered sets. It defines:

FinitePoset	A class for finite posets
FinitePosets_n	A class for finite posets up to isomorphism (i.e. unlabeled posets)
Poset()	Construct a finite poset from various forms of input data.
is_poset()	Return `True` if a directed graph is acyclic and transitively reduced.

List of Poset methods

Comparing, intervals and relations

is_less_than()	Return `True` if x is strictly less than y in the poset.
is_greater_than()	Return `True` if x is strictly greater than y in the poset.
is_lequal()	Return `True` if x is less than or equal to y in the poset.
is_gequal()	Return `True` if x is greater than or equal to y in the poset.
compare_elements()	Compare two element of the poset.
interval()	Return the list of elements in a closed interval of the poset.
interval_as_poset()	Return the subposet of elements in a closed interval of the poset.
open_interval()	Return the list of elements in an open interval of the poset.
relations()	Return the list of relations in the poset.
relations_iterator()	Return an iterator over relations in the poset.
order_filter()	Return the upper set generated by elements.
order_ideal()	Return the lower set generated by elements.

Covering

covers()	Return `True` if `y` covers `x`.
lower_covers()	Return elements covered by given element.
upper_covers()	Return elements covering given element.
cover_relations()	Return the list of cover relations.
lower_covers_iterator()	Return an iterator over elements covered by given element.
upper_covers_iterator()	Return an iterator over elements covering given element.
cover_relations_iterator()	Return an iterator over cover relations of the poset.
common_upper_covers()	Return the list of all common upper covers of the given elements.
common_lower_covers()	Return the list of all common lower covers of the given elements.
meet()	Return the meet of given elements if it exists; `None` otherwise.
join()	Return the join of given elements if it exists; `None` otherwise.

Properties of the poset

cardinality()	Return the number of elements in the poset.
height()	Return the number of elements in a longest chain of the poset.
width()	Return the number of elements in a longest antichain of the poset.
number_of_relations()	Return the number of relations in the poset.
dimension()	Return the dimension of the poset.
jump_number()	Return the jump number of the poset.
magnitude()	Return the magnitude of the poset.
has_bottom()	Return `True` if the poset has a unique minimal element.
has_top()	Return `True` if the poset has a unique maximal element.
is_bounded()	Return `True` if the poset has both unique minimal and unique maximal element.
is_chain()	Return `True` if the poset is totally ordered.
is_connected()	Return `True` if the poset is connected.
is_graded()	Return `True` if all maximal chains of the poset has same length.
is_ranked()	Return `True` if the poset has a rank function.
is_rank_symmetric()	Return `True` if the poset is rank symmetric.
is_series_parallel()	Return `True` if the poset can be built by ordinal sums and disjoint unions.
is_greedy()	Return `True` if all greedy linear extensions have equal number of jumps.
is_jump_critical()	Return `True` if removal of any element reduces the jump number.
is_eulerian()	Return `True` if the poset is Eulerian.
is_incompara-ble_chain_free()	Return `True` if the poset is (m+n)-free.
is_slender()	Return `True` if the poset is slender.
is_sperner()	Return `True` if the poset is Sperner.
is_join_semilattice()	Return `True` if the poset has a join operation.
is_meet_semilattice()	Return `True` if the poset has a meet operation.

Minimal and maximal elements

bottom()	Return the bottom element of the poset, if it exists.
top()	Return the top element of the poset, if it exists.
maximal_elements()	Return the list of the maximal elements of the poset.
minimal_elements()	Return the list of the minimal elements of the poset.

New posets from old ones

disjoint_union()	Return the disjoint union of the poset with other poset.
ordinal_sum()	Return the ordinal sum of the poset with other poset.
product()	Return the Cartesian product of the poset with other poset.
ordinal_product()	Return the ordinal product of the poset with other poset.
rees_product()	Return the Rees product of the poset with other poset.
lexicographic_sum()	Return the lexicographic sum of posets.
star_product()	Return the star product of the poset with other poset.
with_bounds()	Return the poset with bottom and top element adjoined.
without_bounds()	Return the poset with bottom and top element removed.
dual()	Return the dual of the poset.
completion_by_cuts()	Return the Dedekind-MacNeille completion of the poset.
intervals_poset()	Return the poset of intervals of the poset.
connected_components()	Return the connected components of the poset as subposets.
factor()	Return the decomposition of the poset as a Cartesian product.
ordinal_summands()	Return the ordinal summands of the poset.
subposet()	Return the subposet containing elements with partial order induced by this poset.
random_subposet()	Return a random subposet that contains each element with given probability.
relabel()	Return a copy of this poset with its elements relabelled.
canonical_label()	Return copy of the poset canonically (re)labelled to integers.
slant_sum()	Return the slant sum poset of two posets.

Chains, antichains & linear intervals

is_chain_of_poset()	Return `True` if elements in the given list are comparable.
is_antichain_of_poset()	Return `True` if elements in the given list are incomparable.
is_linear_interval()	Return whether the given interval is a total order.
chains()	Return the chains of the poset.
antichains()	Return the antichains of the poset.
maximal_chains()	Return the maximal chains of the poset.
maximal_antichains()	Return the maximal antichains of the poset.
maximal_chains_iterator()	Return an iterator over the maximal chains of the poset.
maximal_chain_length()	Return the maximum length of maximal chains of the poset.
antichains_iterator()	Return an iterator over the antichains of the poset.
random_maximal_chain()	Return a random maximal chain.
random_maximal_antichain()	Return a random maximal antichain.
linear_intervals_count()	Return the enumeration of linear intervals in the poset.

Drawing

show()	Display the Hasse diagram of the poset.
plot()	Return a Graphic object corresponding the Hasse diagram of the poset.
graphviz_string()	Return a representation in the DOT language, ready to render in graphviz.

Comparing posets

is_isomorphic()	Return `True` if both posets are isomorphic.
is_induced_subposet()	Return `True` if given poset is an induced subposet of this poset.

Polynomials

chain_polynomial()	Return the chain polynomial of the poset.
characteristic_polynomial()	Return the characteristic polynomial of the poset.
f_polynomial()	Return the f-polynomial of the poset.
flag_f_polynomial()	Return the flag f-polynomial of the poset.
h_polynomial()	Return the h-polynomial of the poset.
flag_h_polynomial()	Return the flag h-polynomial of the poset.
order_polynomial()	Return the order polynomial of the poset.
zeta_polynomial()	Return the zeta polynomial of the poset.
apozeta_polynomial()	Return the apozeta polynomial of the poset.
M_triangle()	Return the M-triangle of the poset.
kazhdan_lusztig_polynomial()	Return the Kazhdan-Lusztig polynomial of the poset.
coxeter_polynomial()	Return the characteristic polynomial of the Coxeter transformation.
degree_polynomial()	Return the generating polynomial of degrees of vertices in the Hasse diagram.
p_partition_enumerator()	Return a P-partition enumerator of the poset.

Polytopes

chain_polytope()	Return the chain polytope of the poset.
order_polytope()	Return the order polytope of the poset.

Graphs

hasse_diagram()	Return the Hasse diagram of the poset as a directed graph.
cover_relations_graph()	Return the (undirected) graph of cover relations.
comparability_graph()	Return the comparability graph of the poset.
incomparability_graph()	Return the incomparability graph of the poset.
frank_network()	Return Frank's network of the poset.
linear_extensions_graph()	Return the linear extensions graph of the poset.

Linear extensions

is_linear_extension()	Return `True` if the given list is a linear extension of the poset.
linear_extension()	Return a linear extension of the poset.
linear_extensions()	Return the enumerated set of all the linear extensions of the poset.
promotion()	Return the (extended) promotion on the linear extension of the poset.
evacuation()	Return evacuation on the linear extension associated to the poset.
with_linear_extension()	Return a copy of `self` with a different default linear extension.
random_linear_extension()	Return a random linear extension.

Matrices

lequal_matrix()	Compute the matrix whose `(i,j)` entry is 1 if `self.linear_extension()[i] < self.linear_extension()[j]` and 0 otherwise.
moebius_function()	Return the value of Möbius function of given elements in the poset.
moebius_function_matrix()	Return a matrix whose `(i,j)` entry is the value of the Möbius function evaluated at `self.linear_extension()[i]` and `self.linear_extension()[j]`.
coxeter_transformation()	Return the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules.
coxeter_smith_form()	Return the Smith form of the Coxeter transformation.

Miscellaneous

sorted()	Return given list sorted by the poset.
isomorphic_subposets()	Return all subposets isomorphic to another poset.
isomorphic_subposets_iterator()	Return an iterator over the subposets isomorphic to another poset.
has_isomorphic_subposet()	Return `True` if the poset contains a subposet isomorphic to another poset.
list()	List the elements of the poset.
cuts()	Return the cuts of the given poset.
dilworth_decomposition()	Return a partition of the points into the minimal number of chains.
greene_shape()	Compute the Greene-Kleitman partition aka Greene shape of the poset `self`.
incidence_algebra()	Return the incidence algebra of `self`.
is_EL_labelling()	Return whether `f` is an EL labelling of the poset.
isomorphic_subposets_iterator()	Return an iterator over the subposets isomorphic to another poset.
isomorphic_subposets()	Return all subposets isomorphic to another poset.
level_sets()	Return elements grouped by maximal number of cover relations from a minimal element.
order_complex()	Return the order complex associated to this poset.
random_order_ideal()	Return a random order ideal of `self` with uniform probability.
rank()	Return the rank of an element, or the rank of the poset.
rank_function()	Return a rank function of the poset, if it exists.
unwrap()	Unwrap an element of this poset.
atkinson()	Return the a-spectrum of a poset whose undirected Hasse diagram is a forest.
spectrum()	Return the a-spectrum of this poset.

Classes and functions

class sage.combinat.posets.posets.**FinitePoset**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: `UniqueRepresentation`, `Parent`

A (finite) n-element poset constructed from a directed acyclic graph.

INPUT:

- `hasse_diagram` – an instance of *FinitePoset*, or a `DiGraph` that is transitively-reduced, acyclic, loop-free, and multiedge-free.
- `elements` – an optional list of elements, with `element[i]` corresponding to vertex `i`. If `elements` is `None`, then it is set to be the vertex set of the digraph. Note that if this option is set, then `elements` is considered as a specified linear extension of the poset and the `linear_extension` attribute is set.

- category – FinitePosets, or a subcategory thereof
- facade – boolean or None (default); whether the *FinitePoset*'s elements should be wrapped to make them aware of the Poset they belong to.
  - If facade = True, the *FinitePoset*'s elements are exactly those given as input.
  - If facade = False, the *FinitePoset*'s elements will become *PosetElement* objects.
  - If facade = None (default) the expected behaviour is the behaviour of facade = True, unless the opposite can be deduced from the context (i.e. for instance if a *FinitePoset* is built from another *FinitePoset*, itself built with facade = False)
- key – any hashable value (default: None)

EXAMPLES:

```
sage: uc = [[2,3], [], [1], [1], [1], [3,4]]
sage: from sage.combinat.posets.posets import FinitePoset
sage: P = FinitePoset(DiGraph(dict([[i,uc[i]] for i in range(len(uc))])),␣
↪facade=False); P
Finite poset containing 6 elements
sage: P.cover_relations()
[[5, 4], [5, 3], [4, 1], [0, 2], [0, 3], [2, 1], [3, 1]]
sage: TestSuite(P).run()
sage: P.category()
Category of finite enumerated posets
sage: P.__class__
<class 'sage.combinat.posets.posets.FinitePoset_with_category'>

sage: Q = sage.combinat.posets.posets.FinitePoset(P, facade = False); Q
Finite poset containing 6 elements

sage: Q is P
True
```

```
>>> from sage.all import *
>>> uc = [[Integer(2),Integer(3)], [], [Integer(1)], [Integer(1)], [Integer(1)],␣
↪[Integer(3),Integer(4)]]
>>> from sage.combinat.posets.posets import FinitePoset
>>> P = FinitePoset(DiGraph(dict([[i,uc[i]] for i in range(len(uc))])),␣
↪facade=False); P
Finite poset containing 6 elements
>>> P.cover_relations()
[[5, 4], [5, 3], [4, 1], [0, 2], [0, 3], [2, 1], [3, 1]]
>>> TestSuite(P).run()
>>> P.category()
Category of finite enumerated posets
>>> P.__class__
<class 'sage.combinat.posets.posets.FinitePoset_with_category'>

>>> Q = sage.combinat.posets.posets.FinitePoset(P, facade = False); Q
Finite poset containing 6 elements

>>> Q is P
True
```

We keep the same underlying Hasse diagram, but change the elements:

```
sage: Q = sage.combinat.posets.posets.FinitePoset(P, elements=[1,2,3,4,5,6],␣
↪facade=False); Q
Finite poset containing 6 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 6], [3, 4], [3, 5], [4, 6], [5, 6]]
```

```
>>> from sage.all import *
>>> Q = sage.combinat.posets.posets.FinitePoset(P, elements=[Integer(1),
↪Integer(2),Integer(3),Integer(4),Integer(5),Integer(6)], facade=False); Q
Finite poset containing 6 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 5], [2, 6], [3, 4], [3, 5], [4, 6], [5, 6]]
```

We test the facade argument:

```
sage: P = Poset(DiGraph({'a':['b'],'b':['c'],'c':['d']}), facade=False)
sage: P.category()
Category of finite enumerated posets
sage: parent(P[0]) is P
True

sage: Q = Poset(DiGraph({'a':['b'],'b':['c'],'c':['d']}), facade=True)
sage: Q.category()
Category of facade finite enumerated posets
sage: parent(Q[0]) is str
True
sage: TestSuite(Q).run(skip = ['_test_an_element']) # is_parent_of is not yet␣
↪implemented
```

```
>>> from sage.all import *
>>> P = Poset(DiGraph({'a':['b'],'b':['c'],'c':['d']}), facade=False)
>>> P.category()
Category of finite enumerated posets
>>> parent(P[Integer(0)]) is P
True

>>> Q = Poset(DiGraph({'a':['b'],'b':['c'],'c':['d']}), facade=True)
>>> Q.category()
Category of facade finite enumerated posets
>>> parent(Q[Integer(0)]) is str
True
>>> TestSuite(Q).run(skip = ['_test_an_element']) # is_parent_of is not yet␣
↪implemented
```

Changing a non facade poset to a facade poset:

```
sage: PQ = Poset(P, facade=True)
sage: PQ.category()
Category of facade finite enumerated posets
sage: parent(PQ[0]) is str
True
```

(continues on next page)

(continued from previous page)

```
sage: PQ is Q
True
```

```
>>> from sage.all import *
>>> PQ = Poset(P, facade=True)
>>> PQ.category()
Category of facade finite enumerated posets
>>> parent(PQ[Integer(0)]) is str
True
>>> PQ is Q
True
```

Changing a facade poset to a non facade poset:

```
sage: QP = Poset(Q, facade = False)
sage: QP.category()
Category of finite enumerated posets
sage: parent(QP[0]) is QP
True
```

```
>>> from sage.all import *
>>> QP = Poset(Q, facade = False)
>>> QP.category()
Category of finite enumerated posets
>>> parent(QP[Integer(0)]) is QP
True
```

Conversion to some other software is possible:

```
sage: P = posets.TamariLattice(3)
sage: libgap(P)                                          # optional - gap_package_
↪qpa
<A poset on 5 points>

sage: P = Poset({1:[2],2:[]})
sage: macaulay2('needsPackage "Posets"')    # optional - macaulay2
Posets
sage: macaulay2(P)    # optional - macaulay2
Relation Matrix: | 1 1 |
                 | 0 1 |
```

```
>>> from sage.all import *
>>> P = posets.TamariLattice(Integer(3))
>>> libgap(P)                                          # optional - gap_package_qpa
<A poset on 5 points>

>>> P = Poset({Integer(1):[Integer(2)],Integer(2):[]})
>>> macaulay2('needsPackage "Posets"')    # optional - macaulay2
Posets
>>> macaulay2(P)    # optional - macaulay2
Relation Matrix: | 1 1 |
                 | 0 1 |
```

Note

A class that inherits from this class needs to define `Element`. This is the class of the elements that the inheriting class contains. For example, for this class, `FinitePoset`, `Element` is `PosetElement`. It can also define `_dual_class` which is the class of dual posets of this class. E.g. `FiniteMeetSemilattice._dual_class` is `FiniteJoinSemilattice`.

Element

alias of *PosetElement*

M_triangle()

Return the M-triangle of the poset.

The poset is expected to be graded.

OUTPUT: an *M_triangle*

The M-triangle is the generating polynomial of the Möbius numbers

$$M(x,y) = \sum_{a \leq b} \mu(a,b) x^{|a|} y^{|b|}.$$

EXAMPLES:

```
sage: P = posets.DiamondPoset(5)
sage: P.M_triangle()                                                        #␣
↪needs sage.combinat
M: x^2*y^2 - 3*x*y^2 + 3*x*y + 2*y^2 - 3*y + 1
```

```
>>> from sage.all import *
>>> P = posets.DiamondPoset(Integer(5))
>>> P.M_triangle()                                                          #␣
↪needs sage.combinat
M: x^2*y^2 - 3*x*y^2 + 3*x*y + 2*y^2 - 3*y + 1
```

antichains(*element_constructor=None*)

Return the antichains of the poset.

An *antichain* of a poset is a set of elements of the poset that are pairwise incomparable.

INPUT:

- `element_constructor` – a function taking an iterable as argument (default: `list`)

OUTPUT:

The enumerated set (of type *PairwiseCompatibleSubsets*) of all antichains of the poset, each of which is given as an `element_constructor`.

EXAMPLES:

```
sage: A = posets.PentagonPoset().antichains(); A
Set of antichains of Finite lattice containing 5 elements
sage: list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
sage: A.cardinality()
8
```

(continues on next page)

(continued from previous page)

```
sage: A[3]
[1, 2]
```

```
>>> from sage.all import *
>>> A = posets.PentagonPoset().antichains(); A
Set of antichains of Finite lattice containing 5 elements
>>> list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
>>> A.cardinality()
8
>>> A[Integer(3)]
[1, 2]
```

To get the antichains as, say, sets, one may use the `element_constructor` option:

```
sage: list(posets.ChainPoset(3).antichains(element_constructor=set))
[set(), {0}, {1}, {2}]
```

```
>>> from sage.all import *
>>> list(posets.ChainPoset(Integer(3)).antichains(element_constructor=set))
[set(), {0}, {1}, {2}]
```

To get the antichains of a given size one can currently use:

```
sage: list(A.elements_of_depth_iterator(2))
[[1, 2], [1, 3]]
```

```
>>> from sage.all import *
>>> list(A.elements_of_depth_iterator(Integer(2)))
[[1, 2], [1, 3]]
```

Eventually the following syntax will be accepted:

```
sage: A.subset(size=2)              # not implemented
```

```
>>> from sage.all import *
>>> A.subset(size=Integer(2))              # not implemented
```

Note

Internally, this uses *sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets* and `RecursivelyEnumeratedSet_forest`. At this point, iterating through this set is about twice slower than using *antichains_iterator()* (tested on `posets.AntichainPoset(15)`). The algorithm is the same (depth first search through the tree), but *antichains_iterator()* manually inlines things which apparently avoids some infrastructure overhead.

On the other hand, this returns a full featured enumerated set, with containment testing, etc.

See also

maximal_antichains(), *chains()*

antichains_iterator()

Return an iterator over the antichains of the poset.

EXAMPLES:

```
sage: it = posets.PentagonPoset().antichains_iterator(); it
<generator object ...antichains_iterator at ...>
sage: next(it), next(it)
([], [4])
```

```
>>> from sage.all import *
>>> it = posets.PentagonPoset().antichains_iterator(); it
<generator object ...antichains_iterator at ...>
>>> next(it), next(it)
([], [4])
```

See also

antichains()

apozeta_polynomial()

Return the apozeta polynomial of the poset `self`.

The poset is assumed to be graded.

The apozeta polynomial of a poset is the unique polynomial $Z^a(q)$ such that for every integer $m > 1$, $Z^a(m)$ is the number of weakly increasing sequences $x_1 \leq x_2 \leq \cdots \leq x_{m-1}$ of elements of the poset whose largest element belongs to the top level of the poset.

When the poset P has a unique maximal element, this is equal to $Z(q-1)$ where Z is the zeta polynomial of P.

The name comes from the greek radical `apo`.

See also

zeta_polynomial()

EXAMPLES:

```
sage: P = posets.NoncrossingPartitions(SymmetricGroup(4))
sage: P.apozeta_polynomial()
8/3*q^3 - 10*q^2 + 37/3*q - 5

sage: P = Poset({"a": "bc", "b": "d", "c": "de"})
sage: P.apozeta_polynomial()
3/2*q^2 - 5/2*q + 1
sage: P.zeta_polynomial()
3/2*q^2 - 1/2*q
```

```
>>> from sage.all import *
>>> P = posets.NoncrossingPartitions(SymmetricGroup(Integer(4)))
>>> P.apozeta_polynomial()
8/3*q^3 - 10*q^2 + 37/3*q - 5

>>> P = Poset({"a": "bc", "b": "d", "c": "de"})
>>> P.apozeta_polynomial()
3/2*q^2 - 5/2*q + 1
>>> P.zeta_polynomial()
3/2*q^2 - 1/2*q
```

atkinson(a)

Return the a-spectrum of a poset whose Hasse diagram is cycle-free as an undirected graph.

Given an element a in a poset P, the a-spectrum is the list of integers whose i-th term contains the number of linear extensions of P with element a located in the i-th position.

INPUT:

- `self` – a poset whose Hasse diagram is a forest
- `a` – an element of the poset

OUTPUT: the a-spectrum of this poset, returned as a list

EXAMPLES:

```
sage: P = Poset({0: [2], 1: [2], 2: [3, 4], 3: [], 4: []})
sage: P.atkinson(0)
[2, 2, 0, 0, 0]

sage: P = Poset({0: [1], 1: [2, 3], 2: [], 3: [], 4: [5, 6], 5: [], 6: []})
sage: P.atkinson(5)
[0, 10, 18, 24, 28, 30, 30]

sage: P = posets.AntichainPoset(10)
sage: P.atkinson(0)
[362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880,␣
↪362880]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(2)], Integer(1): [Integer(2)],␣
↪Integer(2): [Integer(3), Integer(4)], Integer(3): [], Integer(4): []})
>>> P.atkinson(Integer(0))
[2, 2, 0, 0, 0]

>>> P = Poset({Integer(0): [Integer(1)], Integer(1): [Integer(2), Integer(3)],
↪ Integer(2): [], Integer(3): [], Integer(4): [Integer(5), Integer(6)],␣
↪Integer(5): [], Integer(6): []})
>>> P.atkinson(Integer(5))
[0, 10, 18, 24, 28, 30, 30]

>>> P = posets.AntichainPoset(Integer(10))
>>> P.atkinson(Integer(0))
[362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880,␣
↪362880]
```

Note

This function is the implementation of the algorithm from [At1990].

bottom()

Return the unique minimal element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})
>>> P.bottom() is None
True
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.bottom()
0
```

See also

has_bottom(), *top()*

canonical_label(*algorithm=None*)

Return the unique poset on the labels $\{0, \ldots, n-1\}$ (where n is the number of elements in the poset) that is isomorphic to this poset and invariant in the isomorphism class.

INPUT:

- `algorithm` – string (optional); a parameter forwarded to underlying graph function to select the algorithm to use

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: Q = P.canonical_label()
sage: sorted(Q.list())
[0, 1, 2, 3, 4, 5]
sage: Q.is_isomorphic(P)
True
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_
↪extension=True)
```

(continues on next page)

(continued from previous page)

```
>>> P.list()
[1, 2, 3, 4, 6, 12]
>>> Q = P.canonical_label()
>>> sorted(Q.list())
[0, 1, 2, 3, 4, 5]
>>> Q.is_isomorphic(P)
True
```

Canonical labeling of (semi)lattice returns (semi)lattice:

```
sage: D = DiGraph({'a':['b','c']})
sage: P = Poset(D)
sage: ML = MeetSemilattice(D)
sage: P.canonical_label()
Finite poset containing 3 elements
sage: ML.canonical_label()
Finite meet-semilattice containing 3 elements
```

```
>>> from sage.all import *
>>> D = DiGraph({'a':['b','c']})
>>> P = Poset(D)
>>> ML = MeetSemilattice(D)
>>> P.canonical_label()
Finite poset containing 3 elements
>>> ML.canonical_label()
Finite meet-semilattice containing 3 elements
```

See also

- Canonical labeling of directed graphs: `canonical_label()`

cardinality()

Return the number of elements in the poset.

EXAMPLES:

```
sage: Poset([[1,2,3],[4],[4],[4],[]]).cardinality()
5
```

```
>>> from sage.all import *
>>> Poset([[Integer(1),Integer(2),Integer(3)],[Integer(4)],[Integer(4)],
↪[Integer(4)],[]]).cardinality()
5
```

See also

degree_polynomial() for a more refined invariant

chain_polynomial()

Return the chain polynomial of the poset.

The coefficient of q^k is the number of chains of k elements in the poset. List of coefficients of this polynomial is also called a *f-vector* of the poset.

This is multiplicative with respect to ordinal sum.

Note

This is not what has been called the chain polynomial in [St1986]. The latter is identical with the order polynomial in SageMath (*order_polynomial()*).

See also

f_polynomial(), *order_polynomial()*, *ordinal_sum()*

EXAMPLES:

```
sage: P = posets.ChainPoset(3)
sage: t = P.chain_polynomial(); t
q^3 + 3*q^2 + 3*q + 1
sage: t(1) == len(list(P.chains()))
True

sage: P = posets.BooleanLattice(3)
sage: P.chain_polynomial()
6*q^4 + 18*q^3 + 19*q^2 + 8*q + 1

sage: P = posets.AntichainPoset(5)
sage: P.chain_polynomial()
5*q + 1
```

```
>>> from sage.all import *
>>> P = posets.ChainPoset(Integer(3))
>>> t = P.chain_polynomial(); t
q^3 + 3*q^2 + 3*q + 1
>>> t(Integer(1)) == len(list(P.chains()))
True

>>> P = posets.BooleanLattice(Integer(3))
>>> P.chain_polynomial()
6*q^4 + 18*q^3 + 19*q^2 + 8*q + 1

>>> P = posets.AntichainPoset(Integer(5))
>>> P.chain_polynomial()
5*q + 1
```

chain_polytope()

Return the chain polytope of the poset `self`.

The chain polytope of a finite poset P is defined as the subset of $\mathbf{R}^P$ consisting of all maps $x : P \to \mathbf{R}$

satisfying

$$x(p) \geq 0 \text{ for all } p \in P,$$

and

$$x(p_1) + x(p_2) + \ldots + x(p_k) \leq 1 \text{ for all chains } p_1 < p_2 < \ldots < p_k \text{ in } P.$$

This polytope was defined and studied in [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: Q = P.chain_polytope(); Q                                                 #␣
↪needs sage.geometry.polyhedron
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
sage: P = posets.PentagonPoset()
sage: Q = P.chain_polytope(); Q                                                 #␣
↪needs sage.geometry.polyhedron
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices
```

```
>>> from sage.all import *
>>> P = posets.AntichainPoset(Integer(3))
>>> Q = P.chain_polytope(); Q                                                   #␣
↪needs sage.geometry.polyhedron
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
>>> P = posets.PentagonPoset()
>>> Q = P.chain_polytope(); Q                                                   #␣
↪needs sage.geometry.polyhedron
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices
```

chains(*element_constructor=None*, *exclude=None*)

Return the chains of the poset.

A *chain* of a poset is an increasing sequence of distinct elements of the poset.

INPUT:

- `element_constructor` – a function taking an iterable as argument (default: `list`)
- `exclude` – elements of the poset to be excluded (default: `None`)

OUTPUT:

The enumerated set (of type *PairwiseCompatibleSubsets*) of all chains of the poset, each of which is given as an `element_constructor`.

EXAMPLES:

```
sage: C = posets.PentagonPoset().chains(); C
Set of chains of Finite lattice containing 5 elements
sage: list(C)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4],
 [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4],
 [3], [3, 4], [4]]
```

```
>>> from sage.all import *
>>> C = posets.PentagonPoset().chains(); C
Set of chains of Finite lattice containing 5 elements
>>> list(C)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4],
 [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4],
 [3], [3, 4], [4]]
```

Exclusion of elements, tuple (instead of list) as constructor:

```
sage: P = Poset({1: [2, 3], 2: [4], 3: [4, 5]})
sage: list(P.chains(element_constructor=tuple, exclude=[3]))
[(), (1,), (1, 2), (1, 2, 4), (1, 4), (1, 5), (2,), (2, 4), (4,), (5,)]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(2): [Integer(4)],
↪ Integer(3): [Integer(4), Integer(5)]})
>>> list(P.chains(element_constructor=tuple, exclude=[Integer(3)]))
[(), (1,), (1, 2), (1, 2, 4), (1, 4), (1, 5), (2,), (2, 4), (4,), (5,)]
```

To get the chains of a given size one can currently use:

```
sage: list(C.elements_of_depth_iterator(2))
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 4], [2, 3], [2, 4], [3, 4]]
```

```
>>> from sage.all import *
>>> list(C.elements_of_depth_iterator(Integer(2)))
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 4], [2, 3], [2, 4], [3, 4]]
```

Eventually the following syntax will be accepted:

```
sage: C.subset(size=2)              # not implemented
```

```
>>> from sage.all import *
>>> C.subset(size=Integer(2))               # not implemented
```

See also

maximal_chains(), *antichains()*

characteristic_polynomial()

Return the characteristic polynomial of the poset.

The poset is expected to be graded and have a bottom element.

If P is a graded poset with rank n and a unique minimal element $\hat{0}$, then the characteristic polynomial of P is defined to be

$$\sum_{x \in P} \mu(\hat{0}, x) q^{n-\rho(x)} \in \mathbf{Z}[q],$$

where ρ is the rank function, and μ is the Möbius function of P.

See section 3.10 of [EnumComb1].

EXAMPLES:

```
sage: P = posets.DiamondPoset(5)
sage: P.characteristic_polynomial()
q^2 - 3*q + 2

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6], 6: [7]})
sage: P.characteristic_polynomial()
q^4 - 2*q^3 + q
```

```
>>> from sage.all import *
>>> P = posets.DiamondPoset(Integer(5))
>>> P.characteristic_polynomial()
q^2 - 3*q + 2

>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(2): [Integer(4)],
↪ Integer(3): [Integer(5)], Integer(4): [Integer(6)], Integer(5):␣
↪[Integer(6)], Integer(6): [Integer(7)]})
>>> P.characteristic_polynomial()
q^4 - 2*q^3 + q
```

closed_interval(*x*, *y*)

alias of *interval()*.

common_lower_covers(*elmts*)

Return all of the common lower covers of the elements `elmts`.

EXAMPLES:

```
sage: P = Poset({0: [1,2], 1: [3], 2: [3], 3: []})
sage: P.common_lower_covers([1, 2])
[0]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1),Integer(2)], Integer(1): [Integer(3)],␣
↪Integer(2): [Integer(3)], Integer(3): []})
>>> P.common_lower_covers([Integer(1), Integer(2)])
[0]
```

common_upper_covers(*elmts*)

Return all of the common upper covers of the elements `elmts`.

EXAMPLES:

```
sage: P = Poset({0: [1,2], 1: [3], 2: [3], 3: []})
sage: P.common_upper_covers([1, 2])
[3]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1),Integer(2)], Integer(1): [Integer(3)],␣
↪Integer(2): [Integer(3)], Integer(3): []})
>>> P.common_upper_covers([Integer(1), Integer(2)])
[3]
```

comparability_graph()

Return the comparability graph of the poset.

The comparability graph is an undirected graph where vertices are the elements of the poset and there is an edge between two vertices if they are comparable in the poset.

See Wikipedia article Comparability_graph

EXAMPLES:

```
sage: Y = Poset({1: [2], 2: [3, 4]})
sage: g = Y.comparability_graph(); g
Comparability graph on 4 vertices
sage: Y.compare_elements(1, 3) is not None
True
sage: g.has_edge(1, 3)
True
```

```
>>> from sage.all import *
>>> Y = Poset({Integer(1): [Integer(2)], Integer(2): [Integer(3), Integer(4)]}
↪)
>>> g = Y.comparability_graph(); g
Comparability graph on 4 vertices
>>> Y.compare_elements(Integer(1), Integer(3)) is not None
True
>>> g.has_edge(Integer(1), Integer(3))
True
```

See also

incomparability_graph(), sage.graphs.comparability

compare_elements(x, y)

Compare x and y in the poset.

- If $x < y$, return `-1`.
- If $x = y$, return `0`.
- If $x > y$, return `1`.
- If x and y are not comparable, return `None`.

EXAMPLES:

```
sage: P = Poset([[1, 2], [4], [3], [4], []])
sage: P.compare_elements(0, 0)
0
sage: P.compare_elements(0, 4)
-1
sage: P.compare_elements(4, 0)
1
sage: P.compare_elements(1, 2) is None
True
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1), Integer(2)], [Integer(4)], [Integer(3)],␣
↪[Integer(4)], []])
>>> P.compare_elements(Integer(0), Integer(0))
0
>>> P.compare_elements(Integer(0), Integer(4))
-1
>>> P.compare_elements(Integer(4), Integer(0))
1
>>> P.compare_elements(Integer(1), Integer(2)) is None
True
```

completion_by_cuts()

Return the completion by cuts of `self`.

This is the smallest lattice containing the poset. This is also called the Dedekind-MacNeille completion.

See the Wikipedia article Dedekind-MacNeille completion.

OUTPUT: a finite lattice

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.completion_by_cuts().is_isomorphic(P)
True

sage: Y = Poset({1: [2], 2: [3, 4]})
sage: trafficsign = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [5]})
sage: L = Y.completion_by_cuts()
sage: L.is_isomorphic(trafficsign)
True

sage: P = posets.SymmetricGroupBruhatOrderPoset(3)
sage: Q = P.completion_by_cuts(); Q
Finite lattice containing 7 elements
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.completion_by_cuts().is_isomorphic(P)
True

>>> Y = Poset({Integer(1): [Integer(2)], Integer(2): [Integer(3), Integer(4)]}
↪)
>>> trafficsign = LatticePoset({Integer(1): [Integer(2)], Integer(2):␣
↪[Integer(3), Integer(4)], Integer(3): [Integer(5)], Integer(4):␣
↪[Integer(5)]})
>>> L = Y.completion_by_cuts()
>>> L.is_isomorphic(trafficsign)
True

>>> P = posets.SymmetricGroupBruhatOrderPoset(Integer(3))
>>> Q = P.completion_by_cuts(); Q
Finite lattice containing 7 elements
```

See also

cuts(), *irreducibles_poset()*

connected_components()

Return the connected components of the poset as subposets.

EXAMPLES:

```
sage: P = Poset({1: [2, 3], 3: [4, 5], 6: [7, 8]})
sage: parts = sorted(P.connected_components(), key=len); parts
[Finite poset containing 3 elements,
 Finite poset containing 5 elements]
sage: parts[0].cover_relations()
[[6, 7], [6, 8]]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(3): [Integer(4),␣
↪Integer(5)], Integer(6): [Integer(7), Integer(8)]})
>>> parts = sorted(P.connected_components(), key=len); parts
[Finite poset containing 3 elements,
 Finite poset containing 5 elements]
>>> parts[Integer(0)].cover_relations()
[[6, 7], [6, 8]]
```

See also

disjoint_union(), *is_connected()*

cover_relations()

Return the list of pairs `[x, y]` of elements of the poset such that `y` covers `x`.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.cover_relations()
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> P.cover_relations()
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

cover_relations_graph()

Return the (undirected) graph of cover relations.

EXAMPLES:

```
sage: P = Poset({0: [1, 2], 1: [3], 2: [3]})
sage: G = P.cover_relations_graph(); G
Graph on 4 vertices
```

(continues on next page)

(continued from previous page)

```
sage: G.has_edge(3, 1), G.has_edge(3, 0)
(True, False)
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1), Integer(2)], Integer(1): [Integer(3)],
↪ Integer(2): [Integer(3)]})
>>> G = P.cover_relations_graph(); G
Graph on 4 vertices
>>> G.has_edge(Integer(3), Integer(1)), G.has_edge(Integer(3), Integer(0))
(True, False)
```

See also

hasse_diagram()

cover_relations_iterator()

Return an iterator over the cover relations of the poset.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: type(P.cover_relations_iterator())
<class 'generator'>
sage: [z for z in P.cover_relations_iterator()]
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> type(P.cover_relations_iterator())
<class 'generator'>
>>> [z for z in P.cover_relations_iterator()]
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

covers(x, y)

Return `True` if `y` covers `x` and `False` otherwise.

Element y covers x if $x < y$ and there is no z such that $x < z < y$.

EXAMPLES:

```
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.covers(1, 6)
True
sage: P.covers(1, 4)
False
sage: P.covers(1, 5)
False
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(5)], [Integer(2),Integer(6)], [Integer(3)],
```

(continues on next page)

(continued from previous page)

```
↪ [Integer(4)], [], [Integer(6),Integer(3)], [Integer(4)]])
>>> P.covers(Integer(1), Integer(6))
True
>>> P.covers(Integer(1), Integer(4))
False
>>> P.covers(Integer(1), Integer(5))
False
```

coxeter_polynomial(*algorithm='sage'*)

Return the Coxeter polynomial of the poset.

INPUT:

- `algorithm` – optional (default: `"sage"`) ; the unique other option is `"magma"`

OUTPUT: a polynomial in one variable

The output is the characteristic polynomial of the Coxeter transformation. This polynomial only depends on the derived category of modules on the poset.

Note

By Corollary 4.3 of [Lad2021], this polynomial does not depend on the order of the ordinal summands.

See also

ordinal_sum(), *ordinal_summands()*

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.coxeter_polynomial()                                                #␣
↪needs sage.libs.flint
x^5 + x^4 + x + 1

sage: p = posets.SymmetricGroupWeakOrderPoset(3)                            #␣
↪needs sage.groups
sage: p.coxeter_polynomial()                                                #␣
↪needs sage.groups sage.libs.flint
x^6 + x^5 - x^3 + x + 1
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.coxeter_polynomial()                                                  #␣
↪needs sage.libs.flint
x^5 + x^4 + x + 1

>>> p = posets.SymmetricGroupWeakOrderPoset(Integer(3))                      ␣
↪     # needs sage.groups
>>> p.coxeter_polynomial()                                                  #␣
↪needs sage.groups sage.libs.flint
x^6 + x^5 - x^3 + x + 1
```

See also

coxeter_transformation(), *coxeter_smith_form()*

coxeter_smith_form(*algorithm='singular'*)

Return the Smith normal form of x minus the Coxeter transformation matrix.

INPUT:

- `algorithm` – (default: `'singular'`) possible values are `'singular'`, `'sage'`, `'gap'`, `'pari'`, `'maple'`, `'magma'`, `'fricas'`

Beware that speed depends very much on the choice of algorithm. Sage is rather slow, Singular is faster and Pari is fast at least for small sizes.

OUTPUT: list of polynomials in one variable, each one dividing the next one

The output list is a refinement of the characteristic polynomial of the Coxeter transformation, which is its product. This list of polynomials only depends on the derived category of modules on the poset.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.coxeter_smith_form()
↪# needs sage.libs.singular
[1, 1, 1, 1, x^5 + x^4 + x + 1]

sage: P = posets.DiamondPoset(7)
sage: prod(P.coxeter_smith_form()) == P.coxeter_polynomial()
↪# needs sage.libs.singular
True
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.coxeter_smith_form()                                                  #␣
↪needs sage.libs.singular
[1, 1, 1, 1, x^5 + x^4 + x + 1]

>>> P = posets.DiamondPoset(Integer(7))
>>> prod(P.coxeter_smith_form()) == P.coxeter_polynomial()                  #␣
↪needs sage.libs.singular
True
```

See also

coxeter_transformation(), coxeter_matrix

coxeter_transformation()

Return the Coxeter transformation of the poset.

OUTPUT: a square matrix with integer coefficients

The output is the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules. This matrix is usually called the Coxeter transformation.

EXAMPLES:

```
sage: posets.PentagonPoset().coxeter_transformation()                    #␣
↪needs sage.libs.flint
[ 0  0  0  0 -1]
[ 0  0  0  1 -1]
[ 0  1  0  0 -1]
[-1  1  1  0 -1]
[-1  1  0  1 -1]
```

```
>>> from sage.all import *
>>> posets.PentagonPoset().coxeter_transformation()                    #␣
↪needs sage.libs.flint
[ 0  0  0  0 -1]
[ 0  0  0  1 -1]
[ 0  1  0  0 -1]
[-1  1  1  0 -1]
[-1  1  0  1 -1]
```

See also

coxeter_polynomial(), *coxeter_smith_form()*

cuts()

Return the list of cuts of the poset `self`.

A cut is a subset A of `self` such that the set of lower bounds of the set of upper bounds of A is exactly A.

The cuts are computed as the smallest family of subsets of P containing its principal order filters, the whole set P and which is closed by intersection.

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: Pc = P.cuts()
sage: Pc # random
[frozenset({2}),
 frozenset({1}),
 frozenset({0}),
 frozenset(),
 frozenset({0, 1, 2})]
sage: sorted(list(c) for c in Pc)
[[], [0], [0, 1, 2], [1], [2]]
```

```
>>> from sage.all import *
>>> P = posets.AntichainPoset(Integer(3))
>>> Pc = P.cuts()
>>> Pc # random
[frozenset({2}),
 frozenset({1}),
 frozenset({0}),
 frozenset(),
 frozenset({0, 1, 2})]
```

(continues on next page)

(continued from previous page)

```
>>> sorted(list(c) for c in Pc)
[[], [0], [0, 1, 2], [1], [2]]
```

See also

completion_by_cuts()

degree_polynomial()

Return the generating polynomial of degrees of vertices in `self`.

This is the sum

$$\sum_{v \in P} x^{\mathrm{in}(v)} y^{\mathrm{out}(v)},$$

where `in(v)` and `out(v)` are the number of incoming and outgoing edges at vertex v in the Hasse diagram of P.

Because this polynomial is multiplicative for Cartesian product of posets, it is useful to help see if the poset can be isomorphic to a Cartesian product.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.degree_polynomial()
x^2 + 3*x*y + y^2

sage: P = posets.BooleanLattice(4)
sage: P.degree_polynomial().factor()
(x + y)^4
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.degree_polynomial()
x^2 + 3*x*y + y^2

>>> P = posets.BooleanLattice(Integer(4))
>>> P.degree_polynomial().factor()
(x + y)^4
```

See also

cardinality() for the value at $(x, y) = (1, 1)$

diamonds()

Return the list of diamonds of `self`.

A diamond is the following subgraph of the Hasse diagram:

```
  z
 / \
```

(continues on next page)

(continued from previous page)

```
x   y
 \ /
  w
```

Thus each edge represents a cover relation in the Hasse diagram. We represent this as the tuple (w, x, y, z).

OUTPUT: a tuple with

- a list of all diamonds in the Hasse Diagram,
- a boolean checking that every w, x, y that form a V, there is a unique element z, which completes the diamond.

EXAMPLES:

```
sage: P = Poset({0: [1,2], 1: [3], 2: [3], 3: []})
sage: P.diamonds()
([(0, 1, 2, 3)], True)

sage: P = posets.YoungDiagramPoset(Partition([3, 2, 2]))                    #␣
↪needs sage.combinat
sage: P.diamonds()                                                          #␣
↪needs sage.combinat
([((0, 0), (0, 1), (1, 0), (1, 1)), ((1, 0), (1, 1), (2, 0), (2, 1))], False)
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1),Integer(2)], Integer(1): [Integer(3)],␣
↪Integer(2): [Integer(3)], Integer(3): []})
>>> P.diamonds()
([(0, 1, 2, 3)], True)

>>> P = posets.YoungDiagramPoset(Partition([Integer(3), Integer(2),␣
↪Integer(2)]))                    # needs sage.combinat
>>> P.diamonds()                                                            #␣
↪needs sage.combinat
([((0, 0), (0, 1), (1, 0), (1, 1)), ((1, 0), (1, 1), (2, 0), (2, 1))], False)
```

dilworth_decomposition()

Return a partition of the points into the minimal number of chains.

According to Dilworth's theorem, the points of a poset can be partitioned into α chains, where α is the cardinality of its largest antichain. This method returns such a partition.

See Wikipedia article Dilworth%27s_theorem.

ALGORITHM:

We build a bipartite graph in which a vertex v of the poset is represented by two vertices v^-, v^+. For any two u, v such that $u < v$ in the poset we add an edge v^+u^-.

A matching in this graph is equivalent to a partition of the poset into chains: indeed, a chain $v_1...v_k$ gives rise to the matching $v_1^+v_2^-, v_2^+v_3^-, ...$, and from a matching one can build the union of chains.

According to Dilworth's theorem, the number of chains is equal to α (the posets' width).

EXAMPLES:

```
sage: p = posets.BooleanLattice(4)
sage: p.width()                                                             #␣
↪needs networkx
6
sage: p.dilworth_decomposition()  # random                                  #␣
↪needs networkx
[[7, 6, 4], [11, 3], [12, 8, 0], [13, 9, 1], [14, 10, 2], [15, 5]]
```

```
>>> from sage.all import *
>>> p = posets.BooleanLattice(Integer(4))
>>> p.width()                                                               #␣
↪needs networkx
6
>>> p.dilworth_decomposition()  # random                                    #␣
↪needs networkx
[[7, 6, 4], [11, 3], [12, 8, 0], [13, 9, 1], [14, 10, 2], [15, 5]]
```

See also

level_sets() to return elements grouped to antichains.

dimension(*certificate*, *solver*, *integrality_tolerance=False*)

Return the dimension of the Poset.

The (Dushnik-Miller) dimension of a poset is the minimal number of total orders so that the poset is their "intersection". More precisely, the dimension of a poset defined on a set X of points is the smallest integer n such that there exist linear extensions $P_1, ..., P_n$ of P satisfying:

$$u \leq_P v \text{ if and only if } \forall i, u \leq_{P_i} v$$

For more information, see the Wikipedia article Order_dimension.

INPUT:

- `certificate` – boolean (default: `False`); whether to return an integer (the dimension) or a certificate, i.e. a smallest set of linear extensions
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

Note

The speed of this function greatly improves when more efficient MILP solvers (e.g. Gurobi, CPLEX) are installed. See `MixedIntegerLinearProgram` for more information.

Note

Prior to version 8.3 this returned only realizer with `certificate=True`. Now it returns a pair having a realizer as the second element. See Issue #25588 for details.

ALGORITHM:

As explained in [FT00], the dimension of a poset is equal to the (weak) chromatic number of a hypergraph. More precisely:

> Let $inc(P)$ be the set of (ordered) pairs of incomparable elements of P, i.e. all uv and vu such that $u \not\leq_P v$ and $v \not\leq_P u$. Any linear extension of P is a total order on X that can be seen as the union of relations from P along with some relations from $inc(P)$. Thus, the dimension of P is the smallest number of linear extensions of P which *cover* all points of $inc(P)$.
>
> Consequently, $dim(P)$ is equal to the chromatic number of the hypergraph $\mathcal{H}_{inc}$, where $\mathcal{H}_{inc}$ is the hypergraph defined on $inc(P)$ whose sets are all $S \subseteq inc(P)$ such that $P \cup S$ is not acyclic.

We solve this problem through a `Mixed Integer Linear Program`.

The problem is known to be NP-complete.

EXAMPLES:

We create a poset, compute a set of linear extensions and check that we get back the poset from them:

```
sage: P = Poset([[1,4], [3], [4,5,3], [6], [], [6], []])
sage: P.dimension()                                                         #␣
↪needs networkx
3
sage: dim, L = P.dimension(certificate=True)                                #␣
↪needs sage.numerical.mip
sage: L  # random -- architecture-dependent                                 #␣
↪needs sage.numerical.mip
[[0, 2, 4, 5, 1, 3, 6], [2, 5, 0, 1, 3, 4, 6], [0, 1, 2, 3, 5, 6, 4]]
sage: Poset( (L[0], lambda x, y: all(l.index(x) < l.index(y) for l in L)) )␣
↪== P         # needs sage.numerical.mip
True
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(4)], [Integer(3)], [Integer(4),Integer(5),
↪Integer(3)], [Integer(6)], [], [Integer(6)], []])
>>> P.dimension()                                                           #␣
↪needs networkx
3
>>> dim, L = P.dimension(certificate=True)                                  #␣
↪needs sage.numerical.mip
>>> L  # random -- architecture-dependent                                   #␣
↪needs sage.numerical.mip
[[0, 2, 4, 5, 1, 3, 6], [2, 5, 0, 1, 3, 4, 6], [0, 1, 2, 3, 5, 6, 4]]
>>> Poset( (L[Integer(0)], lambda x, y: all(l.index(x) < l.index(y) for l in␣
↪L)) ) == P         # needs sage.numerical.mip
True
```

According to Schnyder's theorem, the incidence poset (of height 2) of a graph has dimension ≤ 3 if and only if the graph is planar:

```
sage: G = graphs.CompleteGraph(4)
sage: P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges(sort=True)}))
sage: P.dimension()                                                          #␣
↪needs networkx
3

sage: G = graphs.CompleteBipartiteGraph(3,3)
sage: P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges(sort=True)}))
sage: P.dimension()  # not tested (around 4s with CPLEX)
4
```

```
>>> from sage.all import *
>>> G = graphs.CompleteGraph(Integer(4))
>>> P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges(sort=True)}))
>>> P.dimension()                                                            #␣
↪needs networkx
3

>>> G = graphs.CompleteBipartiteGraph(Integer(3),Integer(3))
>>> P = Poset(DiGraph({(u,v):[u,v] for u,v,_ in G.edges(sort=True)}))
>>> P.dimension()  # not tested (around 4s with CPLEX)
4
```

disjoint_union(*other*, *labels='pairs'*)

Return a poset isomorphic to disjoint union (also called direct sum) of the poset with `other`.

The disjoint union of P and Q is a poset that contains every element and relation from both P and Q, and where every element of P is incomparable to every element of Q.

Mathematically, it is only defined when P and Q have no common element; here we force that by giving them different names in the resulting poset.

INPUT:

- `other` – poset
- `labels` – (defaults to 'pairs') If set to 'pairs', each element `v` in this poset will be named `(0,v)` and each element `u` in `other` will be named `(1,u)` in the result. If set to 'integers', the elements of the result will be relabeled with consecutive integers.

EXAMPLES:

```
sage: P1 = Poset({'a': 'b'})
sage: P2 = Poset({'c': 'd'})
sage: P = P1.disjoint_union(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[[(0, 'a'), (0, 'b')], [(1, 'c'), (1, 'd')]]
sage: P = P1.disjoint_union(P2, labels='integers')
sage: P.cover_relations()
[[2, 3], [0, 1]]

sage: N5 = posets.PentagonPoset(); N5
Finite lattice containing 5 elements
sage: N5.disjoint_union(N5)  # Union of lattices is not a lattice
Finite poset containing 10 elements
```

```
>>> from sage.all import *
>>> P1 = Poset({'a': 'b'})
>>> P2 = Poset({'c': 'd'})
>>> P = P1.disjoint_union(P2); P
Finite poset containing 4 elements
>>> sorted(P.cover_relations())
[[(0, 'a'), (0, 'b')], [(1, 'c'), (1, 'd')]]
>>> P = P1.disjoint_union(P2, labels='integers')
>>> P.cover_relations()
[[2, 3], [0, 1]]

>>> N5 = posets.PentagonPoset(); N5
Finite lattice containing 5 elements
>>> N5.disjoint_union(N5)  # Union of lattices is not a lattice
Finite poset containing 10 elements
```

We show how to get literally direct sum with elements untouched:

```
sage: P = P1.disjoint_union(P2).relabel(lambda x: x[1])
sage: sorted(P.cover_relations())
[['a', 'b'], ['c', 'd']]
```

```
>>> from sage.all import *
>>> P = P1.disjoint_union(P2).relabel(lambda x: x[Integer(1)])
>>> sorted(P.cover_relations())
[['a', 'b'], ['c', 'd']]
```

See also

connected_components()

dual()

Return the dual poset of the given poset.

In the dual of a poset P we have $x \leq y$ iff $y \leq x$ in P.

EXAMPLES:

```
sage: P = Poset({1: [2, 3], 3: [4]})
sage: P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
sage: Q = P.dual()
sage: Q.cover_relations()
[[4, 3], [3, 1], [2, 1]]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(3): [Integer(4)]}
↪)
>>> P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
>>> Q = P.dual()
```

(continues on next page)

(continued from previous page)

```
>>> Q.cover_relations()
[[4, 3], [3, 1], [2, 1]]
```

Dual of a lattice is a lattice; dual of a meet-semilattice is join-semilattice and vice versa. Also the dual of a (non-)facade poset is again (non-)facade:

```
sage: V = MeetSemilattice({1: [2, 3]}, facade=False)
sage: A = V.dual(); A
Finite join-semilattice containing 3 elements
sage: A(2) < A(1)
True
```

```
>>> from sage.all import *
>>> V = MeetSemilattice({Integer(1): [Integer(2), Integer(3)]}, facade=False)
>>> A = V.dual(); A
Finite join-semilattice containing 3 elements
>>> A(Integer(2)) < A(Integer(1))
True
```

See also

`is_self_dual()`

evacuation()

Compute evacuation on the linear extension associated to the poset `self`.

OUTPUT: an isomorphic poset, with the same default linear extension

Evacuation is defined on a poset `self` of size n by applying the evacuation operator $(\tau_1 \cdots \tau_{n-1})(\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)$, to the default linear extension π of `self` (see *evacuation()*), and relabeling `self` accordingly. For more details see [Stan2009].

EXAMPLES:

```
sage: P = Poset(([1,2], [[1,2]]), linear_extension=True, facade=False)
sage: P.evacuation()
Finite poset containing 2 elements with distinguished linear extension
sage: P.evacuation() == P
True

sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,
↪6]]), linear_extension=True, facade=False)
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 5], [3, 4], [3, 6], [4, 7], [6, 7]]
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2)], [[Integer(1),Integer(2)]]), linear_
↪extension=True, facade=False)
```

(continues on next page)

(continued from previous page)

```
>>> P.evacuation()
Finite poset containing 2 elements with distinguished linear extension
>>> P.evacuation() == P
True

>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6),Integer(7)], [[Integer(1),Integer(2)],[Integer(1),Integer(4)],
↪[Integer(2),Integer(3)],[Integer(2),Integer(5)],[Integer(3),Integer(6)],
↪[Integer(4),Integer(7)],[Integer(5),Integer(6)]]), linear_extension=True,␣
↪facade=False)
>>> P.list()
[1, 2, 3, 4, 5, 6, 7]
>>> Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 3], [2, 5], [3, 4], [3, 6], [4, 7], [6, 7]]
```

Note that the results depend on the linear extension associated to the poset:

```
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,
↪6]]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 3], [5, 6], [5, 4], [6, 7], [4, 7]]
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6),Integer(7)], [[Integer(1),Integer(2)],[Integer(1),Integer(4)],
↪[Integer(2),Integer(3)],[Integer(2),Integer(5)],[Integer(3),Integer(6)],
↪[Integer(4),Integer(7)],[Integer(5),Integer(6)]]))
>>> P.list()
[1, 2, 3, 5, 6, 4, 7]
>>> Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 5], [2, 3], [5, 6], [5, 4], [6, 7], [4, 7]]
```

Here is an example of a poset where the elements are not labelled by $\{1, 2, \ldots, n\}$:

```
sage: P = Poset((divisors(15), attrcall("divides")), linear_extension = True)
sage: P.list()
[1, 3, 5, 15]
sage: Q = P.evacuation(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 3], [1, 5], [3, 15], [5, 15]]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(15)), attrcall("divides")), linear_extension␣
```

(continues on next page)

(continued from previous page)

```
↪= True)
>>> P.list()
[1, 3, 5, 15]
>>> Q = P.evacuation(); Q
Finite poset containing 4 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 3], [1, 5], [3, 15], [5, 15]]
```

- Anne Schilling (2012-02-18)

f_polynomial()

Return the f-polynomial of the poset.

The poset is expected to be bounded.

This is the f-polynomial of the order complex of the poset minus its bounds.

The coefficient of q^i is the number of chains of $i+1$ elements containing both bounds of the poset.

Note

This is slightly different from the `fPolynomial` method in Macaulay2.

EXAMPLES:

```
sage: P = posets.DiamondPoset(5)
sage: P.f_polynomial()
3*q^2 + q

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [7], 6: [7]})
sage: P.f_polynomial()
q^4 + 4*q^3 + 5*q^2 + q
```

```
>>> from sage.all import *
>>> P = posets.DiamondPoset(Integer(5))
>>> P.f_polynomial()
3*q^2 + q

>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(2): [Integer(4)],
↪ Integer(3): [Integer(5)], Integer(4): [Integer(6)], Integer(5):␣
↪[Integer(7)], Integer(6): [Integer(7)]})
```

(continues on next page)

(continued from previous page)

```
>>> P.f_polynomial()
q^4 + 4*q^3 + 5*q^2 + q
```

See also

is_bounded(), *h_polynomial()*, *order_complex()*, sage.topology.cell_complex.GenericCellComplex.f_vector()

factor()

Factor the poset as a Cartesian product of smaller posets.

This only works for connected posets.

The decomposition of a connected poset as a Cartesian product of posets (prime in the sense that they cannot be written as Cartesian products) is unique up to reordering and isomorphism.

OUTPUT: list of posets

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: Q = P*P
sage: Q.factor()
[Finite poset containing 5 elements,
 Finite poset containing 5 elements]

sage: P1 = posets.ChainPoset(3)
sage: P2 = posets.ChainPoset(7)
sage: P1.factor()
[Finite lattice containing 3 elements]
sage: (P1 * P2).factor()
[Finite poset containing 7 elements,
 Finite poset containing 3 elements]

sage: P = posets.TamariLattice(4)
sage: (P*P).factor()
[Finite poset containing 14 elements,
Finite poset containing 14 elements]
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> Q = P*P
>>> Q.factor()
[Finite poset containing 5 elements,
 Finite poset containing 5 elements]

>>> P1 = posets.ChainPoset(Integer(3))
>>> P2 = posets.ChainPoset(Integer(7))
>>> P1.factor()
[Finite lattice containing 3 elements]
>>> (P1 * P2).factor()
[Finite poset containing 7 elements,
```

(continues on next page)

(continued from previous page)

```
 Finite poset containing 3 elements]

>>> P = posets.TamariLattice(Integer(4))
>>> (P*P).factor()
[Finite poset containing 14 elements,
Finite poset containing 14 elements]
```

product()

REFERENCES:

flag_f_polynomial()

Return the flag f-polynomial of the poset.

The poset is expected to be bounded and ranked.

This is the sum, over all chains containing both bounds, of a monomial encoding the ranks of the elements of the chain.

More precisely, if P is a bounded ranked poset, then the flag f-polynomial of P is defined as the polynomial

$$\sum_{\substack{p_0<p_1<\ldots<p_k,\\ p_0=\min P,\ p_k=\max P}} x_{\rho(p_1)}x_{\rho(p_2)}\cdots x_{\rho(p_k)} \in \mathbf{Z}[x_1, x_2, \cdots, x_n],$$

where $\min P$ and $\max P$ are (respectively) the minimum and the maximum of P, where ρ is the rank function of P (normalized to satisfy $\rho(\min P) = 0$), and where n is the rank of $\max P$. (Note that the indeterminate x_0 does not actually appear in the polynomial.)

For technical reasons, the polynomial is returned in the slightly larger ring $\mathbf{Z}[x_0, x_1, x_2, \cdots, x_{n+1}]$ by this method.

See Wikipedia article h-vector.

EXAMPLES:

```
sage: P = posets.DiamondPoset(5)
sage: P.flag_f_polynomial()
3*x1*x2 + x2

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: fl = P.flag_f_polynomial(); fl
2*x1*x2*x3 + 2*x1*x3 + 2*x2*x3 + x3
sage: q = polygen(ZZ,'q')
sage: fl(q,q,q,q) == P.f_polynomial()
True

sage: P = Poset({1: [2, 3, 4], 2: [5], 3: [5], 4: [5], 5: [6]})
sage: P.flag_f_polynomial()
3*x1*x2*x3 + 3*x1*x3 + x2*x3 + x3
```

```
>>> from sage.all import *
>>> P = posets.DiamondPoset(Integer(5))
```

(continues on next page)

(continued from previous page)

```
>>> P.flag_f_polynomial()
3*x1*x2 + x2

>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(2): [Integer(4)],
↪ Integer(3): [Integer(5)], Integer(4): [Integer(6)], Integer(5):␣
↪[Integer(6)]})
>>> fl = P.flag_f_polynomial(); fl
2*x1*x2*x3 + 2*x1*x3 + 2*x2*x3 + x3
>>> q = polygen(ZZ,'q')
>>> fl(q,q,q,q) == P.f_polynomial()
True

>>> P = Poset({Integer(1): [Integer(2), Integer(3), Integer(4)], Integer(2):␣
↪[Integer(5)], Integer(3): [Integer(5)], Integer(4): [Integer(5)],␣
↪Integer(5): [Integer(6)]})
>>> P.flag_f_polynomial()
3*x1*x2*x3 + 3*x1*x3 + x2*x3 + x3
```

See also

is_bounded(), *flag_h_polynomial()*

flag_h_polynomial()

Return the flag h-polynomial of the poset.

The poset is expected to be bounded and ranked.

If P is a bounded ranked poset whose maximal element has rank n (where the minimal element is set to have rank 0), then the flag h-polynomial of P is defined as the polynomial

$$\prod_{k=1}^{n}(1-x_k)\cdot f\left(\frac{x_1}{1-x_1},\frac{x_2}{1-x_2},\cdots,\frac{x_n}{1-x_n}\right)\in\mathbf{Z}[x_1,x_2,\cdots,x_n],$$

where f is the flag f-polynomial of P (see *flag_f_polynomial()*).

For technical reasons, the polynomial is returned in the slightly larger ring $\mathbf{Q}[x_0,x_1,x_2,\cdots,x_{n+1}]$ by this method.

See Wikipedia article h-vector.

EXAMPLES:

```
sage: P = posets.DiamondPoset(5)
sage: P.flag_h_polynomial()
2*x1*x2 + x2

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: fl = P.flag_h_polynomial(); fl
-x1*x2*x3 + x1*x3 + x2*x3 + x3
sage: q = polygen(ZZ,'q')
sage: fl(q,q,q,q) == P.h_polynomial()
True
```

(continues on next page)

(continued from previous page)

```
sage: P = Poset({1: [2, 3, 4], 2: [5], 3: [5], 4: [5], 5: [6]})
sage: P.flag_h_polynomial()
2*x1*x3 + x3

sage: P = posets.ChainPoset(4)
sage: P.flag_h_polynomial()
x3
```

```
>>> from sage.all import *
>>> P = posets.DiamondPoset(Integer(5))
>>> P.flag_h_polynomial()
2*x1*x2 + x2

>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(2): [Integer(4)],
... Integer(3): [Integer(5)], Integer(4): [Integer(6)], Integer(5):␣
...[Integer(6)]})
>>> fl = P.flag_h_polynomial(); fl
-x1*x2*x3 + x1*x3 + x2*x3 + x3
>>> q = polygen(ZZ,'q')
>>> fl(q,q,q,q) == P.h_polynomial()
True

>>> P = Poset({Integer(1): [Integer(2), Integer(3), Integer(4)], Integer(2):␣
...[Integer(5)], Integer(3): [Integer(5)], Integer(4): [Integer(5)],␣
...Integer(5): [Integer(6)]})
>>> P.flag_h_polynomial()
2*x1*x3 + x3

>>> P = posets.ChainPoset(Integer(4))
>>> P.flag_h_polynomial()
x3
```

See also

is_bounded(), *flag_f_polynomial()*

frank_network()

Return Frank's network of the poset.

This is defined in Section 8 of [BF1999].

OUTPUT:

A pair (G, e), where G is Frank's network of P encoded as a `DiGraph`, and e is the cost function on its edges encoded as a dictionary (indexed by these edges, which in turn are encoded as tuples of 2 vertices).

Note

Frank's network of P is a certain directed graph with $2|P|+2$ vertices, defined in Section 8 of [BF1999]. Its set of vertices consists of two vertices $(0, p)$ and $(1, p)$ for each element p of P, as well as two vertices $(-1, 0)$ and $(2, 0)$. (These notations are not the ones used in [BF1999]; see the table below for their

relation.) The edges are:

- for each p in P, an edge from $(-1, 0)$ to $(0, p)$;
- for each p in P, an edge from $(1, p)$ to $(2, 0)$;
- for each p and q in P such that $p \geq q$, an edge from $(0, p)$ to $(1, q)$.

We make this digraph into a network in the sense of flow theory as follows: The vertex $(-1, 0)$ is considered as the source of this network, and the vertex $(2, 0)$ as the sink. The cost function is defined to be 1 on the edge from $(0, p)$ to $(1, p)$ for each $p \in P$, and to be 0 on every other edge. The capacity is 1 on each edge. Here is how to translate this notations into that used in [BF1999]:

```
our notations                    [BF1999]
   (-1, 0)                         s
   (0, p)                        x_p
   (1, p)                        y_p
   (2, 0)                         t
    a[e]                         a(e)
```

EXAMPLES:

```
sage: ps = [[16,12,14,-13],[[12,14],[14,-13],[12,16],[16,-13]]]
sage: G, e = Poset(ps).frank_network()

AUTHOR:

- Darij Grinberg (2013-05-09)

ge(*x*, *y*)

alias of *is_gequal()*.

graphviz_string(*graph_string='graph'*, *edge_string='--'*)

Return a representation in the DOT language, ready to render in graphviz.

See http://www.graphviz.org/doc/info/lang.html for more information about graphviz.

EXAMPLES:

```
sage: P = Poset({'a':['b'],'b':['d'],'c':['d'],'d':['f'],'e':['f'],'f':[]})
sage: print(P.graphviz_string())
graph {
"f";"d";"b";"a";"c";"e";
"f"--"e";"d"--"c";"b"--"a";"d"--"b";"f"--"d";
}
```

```
>>> from sage.all import *
>>> P = Poset({'a':['b'],'b':['d'],'c':['d'],'d':['f'],'e':['f'],'f':[]})
>>> print(P.graphviz_string())
graph {
"f";"d";"b";"a";"c";"e";
"f"--"e";"d"--"c";"b"--"a";"d"--"b";"f"--"d";
}
```

greene_shape()

Return the Greene-Kleitman partition of `self`.

The Greene-Kleitman partition of a finite poset P is the partition $(c_1 - c_0, c_2 - c_1, c_3 - c_2, \ldots)$, where c_k is the maximum cardinality of a union of k chains of P. Equivalently, this is the conjugate of the partition $(a_1 - a_0, a_2 - a_1, a_3 - a_2, \ldots)$, where a_k is the maximum cardinality of a union of k antichains of P.

See many sources, e. g., [BF1999], for proofs of this equivalence.

EXAMPLES:

```
sage: # needs sage.combinat
sage: P = Poset([[3,2,1], [[3,1],[2,1]]])
sage: P.greene_shape()
[2, 1]
sage: P = Poset([[1,2,3,4], [[1,4],[2,4],[4,3]]])
sage: P.greene_shape()
[3, 1]
sage: P = Poset([[1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22],
....:             [[1,4],[2,4],[4,3]]])
sage: P.greene_shape()
```

(continues on next page)

(continued from previous page)

```
[3, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: P = Poset([[],[]])
sage: P.greene_shape()
[]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> P = Poset([[Integer(3),Integer(2),Integer(1)], [[Integer(3),Integer(1)],
↪[Integer(2),Integer(1)]]])
>>> P.greene_shape()
[2, 1]
>>> P = Poset([[Integer(1),Integer(2),Integer(3),Integer(4)], [[Integer(1),
↪Integer(4)],[Integer(2),Integer(4)],[Integer(4),Integer(3)]]])
>>> P.greene_shape()
[3, 1]
>>> P = Poset([[Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6),Integer(7),Integer(8),Integer(9),Integer(10),Integer(11),
↪Integer(12),Integer(13),Integer(14),Integer(15),Integer(16),Integer(17),
↪Integer(18),Integer(19),Integer(20),Integer(21),Integer(22)],
...             [[Integer(1),Integer(4)],[Integer(2),Integer(4)],[Integer(4),
↪Integer(3)]]])
>>> P.greene_shape()
[3, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
>>> P = Poset([[],[]])
>>> P.greene_shape()
[]
```

gt(*x*, *y*)

alias of *is_greater_than()*.

h_polynomial()

Return the h-polynomial of a bounded poset `self`.

This is the h-polynomial of the order complex of the poset minus its bounds.

This is related to the f-polynomial by a simple change of variables:

$$h(q) = (1-q)^{\deg f} f\left(\frac{q}{1-q}\right),$$

where f and h denote the f-polynomial and the h-polynomial, respectively.

See Wikipedia article h-vector.

Warning

This is slightly different from the `hPolynomial` method in Macaulay2.

EXAMPLES:

```
sage: P = posets.AntichainPoset(3).order_ideals_lattice()
sage: P.h_polynomial()
q^3 + 4*q^2 + q
sage: P = posets.DiamondPoset(5)
sage: P.h_polynomial()
2*q^2 + q
sage: P = Poset({1: []})
sage: P.h_polynomial()
1
```

```
>>> from sage.all import *
>>> P = posets.AntichainPoset(Integer(3)).order_ideals_lattice()
>>> P.h_polynomial()
q^3 + 4*q^2 + q
>>> P = posets.DiamondPoset(Integer(5))
>>> P.h_polynomial()
2*q^2 + q
>>> P = Poset({Integer(1): []})
>>> P.h_polynomial()
1
```

See also

is_bounded(), *f_polynomial()*, *order_complex()*, sage.topology.simplicial_complex.SimplicialComplex.h_vector()

has_bottom()

Return `True` if the poset has a unique minimal element, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1], 1:[]})
sage: Q.has_bottom()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)], Integer(1):[Integer(3)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> P.has_bottom()
False
>>> Q = Poset({Integer(0):[Integer(1)], Integer(1):[]})
>>> Q.has_bottom()
True
```

See also

- Dual Property: *has_top()*

- Stronger properties: *is_bounded()*
- Other: *bottom()*

has_isomorphic_subposet(*other*)

Return `True` if the poset contains a subposet isomorphic to `other`.

By subposet we mean that there exist a set `X` of elements such that `self.subposet(X)` is isomorphic to `other`.

INPUT:

- `other` – a finite poset

EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: T = Poset({1:[2,3], 2:[4,5], 3:[6,7]})
sage: N5 = posets.PentagonPoset()

sage: N5.has_isomorphic_subposet(T)
False
sage: N5.has_isomorphic_subposet(D)
True

sage: len([P for P in Posets(5) if P.has_isomorphic_subposet(D)])
11
```

```
>>> from sage.all import *
>>> D = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4)],␣
↪Integer(3):[Integer(4)]})
>>> T = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4),
↪Integer(5)], Integer(3):[Integer(6),Integer(7)]})
>>> N5 = posets.PentagonPoset()

>>> N5.has_isomorphic_subposet(T)
False
>>> N5.has_isomorphic_subposet(D)
True

>>> len([P for P in Posets(Integer(5)) if P.has_isomorphic_subposet(D)])
11
```

has_top()

Return `True` if the poset has a unique maximal element, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: Q.has_top()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)], Integer(1):[Integer(3)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4), Integer(5)], Integer(4):[],
↪ Integer(5):[]})
>>> P.has_top()
False
>>> Q = Poset({Integer(0):[Integer(3)], Integer(1):[Integer(3)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> Q.has_top()
True
```

See also

- Dual Property: *has_bottom()*
- Stronger properties: *is_bounded()*
- Other: *top()*

hasse_diagram()

Return the Hasse diagram of the poset as a Sage DiGraph.

The Hasse diagram is a directed graph where vertices are the elements of the poset and there is an edge from u to v whenever v covers u in the poset.

If dot2tex is installed, then this sets the Hasse diagram's latex options to use the dot2tex formatting.

EXAMPLES:

```
sage: P = posets.DivisorLattice(12)
sage: H = P.hasse_diagram(); H
Digraph on 6 vertices
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: H.edges(sort=True, labels=False)
[(1, 2), (1, 3), (2, 4), (2, 6), (3, 6), (4, 12), (6, 12)]
```

```
>>> from sage.all import *
>>> P = posets.DivisorLattice(Integer(12))
>>> H = P.hasse_diagram(); H
Digraph on 6 vertices
>>> P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
>>> H.edges(sort=True, labels=False)
[(1, 2), (1, 3), (2, 4), (2, 6), (3, 6), (4, 12), (6, 12)]
```

height(*certificate=False*)

Return the height (number of elements in a longest chain) of the poset.

INPUT:

- certificate – boolean (default: False); whether to return a certificate

OUTPUT:

- If `certificate=True` return `(h, c)`, where `h` is the height and `c` is a chain of maximum cardinality. If `certificate=False` return only the height.

EXAMPLES:

```
sage: P = Poset({0: [1], 2: [3, 4], 4: [5, 6]})
sage: P.height()
3
sage: posets.PentagonPoset().height(certificate=True)
(4, [0, 2, 3, 4])
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1)], Integer(2): [Integer(3), Integer(4)],
↪ Integer(4): [Integer(5), Integer(6)]})
>>> P.height()
3
>>> posets.PentagonPoset().height(certificate=True)
(4, [0, 2, 3, 4])
```

incidence_algebra(*R*, *prefix='I'*)

Return the incidence algebra of `self` over `R`.

OUTPUT: an instance of *sage.combinat.posets.incidence_algebras.IncidenceAlgebra*

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: P.incidence_algebra(QQ)
Incidence algebra of Finite lattice containing 16 elements
 over Rational Field
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> P.incidence_algebra(QQ)
Incidence algebra of Finite lattice containing 16 elements
 over Rational Field
```

incomparability_graph()

Return the incomparability graph of the poset.

This is the complement of the comparability graph, i.e. an undirected graph where vertices are the elements of the poset and there is an edge between vertices if they are not comparable in the poset.

EXAMPLES:

```
sage: Y = Poset({1: [2], 2: [3, 4]})
sage: g = Y.incomparability_graph(); g
Incomparability graph on 4 vertices
sage: Y.compare_elements(1, 3) is not None
True
sage: g.has_edge(1, 3)
False
```

```
>>> from sage.all import *
>>> Y = Poset({Integer(1): [Integer(2)], Integer(2): [Integer(3), Integer(4)]}
```

(continues on next page)

(continued from previous page)

```
↪)
>>> g = Y.incomparability_graph(); g
Incomparability graph on 4 vertices
>>> Y.compare_elements(Integer(1), Integer(3)) is not None
True
>>> g.has_edge(Integer(1), Integer(3))
False
```

See also

comparability_graph()

interval (x, y)

Return a list of the elements z such that $x \leq z \leq y$.

INPUT:

- `x` – any element of the poset
- `y` – any element of the poset

See also

open_interval()

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: P = Poset(dag)
sage: I = set(map(P,[2,5,6,4,7]))
sage: I == set(P.interval(2,7))
True
```

```
>>> from sage.all import *
>>> uc = [[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
↪Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
↪[]]
>>> dag = DiGraph(dict(zip(range(len(uc)),uc)))
>>> P = Poset(dag)
>>> I = set(map(P,[Integer(2),Integer(5),Integer(6),Integer(4),Integer(7)]))
>>> I == set(P.interval(Integer(2),Integer(7)))
True
```

```
sage: dg = DiGraph({"a":["b","c"], "b":["d"], "c":["d"]})
sage: P = Poset(dg, facade = False)
sage: P.interval("a","d")
[a, b, c, d]
```

```
>>> from sage.all import *
>>> dg = DiGraph({"a":["b","c"], "b":["d"], "c":["d"]})
>>> P = Poset(dg, facade = False)
>>> P.interval("a","d")
[a, b, c, d]
```

interval_as_poset(x, y)

Return the subposet of elements z such that $x \leq z \leq y$.

INPUT:

- `x` – any element of the poset
- `y` – any element of the poset

See also

interval(), *open_interval()*, *subposet()*

This tries to preserve the category if possible. In particular, the output is a lattice when the poset is a lattice.

EXAMPLES:

```
sage: W = Permutations(4)
sage: P = W.weak_lattice()
sage: Q = P.interval_as_poset(Permutation([1,2,4,3]),P.top()); Q
Finite lattice containing 12 elements
sage: Q.category()
Category of finite enumerated chain graded lattice posets

sage: P = posets.TamariLattice(4)
sage: Q = P.interval_as_poset((1,0,1,1,0,0,1,0,0),P.top()); Q
Finite lattice containing 7 elements
sage: Q.category()
Category of facade finite enumerated trim congruence uniform
lattice posets

sage: P = posets.BooleanLattice(2).order_ideals_lattice()
sage: Q = P.interval_as_poset(Set([0]),P.top()); Q
Finite lattice containing 5 elements
sage: Q.category()
Category of facade finite enumerated distributive lattices
```

```
>>> from sage.all import *
>>> W = Permutations(Integer(4))
>>> P = W.weak_lattice()
>>> Q = P.interval_as_poset(Permutation([Integer(1),Integer(2),Integer(4),
↪Integer(3)]),P.top()); Q
Finite lattice containing 12 elements
>>> Q.category()
Category of finite enumerated chain graded lattice posets

>>> P = posets.TamariLattice(Integer(4))
```

(continues on next page)

(continued from previous page)

```
>>> Q = P.interval_as_poset((Integer(1),Integer(0),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(1),Integer(0),Integer(0)),P.top()); Q
Finite lattice containing 7 elements
>>> Q.category()
Category of facade finite enumerated trim congruence uniform
lattice posets

>>> P = posets.BooleanLattice(Integer(2)).order_ideals_lattice()
>>> Q = P.interval_as_poset(Set([Integer(0)]),P.top()); Q
Finite lattice containing 5 elements
>>> Q.category()
Category of facade finite enumerated distributive lattices
```

intervals_number()

alias of *number_of_relations()*.

intervals_poset()

Return the natural partial order on the set of intervals of the poset.

OUTPUT: a finite poset

The poset of intervals of a poset P has the set of intervals $[x, y]$ in P as elements, endowed with the order relation defined by $[x_1, y_1] \leq [x_2, y_2]$ if and only if $x_1 \leq x_2$ and $y_1 \leq y_2$.

This is also called P to the power *2*, meaning the poset of poset-morphisms from the 2-chain to P.

If P is a lattice, the result is also a lattice.

EXAMPLES:

```
sage: P = Poset({0:[1]})
sage: P.intervals_poset()
Finite poset containing 3 elements

sage: P = posets.PentagonPoset()
sage: P.intervals_poset()
Finite lattice containing 13 elements
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(1)]})
>>> P.intervals_poset()
Finite poset containing 3 elements

>>> P = posets.PentagonPoset()
>>> P.intervals_poset()
Finite lattice containing 13 elements
```

is_EL_labelling(*f*, *return_raising_chains=False*)

Return `True` if `f` is an EL labelling of `self`.

A labelling f of the edges of the Hasse diagram of a poset is called an EL labelling (edge lexicographic labelling) if for any two elements u and v with $u \leq v$,

- there is a unique f-raising chain from u to v in the Hasse diagram, and this chain is lexicographically first among all chains from u to v.

For more details, see [Bj1980].

INPUT:

- `f` – a function taking two elements `a` and `b` in `self` such that `b` covers `a` and returning elements in a totally ordered set.
- `return_raising_chains` (optional; default: `False`) if `True`, returns the set of all raising chains in `self`, if possible.

EXAMPLES:

Let us consider a Boolean poset:

```
sage: P = Poset([[(0,0),(0,1),(1,0),(1,1)],[[(0,0),(0,1)],[(0,0),(1,0)],[(0,
↪1),(1,1)],[(1,0),(1,1)]]],facade=True)
sage: label = lambda a,b: min( i for i in [0,1] if a[i] != b[i] )
sage: P.is_EL_labelling(label)
True
sage: P.is_EL_labelling(label,return_raising_chains=True)
{((0, 0), (0, 1)): [1],
 ((0, 0), (1, 0)): [0],
 ((0, 0), (1, 1)): [0, 1],
 ((0, 1), (1, 1)): [0],
 ((1, 0), (1, 1)): [1]}
```

```
>>> from sage.all import *
>>> P = Poset([[(Integer(0),Integer(0)),(Integer(0),Integer(1)),(Integer(1),
↪Integer(0)),(Integer(1),Integer(1))],[[(Integer(0),Integer(0)),(Integer(0),
↪Integer(1))],[(Integer(0),Integer(0)),(Integer(1),Integer(0))],[(Integer(0),
↪Integer(1)),(Integer(1),Integer(1))],[(Integer(1),Integer(0)),(Integer(1),
↪Integer(1))]]],facade=True)
>>> label = lambda a,b: min( i for i in [Integer(0),Integer(1)] if a[i] !=␣
↪b[i] )
>>> P.is_EL_labelling(label)
True
>>> P.is_EL_labelling(label,return_raising_chains=True)
{((0, 0), (0, 1)): [1],
 ((0, 0), (1, 0)): [0],
 ((0, 0), (1, 1)): [0, 1],
 ((0, 1), (1, 1)): [0],
 ((1, 0), (1, 1)): [1]}
```

is_antichain_of_poset(*elms*)

Return `True` if `elms` is an antichain of the poset and `False` otherwise.

Set of elements are an *antichain* of a poset if they are pairwise incomparable.

EXAMPLES:

```
sage: P = posets.BooleanLattice(5)
sage: P.is_antichain_of_poset([3, 5, 7])
False
sage: P.is_antichain_of_poset([3, 5, 14])
True
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(5))
>>> P.is_antichain_of_poset([Integer(3), Integer(5), Integer(7)])
False
>>> P.is_antichain_of_poset([Integer(3), Integer(5), Integer(14)])
True
```

is_bounded()

Return `True` if the poset is bounded, and `False` otherwise.

A poset is bounded if it contains both a unique maximal element and a unique minimal element.

EXAMPLES:

```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.is_bounded()
False
sage: Q = posets.DiamondPoset(5)
sage: Q.is_bounded()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)], Integer(1):[Integer(3)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4), Integer(5)], Integer(4):[],
↪ Integer(5):[]})
>>> P.is_bounded()
False
>>> Q = posets.DiamondPoset(Integer(5))
>>> Q.is_bounded()
True
```

See also

- Weaker properties: *has_bottom()*, *has_top()*
- Other: *with_bounds()*, *without_bounds()*

is_chain()

Return `True` if the poset is totally ordered ("chain"), and `False` otherwise.

EXAMPLES:

```
sage: I = Poset({0:[1], 1:[2], 2:[3], 3:[4]})
sage: I.is_chain()
True

sage: II = Poset({0:[1], 2:[3]})
sage: II.is_chain()
False

sage: V = Poset({0:[1, 2]})
sage: V.is_chain()
False
```

```
>>> from sage.all import *
>>> I = Poset({Integer(0):[Integer(1)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)]})
>>> I.is_chain()
True

>>> II = Poset({Integer(0):[Integer(1)], Integer(2):[Integer(3)]})
>>> II.is_chain()
False

>>> V = Poset({Integer(0):[Integer(1), Integer(2)]})
>>> V.is_chain()
False
```

is_chain_of_poset(*elms*, *ordered=False*)

Return `True` if `elms` is a chain of the poset, and `False` otherwise.

Set of elements are a *chain* of a poset if they are comparable to each other.

INPUT:

- `elms` – list or other iterable containing some elements of the poset
- `ordered` – boolean; if `True`, then return `True` only if elements in `elms` are strictly increasing in the poset. This makes no sense if `elms` is a set. If `False` (the default), then elements can be repeated and be in any order.

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: sorted(P.list())
[1, 2, 3, 4, 6, 12]
sage: P.is_chain_of_poset([12, 3])
True
sage: P.is_chain_of_poset({3, 4, 12})
False
sage: P.is_chain_of_poset([12, 3], ordered=True)
False
sage: P.is_chain_of_poset((1, 1, 3))
True
sage: P.is_chain_of_poset((1, 1, 3), ordered=True)
False
sage: P.is_chain_of_poset((1, 3), ordered=True)
True
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")))
>>> sorted(P.list())
[1, 2, 3, 4, 6, 12]
>>> P.is_chain_of_poset([Integer(12), Integer(3)])
True
>>> P.is_chain_of_poset({Integer(3), Integer(4), Integer(12)})
False
>>> P.is_chain_of_poset([Integer(12), Integer(3)], ordered=True)
False
```

(continues on next page)

(continued from previous page)

```
>>> P.is_chain_of_poset((Integer(1), Integer(1), Integer(3)))
True
>>> P.is_chain_of_poset((Integer(1), Integer(1), Integer(3)), ordered=True)
False
>>> P.is_chain_of_poset((Integer(1), Integer(3)), ordered=True)
True
```

is_connected()

Return `True` if the poset is connected, and `False` otherwise.

A poset is connected if its Hasse diagram is connected.

If a poset is not connected, then it can be divided to parts S_1 and S_2 so that every element of S_1 is incomparable to every element of S_2.

EXAMPLES:

```
sage: P = Poset({1:[2, 3], 3:[4, 5]})
sage: P.is_connected()
True

sage: P = Poset({1:[2, 3], 3:[4, 5], 6:[7, 8]})
sage: P.is_connected()
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1):[Integer(2), Integer(3)], Integer(3):[Integer(4),␣
↪Integer(5)]})
>>> P.is_connected()
True

>>> P = Poset({Integer(1):[Integer(2), Integer(3)], Integer(3):[Integer(4),␣
↪Integer(5)], Integer(6):[Integer(7), Integer(8)]})
>>> P.is_connected()
False
```

See also

connected_components()

is_d_complete()

Return `True` if a poset is d-complete and `False` otherwise.

See also

- *d_complete*

EXAMPLES:

```
sage: from sage.combinat.posets.posets import FinitePoset
sage: A = Poset({0: [1,2]})

sage: B = Posets.DoubleTailedDiamond(3)
sage: B.is_d_complete()
True

sage: C = Poset({0: [2], 1: [2], 2: [3, 4], 3: [5], 4: [5], 5: [6]})
sage: C.is_d_complete()
False

sage: D = Poset({0: [1, 2], 1: [4], 2: [4], 3: [4]})
sage: D.is_d_complete()
False

sage: P = Posets.YoungDiagramPoset(Partition([3, 2, 2]), dual=True)          #␣
↪needs sage.combinat
sage: P.is_d_complete()                                                      #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.posets import FinitePoset
>>> A = Poset({Integer(0): [Integer(1),Integer(2)]})
>>> A.is_d_complete()
False

>>> from sage.combinat.posets.poset_examples import Posets
>>> B = Posets.DoubleTailedDiamond(Integer(3))
>>> B.is_d_complete()
True

>>> C = Poset({Integer(0): [Integer(2)], Integer(1): [Integer(2)],␣
↪Integer(2): [Integer(3), Integer(4)], Integer(3): [Integer(5)], Integer(4):␣
↪[Integer(5)], Integer(5): [Integer(6)]})
>>> C.is_d_complete()
False

>>> D = Poset({Integer(0): [Integer(1), Integer(2)], Integer(1): [Integer(4)],
↪ Integer(2): [Integer(4)], Integer(3): [Integer(4)]})
>>> D.is_d_complete()
False

>>> P = Posets.YoungDiagramPoset(Partition([Integer(3), Integer(2),␣
↪Integer(2)]), dual=True)          # needs sage.combinat
>>> P.is_d_complete()                                                        #␣
↪needs sage.combinat
True
```

is_eulerian(*k=None*, *certificate=False*)

Return `True` if the poset is Eulerian, and `False` otherwise.

The poset is expected to be graded and bounded.

A poset is Eulerian if every non-trivial interval has the same number of elements of even rank as of odd rank. A poset is k-eulerian if every non-trivial interval up to rank k is Eulerian.

See Wikipedia article Eulerian_poset.

INPUT:

- `k` – integer; only check if the poset is k-eulerian. If `None` (the default), check if the poset is Eulerian.
- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `True, None` or `False, (a, b)`, where the interval `(a, b)` is not Eulerian. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: P = Poset({0: [1, 2, 3], 1: [4, 5], 2: [4, 6], 3: [5, 6],
....:            4: [7, 8], 5: [7, 8], 6: [7, 8], 7: [9], 8: [9]})
sage: P.is_eulerian()                                                       #␣
↪needs sage.libs.flint
True
sage: P = Poset({0: [1, 2, 3], 1: [4, 5, 6], 2: [4, 6], 3: [5,6],
....:            4: [7], 5:[7], 6:[7]})
sage: P.is_eulerian()                                                       #␣
↪needs sage.libs.flint
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1), Integer(2), Integer(3)], Integer(1):␣
↪[Integer(4), Integer(5)], Integer(2): [Integer(4), Integer(6)], Integer(3):␣
↪[Integer(5), Integer(6)],
...            Integer(4): [Integer(7), Integer(8)], Integer(5): [Integer(7),␣
↪Integer(8)], Integer(6): [Integer(7), Integer(8)], Integer(7): [Integer(9)],
↪ Integer(8): [Integer(9)]})
>>> P.is_eulerian()                                                         #␣
↪needs sage.libs.flint
True
>>> P = Poset({Integer(0): [Integer(1), Integer(2), Integer(3)], Integer(1):␣
↪[Integer(4), Integer(5), Integer(6)], Integer(2): [Integer(4), Integer(6)],␣
↪Integer(3): [Integer(5),Integer(6)],
...            Integer(4): [Integer(7)], Integer(5):[Integer(7)],␣
↪Integer(6):[Integer(7)]})
>>> P.is_eulerian()                                                         #␣
↪needs sage.libs.flint
False
```

Canonical examples of Eulerian posets are the face lattices of convex polytopes:

```
sage: P = polytopes.cube().face_lattice()                                   #␣
↪needs sage.geometry.polyhedron
sage: P.is_eulerian()                                                       #␣
↪needs sage.geometry.polyhedron sage.libs.flint
True
```

```
>>> from sage.all import *
>>> P = polytopes.cube().face_lattice()                                    #␣
↪needs sage.geometry.polyhedron
>>> P.is_eulerian()                                                        #␣
↪needs sage.geometry.polyhedron sage.libs.flint
True
```

A poset that is 3- but not 4-eulerian:

```
sage: P = Poset(DiGraph('MWW@_?W?@_?W??@??O@_?W?@_?W?@??O??')); P
Finite poset containing 14 elements
sage: P.is_eulerian(k=3)                                                   #␣
↪needs sage.libs.flint
True
sage: P.is_eulerian(k=4)                                                   #␣
↪needs sage.libs.flint
False
```

```
>>> from sage.all import *
>>> P = Poset(DiGraph('MWW@_?W?@_?W??@??O@_?W?@_?W?@??O??')); P
Finite poset containing 14 elements
>>> P.is_eulerian(k=Integer(3))                                             ␣
↪     # needs sage.libs.flint
True
>>> P.is_eulerian(k=Integer(4))                                             ␣
↪     # needs sage.libs.flint
False
```

Getting an interval that is not Eulerian:

```
sage: P = posets.DivisorLattice(12)
sage: P.is_eulerian(certificate=True)                                      #␣
↪needs sage.libs.flint
(False, (1, 4))
```

```
>>> from sage.all import *
>>> P = posets.DivisorLattice(Integer(12))
>>> P.is_eulerian(certificate=True)                                        #␣
↪needs sage.libs.flint
(False, (1, 4))
```

is_gequal(x, y)

Return `True` if x is greater than or equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> P.is_gequal(Integer(3), Integer(1))
True
>>> P.is_gequal(Integer(2), Integer(2))
True
>>> P.is_gequal(Integer(0), Integer(1))
False
```

See also

is_greater_than(), *is_lequal()*.

is_graded()

Return `True` if the poset is graded, and `False` otherwise.

A poset is graded if all its maximal chains have the same length.

There are various competing definitions for graded posets (see Wikipedia article Graded_poset). This definition is from section 3.1 of Richard Stanley's *Enumerative Combinatorics, Vol. 1* [EnumComb1]. Some sources call these posets *tiered*.

Every graded poset is ranked. The converse is true for bounded posets, including lattices.

EXAMPLES:

```
sage: P = posets.PentagonPoset()  # Not even ranked
sage: P.is_graded()
False

sage: P = Poset({1:[2, 3], 3:[4]})  # Ranked, but not graded
sage: P.is_graded()
False

sage: P = Poset({1:[3, 4], 2:[3, 4], 5:[6]})
sage: P.is_graded()
True

sage: P = Poset([[1], [2], [], [4], []])
sage: P.is_graded()
False
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()  # Not even ranked
>>> P.is_graded()
False

>>> P = Poset({Integer(1):[Integer(2), Integer(3)], Integer(3):[Integer(4)]})␣
↪ # Ranked, but not graded
>>> P.is_graded()
False
```

(continues on next page)

(continued from previous page)

```
>>> P = Poset({Integer(1):[Integer(3), Integer(4)], Integer(2):[Integer(3),␣
↪Integer(4)], Integer(5):[Integer(6)]})
>>> P.is_graded()
True

>>> P = Poset([[Integer(1)], [Integer(2)], [], [Integer(4)], []])
>>> P.is_graded()
False
```

See also

is_ranked(), *level_sets()*

is_greater_than(*x*, *y*)

Return `True` if x is greater than but not equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_greater_than(3, 1)
True
sage: P.is_greater_than(1, 2)
False
sage: P.is_greater_than(3, 3)
False
sage: P.is_greater_than(0, 1)
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> P.is_greater_than(Integer(3), Integer(1))
True
>>> P.is_greater_than(Integer(1), Integer(2))
False
>>> P.is_greater_than(Integer(3), Integer(3))
False
>>> P.is_greater_than(Integer(0), Integer(1))
False
```

For non-facade posets also > works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(2) > P(3)
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(3): [Integer(1), Integer(2)]}, facade=False)
>>> P(Integer(2)) > P(Integer(3))
True
```

See also

is_gequal(), *is_less_than()*.

is_greedy(*certificate=False*)

Return `True` if the poset is greedy, and `False` otherwise.

A poset is *greedy* if every greedy linear extension has the same number of jumps.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (A, B))` where A and B are greedy linear extension so that B has more jumps. If `certificate=False` return `True` or `False`.

EXAMPLES:

This is not a self-dual property:

```
sage: W = Poset({1: [3, 4], 2: [4, 5]})
sage: M = W.dual()
sage: W.is_greedy()
True
sage: M.is_greedy()
False
```

```
>>> from sage.all import *
>>> W = Poset({Integer(1): [Integer(3), Integer(4)], Integer(2): [Integer(4),␣
↪Integer(5)]})
>>> M = W.dual()
>>> W.is_greedy()
True
>>> M.is_greedy()
False
```

Getting a certificate:

```
sage: N = Poset({1: [3], 2: [3, 4]})
sage: N.is_greedy(certificate=True)
(False, ([1, 2, 4, 3], [2, 4, 1, 3]))
```

```
>>> from sage.all import *
>>> N = Poset({Integer(1): [Integer(3)], Integer(2): [Integer(3), Integer(4)]}
↪)
>>> N.is_greedy(certificate=True)
(False, ([1, 2, 4, 3], [2, 4, 1, 3]))
```

is_incomparable_chain_free(*m*, *n=None*)

Return `True` if the poset is $(m+n)$-free, and `False` otherwise.

A poset is $(m+n)$-free if there is no incomparable chains of lengths m and n. Three cases have special name (see [EnumComb1], exercise 3.15):

- "interval order" is $(2+2)$-free

- "semiorder" (or "unit interval order") is $(1+3)$-free and $(2+2)$-free
- "weak order" is $(1+2)$-free.

INPUT:

- `m`, `n` – positive integers

It is also possible to give a list of integer pairs as argument. See below for an example.

EXAMPLES:

```
sage: B3 = posets.BooleanLattice(3)
sage: B3.is_incomparable_chain_free(1, 3)
True
sage: B3.is_incomparable_chain_free(2, 2)
False

sage: IP6 = posets.IntegerPartitions(6)                                 #␣
↪needs sage.combinat
sage: IP6.is_incomparable_chain_free(1, 3)                              #␣
↪needs sage.combinat
False
sage: IP6.is_incomparable_chain_free(2, 2)                              #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> B3 = posets.BooleanLattice(Integer(3))
>>> B3.is_incomparable_chain_free(Integer(1), Integer(3))
True
>>> B3.is_incomparable_chain_free(Integer(2), Integer(2))
False

>>> IP6 = posets.IntegerPartitions(Integer(6))                          ␣
↪     # needs sage.combinat
>>> IP6.is_incomparable_chain_free(Integer(1), Integer(3))              ␣
↪              # needs sage.combinat
False
>>> IP6.is_incomparable_chain_free(Integer(2), Integer(2))              ␣
↪              # needs sage.combinat
True
```

A list of pairs as an argument:

```
sage: B3.is_incomparable_chain_free([[1, 3], [2, 2]])
False
```

```
>>> from sage.all import *
>>> B3.is_incomparable_chain_free([[Integer(1), Integer(3)], [Integer(2),␣
↪Integer(2)]])
False
```

We show how to get an incomparable chain pair:

```
sage: P = posets.PentagonPoset()
sage: chains_1_2 = Poset({0:[], 1:[2]})
sage: incomps = P.isomorphic_subposets(chains_1_2)[0]
sage: sorted(incomps.list()), incomps.cover_relations()
([1, 2, 3], [[2, 3]])
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> chains_1_2 = Poset({Integer(0):[], Integer(1):[Integer(2)]})
>>> incomps = P.isomorphic_subposets(chains_1_2)[Integer(0)]
>>> sorted(incomps.list()), incomps.cover_relations()
([1, 2, 3], [[2, 3]])
```

AUTHOR:

- Eric Rowland (2013-05-28)

is_induced_subposet(*other*)

Return `True` if the poset is an induced subposet of `other`, and `False` otherwise.

A poset P is an induced subposet of Q if every element of P is an element of Q, and $x \leq_P y$ iff $x \leq_Q y$. Note that "induced" here has somewhat different meaning compared to that of graphs.

INPUT:

- `other` – poset

Note

This method does not check whether the poset is a *isomorphic* (i.e., up to relabeling) subposet of `other`, but only if `other` directly contains the poset as an induced subposet. For isomorphic subposets see *has_isomorphic_subposet()*.

EXAMPLES:

```
sage: P = Poset({1:[2, 3]})
sage: Q = Poset({1:[2, 4], 2:[3]})
sage: P.is_induced_subposet(Q)
False
sage: R = Poset({0:[1], 1:[3, 4], 3:[5], 4:[2]})
sage: P.is_induced_subposet(R)
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1):[Integer(2), Integer(3)]})
>>> Q = Poset({Integer(1):[Integer(2), Integer(4)], Integer(2):[Integer(3)]})
>>> P.is_induced_subposet(Q)
False
>>> R = Poset({Integer(0):[Integer(1)], Integer(1):[Integer(3), Integer(4)],␣
↪Integer(3):[Integer(5)], Integer(4):[Integer(2)]})
>>> P.is_induced_subposet(R)
True
```

is_isomorphic(*other*, ***kwds*)

Return `True` if both posets are isomorphic.

EXAMPLES:

```
sage: P = Poset(([1,2,3],[[1,3],[2,3]]))
sage: Q = Poset(([4,5,6],[[4,6],[5,6]]))
sage: P.is_isomorphic(Q)
True
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3)],[[Integer(1),Integer(3)],
↪[Integer(2),Integer(3)]]))
>>> Q = Poset(([Integer(4),Integer(5),Integer(6)],[[Integer(4),Integer(6)],
↪[Integer(5),Integer(6)]]))
>>> P.is_isomorphic(Q)
True
```

is_join_semilattice(*certificate=False*)

Return `True` if the poset has a join operation, and `False` otherwise.

A join is the least upper bound for given elements, if it exists.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (a, b))` where elements a and b have no least upper bound. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: P = Poset([[1,3,2], [4], [4,5,6], [6], [7], [7], [7], []])
sage: P.is_join_semilattice()
True

sage: P = Poset({1:[3, 4], 2:[3, 4], 3:[5], 4:[5]})
sage: P.is_join_semilattice()
False
sage: P.is_join_semilattice(certificate=True)
(False, (2, 1))
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(3),Integer(2)], [Integer(4)], [Integer(4),
↪Integer(5),Integer(6)], [Integer(6)], [Integer(7)], [Integer(7)],␣
↪[Integer(7)], []])
>>> P.is_join_semilattice()
True

>>> P = Poset({Integer(1):[Integer(3), Integer(4)], Integer(2):[Integer(3),␣
↪Integer(4)], Integer(3):[Integer(5)], Integer(4):[Integer(5)]})
>>> P.is_join_semilattice()
False
>>> P.is_join_semilattice(certificate=True)
(False, (2, 1))
```

See also

- Dual property: *is_meet_semilattice()*
- Stronger properties: is_lattice()

is_jump_critical(*certificate=False*)

Return True if the poset is jump-critical, and False otherwise.

A poset P is *jump-critical* if every proper subposet has smaller jump number.

INPUT:

- certificate – boolean (default: False); whether to return a certificate

OUTPUT:

- If certificate=True return either (True, None) or (False, e) so that removing element e from the poset does not decrease the jump number. If certificate=False return True or False.

EXAMPLES:

```
sage: P = Poset({1: [3, 6], 2: [3, 4, 5], 4: [6, 7], 5: [7]})
sage: P.is_jump_critical()
True

sage: P = posets.PentagonPoset()
sage: P.is_jump_critical()
False
sage: P.is_jump_critical(certificate=True)
(False, 3)
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1): [Integer(3), Integer(6)], Integer(2): [Integer(3),␣
↪Integer(4), Integer(5)], Integer(4): [Integer(6), Integer(7)], Integer(5):␣
↪[Integer(7)]})
>>> P.is_jump_critical()
True

>>> P = posets.PentagonPoset()
>>> P.is_jump_critical()
False
>>> P.is_jump_critical(certificate=True)
(False, 3)
```

See also

jump_number()

is_lequal(*x*, *y*)

Return True if x is less than or equal to y in the poset, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(2, 2)
True
sage: P.is_lequal(0, 1)
False
sage: P.is_lequal(3, 2)
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> P.is_lequal(Integer(2), Integer(4))
True
>>> P.is_lequal(Integer(2), Integer(2))
True
>>> P.is_lequal(Integer(0), Integer(1))
False
>>> P.is_lequal(Integer(3), Integer(2))
False
```

See also

is_less_than(), *is_gequal()*.

is_less_than(*x*, *y*)

Return `True` if x is less than but not equal to y in the poset, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_less_than(1, 3)
True
sage: P.is_less_than(0, 1)
False
sage: P.is_less_than(2, 2)
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> P.is_less_than(Integer(1), Integer(3))
True
>>> P.is_less_than(Integer(0), Integer(1))
False
>>> P.is_less_than(Integer(2), Integer(2))
False
```

For non-facade posets also < works:

```
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(1) < P(2)
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(3): [Integer(1), Integer(2)]}, facade=False)
>>> P(Integer(1)) < P(Integer(2))
False
```

See also

is_lequal(), *is_greater_than()*.

is_linear_extension(*l*)

Return whether `l` is a linear extension of `self`.

INPUT:

- `l` – list (or iterable) containing all of the elements of `self` exactly once

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), facade=True, linear_
↪extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.is_linear_extension([1, 2, 4, 3, 6, 12])
True
sage: P.is_linear_extension([1, 2, 4, 6, 3, 12])
False

sage: [p for p in Permutations(list(P)) if P.is_linear_extension(p)]
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
sage: list(P.linear_extensions())
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")), facade=True,␣
↪linear_extension=True)
>>> P.list()
[1, 2, 3, 4, 6, 12]
>>> P.is_linear_extension([Integer(1), Integer(2), Integer(4), Integer(3),␣
↪Integer(6), Integer(12)])
True
```

(continues on next page)

(continued from previous page)

```
>>> P.is_linear_extension([Integer(1), Integer(2), Integer(4), Integer(6),␣
↪Integer(3), Integer(12)])
False

>>> [p for p in Permutations(list(P)) if P.is_linear_extension(p)]
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
>>> list(P.linear_extensions())
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
```

Note

This is used and systematically tested in *LinearExtensionsOfPoset*

See also

linear_extension(), *linear_extensions()*

is_linear_interval(*x*, *y*)

Return whether the interval `[x, y]` is linear.

This means that this interval is a total order.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.is_linear_interval(0, 4)
False
sage: P.is_linear_interval(0, 3)
True
sage: P.is_linear_interval(1, 3)
False
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.is_linear_interval(Integer(0), Integer(4))
False
>>> P.is_linear_interval(Integer(0), Integer(3))
True
>>> P.is_linear_interval(Integer(1), Integer(3))
False
```

is_meet_semilattice(*certificate=False*)

Return `True` if the poset has a meet operation, and `False` otherwise.

A meet is the greatest lower bound for given elements, if it exists.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (a, b))` where elements a and b have no greatest lower bound. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: P = Poset({1:[2, 3, 4], 2:[5, 6], 3:[6], 4:[6, 7]})
sage: P.is_meet_semilattice()
True

sage: Q = P.dual()
sage: Q.is_meet_semilattice()
False

sage: V = posets.IntegerPartitions(5)                                    #␣
↪needs sage.combinat
sage: V.is_meet_semilattice(certificate=True)                            #␣
↪needs sage.combinat
(False, ((2, 2, 1), (3, 1, 1)))
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1):[Integer(2), Integer(3), Integer(4)],␣
↪Integer(2):[Integer(5), Integer(6)], Integer(3):[Integer(6)],␣
↪Integer(4):[Integer(6), Integer(7)]})
>>> P.is_meet_semilattice()
True

>>> Q = P.dual()
>>> Q.is_meet_semilattice()
False

>>> V = posets.IntegerPartitions(Integer(5))                                ␣
↪     # needs sage.combinat
>>> V.is_meet_semilattice(certificate=True)                              #␣
↪needs sage.combinat
(False, ((2, 2, 1), (3, 1, 1)))
```

See also

- Dual property: *is_join_semilattice()*
- Stronger properties: `is_lattice()`

is_parent_of(*x*)

Return `True` if `x` is an element of the poset.

is_rank_symmetric()

Return `True` if the poset is rank symmetric, and `False` otherwise.

The poset is expected to be graded and connected.

A poset of rank h (maximal chains have $h+1$ elements) is rank symmetric if the number of elements are equal in ranks i and $h-i$ for every i in $0, 1, \ldots, h$.

EXAMPLES:

```
sage: P = Poset({1:[3, 4, 5], 2:[3, 4, 5], 3:[6], 4:[7], 5:[7]})
sage: P.is_rank_symmetric()
True
sage: P = Poset({1:[2], 2:[3, 4], 3:[5], 4:[5]})
sage: P.is_rank_symmetric()
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1):[Integer(3), Integer(4), Integer(5)],␣
↪Integer(2):[Integer(3), Integer(4), Integer(5)], Integer(3):[Integer(6)],␣
↪Integer(4):[Integer(7)], Integer(5):[Integer(7)]})
>>> P.is_rank_symmetric()
True
>>> P = Poset({Integer(1):[Integer(2)], Integer(2):[Integer(3), Integer(4)],␣
↪Integer(3):[Integer(5)], Integer(4):[Integer(5)]})
>>> P.is_rank_symmetric()
False
```

is_ranked()

Return `True` if the poset is ranked, and `False` otherwise.

A poset is ranked if there is a function r from poset elements to integers so that $r(x) = r(y) + 1$ when x covers y.

Informally said a ranked poset can be "levelized": every element is on a "level", and every cover relation goes only one level up.

EXAMPLES:

```
sage: P = Poset( ([1, 2, 3, 4], [[1, 2], [2, 4], [3, 4]] ))
sage: P.is_ranked()
True

sage: P = Poset([[1, 5], [2, 6], [3], [4],[], [6, 3], [4]])
sage: P.is_ranked()
False
```

```
>>> from sage.all import *
>>> P = Poset( ([Integer(1), Integer(2), Integer(3), Integer(4)],␣
↪[[Integer(1), Integer(2)], [Integer(2), Integer(4)], [Integer(3),␣
↪Integer(4)]] ))
>>> P.is_ranked()
True

>>> P = Poset([[Integer(1), Integer(5)], [Integer(2), Integer(6)],␣
↪[Integer(3)], [Integer(4)],[], [Integer(6), Integer(3)], [Integer(4)]])
>>> P.is_ranked()
False
```

> **See also**
>
> *rank_function()*, *rank()*, *is_graded()*

is_series_parallel()

Return `True` if the poset is series-parallel, and `False` otherwise.

A poset is *series-parallel* if it can be built up from one-element posets using the operations of disjoint union and ordinal sum. This is also called *N-free* property: every poset that is not series-parallel contains a subposet isomorphic to the 4-element N-shaped poset where $a > c, d$ and $b > d$.

> **Note**
>
> Some papers use the term N-free for posets having no N-shaped poset as a *cover-preserving subposet*. This definition is not used here.

See Wikipedia article Series-parallel partial order.

EXAMPLES:

```
sage: VA = Poset({1: [2, 3], 4: [5], 6: [5]})
sage: VA.is_series_parallel()
True
sage: big_N = Poset({1: [2, 4], 2: [3], 4:[7], 5:[6], 6:[7]})
sage: big_N.is_series_parallel()
False
```

```
>>> from sage.all import *
>>> VA = Poset({Integer(1): [Integer(2), Integer(3)], Integer(4):␣
↪[Integer(5)], Integer(6): [Integer(5)]})
>>> VA.is_series_parallel()
True
>>> big_N = Poset({Integer(1): [Integer(2), Integer(4)], Integer(2):␣
↪[Integer(3)], Integer(4):[Integer(7)], Integer(5):[Integer(6)],␣
↪Integer(6):[Integer(7)]})
>>> big_N.is_series_parallel()
False
```

is_slender(*certificate=False*)

Return `True` if the poset is slender, and `False` otherwise.

A finite graded poset is *slender* if every rank 2 interval contains three or four elements, as defined in [Stan2009]. (This notion of "slender" is unrelated to the eponymous notion defined by Graetzer and Kelly in "The Free $\mathfrak{m}$-Lattice on the Poset H", Order 1 (1984), 47–65.)

This function *does not* check if the poset is graded or not. Instead it just returns `True` if the poset does not contain 5 distinct elements x, y, a, b and c such that $x \lessdot a, b, c \lessdot y$ where $\lessdot$ is the covering relation.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return either `(True, None)` or `(False, (a, b))` so that the interval $[a, b]$ has at least five elements. If `certificate=False` return `True` or `False`.

EXAMPLES:

```
sage: P = Poset(([1, 2, 3, 4], [[1, 2], [1, 3], [2, 4], [3, 4]]))
sage: P.is_slender()
True
sage: P = Poset(([1,2,3,4,5],[[1,2],[1,3],[1,4],[2,5],[3,5],[4,5]]))
sage: P.is_slender()
False

sage: # needs sage.groups
sage: W = WeylGroup(['A', 2])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
sage: W = WeylGroup(['A', 3])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True

sage: P = posets.IntegerPartitions(6)                                    #␣
↪needs sage.combinat
sage: P.is_slender(certificate=True)                                     #␣
↪needs sage.combinat
(False, ((6,), (3, 2, 1)))
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1), Integer(2), Integer(3), Integer(4)], [[Integer(1),
↪ Integer(2)], [Integer(1), Integer(3)], [Integer(2), Integer(4)],␣
↪[Integer(3), Integer(4)]]))
>>> P.is_slender()
True
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],
↪[[Integer(1),Integer(2)],[Integer(1),Integer(3)],[Integer(1),Integer(4)],
↪[Integer(2),Integer(5)],[Integer(3),Integer(5)],[Integer(4),Integer(5)]]))
>>> P.is_slender()
False

>>> # needs sage.groups
>>> W = WeylGroup(['A', Integer(2)])
>>> G = W.bruhat_poset()
>>> G.is_slender()
True
>>> W = WeylGroup(['A', Integer(3)])
>>> G = W.bruhat_poset()
>>> G.is_slender()
True

>>> P = posets.IntegerPartitions(Integer(6))                                ␣
↪     # needs sage.combinat
>>> P.is_slender(certificate=True)                                        #␣
↪needs sage.combinat
(False, ((6,), (3, 2, 1)))
```

is_sperner()

Return `True` if the poset is Sperner, and `False` otherwise.

The poset is expected to be ranked.

A poset is Sperner, if no antichain is larger than the largest rank level (one of the sets of elements of the same rank) in the poset.

See Wikipedia article Sperner_property_of_a_partially_ordered_set

See also

width(), dilworth_decomposition()

EXAMPLES:

```
sage: posets.SetPartitions(3).is_sperner()                                  #␣
↪needs sage.combinat
True

sage: P = Poset({0: [3,4,5], 1: [5], 2: [5]})
sage: P.is_sperner()                                                        #␣
↪needs networkx
False
```

```
>>> from sage.all import *
>>> posets.SetPartitions(Integer(3)).is_sperner()                           ␣
↪     # needs sage.combinat
True

>>> P = Poset({Integer(0): [Integer(3),Integer(4),Integer(5)], Integer(1):␣
↪[Integer(5)], Integer(2): [Integer(5)]})
>>> P.is_sperner()                                                          #␣
↪needs networkx
False
```

isomorphic_subposets(*other*)

Return a list of subposets of `self` isomorphic to `other`.

By subposet we mean `self.subposet(X)` which is isomorphic to `other` and where `X` is a subset of elements of `self`.

INPUT:

- `other` – a finite poset

EXAMPLES:

```
sage: C2 = Poset({0:[1]})
sage: C3 = Poset({'a':['b'], 'b':['c']})
sage: L = sorted(x.cover_relations() for x in C3.isomorphic_subposets(C2))
sage: for x in L: print(x)
[['a', 'b']]
[['a', 'c']]
[['b', 'c']]

sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
```

(continues on next page)

(continued from previous page)

```
sage: N5 = posets.PentagonPoset()
sage: len(N5.isomorphic_subposets(D))
2
```

```
>>> from sage.all import *
>>> C2 = Poset({Integer(0):[Integer(1)]})
>>> C3 = Poset({'a':['b'], 'b':['c']})
>>> L = sorted(x.cover_relations() for x in C3.isomorphic_subposets(C2))
>>> for x in L: print(x)
[['a', 'b']]
[['a', 'c']]
[['b', 'c']]

>>> D = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4)],␣
↪Integer(3):[Integer(4)]})
>>> N5 = posets.PentagonPoset()
>>> len(N5.isomorphic_subposets(D))
2
```

Note

If this function takes too much time, try using *isomorphic_subposets_iterator()*.

isomorphic_subposets_iterator(*other*)

Return an iterator over the subposets of `self` isomorphic to `other`.

By subposet we mean `self.subposet(X)` which is isomorphic to `other` and where `X` is a subset of elements of `self`.

INPUT:

- `other` – a finite poset

EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: N5 = posets.PentagonPoset()
sage: for P in N5.isomorphic_subposets_iterator(D):
....:     print(P.cover_relations())
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
```

```
>>> from sage.all import *
>>> D = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4)],␣
↪Integer(3):[Integer(4)]})
>>> N5 = posets.PentagonPoset()
>>> for P in N5.isomorphic_subposets_iterator(D):
...     print(P.cover_relations())
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
```

(continues on next page)

(continued from previous page)

```
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
```

Warning

This function will return same subposet as many times as there are automorphism on it. This is due to `subgraph_search_iterator()` returning labelled subgraphs. On the other hand, this function does not eat memory like *isomorphic_subposets()* does.

See also

sage.combinat.posets.lattices.FiniteLatticePoset.isomorphic_sublattices_iterator().

join(*x*, *y*)

Return the join of two elements `x, y` in the poset if the join exists; and `None` otherwise.

EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: D.join(2, 3)
4
sage: P = Poset({'e':['b'], 'f':['b', 'c', 'd'], 'g':['c', 'd'],
....:            'b':['a'], 'c':['a']})
sage: P.join('a', 'b')
'a'
sage: P.join('e', 'a')
'a'
sage: P.join('c', 'b')
'a'
sage: P.join('e', 'f')
'b'
sage: P.join('e', 'g')
'a'
sage: P.join('c', 'd') is None
True
sage: P.join('g', 'f') is None
True
```

```
>>> from sage.all import *
>>> D = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4)],␣
↪Integer(3):[Integer(4)]})
>>> D.join(Integer(2), Integer(3))
4
>>> P = Poset({'e':['b'], 'f':['b', 'c', 'd'], 'g':['c', 'd'],
...            'b':['a'], 'c':['a']})
>>> P.join('a', 'b')
'a'
>>> P.join('e', 'a')
'a'
```

(continues on next page)

(continued from previous page)

```
>>> P.join('c', 'b')
'a'
>>> P.join('e', 'f')
'b'
>>> P.join('e', 'g')
'a'
>>> P.join('c', 'd') is None
True
>>> P.join('g', 'f') is None
True
```

jump_number(*certificate=False*)

Return the jump number of the poset.

A *jump* in a linear extension $[e_1, \ldots, e_n]$ of a poset P is a pair (e_i, e_{i+1}) so that e_{i+1} does not cover e_i in P. The jump number of a poset is the minimal number of jumps in linear extensions of a poset.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return a pair (n, l) where n is the jump number and l is a linear extension with n jumps. If `certificate=False` return only the jump number.

EXAMPLES:

```
sage: B3 = posets.BooleanLattice(3)
sage: B3.jump_number()
3

sage: N = Poset({1: [3, 4], 2: [3]})
sage: N.jump_number(certificate=True)
(1, [1, 4, 2, 3])
```

```
>>> from sage.all import *
>>> B3 = posets.BooleanLattice(Integer(3))
>>> B3.jump_number()
3

>>> N = Poset({Integer(1): [Integer(3), Integer(4)], Integer(2): [Integer(3)]}
↪)
>>> N.jump_number(certificate=True)
(1, [1, 4, 2, 3])
```

ALGORITHM:

It is known that every poset has a greedy linear extension – an extension $[e_1, e_2, \ldots, e_n]$ where every e_{i+1} is an upper cover of e_i if that is possible – with the smallest possible number of jumps; see [Sys1987].

Hence it suffices to test only those. We do that by backtracking.

The problem is proven to be NP-complete.

See also

is_jump_critical()

kazhdan_lusztig_polynomial (*x=None*, *y=None*, *q=None*, *canonical_labels=None*)

Return the Kazhdan-Lusztig polynomial $P_{x,y}(q)$ of the poset.

The poset is expected to be ranked.

We follow the definition given in [EPW14]. Let G denote a graded poset with unique minimal and maximal elements and χ_G denote the characteristic polynomial of G. Let I_x and F^x denote the principal order ideal and filter of x respectively. Define the *Kazhdan-Lusztig polynomial* of G as the unique polynomial $P_G(q)$ satisfying the following:

1. If $\operatorname{rank} G = 0$, then $P_G(q) = 1$.
2. If $\operatorname{rank} G > 0$, then $\deg P_G(q) < \frac{1}{2} \operatorname{rank} G$.
3. We have

$$q^{\operatorname{rank} G} P_G(q^{-1}) = \sum_{x \in G} \chi_{I_x}(q) P_{F^x}(q).$$

We then extend this to $P_{x,y}(q)$ by considering the subposet corresponding to the (closed) interval $[x, y]$. We also define $P_\emptyset(q) = 0$ (so if $x \not\leq y$, then $P_{x,y}(q) = 0$).

INPUT:

- `q` – (default: $q \in \mathbf{Z}[q]$) the indeterminate q
- `x` – (default: the minimal element) the element x
- `y` – (default: the maximal element) the element y
- `canonical_labels` – (optional) for subposets, use the canonical labeling (this can limit recursive calls for posets with large amounts of symmetry, but producing the labeling takes time); if not specified, this is `True` if `x` and `y` are both not specified and `False` otherwise

EXAMPLES:

```
sage: L = posets.BooleanLattice(3)
sage: L.kazhdan_lusztig_polynomial()
1
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(3))
>>> L.kazhdan_lusztig_polynomial()
1
```

```
sage: L = posets.SymmetricGroupWeakOrderPoset(4)
sage: L.kazhdan_lusztig_polynomial()
1
sage: x = '2314'
sage: y = '3421'
sage: L.kazhdan_lusztig_polynomial(x, y)
-q + 1
sage: L.kazhdan_lusztig_polynomial(x, y, var('t'))                    #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.symbolic
-t + 1
```

```
>>> from sage.all import *
>>> L = posets.SymmetricGroupWeakOrderPoset(Integer(4))
>>> L.kazhdan_lusztig_polynomial()
1
>>> x = '2314'
>>> y = '3421'
>>> L.kazhdan_lusztig_polynomial(x, y)
-q + 1
>>> L.kazhdan_lusztig_polynomial(x, y, var('t'))                              #␣
↪needs sage.symbolic
-t + 1
```

AUTHORS:

- Travis Scrimshaw (27-12-2014)

le(*x*, *y*)

alias of *is_lequal()*.

lequal_matrix(*ring=Integer Ring*, *sparse=False*)

Compute the matrix whose `(i,j)` entry is 1 if `self.linear_extension()[i] < self.linear_extension()[j]` and 0 otherwise.

INPUT:

- `ring` – the ring of coefficients (default: `ZZ`)
- `sparse` – whether the returned matrix is sparse or not (default: `True`)

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade=False)
sage: LEQM = P.lequal_matrix(); LEQM
[1 1 1 1 1 1 1 1]
[0 1 0 1 0 0 0 1]
[0 0 1 1 1 0 1 1]
[0 0 0 1 0 0 0 1]
[0 0 0 0 1 0 0 1]
[0 0 0 0 0 1 1 1]
[0 0 0 0 0 0 1 1]
[0 0 0 0 0 0 0 1]
sage: LEQM[1,3]
1
sage: P.linear_extension()[1] < P.linear_extension()[3]
True
sage: LEQM[2,5]
0
sage: P.linear_extension()[2] < P.linear_extension()[5]
False
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
```

(continues on next page)

(continued from previous page)

```
↪Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
↪[]], facade=False)
>>> LEQM = P.lequal_matrix(); LEQM
[1 1 1 1 1 1 1 1]
[0 1 0 1 0 0 0 1]
[0 0 1 1 1 0 1 1]
[0 0 0 1 0 0 0 1]
[0 0 0 0 1 0 0 1]
[0 0 0 0 0 1 1 1]
[0 0 0 0 0 0 1 1]
[0 0 0 0 0 0 0 1]
>>> LEQM[Integer(1),Integer(3)]
1
>>> P.linear_extension()[Integer(1)] < P.linear_extension()[Integer(3)]
True
>>> LEQM[Integer(2),Integer(5)]
0
>>> P.linear_extension()[Integer(2)] < P.linear_extension()[Integer(5)]
False
```

We now demonstrate the usage of the optional parameters:

```
sage: P.lequal_matrix(ring=QQ, sparse=False).parent()                    #␣
↪needs sage.libs.flint
Full MatrixSpace of 8 by 8 dense matrices over Rational Field
```

```
>>> from sage.all import *
>>> P.lequal_matrix(ring=QQ, sparse=False).parent()                      #␣
↪needs sage.libs.flint
Full MatrixSpace of 8 by 8 dense matrices over Rational Field
```

level_sets()

Return elements grouped by maximal number of cover relations from a minimal element.

This returns a list of lists `l` such that `l[i]` is the set of minimal elements of the poset obtained by removing the elements in `l[0], l[1], ..., l[i-1]`. (In particular, `l[0]` is the set of minimal elements of `self`.)

Every level is an antichain of the poset.

EXAMPLES:

```
sage: P = Poset({0:[1,2],1:[3],2:[3],3:[]})
sage: P.level_sets()
[[0], [1, 2], [3]]

sage: Q = Poset({0:[1,2], 1:[3], 2:[4], 3:[4]})
sage: Q.level_sets()
[[0], [1, 2], [3], [4]]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(1),Integer(2)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[]})
>>> P.level_sets()
```

(continues on next page)

(continued from previous page)

```
[[0], [1, 2], [3]]

>>> Q = Poset({Integer(0):[Integer(1),Integer(2)], Integer(1):[Integer(3)],␣
↪Integer(2):[Integer(4)], Integer(3):[Integer(4)]})
>>> Q.level_sets()
[[0], [1, 2], [3], [4]]
```

See also

dilworth_decomposition() to return elements grouped to chains.

lexicographic_sum(*P*)

Return the lexicographic sum using this poset as index.

In the lexicographic sum of posets P_t by index poset T we have $x \leq y$ if either $x \leq y$ in P_t for some $t \in T$, or $x \in P_i$, $y \in P_j$ and $i \leq j$ in T.

Informally said we substitute every element of T by corresponding poset P_t.

Mathematically, it is only defined when all P_t have no common element; here we force that by giving them different names in the resulting poset.

disjoint_union() and *ordinal_sum()* are special cases of lexicographic sum where the index poset is an (anti)chain. *ordinal_product()* is a special case where every P_t is same poset.

INPUT:

- `P` – dictionary whose keys are elements of this poset, values are posets

EXAMPLES:

```
sage: N = Poset({1: [3, 4], 2: [4]})
sage: P = {1: posets.PentagonPoset(), 2: N,
....:      3: posets.ChainPoset(3), 4: posets.AntichainPoset(4)}
sage: NP = N.lexicographic_sum(P); NP
Finite poset containing 16 elements
sage: sorted(NP.minimal_elements())
[(1, 0), (2, 1), (2, 2)]
```

```
>>> from sage.all import *
>>> N = Poset({Integer(1): [Integer(3), Integer(4)], Integer(2): [Integer(4)]}
↪)
>>> P = {Integer(1): posets.PentagonPoset(), Integer(2): N,
...      Integer(3): posets.ChainPoset(Integer(3)), Integer(4): posets.
↪AntichainPoset(Integer(4))}
>>> NP = N.lexicographic_sum(P); NP
Finite poset containing 16 elements
>>> sorted(NP.minimal_elements())
[(1, 0), (2, 1), (2, 2)]
```

linear_extension(*linear_extension=None*, *check=True*)

Return a linear extension of this poset.

A linear extension of a finite poset P of size n is a total ordering $\pi := \pi_0\pi_1\ldots\pi_{n-1}$ of its elements such that $i < j$ whenever $\pi_i < \pi_j$ in the poset P.

INPUT:

- `linear_extension` – (default: `None`) a list of the elements of `self`
- `check` – boolean (default: `True`); whether to check that `linear_extension` is indeed a linear extension of `self`

EXAMPLES:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade=True)
```

Without optional argument, the default linear extension of the poset is returned, as a plain list:

```
sage: P.linear_extension()
[1, 3, 5, 15]
```

```
>>> from sage.all import *
>>> P.linear_extension()
[1, 3, 5, 15]
```

Otherwise, a full-featured linear extension is constructed as an element of `P.linear_extensions()`:

```
sage: l = P.linear_extension([1,5,3,15]); l
[1, 5, 3, 15]
sage: type(l)
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_
↪category.element_class'>
sage: l.parent()
The set of all linear extensions of Finite poset containing 4 elements
```

```
>>> from sage.all import *
>>> l = P.linear_extension([Integer(1),Integer(5),Integer(3),Integer(15)]); l
[1, 5, 3, 15]
>>> type(l)
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_
↪category.element_class'>
>>> l.parent()
The set of all linear extensions of Finite poset containing 4 elements
```

By default, the linear extension is checked for correctness:

```
sage: l = P.linear_extension([1,3,15,5])
Traceback (most recent call last):
...
ValueError: [1, 3, 15, 5] is not a linear extension of Finite poset␣
↪containing 4 elements
```

```
>>> from sage.all import *
>>> l = P.linear_extension([Integer(1),Integer(3),Integer(15),Integer(5)])
Traceback (most recent call last):
...
```

(continues on next page)

(continued from previous page)

```
ValueError: [1, 3, 15, 5] is not a linear extension of Finite poset␣
↪containing 4 elements
```

This can be disabled (at your own risks!) with:

```
sage: P.linear_extension([1,3,15,5], check=False)
[1, 3, 15, 5]
```

```
>>> from sage.all import *
>>> P.linear_extension([Integer(1),Integer(3),Integer(15),Integer(5)],␣
↪check=False)
[1, 3, 15, 5]
```

See also

is_linear_extension(), *linear_extensions()*

Todo

- Is it acceptable to have those two features for a single method?
- In particular, we miss a short idiom to get the default linear extension

linear_extensions(*facade=False*)

Return the enumerated set of all the linear extensions of this poset.

INPUT:

- `facade` – boolean (default: `False`); whether to return the linear extensions as plain lists

Warning

The `facade` option is not yet fully functional:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_
↪extension=True)
sage: L = P.linear_extensions(facade=True); L
The set of all linear extensions of
 Finite poset containing 6 elements with distinguished linear extension
sage: L([1, 2, 3, 4, 6, 12])
Traceback (most recent call last):
...
TypeError: Cannot convert list to sage.structure.element.Element
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_
↪extension=True)
>>> L = P.linear_extensions(facade=True); L
The set of all linear extensions of
 Finite poset containing 6 elements with distinguished linear extension
>>> L([Integer(1), Integer(2), Integer(3), Integer(4), Integer(6),␣
↪Integer(12)])
Traceback (most recent call last):
...
TypeError: Cannot convert list to sage.structure.element.Element
```

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: L = P.linear_extensions(); L
The set of all linear extensions of
 Finite poset containing 6 elements with distinguished linear extension
sage: l = L.an_element(); l
[1, 2, 3, 4, 6, 12]
sage: L.cardinality()
5
sage: L.list()
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_
↪extension=True)
>>> P.list()
[1, 2, 3, 4, 6, 12]
>>> L = P.linear_extensions(); L
The set of all linear extensions of
 Finite poset containing 6 elements with distinguished linear extension
>>> l = L.an_element(); l
[1, 2, 3, 4, 6, 12]
>>> L.cardinality()
5
>>> L.list()
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
```

Each element is aware that it is a linear extension of P:

```
sage: type(l.parent())
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_
↪category'>
```

```
>>> from sage.all import *
>>> type(l.parent())
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_
↪category'>
```

With `facade=True`, the elements of `L` are plain lists instead:

```
sage: L = P.linear_extensions(facade=True)
sage: l = L.an_element()
sage: type(l)
<class 'list'>
```

```
>>> from sage.all import *
>>> L = P.linear_extensions(facade=True)
>>> l = L.an_element()
>>> type(l)
<class 'list'>
```

Warning

In Sage <= 4.8, this function used to return a plain list of lists. To recover the previous functionality, please use:

```
sage: L = list(P.linear_extensions(facade=True)); L
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
sage: type(L[0])
<class 'list'>
```

```
>>> from sage.all import *
>>> L = list(P.linear_extensions(facade=True)); L
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
>>> type(L[Integer(0)])
<class 'list'>
```

See also

linear_extension(), *is_linear_extension()*

linear_extensions_graph()

Return the linear extensions graph of the poset.

Vertices of the graph are linear extensions of the poset. Two vertices are connected by an edge if the linear extensions differ by only one adjacent transposition.

EXAMPLES:

```
sage: N = Poset({1: [3, 4], 2: [4]})
sage: G = N.linear_extensions_graph(); G
Graph on 5 vertices
sage: G.neighbors(N.linear_extension([1,2,3,4]))
```

(continues on next page)

(continued from previous page)

```
[[2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3]]

sage: chevron = Poset({1: [2, 6], 2: [3], 4: [3, 5], 6: [5]})
sage: G = chevron.linear_extensions_graph(); G
Graph on 22 vertices
sage: G.size()
36
```

```
>>> from sage.all import *
>>> N = Poset({Integer(1): [Integer(3), Integer(4)], Integer(2): [Integer(4)]}
↪)
>>> G = N.linear_extensions_graph(); G
Graph on 5 vertices
>>> G.neighbors(N.linear_extension([Integer(1),Integer(2),Integer(3),
↪Integer(4)]))
[[2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3]]

>>> chevron = Poset({Integer(1): [Integer(2), Integer(6)], Integer(2):␣
↪[Integer(3)], Integer(4): [Integer(3), Integer(5)], Integer(6):␣
↪[Integer(5)]})
>>> G = chevron.linear_extensions_graph(); G
Graph on 22 vertices
>>> G.size()
36
```

linear_intervals_count()

Return the enumeration of linear intervals w.r.t. their cardinality.

An interval is linear if it is a total order.

OUTPUT: list of integers

See also

is_linear_interval()

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.linear_intervals_count()
[5, 5, 2]
sage: P = posets.TamariLattice(4)
sage: P.linear_intervals_count()
[14, 21, 12, 2]
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.linear_intervals_count()
[5, 5, 2]
>>> P = posets.TamariLattice(Integer(4))
>>> P.linear_intervals_count()
[14, 21, 12, 2]
```

list()

List the elements of the poset. This just returns the result of *linear_extension()*.

EXAMPLES:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] }, facade = False)
sage: D.list()
[0, 1, 2, 3, 4]
sage: type(D.list()[0])
<class 'sage.combinat.posets.posets.FinitePoset_with_category.element_class'>
```

```
>>> from sage.all import *
>>> D = Poset({ Integer(0):[Integer(1),Integer(2)], Integer(1):[Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)] }, facade = False)
>>> D.list()
[0, 1, 2, 3, 4]
>>> type(D.list()[Integer(0)])
<class 'sage.combinat.posets.posets.FinitePoset_with_category.element_class'>
```

lower_covers(x)

Return the list of lower covers of the element `x`.

A lower cover of x is an element y such that $y < x$ and there is no element z so that $y < z < x$.

EXAMPLES:

```
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.lower_covers(3)
[2, 5]
sage: P.lower_covers(0)
[]
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(5)], [Integer(2),Integer(6)], [Integer(3)],
↪ [Integer(4)], [], [Integer(6),Integer(3)], [Integer(4)]])
>>> P.lower_covers(Integer(3))
[2, 5]
>>> P.lower_covers(Integer(0))
[]
```

See also

upper_covers()

lower_covers_iterator(x)

Return an iterator over the lower covers of the element `x`.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[]})
sage: l0 = P.lower_covers_iterator(3)
sage: type(l0)
<class 'generator'>
```

(continues on next page)

(continued from previous page)

```
sage: next(l0)
2
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[]})
>>> l0 = P.lower_covers_iterator(Integer(3))
>>> type(l0)
<class 'generator'>
>>> next(l0)
2
```

lt(*x*, *y*)

alias of *is_less_than()*.

magnitude()

Return the magnitude of `self`.

The magnitude is an integer defined as the sum of all Möbius numbers, and can be seen as some kind of Euler characteristic of the poset. It is additive under disjoint union and multiplicative under Cartesian product.

REFERENCES:

- [Lein2008] Tom Leinster, *The Euler Characteristic of a Category*, Documenta Mathematica, Vol. 13 (2008), 21-49 https://www.math.uni-bielefeld.de/documenta/vol-13/02.html
- https://golem.ph.utexas.edu/category/2011/06/the_magnitude_of_an_enriched_c.html

EXAMPLES:

```
sage: # needs sage.groups sage.libs.flint
sage: P = posets.PentagonPoset()
sage: P.magnitude()
1
sage: W = SymmetricGroup(4)
sage: P = W.noncrossing_partition_lattice().without_bounds()
sage: P.magnitude()
-4
sage: P = posets.TamariLattice(4).without_bounds()
sage: P.magnitude()
0
```

```
>>> from sage.all import *
>>> # needs sage.groups sage.libs.flint
>>> P = posets.PentagonPoset()
>>> P.magnitude()
1
>>> W = SymmetricGroup(Integer(4))
>>> P = W.noncrossing_partition_lattice().without_bounds()
>>> P.magnitude()
-4
>>> P = posets.TamariLattice(Integer(4)).without_bounds()
>>> P.magnitude()
0
```

See also

order_complex()

maximal_antichains()

Return the maximal antichains of the poset.

An antichain a of poset P is *maximal* if there is no element $e \in P \setminus a$ such that $a \cup \{e\}$ is an antichain.

EXAMPLES:

```
sage: P = Poset({'a':['b', 'c'], 'b':['d','e']})
sage: [sorted(anti) for anti in P.maximal_antichains()]
[['a'], ['b', 'c'], ['c', 'd', 'e']]

sage: posets.PentagonPoset().maximal_antichains()
[[0], [1, 2], [1, 3], [4]]
```

```
>>> from sage.all import *
>>> P = Poset({'a':['b', 'c'], 'b':['d','e']})
>>> [sorted(anti) for anti in P.maximal_antichains()]
[['a'], ['b', 'c'], ['c', 'd', 'e']]

>>> posets.PentagonPoset().maximal_antichains()
[[0], [1, 2], [1, 3], [4]]
```

See also

antichains(), *maximal_chains()*

maximal_chain_length()

Return the maximum length of a maximal chain in the poset.

The length here is the number of vertices.

EXAMPLES:

```
sage: P = posets.TamariLattice(5)
sage: P.maximal_chain_length()
11
```

```
>>> from sage.all import *
>>> P = posets.TamariLattice(Integer(5))
>>> P.maximal_chain_length()
11
```

See also

maximal_chains(), *maximal_chains_iterator()*

maximal_chains(*partial=None*)

Return all maximal chains of this poset.

Each chain is listed in increasing order.

INPUT:

- `partial` – list (optional); if given, the list `partial` is assumed to be the start of a maximal chain, and the function will find all maximal chains starting with the elements in `partial`

This is used in constructing the order complex for the poset.

EXAMPLES:

```
sage: P = posets.BooleanLattice(3)
sage: P.maximal_chains()
[[0, 1, 3, 7], [0, 1, 5, 7], [0, 2, 3, 7],
 [0, 2, 6, 7], [0, 4, 5, 7], [0, 4, 6, 7]]
sage: P.maximal_chains(partial=[0,2])
[[0, 2, 3, 7], [0, 2, 6, 7]]
sage: Q = posets.ChainPoset(6)
sage: Q.maximal_chains()
[[0, 1, 2, 3, 4, 5]]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(3))
>>> P.maximal_chains()
[[0, 1, 3, 7], [0, 1, 5, 7], [0, 2, 3, 7],
 [0, 2, 6, 7], [0, 4, 5, 7], [0, 4, 6, 7]]
>>> P.maximal_chains(partial=[Integer(0),Integer(2)])
[[0, 2, 3, 7], [0, 2, 6, 7]]
>>> Q = posets.ChainPoset(Integer(6))
>>> Q.maximal_chains()
[[0, 1, 2, 3, 4, 5]]
```

See also

maximal_antichains(), chains()

maximal_chains_iterator(*partial=None*)

Return an iterator over maximal chains.

Each chain is listed in increasing order.

INPUT:

- `partial` – list (optional); if given, the list `partial` is assumed to be the start of a maximal chain, and the function will yield all maximal chains starting with the elements in `partial`

EXAMPLES:

```
sage: P = posets.BooleanLattice(3)
sage: it = P.maximal_chains_iterator()
sage: next(it)
[0, 1, 3, 7]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(3))
```

(continues on next page)

(continued from previous page)

```
>>> it = P.maximal_chains_iterator()
>>> next(it)
[0, 1, 3, 7]
```

See also

antichains_iterator()

maximal_elements()

Return the list of the maximal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})
>>> P.maximal_elements()
[4]
```

See also

minimal_elements().

meet(x, y)

Return the meet of two elements `x, y` in the poset if the meet exists; and `None` otherwise.

EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: D.meet(2, 3)
1
sage: P = Poset({'a':['b', 'c'], 'b':['e', 'f'], 'c':['f', 'g'],
....:            'd':['f', 'g']})
sage: P.meet('a', 'b')
'a'
sage: P.meet('e', 'a')
'a'
sage: P.meet('c', 'b')
'a'
sage: P.meet('e', 'f')
'b'
sage: P.meet('e', 'g')
'a'
sage: P.meet('c', 'd') is None
True
```

(continues on next page)

(continued from previous page)

```
sage: P.meet('g', 'f') is None
True
```

```
>>> from sage.all import *
>>> D = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4)],␣
↪Integer(3):[Integer(4)]})
>>> D.meet(Integer(2), Integer(3))
1
>>> P = Poset({'a':['b', 'c'], 'b':['e', 'f'], 'c':['f', 'g'],
...            'd':['f', 'g']})
>>> P.meet('a', 'b')
'a'
>>> P.meet('e', 'a')
'a'
>>> P.meet('c', 'b')
'a'
>>> P.meet('e', 'f')
'b'
>>> P.meet('e', 'g')
'a'
>>> P.meet('c', 'd') is None
True
>>> P.meet('g', 'f') is None
True
```

minimal_elements()

Return the list of the minimal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})
>>> P(Integer(0)) in P.minimal_elements()
True
>>> P(Integer(1)) in P.minimal_elements()
True
>>> P(Integer(2)) in P.minimal_elements()
True
```

See also

maximal_elements().

moebius_function(*x*, *y*)

Return the value of the Möbius function of the poset on the elements x and y.

EXAMPLES:

```
sage: P = Poset([[1,2,3],[4],[4],[4],[]])
sage: P.moebius_function(P(0),P(4))
2
sage: sum(P.moebius_function(P(0),v) for v in P)
0
sage: sum(abs(P.moebius_function(P(0),v))
....:     for v in P)
6
sage: for u,v in P.cover_relations_iterator():
....:     if P.moebius_function(u,v) != -1:
....:         print("Bug in moebius_function!")
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(2),Integer(3)],[Integer(4)],[Integer(4)],
↪[Integer(4)],[]])
>>> P.moebius_function(P(Integer(0)),P(Integer(4)))
2
>>> sum(P.moebius_function(P(Integer(0)),v) for v in P)
0
>>> sum(abs(P.moebius_function(P(Integer(0)),v))
...     for v in P)
6
>>> for u,v in P.cover_relations_iterator():
...     if P.moebius_function(u,v) != -Integer(1):
...         print("Bug in moebius_function!")
```

```
sage: Q = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: Q.moebius_function(Q(0),Q(7))
0
sage: Q.moebius_function(Q(0),Q(5))
0
sage: Q.moebius_function(Q(2),Q(7))
2
sage: Q.moebius_function(Q(3),Q(3))
1
sage: sum([Q.moebius_function(Q(0),v) for v in Q])
0
```

```
>>> from sage.all import *
>>> Q = Poset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
↪Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
↪[]])
>>> Q.moebius_function(Q(Integer(0)),Q(Integer(7)))
0
>>> Q.moebius_function(Q(Integer(0)),Q(Integer(5)))
0
>>> Q.moebius_function(Q(Integer(2)),Q(Integer(7)))
2
```

(continues on next page)

(continued from previous page)

```
>>> Q.moebius_function(Q(Integer(3)),Q(Integer(3)))
1
>>> sum([Q.moebius_function(Q(Integer(0)),v) for v in Q])
0
```

moebius_function_matrix(*ring=Integer Ring*, *sparse=False*)

Return a matrix whose `(i,j)` entry is the value of the Möbius function evaluated at `self.linear_extension()[i]` and `self.linear_extension()[j]`.

INPUT:

- `ring` – the ring of coefficients (default: `ZZ`)
- `sparse` – whether the returned matrix is sparse or not (default: `True`)

EXAMPLES:

```
sage: P = Poset([[4,2,3],[],[1],[1],[1]])
sage: x,y = (P.linear_extension()[0],P.linear_extension()[1])
sage: P.moebius_function(x,y)
-1
sage: M = P.moebius_function_matrix(); M                                    #␣
↪needs sage.libs.flint
[ 1 -1 -1 -1  2]
[ 0  1  0  0 -1]
[ 0  0  1  0 -1]
[ 0  0  0  1 -1]
[ 0  0  0  0  1]
sage: M[0,4]                                                                #␣
↪needs sage.libs.flint
2
sage: M[0,1]                                                                #␣
↪needs sage.libs.flint
-1
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(4),Integer(2),Integer(3)],[],[Integer(1)],
↪[Integer(1)],[Integer(1)]])
>>> x,y = (P.linear_extension()[Integer(0)],P.linear_extension()[Integer(1)])
>>> P.moebius_function(x,y)
-1
>>> M = P.moebius_function_matrix(); M                                      #␣
↪needs sage.libs.flint
[ 1 -1 -1 -1  2]
[ 0  1  0  0 -1]
[ 0  0  1  0 -1]
[ 0  0  0  1 -1]
[ 0  0  0  0  1]
>>> M[Integer(0),Integer(4)]                                                ␣
↪              # needs sage.libs.flint
2
>>> M[Integer(0),Integer(1)]                                                ␣
↪              # needs sage.libs.flint
-1
```

We now demonstrate the usage of the optional parameters:

```
sage: P.moebius_function_matrix(ring=QQ, sparse=False).parent()                #␣
↪needs sage.libs.flint
Full MatrixSpace of 5 by 5 dense matrices over Rational Field
```

```
>>> from sage.all import *
>>> P.moebius_function_matrix(ring=QQ, sparse=False).parent()                #␣
↪needs sage.libs.flint
Full MatrixSpace of 5 by 5 dense matrices over Rational Field
```

number_of_relations()

Return the number of relations in the poset.

A relation is a pair of elements x and y such that $x \leq y$ in the poset.

Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.number_of_relations()
13

sage: posets.TamariLattice(4).number_of_relations()
68
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.number_of_relations()
13

>>> posets.TamariLattice(Integer(4)).number_of_relations()
68
```

See also

relations_iterator(), *relations()*

open_interval(x, y)

Return the list of elements z such that $x < z < y$ in the poset.

EXAMPLES:

```
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.open_interval(2, 100)
[4, 10, 20, 50]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))
>>> P.open_interval(Integer(2), Integer(100))
[4, 10, 20, 50]
```

See also

interval()

order_complex(*on_ints=False*)

Return the order complex associated to this poset.

The order complex is the simplicial complex with vertices equal to the elements of the poset, and faces given by the chains.

INPUT:

- `on_ints` – boolean (default: `False`)

OUTPUT: an order complex of type `SimplicialComplex`

EXAMPLES:

```
sage: P = posets.BooleanLattice(3)
sage: S = P.order_complex(); S
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and 6 facets
sage: S.f_vector()
[1, 8, 19, 18, 6]
sage: S.homology()       # S is contractible
{0: 0, 1: 0, 2: 0, 3: 0}
sage: Q = P.subposet([1,2,3,4,5,6])
sage: Q.order_complex().homology()     # a circle
{0: 0, 1: Z}

sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: P.order_complex()
Simplicial complex with vertex set (1, 3, 5, 15) and
 facets {(1, 3, 15), (1, 5, 15)}
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(3))
>>> S = P.order_complex(); S
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and 6 facets
>>> S.f_vector()
[1, 8, 19, 18, 6]
>>> S.homology()       # S is contractible
{0: 0, 1: 0, 2: 0, 3: 0}
>>> Q = P.subposet([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6)])
>>> Q.order_complex().homology()     # a circle
{0: 0, 1: Z}

>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade=True)
>>> P.order_complex()
Simplicial complex with vertex set (1, 3, 5, 15) and
 facets {(1, 3, 15), (1, 5, 15)}
```

If `on_ints`, then the elements of the poset are labelled $0, 1, \ldots$ in the chain complex:

```
sage: P.order_complex(on_ints=True)
Simplicial complex with vertex set (0, 1, 2, 3) and
 facets {(0, 1, 3), (0, 2, 3)}
```

```
>>> from sage.all import *
>>> P.order_complex(on_ints=True)
Simplicial complex with vertex set (0, 1, 2, 3) and
 facets {(0, 1, 3), (0, 2, 3)}
```

order_filter(*elements*)

Return the order filter generated by the elements of an iterable `elements`.

I is an order filter if, for any x in I and y such that $y \geq x$, then y is in I. This is also called upper set or upset.

EXAMPLES:

```
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_filter([20, 25])
[20, 40, 25, 50, 100, 200, 125, 250, 500, 1000]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))
>>> P.order_filter([Integer(20), Integer(25)])
[20, 40, 25, 50, 100, 200, 125, 250, 500, 1000]
```

See also

order_ideal(), principal_order_filter().

order_ideal(*elements*)

Return the order ideal generated by the elements of an iterable `elements`.

I is an order ideal if, for any x in I and y such that $y \leq x$, then y is in I. This is also called lower set or downset.

EXAMPLES:

```
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_ideal([20, 25])
[1, 2, 4, 5, 10, 20, 25]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))
>>> P.order_ideal([Integer(20), Integer(25)])
[1, 2, 4, 5, 10, 20, 25]
```

See also

order_filter(), principal_order_ideal().

order_ideal_cardinality(*elements*)

Return the cardinality of the order ideal generated by `elements`.

The elements I is an order ideal if, for any $x \in I$ and y such that $y \leq x$, then $y \in I$.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: P.order_ideal_cardinality([7,10])
10
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> P.order_ideal_cardinality([Integer(7),Integer(10)])
10
```

order_ideal_plot(*elements*)

Return a plot of the order ideal generated by the elements of an iterable `elements`.

I is an order ideal if, for any x in I and y such that $y \leq x$, then y is in I. This is also called lower set or downset.

EXAMPLES:

```
sage: # needs sage.plot
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_ideal_plot([20, 25])
Graphics object consisting of 41 graphics primitives
```

```
>>> from sage.all import *
>>> # needs sage.plot
>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))
>>> P.order_ideal_plot([Integer(20), Integer(25)])
Graphics object consisting of 41 graphics primitives
```

order_polynomial()

Return the order polynomial of the poset.

The order polynomial $\Omega_P(q)$ of a poset P is defined as the unique polynomial S such that for each integer $m \geq 1$, $S(m)$ is the number of order-preserving maps from P to $\{1, \ldots, m\}$.

See sections 3.12 and 3.15 of [EnumComb1], and also [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: P.order_polynomial()
q^3

sage: P = posets.ChainPoset(3)
sage: f = P.order_polynomial(); f
1/6*q^3 + 1/2*q^2 + 1/3*q
sage: [f(i) for i in range(4)]
[0, 1, 4, 10]
```

```
>>> from sage.all import *
>>> P = posets.AntichainPoset(Integer(3))
>>> P.order_polynomial()
q^3

>>> P = posets.ChainPoset(Integer(3))
>>> f = P.order_polynomial(); f
1/6*q^3 + 1/2*q^2 + 1/3*q
>>> [f(i) for i in range(Integer(4))]
[0, 1, 4, 10]
```

See also

order_polytope()

order_polytope()

Return the order polytope of the poset `self`.

The order polytope of a finite poset P is defined as the subset of $\mathbf{R}^P$ consisting of all maps $x : P \to \mathbf{R}$ satisfying

$$0 \leq x(p) \leq 1 \text{ for all } p \in P,$$

and

$$x(p) \leq x(q) \text{ for all } p, q \in P \text{ satisfying } p < q.$$

This polytope was defined and studied in [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: Q = P.order_polytope(); Q                                             #␣
↪needs sage.geometry.polyhedron
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
sage: P = posets.PentagonPoset()
sage: Q = P.order_polytope(); Q                                             #␣
↪needs sage.geometry.polyhedron
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices

sage: P = Poset([[1,2,3],[[1,2],[1,3]]])
sage: Q = P.order_polytope()                                                #␣
↪needs sage.geometry.polyhedron
sage: Q.contains((1,0,0))                                                   #␣
↪needs sage.geometry.polyhedron
False
sage: Q.contains((0,1,1))                                                   #␣
↪needs sage.geometry.polyhedron
True
```

```
>>> from sage.all import *
>>> P = posets.AntichainPoset(Integer(3))
```

(continues on next page)

(continued from previous page)

```
>>> Q = P.order_polytope(); Q                                                #␣
↪needs sage.geometry.polyhedron
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
>>> P = posets.PentagonPoset()
>>> Q = P.order_polytope(); Q                                                #␣
↪needs sage.geometry.polyhedron
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices

>>> P = Poset([[Integer(1),Integer(2),Integer(3)],[[Integer(1),Integer(2)],
↪[Integer(1),Integer(3)]]])
>>> Q = P.order_polytope()                                                   #␣
↪needs sage.geometry.polyhedron
>>> Q.contains((Integer(1),Integer(0),Integer(0)))                                ␣
↪                        # needs sage.geometry.polyhedron
False
>>> Q.contains((Integer(0),Integer(1),Integer(1)))                                ␣
↪                        # needs sage.geometry.polyhedron
True
```

ordinal_product(*other*, *labels='pairs'*)

Return the ordinal product of `self` and `other`.

The ordinal product of two posets P and Q is a partial order on the Cartesian product of the underlying sets of P and Q, defined as follows (see [EnumComb1], p. 284).

In the ordinal product, $(p, q) \leq (p', q')$ if either $p \leq p'$ or $p = p'$ and $q \leq q'$.

This construction is not symmetric in P and Q. Informally said we put a copy of Q in place of every element of P.

INPUT:

- `other` – a poset
- `labels` – either `'integers'` or `'pairs'` (default); how the resulting poset will be labeled

EXAMPLES:

```
sage: P1 = Poset((['a', 'b'], [['a', 'b']]))
sage: P2 = Poset((['c', 'd'], [['c', 'd']]))
sage: P = P1.ordinal_product(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[[('a', 'c'), ('a', 'd')], [('a', 'd'), ('b', 'c')],
[('b', 'c'), ('b', 'd')]]
```

```
>>> from sage.all import *
>>> P1 = Poset((['a', 'b'], [['a', 'b']]))
>>> P2 = Poset((['c', 'd'], [['c', 'd']]))
>>> P = P1.ordinal_product(P2); P
Finite poset containing 4 elements
>>> sorted(P.cover_relations())
[[('a', 'c'), ('a', 'd')], [('a', 'd'), ('b', 'c')],
[('b', 'c'), ('b', 'd')]]
```

See also

product(), *ordinal_sum()*

ordinal_sum(*other*, *labels='pairs'*)

Return a poset or (semi)lattice isomorphic to ordinal sum of the poset with `other`.

The ordinal sum of P and Q is a poset that contains every element and relation from both P and Q, and where every element of P is smaller than any element of Q.

Mathematically, it is only defined when P and Q have no common element; here we force that by giving them different names in the resulting poset.

The ordinal sum on lattices is a lattice; resp. for meet- and join-semilattices.

INPUT:

- `other` – poset
- `labels` – (defaults to 'pairs') If set to 'pairs', each element `v` in this poset will be named `(0,v)` and each element `u` in `other` will be named `(1,u)` in the result. If set to 'integers', the elements of the result will be relabeled with consecutive integers.

EXAMPLES:

```
sage: P1 = Poset( ([1, 2, 3, 4], [[1, 2], [1, 3], [1, 4]]) )
sage: P2 = Poset( ([1, 2, 3,], [[2,1], [3,1]]) )
sage: P3 = P1.ordinal_sum(P2); P3
Finite poset containing 7 elements
sage: len(P1.maximal_elements())*len(P2.minimal_elements())
6
sage: len(P1.cover_relations()+P2.cover_relations())
5
sage: len(P3.cover_relations()) # Every element of P2 is greater than␣
↪elements of P1.
11
sage: P3.list()  # random
[(0, 1), (0, 2), (0, 4), (0, 3), (1, 2), (1, 3), (1, 1)]
sage: P4 = P1.ordinal_sum(P2, labels='integers')
sage: P4.list()  # random
[0, 1, 2, 3, 5, 6, 4]
```

```
>>> from sage.all import *
>>> P1 = Poset( ([Integer(1), Integer(2), Integer(3), Integer(4)],␣
↪[[Integer(1), Integer(2)], [Integer(1), Integer(3)], [Integer(1),␣
↪Integer(4)]]) )
>>> P2 = Poset( ([Integer(1), Integer(2), Integer(3),], [[Integer(2),
↪Integer(1)], [Integer(3),Integer(1)]]) )
>>> P3 = P1.ordinal_sum(P2); P3
Finite poset containing 7 elements
>>> len(P1.maximal_elements())*len(P2.minimal_elements())
6
>>> len(P1.cover_relations()+P2.cover_relations())
5
>>> len(P3.cover_relations()) # Every element of P2 is greater than elements␣
```

(continues on next page)

(continued from previous page)

```
↪of P1.
11
>>> P3.list()  # random
[(0, 1), (0, 2), (0, 4), (0, 3), (1, 2), (1, 3), (1, 1)]
>>> P4 = P1.ordinal_sum(P2, labels='integers')
>>> P4.list()  # random
[0, 1, 2, 3, 5, 6, 4]
```

Return type depends on input types:

```
sage: P = Poset({1:[2]}); P
Finite poset containing 2 elements
sage: JL = JoinSemilattice({1:[2]}); JL
Finite join-semilattice containing 2 elements
sage: L = LatticePoset({1:[2]}); L
Finite lattice containing 2 elements
sage: P.ordinal_sum(L)
Finite poset containing 4 elements
sage: L.ordinal_sum(JL)
Finite join-semilattice containing 4 elements
sage: L.ordinal_sum(L)
Finite lattice containing 4 elements
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1):[Integer(2)]}); P
Finite poset containing 2 elements
>>> JL = JoinSemilattice({Integer(1):[Integer(2)]}); JL
Finite join-semilattice containing 2 elements
>>> L = LatticePoset({Integer(1):[Integer(2)]}); L
Finite lattice containing 2 elements
>>> P.ordinal_sum(L)
Finite poset containing 4 elements
>>> L.ordinal_sum(JL)
Finite join-semilattice containing 4 elements
>>> L.ordinal_sum(L)
Finite lattice containing 4 elements
```

See also

ordinal_summands(), *disjoint_union()*, *sage.combinat.posets.lattices.FiniteLatticePoset.vertical_composition()*

ordinal_summands()

Return the ordinal summands of the poset as subposets.

The ordinal summands of a poset P is the longest list of non-empty subposets $P_1, \ldots, P_n$ whose ordinal sum is P. This decomposition is unique.

EXAMPLES:

```
sage: P = Poset({'a': ['c', 'd'], 'b': ['d'], 'c': ['x', 'y'],
....: 'd': ['x', 'y']})
```

(continues on next page)

(continued from previous page)

```
sage: parts = P.ordinal_summands(); parts
[Finite poset containing 4 elements, Finite poset containing 2 elements]
sage: sorted(parts[0])
['a', 'b', 'c', 'd']
sage: Q = parts[0].ordinal_sum(parts[1])
sage: Q.is_isomorphic(P)
True
```

```
>>> from sage.all import *
>>> P = Poset({'a': ['c', 'd'], 'b': ['d'], 'c': ['x', 'y'],
... 'd': ['x', 'y']})
>>> parts = P.ordinal_summands(); parts
[Finite poset containing 4 elements, Finite poset containing 2 elements]
>>> sorted(parts[Integer(0)])
['a', 'b', 'c', 'd']
>>> Q = parts[Integer(0)].ordinal_sum(parts[Integer(1)])
>>> Q.is_isomorphic(P)
True
```

See also

ordinal_sum()

ALGORITHM:

Suppose that a poset P is the ordinal sum of posets L and U. Then P contains maximal antichains l and u such that every element of u covers every element of l; they correspond to maximal elements of L and minimal elements of U.

We consider a linear extension $x_1, \ldots, x_n$ of the poset's elements.

We keep track of the maximal elements of subposet induced by elements $0, \ldots, x_i$ and minimal elements of subposet induced by elements $x_{i+1}, \ldots, x_n$, incrementing i one by one. We then check if l and u fit the previous description.

p_partition_enumerator(*tup*, *R*, *weights=None*, *check=False*)

Return a P-partition enumerator of `self`.

Given a total order $\prec$ on the elements of a finite poset P (the order of P and the total order $\prec$ can be unrelated; in particular, the latter does not have to extend the former), a P-partition enumerator is the quasisymmetric function $\sum_f \prod_{p \in P} x_{f(p)}$, where the first sum is taken over all P-partitions f.

A P-partition is a function $f : P \to \{1, 2, 3, ...\}$ satisfying the following properties for any two elements i and j of P satisfying $i <_P j$:

- if $i \prec j$ then $f(i) \leq f(j)$,
- if $j \prec i$ then $f(i) < f(j)$.

The optional argument `weights` allows constructing a generalized ("weighted") version of the P-partition enumerator. Namely, `weights` should be a dictionary whose keys are the elements of `P`. Then, the generalized P-partition enumerator corresponding to weights `weights` is $\sum_f \prod_{p \in P} x_{f(p)}^{w(p)}$, where the sum is again over all P-partitions f. Here, $w(p)$ is `weights[p]`. The classical P-partition enumerator is the particular case obtained when all p satisfy $w(p) = 1$.

In the language of [Grinb2016a], the generalized P-partition enumerator is the quasisymmetric function $\Gamma(\mathbf{E}, w)$, where $\mathbf{E}$ is the special double poset $(P, <_P, \prec)$, and where w is the dictionary `weights` (regarded as a function from P to the positive integers).

INPUT:

- `tup` – the tuple containing all elements of P (each of them exactly once), in the order dictated by the total order $\prec$
- `R` – a commutative ring
- `weights` – (optional) a dictionary of positive integers, indexed by elements of P; any missing item will be understood as 1

OUTPUT:

The P-partition enumerator of `self` according to `tup` in the algebra $QSym$ of quasisymmetric functions over the base ring R.

EXAMPLES:

```
sage: # needs sage.combinat
sage: P = Poset([[1,2,3,4],[[1,4],[2,4],[4,3]]])
sage: FP = P.p_partition_enumerator((3,1,2,4), QQ, check=True); FP
2*M[1, 1, 1, 1] + 2*M[1, 2, 1] + M[2, 1, 1] + M[3, 1]
sage: expansion = FP.expand(5)
sage: xs = expansion.parent().gens()
sage: expansion == sum(xs[a]*xs[b]*xs[c]*xs[d]
....:                  for a in range(5) for b in range(5)
....:                  for c in range(5) for d in range(5)
....:                  if a <= b and c <= b and b < d)
True

sage: P = Poset([[],[]])
sage: FP = P.p_partition_enumerator((), QQ, check=True); FP                #␣
↪needs sage.combinat
M[]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> P = Poset([[Integer(1),Integer(2),Integer(3),Integer(4)],[[Integer(1),
↪Integer(4)],[Integer(2),Integer(4)],[Integer(4),Integer(3)]]])
>>> FP = P.p_partition_enumerator((Integer(3),Integer(1),Integer(2),
↪Integer(4)), QQ, check=True); FP
2*M[1, 1, 1, 1] + 2*M[1, 2, 1] + M[2, 1, 1] + M[3, 1]
>>> expansion = FP.expand(Integer(5))
>>> xs = expansion.parent().gens()
>>> expansion == sum(xs[a]*xs[b]*xs[c]*xs[d]
...                  for a in range(Integer(5)) for b in range(Integer(5))
...                  for c in range(Integer(5)) for d in range(Integer(5))
...                  if a <= b and c <= b and b < d)
True

>>> P = Poset([[],[]])
>>> FP = P.p_partition_enumerator((), QQ, check=True); FP                #␣
↪needs sage.combinat
M[]
```

With the `weights` parameter:

```
sage: P = Poset([[1,2,3,4],[[1,4],[2,4],[4,3]]])
sage: FP = P.p_partition_enumerator((3,1,2,4), QQ,                              #␣
↪needs sage.combinat
....:           weights={1: 1, 2: 2, 3: 1, 4: 1}, check=True); FP

```

plot(*label_elements=True*, *element_labels=None*, *layout='acyclic'*, *cover_labels=None*, ***kwds*)

Return a Graphic object for the Hasse diagram of the poset.

If the poset is ranked, the plot uses the rank function for the heights of the elements.

INPUT:

- Options to change element look:
  - `element_colors` – dictionary where keys are colors and values are lists of elements
  - `element_color` – a color for elements not set in `element_colors`
  - `element_shape` – the shape of elements, like `'s'` for square; see https://matplotlib.org/api/markers_api.html for the list
  - `element_size` – (default: 200) the size of elements
  - `label_elements` – boolean (default: `True`); whether to display element labels
  - `element_labels` (default: `None`); a dictionary where keys are elements and values are labels to show
- Options to change cover relation look:
  - `cover_colors` – dictionary where keys are colors and values are lists of cover relations given as pairs of elements
  - `cover_color` – a color for elements not set in `cover_colors`
  - `cover_style` – style for cover relations: `'solid'`, `'dashed'`, `'dotted'` or `'dashdot'`
  - `cover_labels` – dictionary, list or function representing labels of the covers of the poset. When set to `None` (default) no label is displayed on the edges of the Hasse Diagram.
  - `cover_labels_background` – a background color for cover relations. The default is "white". To achieve a transparent background use "transparent".
- Options to change overall look:
  - `figsize` – (default: 8) size of the whole plot
  - `title` – a title for the plot
  - `fontsize` – fontsize for the title
  - `border` – (default: `False`) whether to draw a border over the plot

> **Note**
>
> All options of `GenericGraph.plot` are also available through this function.

EXAMPLES:

This function can be used without any parameters:

```
sage: # needs sage.plot
sage: D12 = posets.DivisorLattice(12)
sage: D12.plot()
Graphics object consisting of 14 graphics primitives
```

```
>>> from sage.all import *
>>> # needs sage.plot
>>> D12 = posets.DivisorLattice(Integer(12))
>>> D12.plot()
Graphics object consisting of 14 graphics primitives
```

Just the abstract form of the poset; examples of relabeling:

```
sage: # needs sage.plot
sage: D12.plot(label_elements=False)
Graphics object consisting of 8 graphics primitives
sage: d = {1: 0, 2: 'a', 3: 'b', 4: 'c', 6: 'd', 12: 1}
sage: D12.plot(element_labels=d)
Graphics object consisting of 14 graphics primitives
sage: d = {i: str(factor(i)) for i in D12}
sage: D12.plot(element_labels=d)
Graphics object consisting of 14 graphics primitives
```

```
>>> from sage.all import *
>>> # needs sage.plot
>>> D12.plot(label_elements=False)
Graphics object consisting of 8 graphics primitives
>>> d = {Integer(1): Integer(0), Integer(2): 'a', Integer(3): 'b',␣
↪Integer(4): 'c', Integer(6): 'd', Integer(12): Integer(1)}
>>> D12.plot(element_labels=d)
Graphics object consisting of 14 graphics primitives
>>> d = {i: str(factor(i)) for i in D12}
>>> D12.plot(element_labels=d)
Graphics object consisting of 14 graphics primitives
```

Some settings for coverings:

```
sage: # needs sage.plot
sage: d = {(a, b): b/a for a, b in D12.cover_relations()}
sage: D12.plot(cover_labels=d, cover_color='gray', cover_style='dotted')
Graphics object consisting of 21 graphics primitives
```

```
>>> from sage.all import *
>>> # needs sage.plot
>>> d = {(a, b): b/a for a, b in D12.cover_relations()}
>>> D12.plot(cover_labels=d, cover_color='gray', cover_style='dotted')
Graphics object consisting of 21 graphics primitives
```

To emphasize some elements and show some options:

```
sage: # needs sage.plot
sage: L = LatticePoset({0: [1, 2, 3, 4], 1: [12], 2: [6, 7],
```

(continues on next page)

(continued from previous page)

```
....:                   3: [5, 9], 4: [5, 6, 10, 11], 5: [13],
....:                   6: [12], 7: [12, 8, 9], 8: [13], 9: [13],
....:                   10: [12], 11: [12], 12: [13]})
sage: F = L.frattini_sublattice()
sage: F_internal = [c for c in F.cover_relations()
....:               if c in L.cover_relations()]
sage: L.plot(figsize=12, border=True, element_shape='s',
....:        element_size=400, element_color='white',
....:        element_colors={'blue': F, 'green': L.double_irreducibles()},
....:        cover_color='lightgray', cover_colors={'black': F_internal},
....:        title='The Frattini\nsublattice in blue', fontsize=10)
Graphics object consisting of 39 graphics primitives
```

```
>>> from sage.all import *
>>> # needs sage.plot
>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3),␣
↪Integer(4)], Integer(1): [Integer(12)], Integer(2): [Integer(6),␣
↪Integer(7)],
...                   Integer(3): [Integer(5), Integer(9)], Integer(4):␣
↪[Integer(5), Integer(6), Integer(10), Integer(11)], Integer(5):␣
↪[Integer(13)],
...                   Integer(6): [Integer(12)], Integer(7): [Integer(12),␣
↪Integer(8), Integer(9)], Integer(8): [Integer(13)], Integer(9):␣
↪[Integer(13)],
...                   Integer(10): [Integer(12)], Integer(11): [Integer(12)],␣
↪Integer(12): [Integer(13)]})
>>> F = L.frattini_sublattice()
>>> F_internal = [c for c in F.cover_relations()
...               if c in L.cover_relations()]
>>> L.plot(figsize=Integer(12), border=True, element_shape='s',
...        element_size=Integer(400), element_color='white',
...        element_colors={'blue': F, 'green': L.double_irreducibles()},
...        cover_color='lightgray', cover_colors={'black': F_internal},
...        title='The Frattini\nsublattice in blue', fontsize=Integer(10))
Graphics object consisting of 39 graphics primitives
```

product(*other*)

Return the Cartesian product of the poset with `other`.

The Cartesian (or 'direct') product of P and Q is defined by $(p, q) \leq (p', q')$ iff $p \leq p'$ in P and $q \leq q'$ in Q.

Product of (semi)lattices are returned as a (semi)lattice.

EXAMPLES:

```
sage: P = posets.ChainPoset(3)
sage: Q = posets.ChainPoset(4)
sage: PQ = P.product(Q) ; PQ
Finite lattice containing 12 elements
sage: len(PQ.cover_relations())
17
sage: Q.product(P).is_isomorphic(PQ)
True
```

(continues on next page)

(continued from previous page)

```
sage: P = posets.BooleanLattice(2)
sage: Q = P.product(P)
sage: Q.is_isomorphic(posets.BooleanLattice(4))
True
```

```
>>> from sage.all import *
>>> P = posets.ChainPoset(Integer(3))
>>> Q = posets.ChainPoset(Integer(4))
>>> PQ = P.product(Q) ; PQ
Finite lattice containing 12 elements
>>> len(PQ.cover_relations())
17
>>> Q.product(P).is_isomorphic(PQ)
True

>>> P = posets.BooleanLattice(Integer(2))
>>> Q = P.product(P)
>>> Q.is_isomorphic(posets.BooleanLattice(Integer(4)))
True
```

One can also simply use $*$:

```
sage: P = posets.ChainPoset(2)
sage: Q = posets.ChainPoset(3)
sage: P*Q
Finite lattice containing 6 elements
```

```
>>> from sage.all import *
>>> P = posets.ChainPoset(Integer(2))
>>> Q = posets.ChainPoset(Integer(3))
>>> P*Q
Finite lattice containing 6 elements
```

See also

CartesianProductPoset, *factor()*

promotion(*i=1*)

Compute the (extended) promotion on the linear extension of the poset `self`.

INPUT:

- `i` – integer between 1 and n (default: 1)

OUTPUT: an isomorphic poset, with the same default linear extension

The extended promotion is defined on a poset `self` of size n by applying the promotion operator $\tau_i\tau_{i+1}\cdots\tau_{n-1}$ to the default linear extension π of `self` (see *promotion()*), and relabeling `self` accordingly. For more details see [Stan2009].

When the elements of the poset `self` are labelled by $\{1, 2, \ldots, n\}$, the linear extension is the identity, and $i = 1$, the above algorithm corresponds to the promotion operator on posets defined by Schützenberger as

follows. Remove 1 from `self` and replace it by the minimum j of all labels covering 1 in the poset. Then, remove j and replace it by the minimum of all labels covering j, and so on. This process ends when a label is a local maximum. Place the label $n + 1$ at this vertex. Finally, decrease all labels by 1.

EXAMPLES:

```
sage: P = Poset(([1,2], [[1,2]]), linear_extension=True, facade=False)
sage: P.promotion()
Finite poset containing 2 elements with distinguished linear extension
sage: P == P.promotion()
True

sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,
↪6]]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 5], [3, 7], [5, 7], [6, 4]]
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2)], [[Integer(1),Integer(2)]]), linear_
↪extension=True, facade=False)
>>> P.promotion()
Finite poset containing 2 elements with distinguished linear extension
>>> P == P.promotion()
True

>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6),Integer(7)], [[Integer(1),Integer(2)],[Integer(1),Integer(4)],
↪[Integer(2),Integer(3)],[Integer(2),Integer(5)],[Integer(3),Integer(6)],
↪[Integer(4),Integer(7)],[Integer(5),Integer(6)]]))
>>> P.list()
[1, 2, 3, 5, 6, 4, 7]
>>> Q = P.promotion(Integer(4)); Q
Finite poset containing 7 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 5], [3, 7], [5, 7], [6, 4]]
```

Note that if one wants to obtain the promotion defined by Schützenberger's algorithm directly on the poset, one needs to make sure the linear extension is the identity:

```
sage: P = P.with_linear_extension([1,2,3,4,5,6,7])
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 4], [3, 5], [4, 5], [6, 7]]
sage: Q = P.promotion()
sage: Q.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 5], [3, 6], [4, 7], [5, 7]]
```

```
>>> from sage.all import *
>>> P = P.with_linear_extension([Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5),Integer(6),Integer(7)])
>>> P.list()
[1, 2, 3, 4, 5, 6, 7]
>>> Q = P.promotion(Integer(4)); Q
Finite poset containing 7 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 4], [3, 5], [4, 5], [6, 7]]
>>> Q = P.promotion()
>>> Q.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 5], [3, 6], [4, 7], [5, 7]]
```

Here is an example for a poset not labelled by $\{1, 2, \ldots, n\}$:

```
sage: P = Poset((divisors(30), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 5, 6, 10, 15, 30]
sage: P.cover_relations()
[[1, 2], [1, 3], [1, 5], [2, 6], [2, 10], [3, 6], [3, 15],
 [5, 10], [5, 15], [6, 30], [10, 30], [15, 30]]
sage: Q = P.promotion(4); Q
Finite poset containing 8 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [1, 6], [2, 5], [2, 15], [3, 5], [3, 10],
 [5, 30], [6, 10], [6, 15], [10, 30], [15, 30]]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(30)), attrcall("divides")), linear_
↪extension=True)
>>> P.list()
[1, 2, 3, 5, 6, 10, 15, 30]
>>> P.cover_relations()
[[1, 2], [1, 3], [1, 5], [2, 6], [2, 10], [3, 6], [3, 15],
 [5, 10], [5, 15], [6, 30], [10, 30], [15, 30]]
>>> Q = P.promotion(Integer(4)); Q
Finite poset containing 8 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 3], [1, 6], [2, 5], [2, 15], [3, 5], [3, 10],
 [5, 30], [6, 10], [6, 15], [10, 30], [15, 30]]
```

AUTHOR:

- Anne Schilling (2012-02-18)

random_linear_extension()

Return a random linear extension of the poset.

The distribution is not uniform.

EXAMPLES:

```
sage: set_random_seed(0)  # results are reproducible
sage: P = posets.BooleanLattice(4)
sage: P.random_linear_extension()
[0, 1, 2, 8, 3, 10, 4, 5, 6, 7, 9, 11, 12, 13, 14, 15]
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))  # results are reproducible
>>> P = posets.BooleanLattice(Integer(4))
>>> P.random_linear_extension()
[0, 1, 2, 8, 3, 10, 4, 5, 6, 7, 9, 11, 12, 13, 14, 15]
```

random_maximal_antichain()

Return a random maximal antichain of the poset.

The distribution is not uniform.

EXAMPLES:

```
sage: set_random_seed(0)  # results are reproducible
sage: P = posets.BooleanLattice(4)
sage: P.random_maximal_antichain()
[3, 14, 13]
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))  # results are reproducible
>>> P = posets.BooleanLattice(Integer(4))
>>> P.random_maximal_antichain()
[3, 14, 13]
```

random_maximal_chain()

Return a random maximal chain of the poset.

The distribution is not uniform.

EXAMPLES:

```
sage: set_random_seed(0)  # results are reproducible
sage: P = posets.BooleanLattice(4)
sage: P.random_maximal_chain()
[0, 1, 3, 11, 15]
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))  # results are reproducible
>>> P = posets.BooleanLattice(Integer(4))
>>> P.random_maximal_chain()
[0, 1, 3, 11, 15]
```

random_order_ideal(*direction='down'*)

Return a random order ideal with uniform probability.

INPUT:

- `direction` – `'up'`, `'down'` or `'antichain'` (default: `'down'`)

OUTPUT:

A randomly selected order ideal (or order filter if `direction='up'`, or antichain if `direction='antichain'`) where all order ideals have equal probability of occurring.

ALGORITHM:

Uses the coupling from the past algorithm described in [Propp1997].

EXAMPLES:

```
sage: P = posets.BooleanLattice(3)
sage: P.random_order_ideal()  # random
[0, 1, 2, 3, 4, 5, 6]
sage: P.random_order_ideal(direction='up')  # random
[6, 7]
sage: P.random_order_ideal(direction='antichain')  # random
[1, 2]

sage: P = posets.TamariLattice(5)
sage: a = P.random_order_ideal('antichain')
sage: P.is_antichain_of_poset(a)
True
sage: a = P.random_order_ideal('up')
sage: P.is_order_filter(a)
True
sage: a = P.random_order_ideal('down')
sage: P.is_order_ideal(a)
True
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(3))
>>> P.random_order_ideal()  # random
[0, 1, 2, 3, 4, 5, 6]
>>> P.random_order_ideal(direction='up')  # random
[6, 7]
>>> P.random_order_ideal(direction='antichain')  # random
[1, 2]

>>> P = posets.TamariLattice(Integer(5))
>>> a = P.random_order_ideal('antichain')
>>> P.is_antichain_of_poset(a)
True
>>> a = P.random_order_ideal('up')
>>> P.is_order_filter(a)
True
>>> a = P.random_order_ideal('down')
>>> P.is_order_ideal(a)
True
```

random_subposet(*p*)

Return a random subposet that contains each element with probability `p`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(3)
sage: set_random_seed(0)  # Results are reproducible
sage: Q = P.random_subposet(0.5)
sage: Q.cover_relations()
[[0, 2], [0, 5], [2, 3], [3, 7], [5, 7]]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(3))
>>> set_random_seed(Integer(0))  # Results are reproducible
>>> Q = P.random_subposet(RealNumber('0.5'))
>>> Q.cover_relations()
[[0, 2], [0, 5], [2, 3], [3, 7], [5, 7]]
```

rank(*element=None*)

Return the rank of an element `element` in the poset `self`, or the rank of the poset if `element` is `None`.

(The rank of a poset is the length of the longest chain of elements of the poset. This is sometimes called the length of a poset.)

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: P.rank(5)
2
sage: P.rank()
3
sage: Q = Poset([[1,2],[3],[],[]])

sage: P = posets.SymmetricGroupBruhatOrderPoset(4)
sage: [(v,P.rank(v)) for v in P]
[('1234', 0),
 ('1243', 1),
...
 ('4312', 5),
 ('4321', 6)]
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
↪Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
↪[]], facade = False)
>>> P.rank(Integer(5))
2
>>> P.rank()
3
>>> Q = Poset([[Integer(1),Integer(2)],[Integer(3)],[],[]])

>>> P = posets.SymmetricGroupBruhatOrderPoset(Integer(4))
>>> [(v,P.rank(v)) for v in P]
[('1234', 0),
```

(continues on next page)

(continued from previous page)

```
 ('1243', 1),
...
 ('4312', 5),
 ('4321', 6)]
```

rank_function()

Return the (normalized) rank function of the poset, if it exists.

A *rank function* of a poset P is a function r that maps elements of P to integers and satisfies: $r(x) = r(y)+1$ if x covers y. The function r is normalized such that its minimum value on every connected component of the Hasse diagram of P is 0. This determines the function r uniquely (when it exists).

OUTPUT:

- a lambda function, if the poset admits a rank function
- `None`, if the poset does not admit a rank function

EXAMPLES:

```
sage: P = Poset(([1,2,3,4],[[1,4],[2,3],[3,4]]), facade=True)
sage: P.rank_function() is not None
True
sage: P = Poset(([1,2,3,4,5],[[1,2],[2,3],[3,4],[1,5],[5,4]]), facade=True)
sage: P.rank_function() is not None
False
sage: P = Poset(([1,2,3,4,5,6,7,8],[[1,4],[2,3],[3,4],[5,7],[6,7]]),␣
↪facade=True)
sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4)],[[Integer(1),
↪Integer(4)],[Integer(2),Integer(3)],[Integer(3),Integer(4)]]), facade=True)
>>> P.rank_function() is not None
True
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],
↪[[Integer(1),Integer(2)],[Integer(2),Integer(3)],[Integer(3),Integer(4)],
↪[Integer(1),Integer(5)],[Integer(5),Integer(4)]]), facade=True)
>>> P.rank_function() is not None
False
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6),Integer(7),Integer(8)],[[Integer(1),Integer(4)],[Integer(2),
↪Integer(3)],[Integer(3),Integer(4)],[Integer(5),Integer(7)],[Integer(6),
↪Integer(7)]]), facade=True)
>>> f = P.rank_function(); f is not None
True
>>> f(Integer(5))
0
>>> f(Integer(2))
```

(continues on next page)

(continued from previous page)

```
0
```

rees_product(*other*)

Return the Rees product of `self` and `other`.

This is only defined if both posets are graded.

The underlying set is the set of pairs (p, q) in the Cartesian product such that $\mathrm{rk}(p) \geq \mathrm{rk}(q)$.

This operation was defined by Björner and Welker in [BjWe2005]. Other references are [MBRe2011] and [LSW2012].

EXAMPLES:

```
sage: B3 = posets.BooleanLattice(3)
sage: B3t = B3.subposet(list(range(1,8)))
sage: C3 = posets.ChainPoset(3)
sage: D = B3t.rees_product(C3); D
Finite poset containing 12 elements
sage: sorted(D.minimal_elements())
[(1, 0), (2, 0), (4, 0)]
sage: sorted(D.maximal_elements())
[(7, 0), (7, 1), (7, 2)]
sage: D.with_bounds().moebius_function('bottom','top')
2
```

```
>>> from sage.all import *
>>> B3 = posets.BooleanLattice(Integer(3))
>>> B3t = B3.subposet(list(range(Integer(1),Integer(8))))
>>> C3 = posets.ChainPoset(Integer(3))
>>> D = B3t.rees_product(C3); D
Finite poset containing 12 elements
>>> sorted(D.minimal_elements())
[(1, 0), (2, 0), (4, 0)]
>>> sorted(D.maximal_elements())
[(7, 0), (7, 1), (7, 2)]
>>> D.with_bounds().moebius_function('bottom','top')
2
```

product(), *ordinal_product()*, *star_product()*

relabel(*relabeling=None*)

Return a copy of this poset with its elements relabeled.

INPUT:

- `relabeling` – a function, dictionary, list or tuple

The given function or dictionary must map each (non-wrapped) element of `self` to some distinct object. The given list or tuple must be made of distinct objects.

When the input is a list or a tuple, the relabeling uses the total ordering of the elements of the poset given by `list(self)`.

If no relabeling is given, the poset is relabeled by integers from 0 to $n-1$ according to one of its linear extensions. This means that $i < j$ as integers whenever $i < j$ in the relabeled poset.

EXAMPLES:

Relabeling using a function:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: Q = P.relabel(lambda x: x+1)
sage: Q.list()
[2, 3, 4, 5, 7, 13]
sage: Q.cover_relations()
[[2, 3], [2, 4], [3, 5], [3, 7], [4, 7], [5, 13], [7, 13]]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_
↪extension=True)
>>> P.list()
[1, 2, 3, 4, 6, 12]
>>> P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
>>> Q = P.relabel(lambda x: x+Integer(1))
>>> Q.list()
[2, 3, 4, 5, 7, 13]
>>> Q.cover_relations()
[[2, 3], [2, 4], [3, 5], [3, 7], [4, 7], [5, 13], [7, 13]]
```

Relabeling using a dictionary:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True,␣
↪facade=False)
sage: relabeling = {c.element: i for i, c in enumerate(P)}
sage: relabeling
{1: 0, 2: 1, 3: 2, 4: 3, 6: 4, 12: 5}
sage: Q = P.relabel(relabeling)
sage: Q.list()
[0, 1, 2, 3, 4, 5]
sage: Q.cover_relations()
[[0, 1], [0, 2], [1, 3], [1, 4], [2, 4], [3, 5], [4, 5]]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_
↪extension=True, facade=False)
>>> relabeling = {c.element: i for i, c in enumerate(P)}
>>> relabeling
{1: 0, 2: 1, 3: 2, 4: 3, 6: 4, 12: 5}
>>> Q = P.relabel(relabeling)
>>> Q.list()
[0, 1, 2, 3, 4, 5]
>>> Q.cover_relations()
```

(continues on next page)

(continued from previous page)

```
[[0, 1], [0, 2], [1, 3], [1, 4], [2, 4], [3, 5], [4, 5]]
```

Mind the `c.element`; this is because the relabeling is applied to the elements of the poset without the wrapping. Thanks to this convention, the same relabeling function can be used both for facade or non facade posets.

Relabeling using a list:

```
sage: P = posets.PentagonPoset()
sage: list(P)
[0, 1, 2, 3, 4]
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
sage: Q = P.relabel(list('abcde'))
sage: Q.cover_relations()
[['a', 'b'], ['a', 'c'], ['b', 'e'], ['c', 'd'], ['d', 'e']]
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> list(P)
[0, 1, 2, 3, 4]
>>> P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
>>> Q = P.relabel(list('abcde'))
>>> Q.cover_relations()
[['a', 'b'], ['a', 'c'], ['b', 'e'], ['c', 'd'], ['d', 'e']]
```

Default behaviour is increasing relabeling:

```
sage: a2 = posets.ChainPoset(2)
sage: P = a2 * a2
sage: Q = P.relabel()
sage: Q.cover_relations()
[[0, 1], [0, 2], [1, 3], [2, 3]]
```

```
>>> from sage.all import *
>>> a2 = posets.ChainPoset(Integer(2))
>>> P = a2 * a2
>>> Q = P.relabel()
>>> Q.cover_relations()
[[0, 1], [0, 2], [1, 3], [2, 3]]
```

Relabeling a (semi)lattice gives a (semi)lattice:

```
sage: P = JoinSemilattice({0: [1]})
sage: P.relabel(lambda n: n + 1)
Finite join-semilattice containing 2 elements
```

```
>>> from sage.all import *
>>> P = JoinSemilattice({Integer(0): [Integer(1)]})
>>> P.relabel(lambda n: n + Integer(1))
Finite join-semilattice containing 2 elements
```

> **Note**
>
> As can be seen in the above examples, the default linear extension of `Q` is that of `P` after relabeling. In particular, `P` and `Q` share the same internal Hasse diagram.

relations()

Return the list of all relations of the poset.

A relation is a pair of elements x and y such that $x \leq y$ in the poset.

The number of relations is the dimension of the incidence algebra.

OUTPUT:

A list of pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.relations()
[[1, 1], [1, 2], [1, 3], [1, 4], [0, 0], [0, 2], [0, 3],
[0, 4], [2, 2], [2, 3], [2, 4], [3, 3], [3, 4], [4, 4]]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> P.relations()
[[1, 1], [1, 2], [1, 3], [1, 4], [0, 0], [0, 2], [0, 3],
[0, 4], [2, 2], [2, 3], [2, 4], [3, 3], [3, 4], [4, 4]]
```

> **See also**
>
> *number_of_relations()*, *relations_iterator()*

AUTHOR:

- Rob Beezer (2011-05-04)

relations_iterator(*strict=False*)

Return an iterator for all the relations of the poset.

A relation is a pair of elements x and y such that $x \leq y$ in the poset.

INPUT:

- `strict` – boolean (default: `False`); if `True`, return an iterator over relations $x < y$, excluding all relations $x \leq x$

OUTPUT:

A generator that produces pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: it = P.relations_iterator()
sage: type(it)
<class 'generator'>
sage: next(it), next(it)
([1, 1], [1, 2])

sage: P = posets.PentagonPoset()
sage: list(P.relations_iterator(strict=True))
[[0, 1], [0, 2], [0, 4], [0, 3], [1, 4], [2, 3], [2, 4], [3, 4]]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> it = P.relations_iterator()
>>> type(it)
<class 'generator'>
>>> next(it), next(it)
([1, 1], [1, 2])

>>> P = posets.PentagonPoset()
>>> list(P.relations_iterator(strict=True))
[[0, 1], [0, 2], [0, 4], [0, 3], [1, 4], [2, 3], [2, 4], [3, 4]]
```

See also

number_of_relations(), *relations()*.

AUTHOR:

- Rob Beezer (2011-05-04)

relations_number()

alias of *number_of_relations()*.

show(*label_elements=True*, *element_labels=None*, *cover_labels=None*, ***kwds*)

Displays the Hasse diagram of the poset.

INPUT:

- `label_elements` – boolean (default: `True`); whether to display element labels
- `element_labels` – dictionary (default: `None`) of element labels
- `cover_labels` – dictionary, list or function representing labels of the covers of `self`; when set to `None` (default) no label is displayed on the edges of the Hasse Diagram

Note

This method also accepts:

- All options of `GenericGraph.plot`
- All options of `Graphics.show`

EXAMPLES:

```
sage: # needs sage.plot
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.plot(label_elements=False)
Graphics object consisting of 6 graphics primitives
sage: D.show()
sage: elm_labs = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: D.show(element_labels=elm_labs)
```

```
>>> from sage.all import *
>>> # needs sage.plot
>>> D = Poset({ Integer(0):[Integer(1),Integer(2)], Integer(1):[Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)] })
>>> D.plot(label_elements=False)
Graphics object consisting of 6 graphics primitives
>>> D.show()
>>> elm_labs = {Integer(0):'a', Integer(1):'b', Integer(2):'c', Integer(3):'d
↪', Integer(4):'e'}
>>> D.show(element_labels=elm_labs)
```

One more example with cover labels:

```
sage: # needs sage.plot
sage: P = posets.PentagonPoset()
sage: P.show(cover_labels=lambda a, b: a - b)
```

```
>>> from sage.all import *
>>> # needs sage.plot
>>> P = posets.PentagonPoset()
>>> P.show(cover_labels=lambda a, b: a - b)
```

slant_sum(*p*, *element*, *p_element*)

Return the slant sum poset of posets `self` and `p` by connecting them with a cover relation `(p_element, element)`.

Note

The element names of `self` and `p` must be distinct.

INPUT:

- `p` – the poset used for the slant sum
- `element` – the element of `self` that is the top of the new cover relation
- `p_element` – the element of `p` that is the bottom of the new cover relation

EXAMPLES:

```
sage: R = posets.RibbonPoset(5, [1,2])
sage: H = Poset([[5, 6, 7], [(5, 6), (6,7)]])
sage: SS = R.slant_sum(H, 3, 7)
sage: all(cr in SS.cover_relations() for cr in R.cover_relations())
```

(continues on next page)

(continued from previous page)

```
True
sage: all(cr in SS.cover_relations() for cr in H.cover_relations())
True
sage: SS.covers(7, 3)
True
```

```
>>> from sage.all import *
>>> R = posets.RibbonPoset(Integer(5), [Integer(1),Integer(2)])
>>> H = Poset([[Integer(5), Integer(6), Integer(7)], [(Integer(5),␣
↪Integer(6)), (Integer(6),Integer(7))]])
>>> SS = R.slant_sum(H, Integer(3), Integer(7))
>>> all(cr in SS.cover_relations() for cr in R.cover_relations())
True
>>> all(cr in SS.cover_relations() for cr in H.cover_relations())
True
>>> SS.covers(Integer(7), Integer(3))
True
```

sorted(*l*, *allow_incomparable=True*, *remove_duplicates=False*)

Return the list *l* sorted by the poset.

INPUT:

- `l` – list of elements of the poset
- `allow_incomparable` – boolean (default: `True`); if `True`, return incomparable elements in some order. If `False`, raise an error if `l` is not a chain of the poset.
- `remove_duplicates` – boolean (default: `False`); if `True`, remove duplicates from the output list

EXAMPLES:

```
sage: P = posets.DivisorLattice(36)
sage: P.sorted([1, 4, 1, 6, 2, 12])  # Random order for 4 and 6
[1, 1, 2, 4, 6, 12]
sage: P.sorted([1, 4, 1, 6, 2, 12], remove_duplicates=True)
[1, 2, 4, 6, 12]
sage: P.sorted([1, 4, 1, 6, 2, 12], allow_incomparable=False)
Traceback (most recent call last):
...
ValueError: the list contains incomparable elements

sage: P = Poset({7:[1, 5], 1:[2, 6], 5:[3], 6:[3, 4]})
sage: P.sorted([4, 1, 4, 5, 7])  # Random order for 1 and 5
[7, 1, 5, 4, 4]
sage: P.sorted([1, 4, 4, 7], remove_duplicates=True)
[7, 1, 4]
sage: P.sorted([4, 1, 4, 5, 7], allow_incomparable=False)
Traceback (most recent call last):
...
ValueError: the list contains incomparable elements
```

```
>>> from sage.all import *
>>> P = posets.DivisorLattice(Integer(36))
```

(continues on next page)

(continued from previous page)

```
>>> P.sorted([Integer(1), Integer(4), Integer(1), Integer(6), Integer(2),␣
↪Integer(12)])  # Random order for 4 and 6
[1, 1, 2, 4, 6, 12]
>>> P.sorted([Integer(1), Integer(4), Integer(1), Integer(6), Integer(2),␣
↪Integer(12)], remove_duplicates=True)
[1, 2, 4, 6, 12]
>>> P.sorted([Integer(1), Integer(4), Integer(1), Integer(6), Integer(2),␣
↪Integer(12)], allow_incomparable=False)
Traceback (most recent call last):
...
ValueError: the list contains incomparable elements

>>> P = Poset({Integer(7):[Integer(1), Integer(5)], Integer(1):[Integer(2),␣
↪Integer(6)], Integer(5):[Integer(3)], Integer(6):[Integer(3), Integer(4)]})
>>> P.sorted([Integer(4), Integer(1), Integer(4), Integer(5), Integer(7)])  #␣
↪Random order for 1 and 5
[7, 1, 5, 4, 4]
>>> P.sorted([Integer(1), Integer(4), Integer(4), Integer(7)], remove_
↪duplicates=True)
[7, 1, 4]
>>> P.sorted([Integer(4), Integer(1), Integer(4), Integer(5), Integer(7)],␣
↪allow_incomparable=False)
Traceback (most recent call last):
...
ValueError: the list contains incomparable elements
```

spectrum(a)

Return the a-spectrum of this poset.

The a-spectrum in a poset P is the list of integers whose i-th position contains the number of linear extensions of P that have a in the i-th location.

INPUT:

- `a` – an element of this poset

OUTPUT:

The a-spectrum of this poset, returned as a list.

EXAMPLES:

```
sage: P = posets.ChainPoset(5)
sage: P.spectrum(2)
[0, 0, 1, 0, 0]

sage: P = posets.BooleanLattice(3)
sage: P.spectrum(5)
[0, 0, 0, 4, 12, 16, 16, 0]

sage: P = posets.YoungDiagramPoset(Partition([3,2,1]))                    #␣
↪needs sage.combinat
sage: P.spectrum((0,1))                                                   #␣
↪needs sage.combinat
[0, 8, 6, 2, 0, 0]
```

(continues on next page)

(continued from previous page)

```
sage: P = posets.AntichainPoset(4)
sage: P.spectrum(3)
[6, 6, 6, 6]
```

```
>>> from sage.all import *
>>> P = posets.ChainPoset(Integer(5))
>>> P.spectrum(Integer(2))
[0, 0, 1, 0, 0]

>>> P = posets.BooleanLattice(Integer(3))
>>> P.spectrum(Integer(5))
[0, 0, 0, 4, 12, 16, 16, 0]

>>> P = posets.YoungDiagramPoset(Partition([Integer(3),Integer(2),
↪Integer(1)]))                    # needs sage.combinat
>>> P.spectrum((Integer(0),Integer(1)))                                    ␣
↪              # needs sage.combinat
[0, 8, 6, 2, 0, 0]

>>> P = posets.AntichainPoset(Integer(4))
>>> P.spectrum(Integer(3))
[6, 6, 6, 6]
```

star_product(*other*, *labels='pairs'*)

Return a poset isomorphic to the star product of the poset with `other`.

Both this poset and `other` are expected to be bounded and have at least two elements.

Let P be a poset with top element $\top_P$ and Q be a poset with bottom element $\bot_Q$. The star product of P and Q is the ordinal sum of $P \setminus \top_P$ and $Q \setminus \bot_Q$.

Mathematically, it is only defined when P and Q have no common elements; here we force that by giving them different names in the resulting poset.

INPUT:

- `other` – a poset
- `labels` – string (default: `'pairs'`); if set to 'pairs', each element `v` in this poset will be named `(0, v)` and each element `u` in `other` will be named `(1, u)` in the result. If set to 'integers', the elements of the result will be relabeled with consecutive integers.

EXAMPLES:

This is mostly used to combine two Eulerian posets to third one, and makes sense for graded posets only:

```
sage: B2 = posets.BooleanLattice(2)
sage: B3 = posets.BooleanLattice(3)
sage: P = B2.star_product(B3); P
Finite poset containing 10 elements
sage: P.is_eulerian()                                                    #␣
↪needs sage.libs.flint
True
```

```
>>> from sage.all import *
>>> B2 = posets.BooleanLattice(Integer(2))
>>> B3 = posets.BooleanLattice(Integer(3))
>>> P = B2.star_product(B3); P
Finite poset containing 10 elements
>>> P.is_eulerian()                                                    #␣
↪needs sage.libs.flint
True
```

We can get elements as pairs or as integers:

```
sage: ABC = Poset({'a': ['b'], 'b': ['c']})
sage: XYZ = Poset({'x': ['y'], 'y': ['z']})
sage: ABC.star_product(XYZ).list()
[(0, 'a'), (0, 'b'), (1, 'y'), (1, 'z')]
sage: sorted(ABC.star_product(XYZ, labels='integers'))
[0, 1, 2, 3]
```

```
>>> from sage.all import *
>>> ABC = Poset({'a': ['b'], 'b': ['c']})
>>> XYZ = Poset({'x': ['y'], 'y': ['z']})
>>> ABC.star_product(XYZ).list()
[(0, 'a'), (0, 'b'), (1, 'y'), (1, 'z')]
>>> sorted(ABC.star_product(XYZ, labels='integers'))
[0, 1, 2, 3]
```

subposet(*elements*, *category=None*)

Return the poset containing given elements with partial order induced by this poset.

INPUT:

- elements – some elements
- category – optional category

See also

interval_as_poset()

EXAMPLES:

```
sage: P = Poset({'a': ['c', 'd'], 'b': ['d','e'], 'c': ['f'],
....:            'd': ['f'], 'e': ['f']})
sage: Q = P.subposet(['a', 'b', 'f']); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[['b', 'f'], ['a', 'f']]
```

```
>>> from sage.all import *
>>> P = Poset({'a': ['c', 'd'], 'b': ['d','e'], 'c': ['f'],
...            'd': ['f'], 'e': ['f']})
>>> Q = P.subposet(['a', 'b', 'f']); Q
Finite poset containing 3 elements
```

(continues on next page)

(continued from previous page)

```
>>> Q.cover_relations()
[['b', 'f'], ['a', 'f']]
```

A subposet of a non-facade poset is again a non-facade poset:

```
sage: P = posets.PentagonPoset(facade=False)
sage: Q = P.subposet([0, 1, 2, 4])
sage: Q(1) < Q(2)
False
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset(facade=False)
>>> Q = P.subposet([Integer(0), Integer(1), Integer(2), Integer(4)])
>>> Q(Integer(1)) < Q(Integer(2))
False
```

tikz(*format=None*, *edge_labels=False*, *color_by_label=False*, *prog='dot'*, *rankdir='up'*, *standalone_config=None*, *usepackage=None*, *usetikzlibrary=None*, *macros=None*, *use_sage_preamble=None*, ***kwds*)

Return a TikzPicture illustrating the poset.

If `graphviz` and `dot2tex` are available, it uses these packages for placements of vertices and edges.

INPUT:

- `format` – string (default: `None`), `'dot2tex'` or `'tkz_graph'`. If `None`, it is set to `'dot2tex'` if dot2tex is present, otherwise it is set to `'tkz_graph'`.
- `edge_labels` – bool (default: `False`)
- `color_by_label` – boolean or dictionary or function (default: `False`); whether to color each edge with a different color according to its label; the colors are chosen along a rainbow, unless they are specified by a function or dictionary mapping labels to colors;

When using format `'dot2tex'`, the following inputs are considered:

- `prog` – string (default: `'dot'`) the program used for the layout corresponding to one of the software of the graphviz suite: 'dot', 'neato', 'twopi', 'circo' or 'fdp'.
- `rankdir` – string (default: `'up'`), direction of graph layout when prog is `'dot'`, possible values are `'down'`, `'up'`, `'right'` and `'left'`.

Additional keywords arguments are forwarded to `sage.graphs.graph_latex.GraphLatex.set_option()`.

The following inputs define the preamble of the latex standalone document class file containing the tikzpicture:

- `standalone_config` – list of strings (default: `["border=4mm"]`); latex document class standalone configuration options
- `usepackage` – list of strings (default: `[]`); latex packages
- `usetikzlibrary` – list of strings (default: `[]`); tikz libraries to use
- `macros` – list of strings (default: `[]`); list of newcommands needed for the picture
- `use_sage_preamble` – bool (default: `None`), if `None` it is set to `True` if and only if format is `'tkz_graph'`

OUTPUT:

An instance of `sage.misc.latex_standalone.TikzPicture`.

Note

Prerequisite: dot2tex optional Sage package and graphviz must be installed when using format `'dot2tex'`.

EXAMPLES:

```
sage: P = Poset(([1,2], [[1,2]]), cover_relations=True)
sage: tikz = P.tikz()                    # optional - dot2tex graphviz
↪# long time
sage: _ = tikz.pdf(view=False)           # optional - dot2tex graphviz latex
↪# long time
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2)], [[Integer(1),Integer(2)]]), cover_
↪relations=True)
>>> tikz = P.tikz()                    # optional - dot2tex graphviz        #␣
↪long time
>>> _ = tikz.pdf(view=False)           # optional - dot2tex graphviz latex  #␣
↪long time
```

top()

Return the unique maximal element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4),Integer(5)],Integer(4):[],
↪Integer(5):[]})
>>> P.top() is None
True
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.top()
1
```

See also

has_top(), bottom()

unwrap(*element*)

Return the element `element` of the poset `self` in unwrapped form.

INPUT:

- `element` – an element of `self`

EXAMPLES:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: x = P.an_element(); x
1
sage: x.parent()
Finite poset containing 4 elements
sage: P.unwrap(x)
1
sage: P.unwrap(x).parent()
Integer Ring
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade = False)
>>> x = P.an_element(); x
1
>>> x.parent()
Finite poset containing 4 elements
>>> P.unwrap(x)
1
>>> P.unwrap(x).parent()
Integer Ring
```

For a non facade poset, this is equivalent to using the `.element` attribute:

```
sage: P.unwrap(x) is x.element
True
```

```
>>> from sage.all import *
>>> P.unwrap(x) is x.element
True
```

For a facade poset, this does nothing:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: x = P.an_element()
sage: P.unwrap(x) is x
True
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade=True)
>>> x = P.an_element()
>>> P.unwrap(x) is x
True
```

This method is useful in code where we do not know if `P` is a facade poset or not.

upper_covers(*x*)

Return the list of upper covers of the element `x`.

An upper cover of x is an element y such that $x < y$ and there is no element z so that $x < z < y$.

EXAMPLES:

```
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.upper_covers(1)
[2, 6]
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(5)], [Integer(2),Integer(6)], [Integer(3)],
↪ [Integer(4)], [], [Integer(6),Integer(3)], [Integer(4)]])
>>> P.upper_covers(Integer(1))
[2, 6]
```

See also

lower_covers()

upper_covers_iterator(*x*)

Return an iterator over the upper covers of the element `x`.

EXAMPLES:

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[]})
sage: type(P.upper_covers_iterator(0))
<class 'generator'>
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[]})
>>> type(P.upper_covers_iterator(Integer(0)))
<class 'generator'>
```

width(*certificate=False*)

Return the width of the poset (the size of its longest antichain).

It is computed through a matching in a bipartite graph; see Wikipedia article Dilworth%27s_theorem for more information. The width is also called Dilworth number.

INPUT:

- `certificate` – boolean (default: `False`); whether to return a certificate

OUTPUT:

- If `certificate=True` return `(w, a)`, where w is the width of a poset and a is an antichain of maximum cardinality. If `certificate=False` return only width of the poset.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: P.width()                                                             #␣
↪needs networkx
6
```

(continues on next page)

(continued from previous page)

```
sage: w, max_achain = P.width(certificate=True)
sage: sorted(max_achain)
[3, 5, 6, 9, 10, 12]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> P.width()                                                                #␣
↪needs networkx
6

>>> w, max_achain = P.width(certificate=True)
>>> sorted(max_achain)
[3, 5, 6, 9, 10, 12]
```

with_bounds(*labels=('bottom', 'top')*)

Return the poset with bottom and top elements adjoined.

This function adds top and bottom elements to the poset. It will always add elements, it does not check if the poset already has a bottom or a top element.

For lattices and semilattices this function returns a lattice.

INPUT:

- `labels` – a pair of elements to use as a bottom and top element of the poset. Default is strings `'bottom'` and `'top'`. Either of them can be `None`, and then a new bottom or top element will not be added.

EXAMPLES:

```
sage: V = Poset({0: [1, 2]})
sage: trafficsign = V.with_bounds(); trafficsign
Finite poset containing 5 elements
sage: trafficsign.list()
['bottom', 0, 1, 2, 'top']
sage: trafficsign = V.with_bounds(labels=(-1, -2))
sage: trafficsign.cover_relations()
[[-1, 0], [0, 1], [0, 2], [1, -2], [2, -2]]

sage: Y = V.with_bounds(labels=(-1, None))
sage: Y.cover_relations()
[[-1, 0], [0, 1], [0, 2]]

sage: P = posets.PentagonPoset()  # A lattice
sage: P.with_bounds()
Finite lattice containing 7 elements

sage: P = posets.PentagonPoset(facade=False)
sage: P.with_bounds()
Finite lattice containing 7 elements
```

```
>>> from sage.all import *
>>> V = Poset({Integer(0): [Integer(1), Integer(2)]})
>>> trafficsign = V.with_bounds(); trafficsign
Finite poset containing 5 elements
```

(continues on next page)

(continued from previous page)

```
>>> trafficsign.list()
['bottom', 0, 1, 2, 'top']
>>> trafficsign = V.with_bounds(labels=(-Integer(1), -Integer(2)))
>>> trafficsign.cover_relations()
[[-1, 0], [0, 1], [0, 2], [1, -2], [2, -2]]

>>> Y = V.with_bounds(labels=(-Integer(1), None))
>>> Y.cover_relations()
[[-1, 0], [0, 1], [0, 2]]

>>> P = posets.PentagonPoset()  # A lattice
>>> P.with_bounds()
Finite lattice containing 7 elements

>>> P = posets.PentagonPoset(facade=False)
>>> P.with_bounds()
Finite lattice containing 7 elements
```

See also

without_bounds() for the reverse operation

with_linear_extension(*linear_extension*)

Return a copy of `self` with a different default linear extension.

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: list(P)
[1, 2, 3, 4, 6, 12]
sage: Q = P.with_linear_extension([1,3,2,6,4,12])
sage: list(Q)
[1, 3, 2, 6, 4, 12]
sage: Q.cover_relations()
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_
↪extension=True)
>>> P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
>>> list(P)
[1, 2, 3, 4, 6, 12]
>>> Q = P.with_linear_extension([Integer(1),Integer(3),Integer(2),Integer(6),
↪Integer(4),Integer(12)])
>>> list(Q)
[1, 3, 2, 6, 4, 12]
>>> Q.cover_relations()
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]
```

Note

With the current implementation, this requires relabeling the internal `DiGraph` which is $O(n+m)$, where n is the number of elements and m the number of cover relations.

without_bounds()

Return the poset without its top and bottom elements.

This is useful as an input for the method *order_complex()*.

If there is either no top or no bottom element, this raises a `TypeError`.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: Q = P.without_bounds(); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[[2, 3]]

sage: P = posets.DiamondPoset(5)
sage: Q = P.without_bounds(); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[]
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> Q = P.without_bounds(); Q
Finite poset containing 3 elements
>>> Q.cover_relations()
[[2, 3]]

>>> P = posets.DiamondPoset(Integer(5))
>>> Q = P.without_bounds(); Q
Finite poset containing 3 elements
>>> Q.cover_relations()
[]
```

See also

with_bounds() for the reverse operation

zeta_polynomial()

Return the zeta polynomial of the poset.

The zeta polynomial of a poset is the unique polynomial $Z(q)$ such that for every integer $m > 1$, $Z(m)$ is the number of weakly increasing sequences $x_1 \leq x_2 \leq \cdots \leq x_{m-1}$ of elements of the poset.

The polynomial $Z(q)$ is integral-valued, but generally does not have integer coefficients. It can be computed as

$$Z(q) = \sum_{k \geq 1} \binom{q-2}{k-1} c_k,$$

where c_k is the number of all chains of length k in the poset.

For more information, see section 3.12 of [EnumComb1].

In particular, $Z(2)$ is the number of vertices and $Z(3)$ is the number of intervals.

See also

apozeta_polynomial()

EXAMPLES:

```
sage: posets.ChainPoset(2).zeta_polynomial()
q
sage: posets.ChainPoset(3).zeta_polynomial()
1/2*q^2 + 1/2*q

sage: P = posets.PentagonPoset()
sage: P.zeta_polynomial()
1/6*q^3 + q^2 - 1/6*q

sage: P = posets.DiamondPoset(5)
sage: P.zeta_polynomial()
3/2*q^2 - 1/2*q
```

```
>>> from sage.all import *
>>> posets.ChainPoset(Integer(2)).zeta_polynomial()
q
>>> posets.ChainPoset(Integer(3)).zeta_polynomial()
1/2*q^2 + 1/2*q

>>> P = posets.PentagonPoset()
>>> P.zeta_polynomial()
1/6*q^3 + q^2 - 1/6*q

>>> P = posets.DiamondPoset(Integer(5))
>>> P.zeta_polynomial()
3/2*q^2 - 1/2*q
```

class sage.combinat.posets.posets.**FinitePosets_n**(n)

Bases: UniqueRepresentation, Parent

The finite enumerated set of all posets on n elements, up to an isomorphism.

EXAMPLES:

```
sage: P = Posets(3)
sage: P.cardinality()
5
sage: for p in P: print(p.cover_relations())
[[1, 2], [0, 2]]
[[0, 1], [0, 2]]
[[0, 2]]
[[0, 1], [1, 2]]
[]
```

```
>>> from sage.all import *
>>> P = Posets(Integer(3))
>>> P.cardinality()
5
>>> for p in P: print(p.cover_relations())
[[1, 2], [0, 2]]
[[0, 1], [0, 2]]
[[0, 2]]
[[0, 1], [1, 2]]
[]
```

cardinality(*from_iterator=False*)

Return the cardinality of this object.

Note

By default, this returns pre-computed values obtained from the On-Line Encyclopedia of Integer Sequences (OEIS sequence A000112). To override this, pass the argument `from_iterator=True`.

EXAMPLES:

```
sage: P = Posets(3)
sage: P.cardinality()
5
sage: P.cardinality(from_iterator=True)
5
```

```
>>> from sage.all import *
>>> P = Posets(Integer(3))
>>> P.cardinality()
5
>>> P.cardinality(from_iterator=True)
5
```

sage.combinat.posets.posets.**Poset**(*data=None*, *element_labels=None*, *cover_relations=False*, *linear_extension=False*, *category=None*, *facade=None*, *key=None*)

Construct a finite poset from various forms of input data.

INPUT:

- `data` – different input are accepted by this constructor:

  1. A two-element list or tuple `(E, R)`, where `E` is a collection of elements of the poset and `R` is a collection of relations `x <= y`, each represented as a two-element list/tuple/iterable such as `[x, y]`. The poset is then the transitive closure of the provided relations. If `cover_relations=True`, then `R` is assumed to contain exactly the cover relations of the poset. If `E` is empty, then `E` is taken to be the set of elements appearing in the relations `R`.

  2. A two-element list or tuple `(E, f)`, where `E` is the set of elements of the poset and `f` is a function such that, for any pair `x, y` of elements of `E`, `f(x, y)` returns whether `x <= y`. If `cover_relations=True`, then `f(x, y)` should instead return whether `x` is covered by `y`.

  3. A dictionary of upper covers: `data[x]` is a list of the elements that cover the element x in the poset.

  4. A list or tuple of upper covers: `data[x]` is a list of the elements that cover the element x in the poset.

If the set of elements is not a set of consecutive integers starting from zero, then:

- every element must appear in the data, for example in its own entry.
- `data` must be ordered in the same way as sorted elements.

> **Warning**
>
> If data is a list or tuple of length 2, then it is handled by the case 2 above.

5. An acyclic, loop-free and multi-edge free `DiGraph`. If `cover_relations` is `True`, then the edges of the digraph are assumed to correspond to the cover relations of the poset. Otherwise, the cover relations are computed.
6. A previously constructed poset (the poset itself is returned).

- `element_labels` – (default: `None`) an optional list or dictionary of objects that label the poset elements
- `cover_relations` – boolean (default: `False`); whether the data can be assumed to describe a directed acyclic graph whose arrows are cover relations. Otherwise, the cover relations are first computed.
- `linear_extension` – boolean (default: `False`); whether to use the provided list of elements as default linear extension for the poset. Otherwise a linear extension is computed. If the data is given as the pair `(E, f)`, then `E` is taken to be the linear extension.
- `facade` – boolean or `None` (default); whether the *Poset()*'s elements should be wrapped to make them aware of the Poset they belong to.
  - If `facade = True`, the *Poset()*'s elements are exactly those given as input.
  - If `facade = False`, the *Poset()*'s elements will become *PosetElement* objects.
  - If `facade = None` (default) the expected behaviour is the behaviour of `facade = True`, unless the opposite can be deduced from the context (i.e. for instance if a *Poset()* is built from another *Poset()*, itself built with `facade = False`)

OUTPUT:

`FinitePoset` – an instance of the *FinitePoset* class.

If `category` is specified, then the poset is created in this category instead of `FinitePosets`.

> **See also**
>
> *Posets*, `Posets`, `FinitePosets`

EXAMPLES:

1. Elements and cover relations:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: Poset((elms, rels), cover_relations = True, facade = False)
Finite poset containing 7 elements
```

```
>>> from sage.all import *
>>> elms = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),Integer(6),
↪Integer(7)]
```

(continues on next page)

(continued from previous page)

```
>>> rels = [[Integer(1),Integer(2)],[Integer(3),Integer(4)],[Integer(4),
↪Integer(5)],[Integer(2),Integer(5)]]
>>> Poset((elms, rels), cover_relations = True, facade = False)
Finite poset containing 7 elements
```

Elements and non-cover relations:

```
sage: elms = [1,2,3,4]
sage: rels = [[1,2],[1,3],[1,4],[2,3],[2,4],[3,4]]
sage: P = Poset( [elms,rels] ,cover_relations=False); P
Finite poset containing 4 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [3, 4]]
```

```
>>> from sage.all import *
>>> elms = [Integer(1),Integer(2),Integer(3),Integer(4)]
>>> rels = [[Integer(1),Integer(2)],[Integer(1),Integer(3)],[Integer(1),
↪Integer(4)],[Integer(2),Integer(3)],[Integer(2),Integer(4)],[Integer(3),
↪Integer(4)]]
>>> P = Poset( [elms,rels] ,cover_relations=False); P
Finite poset containing 4 elements
>>> P.cover_relations()
[[1, 2], [2, 3], [3, 4]]
```

2. Elements and function: the standard permutations of [1, 2, 3, 4] with the Bruhat order:

```
sage: elms = Permutations(4)
sage: fcn = lambda p,q : p.bruhat_lequal(q)
sage: Poset((elms, fcn))
Finite poset containing 24 elements
```

```
>>> from sage.all import *
>>> elms = Permutations(Integer(4))
>>> fcn = lambda p,q : p.bruhat_lequal(q)
>>> Poset((elms, fcn))
Finite poset containing 24 elements
```

With a function that identifies the cover relations: the set partitions of $\{1, 2, 3\}$ ordered by refinement:

```
sage: # needs sage.combinat
sage: elms = SetPartitions(3)
sage: def fcn(A, B):
....:     if len(A) != len(B)+1:
....:         return False
....:     for a in A:
....:         if not any(set(a).issubset(b) for b in B):
....:             return False
....:     return True
sage: Poset((elms, fcn), cover_relations=True)
Finite poset containing 5 elements
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> elms = SetPartitions(Integer(3))
>>> def fcn(A, B):
...     if len(A) != len(B)+Integer(1):
...         return False
...     for a in A:
...         if not any(set(a).issubset(b) for b in B):
...             return False
...     return True
>>> Poset((elms, fcn), cover_relations=True)
Finite poset containing 5 elements
```

3. A dictionary of upper covers:

```
sage: Poset({'a':['b','c'], 'b':['d'], 'c':['d'], 'd':[]})
Finite poset containing 4 elements
```

```
>>> from sage.all import *
>>> Poset({'a':['b','c'], 'b':['d'], 'c':['d'], 'd':[]})
Finite poset containing 4 elements
```

4. A list of upper covers, with range(5) as set of vertices:

```
sage: Poset([[1,2],[4],[3],[4],[]])
Finite poset containing 5 elements
```

```
>>> from sage.all import *
>>> Poset([[Integer(1),Integer(2)],[Integer(4)],[Integer(3)],[Integer(4)],[]])
Finite poset containing 5 elements
```

A list of upper covers, with letters as vertices:

```
sage: Poset([["a","b"],["b","c"],["c"]])
Finite poset containing 3 elements
```

```
>>> from sage.all import *
>>> Poset([["a","b"],["b","c"],["c"]])
Finite poset containing 3 elements
```

A list of upper covers and a dictionary of labels:

```
sage: elm_labs = {0:"a",1:"b",2:"c",3:"d",4:"e"}
sage: P = Poset([[1,2],[4],[3],[4],[]], elm_labs, facade=False)
sage: P.list()
[a, b, c, d, e]
```

```
>>> from sage.all import *
>>> elm_labs = {Integer(0):"a",Integer(1):"b",Integer(2):"c",Integer(3):"d",
↪Integer(4):"e"}
>>> P = Poset([[Integer(1),Integer(2)],[Integer(4)],[Integer(3)],[Integer(4)],
↪[]], elm_labs, facade=False)
```

(continues on next page)

(continued from previous page)

```
>>> P.list()
[a, b, c, d, e]
```

Warning

The special case where the argument data is a list or tuple of length 2 is handled by the case 2. So you cannot use this method to input a 2-element poset.

5. An acyclic DiGraph.

```
sage: dag = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: Poset(dag)
Finite poset containing 6 elements
```

```
>>> from sage.all import *
>>> dag = DiGraph({Integer(0):[Integer(2),Integer(3)], Integer(1):[Integer(3),
↪Integer(4)], Integer(2):[Integer(5)], Integer(3):[Integer(5)],␣
↪Integer(4):[Integer(5)]})
>>> Poset(dag)
Finite poset containing 6 elements
```

Any directed acyclic graph without loops or multiple edges, as long as `cover_relations=False`:

```
sage: dig = DiGraph({0:[2,3], 1:[3,4,5], 2:[5], 3:[5], 4:[5]})
sage: dig.allows_multiple_edges()
False
sage: dig.allows_loops()
False
sage: dig.transitive_reduction() == dig
False
sage: Poset(dig, cover_relations=False)
Finite poset containing 6 elements
sage: Poset(dig, cover_relations=True)
Traceback (most recent call last):
...
ValueError: Hasse diagram is not transitively reduced
```

```
>>> from sage.all import *
>>> dig = DiGraph({Integer(0):[Integer(2),Integer(3)], Integer(1):[Integer(3),
↪Integer(4),Integer(5)], Integer(2):[Integer(5)], Integer(3):[Integer(5)],␣
↪Integer(4):[Integer(5)]})
>>> dig.allows_multiple_edges()
False
>>> dig.allows_loops()
False
>>> dig.transitive_reduction() == dig
False
>>> Poset(dig, cover_relations=False)
Finite poset containing 6 elements

```

Default Linear extension

Every poset P obtained with `Poset` comes equipped with a default linear extension, which is also used for enumerating its elements. By default, this linear extension is computed, and has no particular significance:

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: P.list()
[1, 2, 4, 3, 6, 12]
sage: P.linear_extension()
[1, 2, 4, 3, 6, 12]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")))
>>> P.list()
[1, 2, 4, 3, 6, 12]
>>> P.linear_extension()
[1, 2, 4, 3, 6, 12]
```

You may enforce a specific linear extension using the `linear_extension` option:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.linear_extension()
[1, 2, 3, 4, 6, 12]
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_extension=True)
>>> P.list()
[1, 2, 3, 4, 6, 12]
>>> P.linear_extension()
[1, 2, 3, 4, 6, 12]
```

Depending on popular request, `Poset` might eventually get modified to always use the provided list of elements as default linear extension, when it is one.

See also

FinitePoset.linear_extensions()

Facade posets

When `facade = False`, the elements of a poset are wrapped so as to make them aware that they belong to that poset:

```
sage: P = Poset(DiGraph({'d':['c','b'],'c':['a'],'b':['a']}), facade = False)
sage: d,c,b,a = list(P)
```

(continues on next page)

(continued from previous page)

```
sage: a.parent() is P
True
```

```
>>> from sage.all import *
>>> P = Poset(DiGraph({'d':['c','b'],'c':['a'],'b':['a']}), facade = False)
>>> d,c,b,a = list(P)
>>> a.parent() is P
True
```

This allows for comparing elements according to P:

```
sage: c < a
True
```

```
>>> from sage.all import *
>>> c < a
True
```

However, this may have surprising effects:

```
sage: my_elements = ['a','b','c','d']
sage: any(x in my_elements for x in P)
False
```

```
>>> from sage.all import *
>>> my_elements = ['a','b','c','d']
>>> any(x in my_elements for x in P)
False
```

and can be annoying when one wants to manipulate the elements of the poset:

```
sage: a + b
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for +: 'Finite poset containing 4␣
↪elements' and 'Finite poset containing 4 elements'
sage: a.element + b.element
'ab'
```

```
>>> from sage.all import *
>>> a + b
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for +: 'Finite poset containing 4␣
↪elements' and 'Finite poset containing 4 elements'
>>> a.element + b.element
'ab'
```

By default, facade posets are constructed instead:

```
sage: P = Poset(DiGraph({'d':['c','b'],'c':['a'],'b':['a']}))
```

```
>>> from sage.all import *
>>> P = Poset(DiGraph({'d':['c','b'],'c':['a'],'b':['a']}))
```

In this example, the elements of the poset remain plain strings:

```
sage: d,c,b,a = list(P)
sage: type(a)
<class 'str'>
```

```
>>> from sage.all import *
>>> d,c,b,a = list(P)
>>> type(a)
<class 'str'>
```

Of course, those strings are not aware of P. So to compare two such strings, one needs to query P:

```
sage: a < b
True
sage: P.lt(a,b)
False
```

```
>>> from sage.all import *
>>> a < b
True
>>> P.lt(a,b)
False
```

which models the usual mathematical notation $a <_P b$.

Most operations seem to still work, but at this point there is no guarantee whatsoever:

```
sage: P.list()
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('a')
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('b')
['d', 'b']
sage: P.principal_order_ideal('d')
['d']
sage: TestSuite(P).run()
```

```
>>> from sage.all import *
>>> P.list()
['d', 'c', 'b', 'a']
>>> P.principal_order_ideal('a')
['d', 'c', 'b', 'a']
>>> P.principal_order_ideal('b')
['d', 'b']
>>> P.principal_order_ideal('d')
['d']
>>> TestSuite(P).run()
```

Warning

DiGraph is used to construct the poset, and the vertices of a DiGraph are converted to plain Python int's if they are Integer's:

```
sage: G = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: type(G.vertices(sort=True)[0])
<class 'int'>
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(0):[Integer(2),Integer(3)], Integer(1):[Integer(3),
↪Integer(4)], Integer(2):[Integer(5)], Integer(3):[Integer(5)],␣
↪Integer(4):[Integer(5)]})
>>> type(G.vertices(sort=True)[Integer(0)])
<class 'int'>
```

This is worked around by systematically converting back the vertices of a poset to Integer's if they are int's:

```
sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: type(P.an_element().element)
<class 'sage.rings.integer.Integer'>

sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: type(P.an_element())
<class 'sage.rings.integer.Integer'>
```

```
>>> from sage.all import *
>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade = False)
>>> type(P.an_element().element)
<class 'sage.rings.integer.Integer'>

>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade=True)
>>> type(P.an_element())
<class 'sage.rings.integer.Integer'>
```

This may be abusive:

```
sage: P = Poset((range(5), operator.le), facade = True)
sage: P.an_element().parent()
Integer Ring
```

```
>>> from sage.all import *
>>> P = Poset((range(Integer(5)), operator.le), facade = True)
>>> P.an_element().parent()
Integer Ring
```

Unique representation

As most parents, *Poset* have unique representation (see UniqueRepresentation). Namely if two posets are created from two equal data, then they are not only equal but actually identical:

```
sage: data1 = [[1,2],[3],[3]]
sage: data2 = [[1,2],[3],[3]]
sage: P1 = Poset(data1)
```

(continues on next page)

(continued from previous page)

```
sage: P2 = Poset(data2)
sage: P1 == P2
True
sage: P1 is P2
True
```

```
>>> from sage.all import *
>>> data1 = [[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]]
>>> data2 = [[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]]
>>> P1 = Poset(data1)
>>> P2 = Poset(data2)
>>> P1 == P2
True
>>> P1 is P2
True
```

In situations where this behaviour is not desired, one can use the `key` option:

```
sage: P1 = Poset(data1, key = "foo")
sage: P2 = Poset(data2, key = "bar")
sage: P1 is P2
False
sage: P1 == P2
False
```

```
>>> from sage.all import *
>>> P1 = Poset(data1, key = "foo")
>>> P2 = Poset(data2, key = "bar")
>>> P1 is P2
False
>>> P1 == P2
False
```

`key` can be any hashable value and is passed down to `UniqueRepresentation`. It is otherwise ignored by the poset constructor.

`sage.combinat.posets.posets.`**`is_poset`**(*dig*)

Return `True` if a directed graph is acyclic and transitively reduced, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.posets import is_poset
sage: dig = DiGraph({0:[2, 3], 1:[3, 4, 5], 2:[5], 3:[5], 4:[5]})
sage: is_poset(dig)
False
sage: is_poset(dig.transitive_reduction())
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.posets import is_poset
>>> dig = DiGraph({Integer(0):[Integer(2), Integer(3)], Integer(1):[Integer(3),␣
↪Integer(4), Integer(5)], Integer(2):[Integer(5)], Integer(3):[Integer(5)],␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(4):[Integer(5)]})
>>> is_poset(dig)
False
>>> is_poset(dig.transitive_reduction())
True
```

Forest posets

AUTHORS:

- Stefan Grosser (06-2020): initial implementation

class sage.combinat.posets.forest.**ForestPoset**(*hasse_diagram*, *elements*, *category*, *facade*, *key*)

Bases: *FinitePoset*

A forest poset is a poset where the underlying Hasse diagram and is directed acyclic graph.

Hasse diagrams of posets

antichains()	Return all antichains of `self`, organized as a prefix tree.
antichains_iterator()	Return an iterator over the antichains of the poset.
are_comparable()	Return whether `i` and `j` are comparable in the poset.
are_incomparable()	Return whether `i` and `j` are incomparable in the poset.
atoms_of_congruence_lattice()	Return atoms of the congruence lattice.
bottom_moebius_function()	Return the value of the Möbius function of the poset on the elements `zero` and `j`, where `zero` is `self.bottom()`, the unique minimal element of the poset.
cardinality()	Return the number of elements in the poset.
chain_polynomial()	Return the chain polynomial of the poset.
chains()	Return all chains of `self`, organized as a prefix tree.
closed_interval()	Return a list of the elements z of `self` such that $x \leq z \leq y$.
common_lower_covers()	Return the list of all common lower covers of `vertices`.
common_upper_covers()	Return the list of all common upper covers of `vertices`.
congruence()	Return the congruence `start` "extended" by `parts`.
congruences_iterator()	Return an iterator over all congruences of the lattice.
cover_relations()	Return the list of cover relations.
cover_relations_iterator()	Iterate over cover relations.
covers()	Return `True` if y covers x and `False` otherwise.
diamonds()	Return the list of diamonds of `self`.
dual()	Return a poset that is dual to the given poset.
find_nonsemidistributive_elements()	Check if the lattice is semidistributive or not.
find_nonsemimodular_pair()	Return pair of elements showing the lattice is not modular.
find_nontrivial_congruence()	Return a pair that generates non-trivial congruence or `None` if there is not any.
frattini_sublattice()	Return the list of elements of the Frattini sublattice of the lattice.
greedy_linear_extensions_iterator()	Return an iterator over greedy linear extensions of the Hasse diagram.
has_bottom()	Return `True` if the poset has a unique minimal element.

continues on next page

Table 6 – continued from previous page

has_top()	Return `True` if the poset contains a unique maximal element, and `False` otherwise.
interval_iterator()	Return an iterator of the elements z of `self` such that $x \leq z \leq y$.
is_antichain_of_poset()	Return `True` if `elms` is an antichain of the Hasse diagram and `False` otherwise.
is_bounded()	Return `True` if the poset contains a unique maximal element and a unique minimal element, and `False` otherwise.
is_chain()	Return `True` if the poset is totally ordered, and `False` otherwise.
is_complemented()	Return an element of the lattice that has no complement.
is_congruence_normal()	Return `True` if the lattice can be constructed from the one-element lattice with Day doubling constructions of convex subsets.
is_convex_subset()	Return `True` if S is a convex subset of the poset, and `False` otherwise.
is_gequal()	Return `True` if `x` is greater than or equal to `y`, and `False` otherwise.
is_greater_than()	Return `True` if `x` is greater than but not equal to `y`, and `False` otherwise.
is_join_semilattice()	Return `True` if `self` has a join operation, and `False` otherwise.
is_lequal()	Return `True` if i is less than or equal to j in the poset, and `False` otherwise.
is_less_than()	Return `True` if `x` is less than but not equal to `y` in the poset, and `False` otherwise.
is_linear_extension()	Test if an ordering is a linear extension.
is_linear_interval()	Return whether the interval `[t_min, t_max]` is linear.
is_meet_semilattice()	Return `True` if `self` has a meet operation, and `False` otherwise.
is_ranked()	Return `True` if the poset is ranked, and `False` otherwise.
join_matrix()	Return the matrix of joins of `self`, when `self` is a join-semilattice; raise an error otherwise.
kappa()	Return the maximum element greater than the element covered by `a` but not greater than `a`.
kappa_dual()	Return the minimum element smaller than the element covering `a` but not smaller than `a`.
lequal_matrix()	Return a matrix whose `(i,j)` entry is 1 if `i` is less than `j` in the poset, and 0 otherwise.
linear_extension()	Return a linear extension.
linear_extensions()	Return an iterator over all linear extensions.
linear_intervals_count()	Return the enumeration of linear intervals w.r.t. their cardinality.
lower_covers_iterator()	Return the list of elements that are covered by `element`.
maximal_elements()	Return a list of the maximal elements of the poset.
maximal_sublattices()	Return maximal sublattices of the lattice.
meet_matrix()	Return the matrix of meets of `self`, when `self` is a meet-semilattice; raise an error otherwise.
minimal_elements()	Return a list of the minimal elements of the poset.
moebius_function()	Return the value of the Möbius function of the poset on the elements `i` and `j`.
moebius_function_matrix()	Return the matrix of the Möbius function of this poset.
neutral_elements()	Return the list of neutral elements of the lattice.
open_interval()	Return a list of the elements z of `self` such that $x < z < y$.
order_filter()	Return the order filter generated by a list of elements.
order_ideal()	Return the order ideal generated by a list of elements.
order_ideal_cardinality()	Return the cardinality of the order ideal generated by `elements`.
orthocomplementations_iterator()	Return an iterator over orthocomplementations of the lattice.
prime_elements()	Return the join-prime and meet-prime elements of the bounded poset.
principal_congruences_poset()	Return the poset of join-irreducibles of the congruence lattice.

continues on next page

Table 6 – continued from previous page

principal_order_filter()	Return the order filter generated by `i`.
principal_order_ideal()	Return the order ideal generated by i.
pseudocomplement()	Return the pseudocomplement of `element`, if it exists.
rank()	Return the rank of `element`, or the rank of the poset if `element` is `None`. (The rank of a poset is the length of the longest chain of elements of the poset.)
rank_function()	Return the (normalized) rank function of the poset, if it exists.
skeleton()	Return the skeleton of the lattice.
spine()	Return the spine and the maximum chain length.
sublattices_iterator()	Return an iterator over sublattices of the Hasse diagram.
supergreedy_linear_extensions_iterator()	Return an iterator over supergreedy linear extensions of the Hasse diagram.
top()	Return the top element of the poset, if it exists.
upper_covers_iterator()	Return the list of elements that cover `element`.
vertical_decomposition()	Return vertical decomposition of the lattice.

class sage.combinat.posets.hasse_diagram.**HasseDiagram**(*data=None*, *pos=None*, *loops=None*, *format=None*, *weighted=None*, *data_structure='sparse'*, *vertex_labels=True*, *name=None*, *multiedges=None*, *convert_empty_dict_labels_to_None=None*, *sparse=True*, *immutable=False*, *hash_labels=None*)

Bases: `DiGraph`

The Hasse diagram of a poset. This is just a transitively-reduced, directed, acyclic graph without loops or multiple edges.

Note

We assume that `range(n)` is a linear extension of the poset. That is, `range(n)` is the vertex set and a topological sort of the digraph.

This should not be called directly, use Poset instead; all type checking happens there.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]}); H
Hasse diagram of a poset containing 4 elements
sage: TestSuite(H).run()
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[]}); H
Hasse diagram of a poset containing 4 elements
>>> TestSuite(H).run()
```

_precompute_intervals()

Precompute all intervals of the poset.

This will significantly speed up computing congruences. On the other hand, it will cost much more memory. Currently this is a hidden feature. See the example below for how to use it.

EXAMPLES:

```
sage: B4 = posets.BooleanLattice(4)
sage: B4.is_isoform()  # Slow                                                #␣
↪needs sage.combinat sage.modules
True
sage: B4._hasse_diagram._precompute_intervals()
sage: B4 = posets.BooleanLattice(4)
sage: B4.is_isoform()  # Faster now                                         #␣
↪needs sage.combinat sage.modules
True
```

```
>>> from sage.all import *
>>> B4 = posets.BooleanLattice(Integer(4))
>>> B4.is_isoform()  # Slow                                                 #␣
↪needs sage.combinat sage.modules
True
>>> B4._hasse_diagram._precompute_intervals()
>>> B4 = posets.BooleanLattice(Integer(4))
>>> B4.is_isoform()  # Faster now                                           #␣
↪needs sage.combinat sage.modules
True
```

_leq_storage

Store the comparison relation as a list of Python sets.

The i-th item in the list is the set of elements greater than i.

Once computed, this is used to speed up the comparison.

EXAMPLES:

```
sage: H = posets.DiamondPoset(7)._hasse_diagram
sage: H._leq_storage
[{0, 1, 2, 3, 4, 5, 6}, {1, 6}, {2, 6}, {3, 6}, {4, 6}, {5, 6}, {6}]
```

```
>>> from sage.all import *
>>> H = posets.DiamondPoset(Integer(7))._hasse_diagram
>>> H._leq_storage
[{0, 1, 2, 3, 4, 5, 6}, {1, 6}, {2, 6}, {3, 6}, {4, 6}, {5, 6}, {6}]
```

_meet

Return the matrix of meets of `self`.

The `(x,y)`-entry of this matrix is the meet of `x` and `y` in `self` if the meet exists; and -1 otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
↪7:[]})
sage: H._meet                                                               #␣
↪needs sage.modules
```

[ 0  0  2  2  2]
[ 0  1  2  3 -1]
[ 0  1  2 -1  4]
```

_join

Compute a matrix whose `(x,y)`-entry is the join of `x` and `y` in `self` if the join exists; and -1 otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
↪7:[]})
sage: H._join                                                            #␣
↪needs sage.modules
[0 1 2 3 4 5 6 7]
[1 1 4 7 4 7 7 7]
[2 4 2 6 4 5 6 7]
[3 7 6 3 7 7 6 7]
[4 4 4 7 4 7 7 7]
[5 7 5 7 7 5 7 7]
[6 7 6 6 7 7 6 7]
[7 7 7 7 7 7 7 7]

sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H._join                                                            #␣
↪needs sage.modules
[ 0 -1  2  3]
[-1  1  2  3]
[ 2  2  2 -1]
[ 3  3 -1  3]

sage: H = HasseDiagram({0:[2,3],1:[2,3],2:[4],3:[4]})
sage: H._join                                                            #␣

```

antichains(*element_class=<class 'list'>*)

Return all antichains of `self`, organized as a prefix tree.

INPUT:

- `element_class` – (default: `list`) an iterable type

EXAMPLES:

```
sage: # needs sage.modules
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.antichains()
sage: list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
sage: A.cardinality()
8
sage: [1,3] in A
True
sage: [1,4] in A
False
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> P = posets.PentagonPoset()
>>> H = P._hasse_diagram
>>> A = H.antichains()
>>> list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
>>> A.cardinality()
8
>>> [Integer(1),Integer(3)] in A
True
>>> [Integer(1),Integer(4)] in A
False
```

antichains_iterator()

Return an iterator over the antichains of the poset.

Note

The algorithm is based on Freese-Jezek-Nation p. 226. It does a depth first search through the set of all antichains organized in a prefix tree.

EXAMPLES:

```
sage: # needs sage.modules
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.antichains_iterator()
<generator object ...antichains_iterator at ...>
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[4],2:[3],3:[4]})
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]
sage: H = HasseDiagram({0:[],1:[],2:[]})
sage: list(H.antichains_iterator())
[[], [2], [1], [1, 2], [0], [0, 2], [0, 1], [0, 1, 2]]
sage: H = HasseDiagram({0:[1],1:[2],2:[3],3:[4]})
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [0]]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> P = posets.PentagonPoset()
>>> H = P._hasse_diagram
>>> H.antichains_iterator()
<generator object ...antichains_iterator at ...>
>>> list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
```

(continues on next page)

(continued from previous page)

```
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
↪Integer(1):[Integer(4)],Integer(2):[Integer(3)],Integer(3):[Integer(4)]})
>>> list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]
>>> H = HasseDiagram({Integer(0):[],Integer(1):[],Integer(2):[]})
>>> list(H.antichains_iterator())
[[], [2], [1], [1, 2], [0], [0, 2], [0, 1], [0, 1, 2]]
>>> H = HasseDiagram({Integer(0):[Integer(1)],Integer(1):[Integer(2)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)]})
>>> list(H.antichains_iterator())
[[], [4], [3], [2], [1], [0]]
```

are_comparable(*i*, *j*)

Return whether `i` and `j` are comparable in the poset.

INPUT:

- `i`, `j` – vertices of this Hasse diagram

EXAMPLES:

```
sage: # needs sage.modules
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.are_comparable(1,2)
False
sage: V = H.vertices(sort=True)
sage: [ (i,j) for i in V for j in V if H.are_comparable(i,j)]
[(0, 0), (0, 1), (0, 2), (0, 3), (0, 4), (1, 0), (1, 1), (1, 4),
 (2, 0), (2, 2), (2, 3), (2, 4), (3, 0), (3, 2), (3, 3), (3, 4),
 (4, 0), (4, 1), (4, 2), (4, 3), (4, 4)]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> P = posets.PentagonPoset()
>>> H = P._hasse_diagram
>>> H.are_comparable(Integer(1),Integer(2))
False
>>> V = H.vertices(sort=True)
>>> [ (i,j) for i in V for j in V if H.are_comparable(i,j)]
[(0, 0), (0, 1), (0, 2), (0, 3), (0, 4), (1, 0), (1, 1), (1, 4),
 (2, 0), (2, 2), (2, 3), (2, 4), (3, 0), (3, 2), (3, 3), (3, 4),
 (4, 0), (4, 1), (4, 2), (4, 3), (4, 4)]
```

are_incomparable(*i*, *j*)

Return whether `i` and `j` are incomparable in the poset.

INPUT:

- `i`, `j` – vertices of this Hasse diagram

EXAMPLES:

```
sage: # needs sage.modules
sage: P = posets.PentagonPoset()
```

(continues on next page)

(continued from previous page)

```
sage: H = P._hasse_diagram
sage: H.are_incomparable(1,2)
True
sage: V = H.vertices(sort=True)
sage: [ (i,j) for i in V for j in V if H.are_incomparable(i,j)]
[(1, 2), (1, 3), (2, 1), (3, 1)]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> P = posets.PentagonPoset()
>>> H = P._hasse_diagram
>>> H.are_incomparable(Integer(1),Integer(2))
True
>>> V = H.vertices(sort=True)
>>> [ (i,j) for i in V for j in V if H.are_incomparable(i,j)]
[(1, 2), (1, 3), (2, 1), (3, 1)]
```

atoms_of_congruence_lattice()

Return atoms of the congruence lattice.

In other words, return "minimal non-trivial" congruences: A congruence is minimal if the only finer (as a partition of set of elements) congruence is the trivial congruence where every block contains only one element.

See also

congruence()

OUTPUT:

List of congruences, every congruence as *sage.combinat.set_partition.SetPartition*

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3:[4]})
sage: N5.atoms_of_congruence_lattice()                                  #␣
↪needs sage.combinat sage.modules
[{{0}, {1}, {2, 3}, {4}}]
sage: Hex = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [5], 4: [5]})
sage: Hex.atoms_of_congruence_lattice()                                 #␣
↪needs sage.combinat sage.modules
[{{0}, {1}, {2, 4}, {3}, {5}}, {{0}, {1, 3}, {2}, {4}, {5}}]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> N5 = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(4)], Integer(2): [Integer(3)], Integer(3):[Integer(4)]})
>>> N5.atoms_of_congruence_lattice()                                    #␣
↪needs sage.combinat sage.modules
[{{0}, {1}, {2, 3}, {4}}]
>>> Hex = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3)], Integer(2): [Integer(4)], Integer(3): [Integer(5)],␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(4): [Integer(5)]})
>>> Hex.atoms_of_congruence_lattice()                                    #␣
↪needs sage.combinat sage.modules
[{{0}, {1}, {2, 4}, {3}, {5}}, {{0}, {1, 3}, {2}, {4}, {5}}]
```

ALGORITHM:

Every atom is a join-irreducible. Every join-irreducible of $\mathrm{Con}(L)$ is a principal congruence generated by a meet-irreducible element and the only element covering it (and also by a join-irreducible element and the only element covered by it). Hence we check those principal congruences to find the minimal ones.

bottom()

Return the bottom element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.bottom() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.bottom()
0
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})
>>> P.bottom() is None
True
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.bottom()
0
```

bottom_moebius_function(j)

Return the value of the Möbius function of the poset on the elements `zero` and `j`, where `zero` is `self.bottom()`, the unique minimal element of the poset.

EXAMPLES:

```
sage: P = Poset({0: [1,2]})
sage: hasse = P._hasse_diagram
sage: hasse.bottom_moebius_function(1)
-1
sage: hasse.bottom_moebius_function(2)
-1
sage: P = Poset({0: [1,3], 1:[2], 2:[4], 3:[4]})
sage: hasse = P._hasse_diagram
sage: for i in range(5):
....:   print(hasse.bottom_moebius_function(i))
1
-1
0
-1
1
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1),Integer(2)]})
>>> hasse = P._hasse_diagram
>>> hasse.bottom_moebius_function(Integer(1))
-1
>>> hasse.bottom_moebius_function(Integer(2))
-1
>>> P = Poset({Integer(0): [Integer(1),Integer(3)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(4)], Integer(3):[Integer(4)]})
>>> hasse = P._hasse_diagram
>>> for i in range(Integer(5)):
...   print(hasse.bottom_moebius_function(i))
1
-1
0
-1
1
```

cardinality()

Return the number of elements in the poset.

EXAMPLES:

```
sage: Poset([[1,2,3],[4],[4],[4],[]]).cardinality()
5
```

```
>>> from sage.all import *
>>> Poset([[Integer(1),Integer(2),Integer(3)],[Integer(4)],[Integer(4)],
↪[Integer(4)],[]]).cardinality()
5
```

chain_polynomial()

Return the chain polynomial of the poset.

The coefficient of q^k is the number of chains of k elements in the poset. List of coefficients of this polynomial is also called a *f-vector* of the poset.

EXAMPLES:

```
sage: P = posets.ChainPoset(3)
sage: H = P._hasse_diagram
sage: t = H.chain_polynomial(); t
q^3 + 3*q^2 + 3*q + 1
```

```
>>> from sage.all import *
>>> P = posets.ChainPoset(Integer(3))
>>> H = P._hasse_diagram
>>> t = H.chain_polynomial(); t
q^3 + 3*q^2 + 3*q + 1
```

chains(*element_class=<class 'list'>*, *exclude=None*, *conversion=None*)

Return all chains of `self`, organized as a prefix tree.

INPUT:

- `element_class` – (default: `list`) an iterable type
- `exclude` – elements of the poset to be excluded (default: `None`)
- `conversion` – (default: `None`) used to pass the list of elements of the poset in their fixed order

OUTPUT:

The enumerated set (with a forest structure given by prefix ordering) consisting of all chains of `self`, each of which is given as an `element_class`.

If `conversion` is given, then the chains are converted to chain of elements of this list.

EXAMPLES:

```
sage: # needs sage.modules
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.chains()
sage: list(A)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4],
 [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4],
 [3], [3, 4], [4]]
sage: A.cardinality()
20
sage: [1,3] in A
False
sage: [1,4] in A
True
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> P = posets.PentagonPoset()
>>> H = P._hasse_diagram
>>> A = H.chains()
>>> list(A)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4],
 [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4],
 [3], [3, 4], [4]]
>>> A.cardinality()
20
>>> [Integer(1),Integer(3)] in A
False
>>> [Integer(1),Integer(4)] in A
True
```

One can exclude some vertices:

```
sage: # needs sage.modules
sage: list(H.chains(exclude=[4, 3]))
[[], [0], [0, 1], [0, 2], [1], [2]]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> list(H.chains(exclude=[Integer(4), Integer(3)]))
[[], [0], [0, 1], [0, 2], [1], [2]]
```

The `element_class` keyword determines how the chains are being returned:

```
sage: P = Poset({1: [2, 3], 2: [4]})
sage: list(P._hasse_diagram.chains(element_class=tuple))
[(), (0,), (0, 1), (0, 1, 2), (0, 2), (0, 3), (1,), (1, 2), (2,), (3,)]
sage: list(P._hasse_diagram.chains())
[[], [0], [0, 1], [0, 1, 2], [0, 2], [0, 3], [1], [1, 2], [2], [3]]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(2): [Integer(4)]}
↪)
>>> list(P._hasse_diagram.chains(element_class=tuple))
[(), (0,), (0, 1), (0, 1, 2), (0, 2), (0, 3), (1,), (1, 2), (2,), (3,)]
>>> list(P._hasse_diagram.chains())
[[], [0], [0, 1], [0, 1, 2], [0, 2], [0, 3], [1], [1, 2], [2], [3]]
```

(Note that taking the Hasse diagram has renamed the vertices.)

```
sage: list(P._hasse_diagram.chains(element_class=tuple, exclude=[0]))
[(), (1,), (1, 2), (2,), (3,)]
```

```
>>> from sage.all import *
>>> list(P._hasse_diagram.chains(element_class=tuple, exclude=[Integer(0)]))
[(), (1,), (1, 2), (2,), (3,)]
```

See also

antichains()

closed_interval(*x*, *y*)

alias of *interval()*.

common_lower_covers(*vertices*)

Return the list of all common lower covers of `vertices`.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [3], 3: []})
sage: H.common_lower_covers([1, 2])
[0]

sage: from sage.combinat.posets.poset_examples import Posets
sage: H = Posets.YoungDiagramPoset(Partition([3, 2, 2]))._hasse_diagram      #␣
↪needs sage.combinat sage.modules
sage: H.common_lower_covers([4, 5])                                          #␣
↪needs sage.combinat sage.modules
[3]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1),Integer(2)], Integer(1):␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(3)], Integer(2): [Integer(3)], Integer(3): []})
>>> H.common_lower_covers([Integer(1), Integer(2)])
[0]

>>> from sage.combinat.posets.poset_examples import Posets
>>> H = Posets.YoungDiagramPoset(Partition([Integer(3), Integer(2),␣
↪Integer(2)]))._hasse_diagram     # needs sage.combinat sage.modules
>>> H.common_lower_covers([Integer(4), Integer(5)])                    ␣
↪              # needs sage.combinat sage.modules
[3]
```

common_upper_covers(*vertices*)

Return the list of all common upper covers of `vertices`.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [3], 3: []})
sage: H.common_upper_covers([1, 2])
[3]

sage: from sage.combinat.posets.poset_examples import Posets
sage: H = Posets.YoungDiagramPoset(Partition([3, 2, 2]))._hasse_diagram     #␣
↪needs sage.combinat sage.modules
sage: H.common_upper_covers([4, 5])                                        #␣
↪needs sage.combinat sage.modules
[6]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1),Integer(2)], Integer(1):␣
↪[Integer(3)], Integer(2): [Integer(3)], Integer(3): []})
>>> H.common_upper_covers([Integer(1), Integer(2)])
[3]

>>> from sage.combinat.posets.poset_examples import Posets
>>> H = Posets.YoungDiagramPoset(Partition([Integer(3), Integer(2),␣
↪Integer(2)]))._hasse_diagram     # needs sage.combinat sage.modules
>>> H.common_upper_covers([Integer(4), Integer(5)])                    ␣
↪              # needs sage.combinat sage.modules
[6]
```

congruence(*parts*, *start=None*, *stop_pairs=None*)

Return the congruence `start` "extended" by `parts`.

`start` is assumed to be a valid congruence of the lattice, and this is *not* checked.

INPUT:

- `parts` – list of lists; congruences to add
- `start` – a disjoint set; already computed congruence (or `None`)
- `stop_pairs` – list of pairs; list of pairs for stopping computation

OUTPUT:

None, if the congruence generated by start and parts together contains a block that has elements a, b so that (a, b) is in the list stop_pairs. Otherwise the least congruence that contains a block whose subset is p for every p in parts or start, given as sage.sets.disjoint_set.DisjointSet_class.

ALGORITHM:

Use the quadrilateral argument from page 120 of [Dav1997].

Basically we take one block from todo-list, search quadrilateral blocks up and down against the block, and then complete them to closed intervals and add to todo-list.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})
sage: cong = H.congruence([[0, 1]]); cong                                   #␣
↪needs sage.modules
{{0, 1, 3}, {2, 4}}
sage: H.congruence([[0, 2]], start=cong)                                    #␣
↪needs sage.modules
{{0, 1, 2, 3, 4}}

sage: H.congruence([[0, 1]], stop_pairs=[(1, 3)]) is None                   #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3)], Integer(2): [Integer(4)], Integer(3): [Integer(4)]})
>>> cong = H.congruence([[Integer(0), Integer(1)]]); cong                    ␣
↪              # needs sage.modules
{{0, 1, 3}, {2, 4}}
>>> H.congruence([[Integer(0), Integer(2)]], start=cong)                     ␣
↪              # needs sage.modules
{{0, 1, 2, 3, 4}}

>>> H.congruence([[Integer(0), Integer(1)]], stop_pairs=[(Integer(1),␣
↪Integer(3))]) is None                    # needs sage.modules
True
```

congruences_iterator()

Return an iterator over all congruences of the lattice.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram('GY@OQ?OW@?O?')
sage: it = H.congruences_iterator(); it
<generator object ...>
sage: sorted([cong.number_of_subsets() for cong in it])                     #␣
↪needs sage.combinat sage.modules
[1, 2, 2, 2, 4, 4, 4, 8]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram('GY@OQ?OW@?O?')
>>> it = H.congruences_iterator(); it
<generator object ...>
>>> sorted([cong.number_of_subsets() for cong in it])                    #␣
↪needs sage.combinat sage.modules
[1, 2, 2, 2, 4, 4, 4, 8]
```

cover_relations()

Return the list of cover relations.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: H.cover_relations()
[(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(2),Integer(3)],␣
↪Integer(1):[Integer(3),Integer(4)], Integer(2):[Integer(5)],␣
↪Integer(3):[Integer(5)], Integer(4):[Integer(5)]})
>>> H.cover_relations()
[(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]
```

cover_relations_iterator()

Iterate over cover relations.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: list(H.cover_relations_iterator())
[(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(2),Integer(3)],␣
↪Integer(1):[Integer(3),Integer(4)], Integer(2):[Integer(5)],␣
↪Integer(3):[Integer(5)], Integer(4):[Integer(5)]})
>>> list(H.cover_relations_iterator())
[(0, 2), (0, 3), (1, 3), (1, 4), (2, 5), (3, 5), (4, 5)]
```

covers(*x*, *y*)

Return `True` if y covers x and `False` otherwise.

EXAMPLES:

```
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.covers(Q(1),Q(6))
True
```

(continues on next page)

(continued from previous page)

```
sage: Q.covers(Q(1),Q(4))
False
```

```
>>> from sage.all import *
>>> Q = Poset([[Integer(1),Integer(5)],[Integer(2),Integer(6)],[Integer(3)],
↪[Integer(4)],[],[Integer(6),Integer(3)],[Integer(4)]])
>>> Q.covers(Q(Integer(1)),Q(Integer(6)))
True
>>> Q.covers(Q(Integer(1)),Q(Integer(4)))
False
```

coxeter_transformation(*algorithm='cython'*)

Return the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules.

INPUT:

- `algorithm` – `'cython'` (default) or `'matrix'`

This uses either a specific matrix code in Cython, or generic matrices.

See also

lequal_matrix(), *moebius_function_matrix()*

EXAMPLES:

```
sage: # needs sage.libs.flint sage.modules
sage: P = posets.PentagonPoset()._hasse_diagram
sage: M = P.coxeter_transformation(); M
[ 0  0  0  0 -1]
[ 0  0  0  1 -1]
[ 0  1  0  0 -1]
[-1  1  1  0 -1]
[-1  1  0  1 -1]
sage: P.__dict__['coxeter_transformation'].clear_cache()
sage: P.coxeter_transformation(algorithm='matrix') == M
True
```

```
>>> from sage.all import *
>>> # needs sage.libs.flint sage.modules
>>> P = posets.PentagonPoset()._hasse_diagram
>>> M = P.coxeter_transformation(); M
[ 0  0  0  0 -1]
[ 0  0  0  1 -1]
[ 0  1  0  0 -1]
[-1  1  1  0 -1]
[-1  1  0  1 -1]
>>> P.__dict__['coxeter_transformation'].clear_cache()
>>> P.coxeter_transformation(algorithm='matrix') == M
True
```

diamonds()

Return the list of diamonds of `self`.

A diamond is the following subgraph of the Hasse diagram:

```
  z
 / \
x   y
 \ /
  w
```

Thus each edge represents a cover relation in the Hasse diagram. We represent his as the tuple (w, x, y, z).

OUTPUT: a tuple with

- a list of all diamonds in the Hasse Diagram,
- a boolean checking that every w, x, y that form a `V`, there is a unique element z, which completes the diamond.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [3], 3: []})
sage: H.diamonds()
([(0, 1, 2, 3)], True)

sage: P = posets.YoungDiagramPoset(Partition([3, 2, 2]))                    #␣
↪needs sage.combinat sage.modules
sage: H = P._hasse_diagram                                                  #␣
↪needs sage.combinat sage.modules
sage: H.diamonds()                                                          #␣
↪needs sage.combinat sage.modules
([(0, 1, 3, 4), (3, 4, 5, 6)], False)
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1),Integer(2)], Integer(1):␣
↪[Integer(3)], Integer(2): [Integer(3)], Integer(3): []})
>>> H.diamonds()
([(0, 1, 2, 3)], True)

>>> P = posets.YoungDiagramPoset(Partition([Integer(3), Integer(2),␣
↪Integer(2)]))                    # needs sage.combinat sage.modules
>>> H = P._hasse_diagram                                                    #␣
↪needs sage.combinat sage.modules
>>> H.diamonds()                                                            #␣
↪needs sage.combinat sage.modules
([(0, 1, 3, 4), (3, 4, 5, 6)], False)
```

dual()

Return a poset that is dual to the given poset.

This means that it has the same elements but opposite order. The elements are renumbered to ensure that `range(n)` is a linear extension.

EXAMPLES:

```
sage: P = posets.IntegerPartitions(4)                                    #␣
↪needs sage.combinat
sage: H = P._hasse_diagram; H                                            #␣
↪needs sage.combinat
Hasse diagram of a poset containing 5 elements
sage: H.dual()                                                           #␣
↪needs sage.combinat
Hasse diagram of a poset containing 5 elements
```

```
>>> from sage.all import *
>>> P = posets.IntegerPartitions(Integer(4))                                ␣
↪     # needs sage.combinat
>>> H = P._hasse_diagram; H                                               #␣
↪needs sage.combinat
Hasse diagram of a poset containing 5 elements
>>> H.dual()                                                              #␣
↪needs sage.combinat
Hasse diagram of a poset containing 5 elements
```

find_nonsemidistributive_elements(*meet_or_join*)

Check if the lattice is semidistributive or not.

INPUT:

- `meet_or_join` – string `'meet'` or `'join'` to decide if to check for join-semidistributivity or meet-semidistributivity

OUTPUT:

- `None` if the lattice is semidistributive OR
- tuple `(u, e, x, y)` such that $u = e \vee x = e \vee y$ but $u \neq e \vee (x \wedge y)$ if `meet_or_join=='join'` and $u = e \wedge x = e \wedge y$ but $u \neq e \wedge (x \vee y)$ if `meet_or_join=='meet'`

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3, 4], 2:[4, 5], 3:[6],
....:                   4:[6], 5:[6]})
sage: H.find_nonsemidistributive_elements('join') is None                #␣
↪needs sage.modules
False
sage: H.find_nonsemidistributive_elements('meet') is None                #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(2)],␣
↪Integer(1):[Integer(3), Integer(4)], Integer(2):[Integer(4), Integer(5)],␣
↪Integer(3):[Integer(6)],
...                   Integer(4):[Integer(6)], Integer(5):[Integer(6)]})
>>> H.find_nonsemidistributive_elements('join') is None                   #␣
↪needs sage.modules
False
```

(continues on next page)

(continued from previous page)

```
>>> H.find_nonsemidistributive_elements('meet') is None                    #␣
↪needs sage.modules
True
```

find_nonsemimodular_pair(*upper*)

Return pair of elements showing the lattice is not modular.

INPUT:

- `upper` – boolean; if `True`, test whether the lattice is upper semimodular. Otherwise test whether the lattice is lower semimodular.

OUTPUT:

`None`, if the lattice is semimodular. Pair (a, b) violating semimodularity otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3, 4], 2:[4, 5], 3:[6], 4:[6], 5:[6]})
sage: H.find_nonsemimodular_pair(upper=True) is None
True
sage: H.find_nonsemimodular_pair(upper=False)
(5, 3)

sage: H_ = HasseDiagram(H.reverse().relabel(lambda x: 6-x, inplace=False))
sage: H_.find_nonsemimodular_pair(upper=True)
(3, 1)
sage: H_.find_nonsemimodular_pair(upper=False) is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(2)],␣
↪Integer(1):[Integer(3), Integer(4)], Integer(2):[Integer(4), Integer(5)],␣
↪Integer(3):[Integer(6)], Integer(4):[Integer(6)], Integer(5):[Integer(6)]})
>>> H.find_nonsemimodular_pair(upper=True) is None
True
>>> H.find_nonsemimodular_pair(upper=False)
(5, 3)

>>> H_ = HasseDiagram(H.reverse().relabel(lambda x: Integer(6)-x,␣
↪inplace=False))
>>> H_.find_nonsemimodular_pair(upper=True)
(3, 1)
>>> H_.find_nonsemimodular_pair(upper=False) is None
True
```

find_nontrivial_congruence()

Return a pair that generates non-trivial congruence or `None` if there is not any.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [5], 2: [3, 4], 3: [5], 4: [5]})
```

(continues on next page)

(continued from previous page)

```
sage: H.find_nontrivial_congruence()                                    #␣
↪needs sage.modules
{{0, 1}, {2, 3, 4, 5}}

sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.find_nontrivial_congruence() is None                            #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(5)], Integer(2): [Integer(3), Integer(4)], Integer(3):␣
↪[Integer(5)], Integer(4): [Integer(5)]})
>>> H.find_nontrivial_congruence()                                      #␣
↪needs sage.modules
{{0, 1}, {2, 3, 4, 5}}

>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)],␣
↪Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3):␣
↪[Integer(4)]})
>>> H.find_nontrivial_congruence() is None                              #␣
↪needs sage.modules
True
```

ALGORITHM:

See https://www.math.hawaii.edu/~ralph/Preprints/conlat.pdf:

If Θ is a join irreducible element of a $\mathrm{Con}(L)$, then there is at least one join-irreducible j and one meet-irreducible m such that Θ is both the principal congruence generated by (j^*, j), where j^* is the unique lower cover of j, and the principal congruence generated by (m, m^*), where m^* is the unique upper cover of m.

So, we only check join irreducibles or meet irreducibles, whichever is a smaller set. To optimize more we stop computation whenever it finds a pair that we know to generate one-element congruence.

frattini_sublattice()

Return the list of elements of the Frattini sublattice of the lattice.

EXAMPLES:

```
sage: H = posets.PentagonPoset()._hasse_diagram                         #␣
↪needs sage.modules
sage: H.frattini_sublattice()                                           #␣
↪needs sage.modules
[0, 4]
```

```
>>> from sage.all import *
>>> H = posets.PentagonPoset()._hasse_diagram                           #␣
↪needs sage.modules
>>> H.frattini_sublattice()                                            #␣
↪needs sage.modules
[0, 4]
```

greedy_linear_extensions_iterator()

Return an iterator over greedy linear extensions of the Hasse diagram.

A linear extension $[e_1, e_2, \ldots, e_n]$ is *greedy* if for every i either e_{i+1} covers e_i or all upper covers of e_i have at least one lower cover that is not in $[e_1, e_2, \ldots, e_i]$.

Informally said a linear extension is greedy if it "always goes up when possible" and so has no unnecessary jumps.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 2: [3], 1: [4], 3: [4]})
sage: for l in N5.greedy_linear_extensions_iterator():
....:     print(l)
[0, 1, 2, 3, 4]
[0, 2, 3, 1, 4]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> N5 = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(2):␣
↪[Integer(3)], Integer(1): [Integer(4)], Integer(3): [Integer(4)]})
>>> for l in N5.greedy_linear_extensions_iterator():
...     print(l)
[0, 1, 2, 3, 4]
[0, 2, 3, 1, 4]
```

has_bottom()

Return `True` if the poset has a unique minimal element.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_bottom()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})
>>> P.has_bottom()
False
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.has_bottom()
True
```

has_top()

Return `True` if the poset contains a unique maximal element, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_top()
```

(continues on next page)

(continued from previous page)

```
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_top()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4),Integer(5)],Integer(4):[],
↪Integer(5):[]})
>>> P.has_top()
False
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.has_top()
True
```

interval(x, y)

Return a list of the elements z of `self` such that $x \leq z \leq y$.

The order is that induced by the ordering in `self.linear_extension`.

INPUT:

- `x` – any element of the poset
- `y` – any element of the poset

Note

The method *`_precompute_intervals()`* creates a cache which is used if available, making the function very fast.

See also

`interval_iterator()`

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval(2,7))
True
```

```
>>> from sage.all import *
>>> uc = [[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
↪Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
↪[]]
>>> dag = DiGraph(dict(zip(range(len(uc)),uc)))
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
```

(continues on next page)

(continued from previous page)

```
>>> H = HasseDiagram(dag)
>>> I = set([Integer(2),Integer(5),Integer(6),Integer(4),Integer(7)])
>>> I == set(H.interval(Integer(2),Integer(7)))
True
```

interval_iterator(*x*, *y*)

Return an iterator of the elements z of `self` such that $x \leq z \leq y$.

INPUT:

- `x` – any element of the poset
- `y` – any element of the poset

See also

interval()

Note

This becomes much faster when first calling *_leq_storage*, which precomputes the principal upper ideals.

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval_iterator(2,7))
True
```

```
>>> from sage.all import *
>>> uc = [[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
↪Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
↪[]]
>>> dag = DiGraph(dict(zip(range(len(uc)),uc)))
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram(dag)
>>> I = set([Integer(2),Integer(5),Integer(6),Integer(4),Integer(7)])
>>> I == set(H.interval_iterator(Integer(2),Integer(7)))
True
```

is_antichain_of_poset(*elms*)

Return `True` if `elms` is an antichain of the Hasse diagram and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
```

(continues on next page)

(continued from previous page)

```
sage: H.is_antichain_of_poset([1, 2, 3])
True
sage: H.is_antichain_of_poset([0, 2, 3])
False
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)],␣
↪Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3):␣
↪[Integer(4)]})
>>> H.is_antichain_of_poset([Integer(1), Integer(2), Integer(3)])
True
>>> H.is_antichain_of_poset([Integer(0), Integer(2), Integer(3)])
False
```

is_bounded()

Return `True` if the poset contains a unique maximal element and a unique minimal element, and `False` otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.is_bounded()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.is_bounded()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4),Integer(5)],Integer(4):[],
↪Integer(5):[]})
>>> P.is_bounded()
False
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.is_bounded()
True
```

is_chain()

Return `True` if the poset is totally ordered, and `False` otherwise.

EXAMPLES:

```
sage: L = Poset({0:[1],1:[2],2:[3],3:[4]})
sage: L.is_chain()
True
sage: V = Poset({0:[1,2]})
sage: V.is_chain()
False
```

```
>>> from sage.all import *
>>> L = Poset({Integer(0):[Integer(1)],Integer(1):[Integer(2)],
```

(continues on next page)

(continued from previous page)

```
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)]})
>>> L.is_chain()
True
>>> V = Poset({Integer(0):[Integer(1),Integer(2)]})
>>> V.is_chain()
False
```

is_complemented()

Return an element of the lattice that has no complement.

If the lattice is complemented, return `None`.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram

sage: H = HasseDiagram({0:[1, 2], 1:[3], 2:[3], 3:[4]})
sage: H.is_complemented()                                                   #␣
↪needs sage.modules
1

sage: H = HasseDiagram({0:[1, 2, 3], 1:[4], 2:[4], 3:[4]})
sage: H.is_complemented() is None                                           #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(2)],␣
↪Integer(1):[Integer(3)], Integer(2):[Integer(3)], Integer(3):[Integer(4)]})
>>> H.is_complemented()                                                     #␣
↪needs sage.modules
1

>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(2), Integer(3)],␣
↪Integer(1):[Integer(4)], Integer(2):[Integer(4)], Integer(3):[Integer(4)]})
>>> H.is_complemented() is None                                             #␣
↪needs sage.modules
True
```

is_congruence_normal()

Return `True` if the lattice can be constructed from the one-element lattice with Day doubling constructions of convex subsets.

Subsets to double does not need to be lower nor upper pseudo-intervals. On the other hand they must be convex, i.e. doubling a non-convex but municipal subset will give a lattice that returns `False` from this function.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram('IX?Q@?AG?OG?W?O@??')
sage: H.is_congruence_normal()                                              #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram('IX?Q@?AG?OG?W?O@??')
>>> H.is_congruence_normal()                                                #␣
↪needs sage.combinat sage.modules
True
```

The 5-element diamond is the smallest non-example:

```
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.is_congruence_normal()                                             #␣
↪needs sage.combinat sage.modules
False
```

```
>>> from sage.all import *
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)],␣
↪Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3):␣
↪[Integer(4)]})
>>> H.is_congruence_normal()                                                #␣
↪needs sage.combinat sage.modules
False
```

This is done by doubling a non-convex subset:

```
sage: H = HasseDiagram('OQC?a?@CO?G_C@?GA?O??_??@?BO?A_?G??C??_?@???')
sage: H.is_congruence_normal()                                             #␣
↪needs sage.combinat sage.modules
False
```

```
>>> from sage.all import *
>>> H = HasseDiagram('OQC?a?@CO?G_C@?GA?O??_??@?BO?A_?G??C??_?@???')
>>> H.is_congruence_normal()                                                #␣
↪needs sage.combinat sage.modules
False
```

ALGORITHM:

See http://www.math.hawaii.edu/~jb/inflation.pdf

is_convex_subset(S)

Return `True` if S is a convex subset of the poset, and `False` otherwise.

A subset S is *convex* in the poset if $b \in S$ whenever $a, c \in S$ and $a \leq b \leq c$.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: B3 = HasseDiagram({0: [1, 2, 4], 1: [3, 5], 2: [3, 6],
....:                    3: [7], 4: [5, 6], 5: [7], 6: [7]})
sage: B3.is_convex_subset([1, 3, 5, 4])  # Also connected
```

(continues on next page)

(continued from previous page)

```
True
sage: B3.is_convex_subset([1, 3, 4])  # Not connected
True

sage: B3.is_convex_subset([0, 1, 2, 3, 6])  # No, 0 < 4 < 6
False
sage: B3.is_convex_subset([0, 1, 2, 7])  # No, 1 < 3 < 7.
False
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> B3 = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(4)],␣
↪Integer(1): [Integer(3), Integer(5)], Integer(2): [Integer(3), Integer(6)],
...                    Integer(3): [Integer(7)], Integer(4): [Integer(5),␣
↪Integer(6)], Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> B3.is_convex_subset([Integer(1), Integer(3), Integer(5), Integer(4)])  #␣
↪Also connected
True
>>> B3.is_convex_subset([Integer(1), Integer(3), Integer(4)])  # Not connected
True

>>> B3.is_convex_subset([Integer(0), Integer(1), Integer(2), Integer(3),␣
↪Integer(6)])  # No, 0 < 4 < 6
False
>>> B3.is_convex_subset([Integer(0), Integer(1), Integer(2), Integer(7)])  #␣
↪No, 1 < 3 < 7.
False
```

is_gequal (*x*, *y*)

Return `True` if `x` is greater than or equal to `y`, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0,1,4
sage: Q.is_gequal(x,y)
False
sage: Q.is_gequal(y,x)
False
sage: Q.is_gequal(x,z)
False
sage: Q.is_gequal(z,x)
True
sage: Q.is_gequal(z,y)
True
sage: Q.is_gequal(z,z)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> Q = HasseDiagram({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> x,y,z = Integer(0),Integer(1),Integer(4)
>>> Q.is_gequal(x,y)
False
>>> Q.is_gequal(y,x)
False
>>> Q.is_gequal(x,z)
False
>>> Q.is_gequal(z,x)
True
>>> Q.is_gequal(z,y)
True
>>> Q.is_gequal(z,z)
True
```

is_greater_than(*x*, *y*)

Return `True` if `x` is greater than but not equal to `y`, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0,1,4
sage: Q.is_greater_than(x,y)
False
sage: Q.is_greater_than(y,x)
False
sage: Q.is_greater_than(x,z)
False
sage: Q.is_greater_than(z,x)
True
sage: Q.is_greater_than(z,y)
True
sage: Q.is_greater_than(z,z)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> Q = HasseDiagram({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> x,y,z = Integer(0),Integer(1),Integer(4)
>>> Q.is_greater_than(x,y)
False
>>> Q.is_greater_than(y,x)
False
>>> Q.is_greater_than(x,z)
False
>>> Q.is_greater_than(z,x)
True
>>> Q.is_greater_than(z,y)
True
>>> Q.is_greater_than(z,z)
```

(continues on next page)

(continued from previous page)

```
False
```

is_join_semilattice()

Return `True` if `self` has a join operation, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
↪7:[]})
sage: H.is_join_semilattice()                                              #␣
↪needs sage.modules
True
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.is_join_semilattice()                                              #␣
↪needs sage.modules
False
sage: H = HasseDiagram({0:[2,3],1:[2,3],2:[4],3:[4]})
sage: H.is_join_semilattice()                                              #␣
↪needs sage.modules
False
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
↪Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
↪Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
↪Integer(6):[Integer(7)],Integer(7):[]})
>>> H.is_join_semilattice()                                                #␣
↪needs sage.modules
True
>>> H = HasseDiagram({Integer(0):[Integer(2),Integer(3)],
↪Integer(1):[Integer(2),Integer(3)]})
>>> H.is_join_semilattice()                                                #␣
↪needs sage.modules
False
>>> H = HasseDiagram({Integer(0):[Integer(2),Integer(3)],
↪Integer(1):[Integer(2),Integer(3)],Integer(2):[Integer(4)],
↪Integer(3):[Integer(4)]})
>>> H.is_join_semilattice()                                                #␣
↪needs sage.modules
False
```

is_lequal(*i*, *j*)

Return `True` if i is less than or equal to j in the poset, and `False` otherwise.

Note

If the *lequal_matrix()* has been computed, then this method uses the cached data.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0, 1, 4
sage: H.is_lequal(x,y)
False
sage: H.is_lequal(y,x)
False
sage: H.is_lequal(x,z)
True
sage: H.is_lequal(y,z)
True
sage: H.is_lequal(z,z)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> x,y,z = Integer(0), Integer(1), Integer(4)
>>> H.is_lequal(x,y)
False
>>> H.is_lequal(y,x)
False
>>> H.is_lequal(x,z)
True
>>> H.is_lequal(y,z)
True
>>> H.is_lequal(z,z)
True
```

is_less_than(*x*, *y*)

Return `True` if `x` is less than but not equal to `y` in the poset, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x,y,z = 0, 1, 4
sage: H.is_less_than(x,y)
False
sage: H.is_less_than(y,x)
False
sage: H.is_less_than(x,z)
True
sage: H.is_less_than(y,z)
True
sage: H.is_less_than(z,z)
False
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(2)], Integer(1):[Integer(2)],␣
↪Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
```

(continues on next page)

(continued from previous page)

```
>>> x,y,z = Integer(0), Integer(1), Integer(4)
>>> H.is_less_than(x,y)
False
>>> H.is_less_than(y,x)
False
>>> H.is_less_than(x,z)
True
>>> H.is_less_than(y,z)
True
>>> H.is_less_than(z,z)
False
```

is_linear_extension(*lin_ext=None*)

Test if an ordering is a linear extension.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_linear_extension(list(range(4)))
True
sage: H.is_linear_extension([3,2,1,0])
False
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
↪Integer(1):[Integer(3)],Integer(2):[Integer(3)],Integer(3):[]})
>>> H.is_linear_extension(list(range(Integer(4))))
True
>>> H.is_linear_extension([Integer(3),Integer(2),Integer(1),Integer(0)])
False
```

is_linear_interval(*t_min*, *t_max*)

Return whether the interval `[t_min, t_max]` is linear.

This means that this interval is a total order.

EXAMPLES:

```
sage: # needs sage.modules
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.is_linear_interval(0, 4)
False
sage: H.is_linear_interval(0, 3)
True
sage: H.is_linear_interval(1, 3)
False
sage: H.is_linear_interval(1, 1)
True
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> P = posets.PentagonPoset()
>>> H = P._hasse_diagram
>>> H.is_linear_interval(Integer(0), Integer(4))
False
>>> H.is_linear_interval(Integer(0), Integer(3))
True
>>> H.is_linear_interval(Integer(1), Integer(3))
False
>>> H.is_linear_interval(Integer(1), Integer(1))
True
```

is_meet_semilattice()

Return `True` if `self` has a meet operation, and `False` otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
↪7:[]})
sage: H.is_meet_semilattice()                                                #␣
↪needs sage.modules
True

sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_meet_semilattice()                                                #␣
↪needs sage.modules
True

sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.is_meet_semilattice()                                                #␣
↪needs sage.modules
False

sage: H = HasseDiagram({0:[1,2],1:[3,4],2:[3,4]})
sage: H.is_meet_semilattice()                                                #␣
↪needs sage.modules
False
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
↪Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
↪Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
↪Integer(6):[Integer(7)],Integer(7):[]})
>>> H.is_meet_semilattice()                                                  #␣
↪needs sage.modules
True

>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
↪Integer(1):[Integer(3)],Integer(2):[Integer(3)],Integer(3):[]})
>>> H.is_meet_semilattice()                                                  #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.modules
True

>>> H = HasseDiagram({Integer(0):[Integer(2),Integer(3)],
↪Integer(1):[Integer(2),Integer(3)]})
>>> H.is_meet_semilattice()                                              #␣
↪needs sage.modules
False

>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
↪Integer(1):[Integer(3),Integer(4)],Integer(2):[Integer(3),Integer(4)]})
>>> H.is_meet_semilattice()                                              #␣
↪needs sage.modules
False
```

is_ranked()

Return `True` if the poset is ranked, and `False` otherwise.

A poset is *ranked* if it admits a rank function. For more information about the rank function, see *rank_function()* and *is_graded()*.

EXAMPLES:

```
sage: P = Poset([[1],[2],[3],[4],[]])
sage: P.is_ranked()
True
sage: Q = Poset([[1,5],[2,6],[3],[4],[],[6,3],[4]])
sage: Q.is_ranked()
False
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1)],[Integer(2)],[Integer(3)],[Integer(4)],[]])
>>> P.is_ranked()
True
>>> Q = Poset([[Integer(1),Integer(5)],[Integer(2),Integer(6)],[Integer(3)],
↪[Integer(4)],[],[Integer(6),Integer(3)],[Integer(4)]])
>>> Q.is_ranked()
False
```

join_matrix()

Return the matrix of joins of `self`, when `self` is a join-semilattice; raise an error otherwise.

The `(x,y)`-entry of this matrix is the join of `x` and `y` in `self`.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

Note

If `self` is a join-semilattice, then the return of this method is the same as *_join*. Once the matrix has been computed, it is stored in *_join*. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
↪7:[]})
sage: H.join_matrix()                                                    #␣
↪needs sage.modules
[0 1 2 3 4 5 6 7]
[1 1 4 7 4 7 7 7]
[2 4 2 6 4 5 6 7]
[3 7 6 3 7 7 6 7]
[4 4 4 7 4 7 7 7]
[5 7 5 7 7 5 7 7]
[6 7 6 6 7 7 6 7]
[7 7 7 7 7 7 7 7]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
↪Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
↪Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
↪Integer(6):[Integer(7)],Integer(7):[]})
>>> H.join_matrix()                                                      #␣
↪needs sage.modules
[0 1 2 3 4 5 6 7]
[1 1 4 7 4 7 7 7]
[2 4 2 6 4 5 6 7]
[3 7 6 3 7 7 6 7]
[4 4 4 7 4 7 7 7]
[5 7 5 7 7 5 7 7]
[6 7 6 6 7 7 6 7]
[7 7 7 7 7 7 7 7]
```

kappa(a)

Return the maximum element greater than the element covered by `a` but not greater than `a`.

Define $\kappa(a)$ as the maximum element of $(\uparrow a_*) \setminus (\uparrow a)$, where a_* is the element covered by a. It is always a meet-irreducible element, if it exists.

Note

Element `a` is expected to be join-irreducible, and this is *not* checked.

INPUT:

- `a` – a join-irreducible element of the lattice

OUTPUT:

The element $\kappa(a)$ or `None` if there is not a unique greatest element with given constraints.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4, 5], 3: [5], 4: [6], 5:␣
↪[6]})
```

(continues on next page)

(continued from previous page)

```
sage: H.kappa(1)
5
sage: H.kappa(2) is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)],␣
↪Integer(1): [Integer(4)], Integer(2): [Integer(4), Integer(5)], Integer(3):␣
↪[Integer(5)], Integer(4): [Integer(6)], Integer(5): [Integer(6)]})
>>> H.kappa(Integer(1))
5
>>> H.kappa(Integer(2)) is None
True
```

kappa_dual(*a*)

Return the minimum element smaller than the element covering `a` but not smaller than `a`.

Define $\kappa^*(a)$ as the minimum element of $(\downarrow a_*) \setminus (\downarrow a)$, where a_* is the element covering a. It is always a join-irreducible element, if it exists.

Note

Element `a` is expected to be meet-irreducible, and this is *not* checked.

INPUT:

- `a` – a meet-irreducible element of the lattice

OUTPUT:

The element $\kappa^*(a)$ or `None` if there is not a unique smallest element with given constraints.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3, 4], 2: [4, 5], 3: [6], 4: [6], 5:␣
↪[6]})
sage: H.kappa_dual(3)
2
sage: H.kappa_dual(4) is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3), Integer(4)], Integer(2): [Integer(4), Integer(5)], Integer(3):␣
↪[Integer(6)], Integer(4): [Integer(6)], Integer(5): [Integer(6)]})
>>> H.kappa_dual(Integer(3))
2
>>> H.kappa_dual(Integer(4)) is None
True
```

lequal_matrix(*boolean=False*)

Return a matrix whose `(i,j)` entry is 1 if `i` is less than `j` in the poset, and 0 otherwise.

INPUT:

- `boolean` – flag (default: `False`); whether to return a matrix with coefficients in $\mathbf{F}_(2)$ or in $\mathbf{Z}$

↪needs sage.modules
Finite Field of size 2
```

linear_extension()

Return a linear extension.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.linear_extension()
[0, 1, 2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
↪Integer(1):[Integer(3)],Integer(2):[Integer(3)],Integer(3):[]})
>>> H.linear_extension()
[0, 1, 2, 3]
```

linear_extensions()

Return an iterator over all linear extensions.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: list(H.linear_extensions())                                       #␣
↪needs sage.modules
[[0, 1, 2, 3], [0, 2, 1, 3]]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
↪Integer(1):[Integer(3)],Integer(2):[Integer(3)],Integer(3):[]})
>>> list(H.linear_extensions())                                         #␣
↪needs sage.modules
[[0, 1, 2, 3], [0, 2, 1, 3]]
```

linear_intervals_count()

Return the enumeration of linear intervals w.r.t. their cardinality.

An interval is linear if it is a total order.

OUTPUT: an iterator of integers

See also

is_linear_interval()

EXAMPLES:

```
sage: P = posets.BubblePoset(3,3)
sage: H = P._hasse_diagram
sage: list(H.linear_intervals_count())
[245, 735, 438, 144, 24]
```

```
>>> from sage.all import *
>>> P = posets.BubblePoset(Integer(3),Integer(3))
>>> H = P._hasse_diagram
>>> list(H.linear_intervals_count())
[245, 735, 438, 144, 24]
```

lower_covers_iterator(*element*)

Return the list of elements that are covered by `element`.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
↪7:[]})
sage: list(H.lower_covers_iterator(0))
[]
sage: list(H.lower_covers_iterator(4))
[1, 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
↪Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
↪Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
↪Integer(6):[Integer(7)],Integer(7):[]})
>>> list(H.lower_covers_iterator(Integer(0)))
[]
>>> list(H.lower_covers_iterator(Integer(4)))
[1, 2]
```

maximal_elements()

Return a list of the maximal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})
```

(continues on next page)

(continued from previous page)

```
>>> P.maximal_elements()
[4]
```

maximal_sublattices()

Return maximal sublattices of the lattice.

EXAMPLES:

```
sage: L = posets.PentagonPoset()                                              #␣
↪needs sage.modules
sage: ms = L._hasse_diagram.maximal_sublattices()                             #␣
↪needs sage.modules
sage: sorted(ms, key=sorted)                                                  #␣
↪needs sage.modules
[{0, 1, 2, 4}, {0, 1, 3, 4}, {0, 2, 3, 4}]
```

```
>>> from sage.all import *
>>> L = posets.PentagonPoset()                                              #␣
↪needs sage.modules
>>> ms = L._hasse_diagram.maximal_sublattices()                             #␣
↪needs sage.modules
>>> sorted(ms, key=sorted)                                                  #␣
↪needs sage.modules
[{0, 1, 2, 4}, {0, 1, 3, 4}, {0, 2, 3, 4}]
```

meet_matrix()

Return the matrix of meets of `self`, when `self` is a meet-semilattice; raise an error otherwise.

The `(x,y)`-entry of this matrix is the meet of `x` and `y` in `self`.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

Note

If `self` is a meet-semilattice, then the return of this method is the same as *_meet*. Once the matrix has been computed, it is stored in *_meet*. Delete this attribute if you want to recompute the matrix.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
↪7:[]})
sage: H.meet_matrix()                                                         #␣
↪needs sage.modules
[0 0 0 0 0 0 0 0]
[0 1 0 0 1 0 0 1]
[0 0 2 0 2 2 2 2]
[0 0 0 3 0 0 3 3]
[0 1 2 0 4 2 2 4]
[0 0 2 0 2 5 2 5]
[0 0 2 3 2 2 6 6]
[0 1 2 3 4 5 6 7]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
↪Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
↪Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
↪Integer(6):[Integer(7)],Integer(7):[]})
>>> H.meet_matrix()                                                    #␣
↪needs sage.modules
[0 0 0 0 0 0 0 0]
[0 1 0 0 1 0 0 1]
[0 0 2 0 2 2 2 2]
[0 0 0 3 0 0 3 3]
[0 1 2 0 4 2 2 4]
[0 0 2 0 2 5 2 5]
[0 0 2 3 2 2 6 6]
[0 1 2 3 4 5 6 7]
```

REFERENCE:

minimal_elements()

Return a list of the minimal elements of the poset.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})
>>> P(Integer(0)) in P.minimal_elements()
True
>>> P(Integer(1)) in P.minimal_elements()
True
>>> P(Integer(2)) in P.minimal_elements()
True
```

moebius_function(i, j)

Return the value of the Möbius function of the poset on the elements `i` and `j`.

EXAMPLES:

```
sage: P = Poset([[1,2,3],[4],[4],[4],[]])
sage: H = P._hasse_diagram
sage: H.moebius_function(0,4)
2
sage: for u,v in P.cover_relations_iterator():
....:     if P.moebius_function(u,v) != -1:
....:         print("Bug in moebius_function!")
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(2),Integer(3)],[Integer(4)],[Integer(4)],
↪[Integer(4)],[]])
>>> H = P._hasse_diagram
>>> H.moebius_function(Integer(0),Integer(4))
2
>>> for u,v in P.cover_relations_iterator():
...     if P.moebius_function(u,v) != -Integer(1):
...         print("Bug in moebius_function!")
```

moebius_function_matrix(*algorithm='cython'*)

Return the matrix of the Möbius function of this poset.

This returns the matrix over **Z** whose `(x, y)` entry is the value of the Möbius function of `self` evaluated on `x` and `y`, and redefines *moebius_function()* to use it.

INPUT:

- `algorithm` – `'recursive'`, `'matrix'` or `'cython'` (default)

This uses either the recursive formula, a generic matrix inversion or a specific matrix inversion coded in Cython.

OUTPUT: a dense matrix for the algorithm `cython`, a sparse matrix otherwise

Note

The result is cached in `_moebius_function_matrix`.

[ 0  0  0  0  0  0  1 -1]
[ 0  0  0  0  0  0  0  1]
```

neutral_elements()

Return the list of neutral elements of the lattice.

An element a in a lattice is neutral if the sublattice generated by a, x and y is distributive for every x, y in the lattice.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3: [4, 5],
....:                   4: [6], 5: [6]})
sage: sorted(H.neutral_elements())                                       #␣
↪needs sage.modules
[0, 4, 6]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(4)], Integer(2): [Integer(3)], Integer(3): [Integer(4),␣
↪Integer(5)],
...                   Integer(4): [Integer(6)], Integer(5): [Integer(6)]})
>>> sorted(H.neutral_elements())                                         #␣
↪needs sage.modules
[0, 4, 6]
```

ALGORITHM:

Basically we just check the distributivity against all element pairs x, y to see if element a is neutral or not.

If we found that a, x, y is not a distributive triple, we add all three to list of non-neutral elements. If we found a to be neutral, we add it to list of neutral elements. When testing we skip already found neutral elements, as they can't be our x or y.

We skip a, x, y as trivial if it is a chain. We do that by letting x to be a non-comparable to a; y can be any element.

We first try to found x and y from elements not yet tested, so that we could get three birds with one stone.

And last, the top and bottom elements are always neutral and need not be tested.

open_interval(x, y)

Return a list of the elements z of `self` such that $x < z < y$.

The order is that induced by the ordering in `self.linear_extension`.

EXAMPLES:

```
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: set([5,6,4]) == set(H.open_interval(2,7))
True
sage: H.open_interval(7,2)
[]
```

```
>>> from sage.all import *
>>> uc = [[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
...Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
...[]]
>>> dag = DiGraph(dict(zip(range(len(uc)),uc)))
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram(dag)
>>> set([Integer(5),Integer(6),Integer(4)]) == set(H.open_interval(Integer(2),
...Integer(7)))
True
>>> H.open_interval(Integer(7),Integer(2))
[]
```

order_filter(*elements*)

Return the order filter generated by a list of elements.

I is an order filter if, for any x in I and y such that $y \geq x$, then y is in I.

EXAMPLES:

```
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_filter([3,8])
[3, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

```
>>> from sage.all import *
>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram
>>> H.order_filter([Integer(3),Integer(8)])
[3, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

order_ideal(*elements*)

Return the order ideal generated by a list of elements.

I is an order ideal if, for any x in I and y such that $y \leq x$, then y is in I.

EXAMPLES:

```
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal([7,10])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 10]
```

```
>>> from sage.all import *
>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram
>>> H.order_ideal([Integer(7),Integer(10)])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 10]
```

order_ideal_cardinality(*elements*)

Return the cardinality of the order ideal generated by `elements`.

I is an order ideal if, for any x in I and y such that $y \leq x$, then y is in I.

EXAMPLES:

```
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal_cardinality([7,10])
10
```

```
>>> from sage.all import *
>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram
>>> H.order_ideal_cardinality([Integer(7),Integer(10)])
10
```

orthocomplementations_iterator()

Return an iterator over orthocomplementations of the lattice.

OUTPUT: an iterator that gives plain list of integers

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2], 1:[3,4], 3:[5], 4:[5], 2:[6,7],
....:                   6:[8], 7:[8], 5:[9], 8:[9]})
sage: list(H.orthocomplementations_iterator())                              #␣
↪needs sage.groups
[[9, 8, 5, 6, 7, 2, 3, 4, 1, 0], [9, 8, 5, 7, 6, 2, 4, 3, 1, 0]]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],␣
↪Integer(1):[Integer(3),Integer(4)], Integer(3):[Integer(5)],␣
↪Integer(4):[Integer(5)], Integer(2):[Integer(6),Integer(7)],
...                    Integer(6):[Integer(8)], Integer(7):[Integer(8)],␣
↪Integer(5):[Integer(9)], Integer(8):[Integer(9)]})
>>> list(H.orthocomplementations_iterator())                                #␣
↪needs sage.groups
[[9, 8, 5, 6, 7, 2, 3, 4, 1, 0], [9, 8, 5, 7, 6, 2, 4, 3, 1, 0]]
```

ALGORITHM:

As `DiamondPoset(2*n+2)` has $(2n)!/(n!2^n)$ different orthocomplementations, the complexity of listing all of them is necessarily $O(n!)$.

An orthocomplemented lattice is self-dual, so that for example orthocomplement of an atom is a coatom. This function basically just computes list of possible orthocomplementations for every element (i.e. they must be complements and "duals"), and then tries to fit them all.

prime_elements()

Return the join-prime and meet-prime elements of the bounded poset.

An element x of a poset P is join-prime if the subposet induced by $\{y \in P \mid y \not\geq x\}$ has a top element. Meet-prime is defined dually.

> **Note**
>
> The poset is expected to be bounded, and this is *not* checked.

OUTPUT:

A pair (j, m) where j is a list of join-prime elements and m is a list of meet-prime elements.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})
sage: H.prime_elements()
([1, 2], [2, 3])
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3)], Integer(2): [Integer(4)], Integer(3): [Integer(4)]})
>>> H.prime_elements()
([1, 2], [2, 3])
```

principal_congruences_poset()

Return the poset of join-irreducibles of the congruence lattice.

OUTPUT:

A pair (P, D) where P is a poset and D is a dictionary.

Elements of P are pairs (x, y) such that x is an element of the lattice and y is an element covering it. In the poset (a, b) is less than (c, d) iff the principal congruence generated by (a, b) is refinement of the principal congruence generated by (c, d).

D is a dictionary from pairs (x, y) to the congruence (given as DisjointSet) generated by the pair.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3: [4]})
sage: P, D = N5.principal_congruences_poset()                                #␣
↪needs sage.combinat sage.modules
sage: P                                                                      #␣
↪needs sage.combinat sage.modules
Finite poset containing 3 elements
sage: P.bottom()                                                             #␣
↪needs sage.combinat sage.modules
(2, 3)
sage: D[(2, 3)]                                                              #␣
↪needs sage.combinat sage.modules
{{0}, {1}, {2, 3}, {4}}
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> N5 = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(4)], Integer(2): [Integer(3)], Integer(3): [Integer(4)]})
```

(continues on next page)

(continued from previous page)

```
>>> P, D = N5.principal_congruences_poset()                                    #␣
↪needs sage.combinat sage.modules
>>> P                                                                          #␣
↪needs sage.combinat sage.modules
Finite poset containing 3 elements
>>> P.bottom()                                                                 #␣
↪needs sage.combinat sage.modules
(2, 3)
>>> D[(Integer(2), Integer(3))]                                                ␣
↪              # needs sage.combinat sage.modules
{{0}, {1}, {2, 3}, {4}}
```

principal_order_filter(*i*)

Return the order filter generated by `i`.

EXAMPLES:

```
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_filter(2)
[2, 3, 6, 7, 10, 11, 14, 15]
```

```
>>> from sage.all import *
>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram
>>> H.principal_order_filter(Integer(2))
[2, 3, 6, 7, 10, 11, 14, 15]
```

principal_order_ideal(*i*)

Return the order ideal generated by i.

EXAMPLES:

```
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_ideal(6)
[0, 2, 4, 6]
```

```
>>> from sage.all import *
>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram
>>> H.principal_order_ideal(Integer(6))
[0, 2, 4, 6]
```

pseudocomplement(*element*)

Return the pseudocomplement of `element`, if it exists.

The pseudocomplement is the greatest element whose meet with given element is the bottom element. It may not exist, and then the function returns `None`.

INPUT:

- `element` – an element of the lattice

OUTPUT:

An element of the Hasse diagram, i.e. an integer, or `None` if the pseudocomplement does not exist.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})
sage: H.pseudocomplement(2)                                                 #␣
↪needs sage.modules
3

sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.pseudocomplement(2) is None                                         #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3)], Integer(2): [Integer(4)], Integer(3): [Integer(4)]})
>>> H.pseudocomplement(Integer(2))                                          ␣
↪     # needs sage.modules
3

>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)],␣
↪Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3):␣
↪[Integer(4)]})
>>> H.pseudocomplement(Integer(2)) is None                                  ␣
↪     # needs sage.modules
True
```

rank(*element=None*)

Return the rank of `element`, or the rank of the poset if `element` is `None`. (The rank of a poset is the length of the longest chain of elements of the poset.)

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
↪7:[]})
sage: H.rank(5)
2
sage: H.rank()
3
sage: Q = HasseDiagram({0:[1,2],1:[3],2:[],3:[]})
sage: Q.rank()
2
sage: Q.rank(1)
1
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
↪Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
↪Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
↪Integer(6):[Integer(7)],Integer(7):[]})
>>> H.rank(Integer(5))
2
```

(continues on next page)

(continued from previous page)

```
>>> H.rank()
3
>>> Q = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
↪Integer(1):[Integer(3)],Integer(2):[],Integer(3):[]})
>>> Q.rank()
2
>>> Q.rank(Integer(1))
1
```

rank_function()

Return the (normalized) rank function of the poset, if it exists.

A *rank function* of a poset P is a function r that maps elements of P to integers and satisfies: $r(x) = r(y)+1$ if x covers y. The function r is normalized such that its minimum value on every connected component of the Hasse diagram of P is 0. This determines the function r uniquely (when it exists).

OUTPUT:

- a lambda function, if the poset admits a rank function
- `None`, if the poset does not admit a rank function

EXAMPLES:

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]])
sage: P.rank_function() is not None
True
sage: P = Poset(([1,2,3,4],[[1,4],[2,3],[3,4]]), facade = True)
sage: P.rank_function() is not None
True
sage: P = Poset(([1,2,3,4,5],[[1,2],[2,3],[3,4],[1,5],[5,4]]), facade = True)
sage: P.rank_function() is not None
False
sage: P = Poset(([1,2,3,4,5,6,7,8],[[1,4],[2,3],[3,4],[5,7],[6,7]]), facade =␣
↪True)
sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0
```

```
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
↪Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
↪[]])
>>> P.rank_function() is not None
True
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4)],[[Integer(1),
↪Integer(4)],[Integer(2),Integer(3)],[Integer(3),Integer(4)]]), facade =␣
↪True)
>>> P.rank_function() is not None
True
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],
```

(continues on next page)

(continued from previous page)

```
↪[[Integer(1),Integer(2)],[Integer(2),Integer(3)],[Integer(3),Integer(4)],
↪[Integer(1),Integer(5)],[Integer(5),Integer(4)]]), facade = True)
>>> P.rank_function() is not None
False
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6),Integer(7),Integer(8)],[[Integer(1),Integer(4)],[Integer(2),
↪Integer(3)],[Integer(3),Integer(4)],[Integer(5),Integer(7)],[Integer(6),
↪Integer(7)]]), facade = True)
>>> f = P.rank_function(); f is not None
True
>>> f(Integer(5))
0
>>> f(Integer(2))
0
```

skeleton()

Return the skeleton of the lattice.

The lattice is expected to be pseudocomplemented and non-empty.

The skeleton of the lattice is the subposet induced by those elements that are the pseudocomplement to at least one element.

OUTPUT:

List of elements such that the subposet induced by them is the skeleton of the lattice.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3, 4], 2: [4],
....:                   3: [5], 4: [5]})
sage: H.skeleton()                                                          #␣
↪needs sage.modules
[5, 2, 0, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):␣
↪[Integer(3), Integer(4)], Integer(2): [Integer(4)],
...                   Integer(3): [Integer(5)], Integer(4): [Integer(5)]})
>>> H.skeleton()                                                            #␣
↪needs sage.modules
[5, 2, 0, 3]
```

spine()

Return the spine and the maximum chain length.

The poset is assumed to be bounded. The spine is the union of all longest maximal chains.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P._hasse_diagram.spine()
({0, 2, 3, 4}, 4)
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P._hasse_diagram.spine()
({0, 2, 3, 4}, 4)
```

sublattices_iterator(*elms*, *min_e*)

Return an iterator over sublattices of the Hasse diagram.

INPUT:

- `elms` – elements already in sublattice; use set() at start
- `min_e` – smallest new element to add for new sublattices

OUTPUT: list of sublattices as sets of integers

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1:[3], 2:[3]})
sage: it = H.sublattices_iterator(set(), 0); it
<generator object ...sublattices_iterator at ...>
sage: next(it)                                                              #␣
↪needs sage.modules
set()
sage: next(it)                                                              #␣
↪needs sage.modules
{0}
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)],␣
↪Integer(1):[Integer(3)], Integer(2):[Integer(3)]})
>>> it = H.sublattices_iterator(set(), Integer(0)); it
<generator object ...sublattices_iterator at ...>
>>> next(it)                                                                #␣
↪needs sage.modules
set()
>>> next(it)                                                                #␣
↪needs sage.modules
{0}
```

supergreedy_linear_extensions_iterator()

Return an iterator over supergreedy linear extensions of the Hasse diagram.

A linear extension $[e_1, e_2, \ldots, e_n]$ is *supergreedy* if, for every i and j where $i > j$, e_i covers e_j if for every $i > k > j$ at least one lower cover of e_k is not in $[e_1, e_2, \ldots, e_k]$.

Informally said a linear extension is supergreedy if it "always goes as high possible, and withdraw so less as possible". These are also called depth-first linear extensions.

EXAMPLES:

We show the difference between "only greedy" and supergreedy extensions:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 2: [3, 4]})
```

(continues on next page)

(continued from previous page)

```
sage: G_ext = list(H.greedy_linear_extensions_iterator())
sage: SG_ext = list(H.supergreedy_linear_extensions_iterator())
sage: [0, 2, 3, 1, 4] in G_ext
True
sage: [0, 2, 3, 1, 4] in SG_ext
False

sage: len(SG_ext)
4
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(2):␣
↪[Integer(3), Integer(4)]})
>>> G_ext = list(H.greedy_linear_extensions_iterator())
>>> SG_ext = list(H.supergreedy_linear_extensions_iterator())
>>> [Integer(0), Integer(2), Integer(3), Integer(1), Integer(4)] in G_ext
True
>>> [Integer(0), Integer(2), Integer(3), Integer(1), Integer(4)] in SG_ext
False

>>> len(SG_ext)
4
```

top()

Return the top element of the poset, if it exists.

EXAMPLES:

```
sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
↪Integer(2):[Integer(3)],Integer(3):[Integer(4),Integer(5)],Integer(4):[],
↪Integer(5):[]})
>>> P.top() is None
True
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.top()
1
```

upper_covers_iterator(*element*)

Return the list of elements that cover `element`.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
```

(continues on next page)

(continued from previous page)

```
↪7:[]})
sage: list(H.upper_covers_iterator(0))
[1, 2, 3]
sage: list(H.upper_covers_iterator(7))
[]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
↪Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
↪Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
↪Integer(6):[Integer(7)],Integer(7):[]})
>>> list(H.upper_covers_iterator(Integer(0)))
[1, 2, 3]
>>> list(H.upper_covers_iterator(Integer(7)))
[]
```

vertical_decomposition(*return_list=False*)

Return vertical decomposition of the lattice.

This is the backend function for vertical decomposition functions of lattices.

The property of being vertically decomposable is defined for lattices. This is *not* checked, and the function works with any bounded poset.

INPUT:

- `return_list` – boolean (default: `False`); if `False` (the default), return an element that is not the top neither the bottom element of the lattice, but is comparable to all elements of the lattice, if the lattice is vertically decomposable and `None` otherwise. If `True`, return list of decomposition elements.

EXAMPLES:

```
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.vertical_decomposition() is None
True
sage: P = Poset( ([1,2,3,6,12,18,36], attrcall("divides")) )
sage: P._hasse_diagram.vertical_decomposition()
3
sage: P._hasse_diagram.vertical_decomposition(return_list=True)
[3]
```

```
>>> from sage.all import *
>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram
>>> H.vertical_decomposition() is None
True
>>> P = Poset( ([Integer(1),Integer(2),Integer(3),Integer(6),Integer(12),
↪Integer(18),Integer(36)], attrcall("divides")) )
>>> P._hasse_diagram.vertical_decomposition()
3
>>> P._hasse_diagram.vertical_decomposition(return_list=True)
[3]
```

exception sage.combinat.posets.hasse_diagram.**LatticeError**(*fail*, *x*, *y*)

Bases: `ValueError`

Helper exception class to forward elements without meet or join to upper level, so that the user will see "No meet for a and b" instead of "No meet for 1 and 2".

Hochschild lattices

Hochschild lattices were defined in [Cha2020] as posets and shown to be congruence uniform lattices in [Com2021].

The name comes from the Hochschild polytopes introduced by Sanebdlidze in [San2009] for the study of free loop spaces in algebraic topology. The Hasse diagram of the Hochschild lattice is an orientation of the 1-skeleton of the Hochschild polytope.

For $n \geq 1$, the cardinality of the Hochschild lattice H_n is $2^{n-2} \times (n+3)$, starting with $2, 5, 12, 28, 64, 144, 320, 704, 1536, 3328, 7168, 15360, \ldots$.

The underlying set of H_n consists of some words in the alphabet $(0, 1, 2)$, whose precise description can be found in [Com2021].

sage.combinat.posets.hochschild_lattice.**hochschild_fan**(*n*)

Return Saneblidze's fan for the Hochschild polytope.

The dual polytope is obtained from a standard simplex by a sequence of truncations.

See also

hochschild_simplicial_complex(), *sage.combinat.posets.hochschild_lattice.hochschild_lattice()*

EXAMPLES:

```
sage: from sage.combinat.posets.hochschild_lattice import hochschild_fan
sage: F = hochschild_fan(4); F
Rational polyhedral fan in 4-d lattice N
sage: F.f_vector()
(1, 11, 39, 56, 28)
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hochschild_lattice import hochschild_fan
>>> F = hochschild_fan(Integer(4)); F
Rational polyhedral fan in 4-d lattice N
>>> F.f_vector()
(1, 11, 39, 56, 28)
```

sage.combinat.posets.hochschild_lattice.**hochschild_lattice**(*n*)

Return the Hochschild lattice H_n.

INPUT:

- $n \geq 1$ – an integer

The cardinality of H_n is $2^{n-2} \times (n+3)$.

See also

hochschild_simplicial_complex(), *hochschild_fan()*

EXAMPLES:

```
sage: P = posets.HochschildLattice(5); P
Finite lattice containing 64 elements
sage: P.degree_polynomial()
x^5 + 9*x^4*y + 22*x^3*y^2 + 22*x^2*y^3 + 9*x*y^4 + y^5
```

```
>>> from sage.all import *
>>> P = posets.HochschildLattice(Integer(5)); P
Finite lattice containing 64 elements
>>> P.degree_polynomial()
x^5 + 9*x^4*y + 22*x^3*y^2 + 22*x^2*y^3 + 9*x*y^4 + y^5
```

sage.combinat.posets.hochschild_lattice.**hochschild_simplicial_complex**(*n*)

Return a simplicial complex related to the Hochschild lattice H_n.

This is a pure spherical simplicial complex, whose flip graph is isomorphic to the Hasse diagram of H_n.

See also

hochschild_fan(), *sage.combinat.posets.hochschild_lattice.hochschild_lattice()*

EXAMPLES:

```
sage: C = simplicial_complexes.HochschildSphere(3); C
Simplicial complex with 8 vertices and 12 facets
sage: H = C.flip_graph()
sage: P = posets.HochschildLattice(3)
sage: H.is_isomorphic(P.hasse_diagram().to_undirected())
True
```

```
>>> from sage.all import *
>>> C = simplicial_complexes.HochschildSphere(Integer(3)); C
Simplicial complex with 8 vertices and 12 facets
>>> H = C.flip_graph()
>>> P = posets.HochschildLattice(Integer(3))
>>> H.is_isomorphic(P.hasse_diagram().to_undirected())
True
```

Incidence algebras

class sage.combinat.posets.incidence_algebras.**IncidenceAlgebra**(*R*, *P*, *prefix='I'*)

Bases: *CombinatorialFreeModule*

The incidence algebra of a poset.

Let P be a poset and R be a commutative unital associative ring. The *incidence algebra* I_P is the algebra of functions $\alpha\colon P \times P \to R$ such that $\alpha(x, y) = 0$ if $x \not\leq y$ where multiplication is given by convolution:

$$(\alpha * \beta)(x, y) = \sum_{x \leq k \leq y} \alpha(x, k)\beta(k, y).$$

This has a natural basis given by indicator functions for the interval $[a, b]$, i.e. $X_{a,b}(x, y) = \delta_{ax}\delta_{by}$. The incidence algebra is a unital algebra with the identity given by the Kronecker delta $\delta(x, y) = \delta_{xy}$. The Möbius function of P is another element of I_p whose inverse is the ζ function of the poset (so $\zeta(x, y) = 1$ for every interval $[x, y]$).

Todo

Implement the incidence coalgebra.

REFERENCES:

- Wikipedia article Incidence_algebra

class Element

Bases: IndexedFreeModuleElement

An element of an incidence algebra.

is_unit()

Return if self is a unit.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: mu = I.moebius()
sage: mu.is_unit()
True
sage: zeta = I.zeta()
sage: zeta.is_unit()
True
sage: x = mu - I.zeta() + I[2,2]
sage: x.is_unit()
False
sage: y = I.moebius() + I.zeta()
sage: y.is_unit()
True
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> I = P.incidence_algebra(QQ)
>>> mu = I.moebius()
>>> mu.is_unit()
True
>>> zeta = I.zeta()
>>> zeta.is_unit()
True
>>> x = mu - I.zeta() + I[Integer(2),Integer(2)]
>>> x.is_unit()
False
>>> y = I.moebius() + I.zeta()
>>> y.is_unit()
True
```

This depends on the base ring:

```
sage: I = P.incidence_algebra(ZZ)
sage: y = I.moebius() + I.zeta()
sage: y.is_unit()
False
```

```
>>> from sage.all import *
>>> I = P.incidence_algebra(ZZ)
>>> y = I.moebius() + I.zeta()
>>> y.is_unit()
False
```

to_matrix()

Return `self` as a matrix.

We define a matrix $M_{xy} = \alpha(x, y)$ for some element $\alpha \in I_P$ in the incidence algebra I_P and we order the elements $x, y \in P$ by some linear extension of P. This defines an algebra (iso)morphism; in particular, multiplication in the incidence algebra goes to matrix multiplication.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius().to_matrix()
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
sage: I.zeta().to_matrix()
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> I = P.incidence_algebra(QQ)
>>> I.moebius().to_matrix()
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
>>> I.zeta().to_matrix()
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

delta()

alias of *one()*.

moebius()

Return the Möbius function of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius()
I[0, 0] - I[0, 1] - I[0, 2] + I[0, 3] + I[1, 1]
 - I[1, 3] + I[2, 2] - I[2, 3] + I[3, 3]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> I = P.incidence_algebra(QQ)
>>> I.moebius()
I[0, 0] - I[0, 1] - I[0, 2] + I[0, 3] + I[1, 1]
 - I[1, 3] + I[2, 2] - I[2, 3] + I[3, 3]
```

one()

Return the element 1 in `self` (which is the Kronecker delta $\delta(x, y)$).

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
I[0, 0] + I[1, 1] + I[2, 2] + I[3, 3] + I[4, 4] + I[5, 5]
 + I[6, 6] + I[7, 7] + I[8, 8] + I[9, 9] + I[10, 10]
 + I[11, 11] + I[12, 12] + I[13, 13] + I[14, 14] + I[15, 15]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.one()
I[0, 0] + I[1, 1] + I[2, 2] + I[3, 3] + I[4, 4] + I[5, 5]
 + I[6, 6] + I[7, 7] + I[8, 8] + I[9, 9] + I[10, 10]
 + I[11, 11] + I[12, 12] + I[13, 13] + I[14, 14] + I[15, 15]
```

poset()

Return the defining poset of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.poset()
Finite lattice containing 16 elements
sage: I.poset() == P
True
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.poset()
Finite lattice containing 16 elements
>>> I.poset() == P
True
```

product_on_basis(A, B)

Return the product of basis elements indexed by `A` and `B`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
```

(continues on next page)

(continued from previous page)

```
sage: I.product_on_basis((1, 3), (3, 11))
I[1, 11]
sage: I.product_on_basis((1, 3), (2, 2))
0
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.product_on_basis((Integer(1), Integer(3)), (Integer(3), Integer(11)))
I[1, 11]
>>> I.product_on_basis((Integer(1), Integer(3)), (Integer(2), Integer(2)))
0
```

reduced_subalgebra(*prefix='R'*)

Return the reduced incidence subalgebra.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.reduced_subalgebra()
Reduced incidence algebra of Finite lattice containing 16 elements
 over Rational Field
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.reduced_subalgebra()
Reduced incidence algebra of Finite lattice containing 16 elements
 over Rational Field
```

some_elements()

Return a list of elements of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(1)
sage: I = P.incidence_algebra(QQ)
sage: Ielts = I.some_elements(); Ielts # random
[2*I[0, 0] + 2*I[0, 1] + 3*I[1, 1],
 I[0, 0] - I[0, 1] + I[1, 1],
 I[0, 0] + I[0, 1] + I[1, 1]]
sage: [a in I for a in Ielts]
[True, True, True]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(1))
>>> I = P.incidence_algebra(QQ)
>>> Ielts = I.some_elements(); Ielts # random
[2*I[0, 0] + 2*I[0, 1] + 3*I[1, 1],
 I[0, 0] - I[0, 1] + I[1, 1],
 I[0, 0] + I[0, 1] + I[1, 1]]
```

(continues on next page)

(continued from previous page)

```
>>> [a in I for a in Ielts]
[True, True, True]
```

zeta()

Return the ζ function in `self`.

The ζ function on a poset P is given by

$$\zeta(x, y) = \begin{cases} 1 & x \leq y, \\ 0 & x \not\leq y. \end{cases}$$

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.zeta() * I.moebius() == I.one()
True
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.zeta() * I.moebius() == I.one()
True
```

class sage.combinat.posets.incidence_algebras.**ReducedIncidenceAlgebra**(*I*, *prefix='R'*)

Bases: *CombinatorialFreeModule*

The reduced incidence algebra of a poset.

The reduced incidence algebra R_P is a subalgebra of the incidence algebra I_P where $\alpha(x, y) = \alpha(x', y')$ when $[x, y]$ is isomorphic to $[x', y']$ as posets. Thus the delta, Möbius, and zeta functions are all elements of R_P.

class Element

Bases: IndexedFreeModuleElement

An element of a reduced incidence algebra.

is_unit()

Return if `self` is a unit.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: x = R.an_element()
sage: x.is_unit()
True
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> x = R.an_element()
>>> x.is_unit()
True
```

lift()

Return the lift of `self` to the ambient space.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: R = I.reduced_subalgebra()
sage: x = R.an_element(); x
2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
sage: x.lift()
2*I[0, 0] + 2*I[0, 1] + 2*I[0, 2] + 3*I[0, 3] + 2*I[1, 1]
 + 2*I[1, 3] + 2*I[2, 2] + 2*I[2, 3] + 2*I[3, 3]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> I = P.incidence_algebra(QQ)
>>> R = I.reduced_subalgebra()
>>> x = R.an_element(); x
2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
>>> x.lift()
2*I[0, 0] + 2*I[0, 1] + 2*I[0, 2] + 3*I[0, 3] + 2*I[1, 1]
 + 2*I[1, 3] + 2*I[2, 2] + 2*I[2, 3] + 2*I[3, 3]
```

to_matrix()

Return `self` as a matrix.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: mu = R.moebius()
sage: mu.to_matrix()
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> mu = R.moebius()
>>> mu.to_matrix()
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
```

delta()

Return the Kronecker delta function in `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.delta()
R[(0, 0)]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.delta()
R[(0, 0)]
```

lift()

Return the lift morphism from `self` to the ambient space.

EXAMPLES:

```
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.lift
Generic morphism:
  From: Reduced incidence algebra of Finite lattice containing 4 elements␣
↪over Rational Field
  To:   Incidence algebra of Finite lattice containing 4 elements over␣
↪Rational Field
sage: R.an_element() - R.one()
R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
sage: R.lift(R.an_element() - R.one())
I[0, 0] + 2*I[0, 1] + 2*I[0, 2] + 3*I[0, 3] + I[1, 1]
 + 2*I[1, 3] + I[2, 2] + 2*I[2, 3] + I[3, 3]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.lift
Generic morphism:
  From: Reduced incidence algebra of Finite lattice containing 4 elements␣
↪over Rational Field
  To:   Incidence algebra of Finite lattice containing 4 elements over␣
↪Rational Field
>>> R.an_element() - R.one()
R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
>>> R.lift(R.an_element() - R.one())
I[0, 0] + 2*I[0, 1] + 2*I[0, 2] + 3*I[0, 3] + I[1, 1]
 + 2*I[1, 3] + I[2, 2] + 2*I[2, 3] + I[3, 3]
```

moebius()

Return the Möbius function of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
```

(continues on next page)

(continued from previous page)

```
sage: R.moebius()
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.moebius()
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)]
```

one_basis()

Return the index of the element 1 in `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.one_basis()
(0, 0)
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.one_basis()
(0, 0)
```

poset()

Return the defining poset of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.poset()
Finite lattice containing 16 elements
sage: R.poset() == P
True
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.poset()
Finite lattice containing 16 elements
>>> R.poset() == P
True
```

some_elements()

Return a list of elements of `self`.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
```

(continues on next page)

(continued from previous page)

```
sage: R.some_elements()
[2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)],
 R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)],
 R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.some_elements()
[2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)],
 R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)],
 R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]]
```

zeta()

Return the ζ function in `self`.

The ζ function on a poset P is given by

$$\zeta(x, y) = \begin{cases} 1 & x \leq y, \\ 0 & x \not\leq y. \end{cases}$$

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.zeta()
R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.zeta()
R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]
```

Linear extensions of posets

class sage.combinat.posets.linear_extensions.**LinearExtensionOfPoset**

Bases: ClonableArray

A linear extension of a finite poset P of size n is a total ordering $\pi := \pi_0\pi_1 \dots \pi_{n-1}$ of its elements such that $i < j$ whenever $\pi_i < \pi_j$ in the poset P.

When the elements of P are indexed by $\{1, 2, \dots, n\}$, π denotes a permutation of the elements of P in one-line notation.

INPUT:

- `linear_extension` – list of the elements of P
- `poset` – the underlying poset P

See also

Poset, *LinearExtensionsOfPoset*

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]),
....:           linear_extension=True, facade=False)
sage: p = P.linear_extension([1,4,2,3]); p
[1, 4, 2, 3]
sage: p.parent()
The set of all linear extensions of
 Finite poset containing 4 elements with distinguished linear extension
sage: p[0], p[1], p[2], p[3]
(1, 4, 2, 3)
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4)], [[Integer(1),
↪Integer(3)],[Integer(1),Integer(4)],[Integer(2),Integer(3)]]),
...           linear_extension=True, facade=False)
>>> p = P.linear_extension([Integer(1),Integer(4),Integer(2),Integer(3)]); p
[1, 4, 2, 3]
>>> p.parent()
The set of all linear extensions of
 Finite poset containing 4 elements with distinguished linear extension
>>> p[Integer(0)], p[Integer(1)], p[Integer(2)], p[Integer(3)]
(1, 4, 2, 3)
```

Following Schützenberger and later Haiman and Malvenuto-Reutenauer, Stanley [Stan2009] defined a promotion and evacuation operator on any finite poset P using operators τ_i on the linear extensions of P:

```
sage: p.promotion()
[1, 2, 3, 4]
sage: Q = p.promotion().to_poset()
sage: Q.cover_relations()
[[1, 3], [1, 4], [2, 3]]
sage: Q == P
True

sage: p.promotion(3)
[1, 4, 2, 3]
sage: Q = p.promotion(3).to_poset()
sage: Q == P
False
sage: Q.cover_relations()
[[1, 2], [1, 4], [3, 4]]
```

```
>>> from sage.all import *
>>> p.promotion()
[1, 2, 3, 4]
>>> Q = p.promotion().to_poset()
>>> Q.cover_relations()
```

(continues on next page)

(continued from previous page)

```
[[1, 3], [1, 4], [2, 3]]
>>> Q == P
True

>>> p.promotion(Integer(3))
[1, 4, 2, 3]
>>> Q = p.promotion(Integer(3)).to_poset()
>>> Q == P
False
>>> Q.cover_relations()
[[1, 2], [1, 4], [3, 4]]
```

check()

Check whether `self` is indeed a linear extension of the underlying poset.

evacuation()

Compute evacuation on the linear extension of a poset.

Evacuation on a linear extension π of length n is defined as $\pi(\tau_1 \cdots \tau_{n-1})(\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)$. For more details see [Stan2009].

See also

tau(), promotion()

EXAMPLES:

```
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,
↪6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: p.evacuation()
[1, 4, 2, 3, 7, 5, 6]
sage: p.evacuation().evacuation() == p
True
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6),Integer(7)], [[Integer(1),Integer(2)],[Integer(1),Integer(4)],
↪[Integer(2),Integer(3)],[Integer(2),Integer(5)],[Integer(3),Integer(6)],
↪[Integer(4),Integer(7)],[Integer(5),Integer(6)]]))
>>> p = P.linear_extension([Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5),Integer(6),Integer(7)])
>>> p.evacuation()
[1, 4, 2, 3, 7, 5, 6]
>>> p.evacuation().evacuation() == p
True
```

is_greedy()

Return `True` if the linear extension is greedy.

A linear extension $[e_1, e_2, \ldots, e_n]$ is *greedy* if for every i either e_{i+1} covers e_i or all upper covers of e_i have at least one lower cover that is not in $[e_1, e_2, \ldots, e_i]$.

Informally said a linear extension is greedy if it "always goes up when possible" and so has no unnecessary jumps.

EXAMPLES:

```
sage: P = posets.PentagonPoset()                                              #␣
↪needs sage.modules
sage: for l in P.linear_extensions():                                         #␣
↪needs sage.modules
....:     if not l.is_greedy():
....:         print(l)
[0, 2, 1, 3, 4]
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()                                                #␣
↪needs sage.modules
>>> for l in P.linear_extensions():                                           #␣
↪needs sage.modules
...     if not l.is_greedy():
...         print(l)
[0, 2, 1, 3, 4]
```

is_supergreedy()

Return `True` if the linear extension is supergreedy.

A linear extension of a poset P with elements $\{x_1, x_2, ..., x_t\}$ is *super greedy*, if it can be obtained using the following algorithm: choose x_1 to be a minimal element of P; suppose $X = \{x_1, ..., x_i\}$ have been chosen; let M be the set of minimal elements of $P \setminus X$. If there is an element of M which covers an element x_j in X, then let x_{i+1} be one of these such that j is maximal; otherwise, choose x_{i+1} to be any element of M.

Informally, a linear extension is supergreedy if it "always goes up and receedes the least"; in other words, supergreedy linear extensions are depth-first linear extensions. For more details see [KTZ1987].

EXAMPLES:

```
sage: X = [0,1,2,3,4,5,6]
sage: Y = [[0,5],[1,4],[1,5],[3,6],[4,3],[5,6],[6,2]]
sage: P = Poset((X,Y), cover_relations=True, facade=False)
sage: for l in P.linear_extensions():                                         #␣
↪needs sage.modules
....:     if l.is_supergreedy():
....:         print(l)
[1, 4, 3, 0, 5, 6, 2]
[0, 1, 4, 3, 5, 6, 2]
[0, 1, 5, 4, 3, 6, 2]

sage: Q = posets.PentagonPoset()                                              #␣
↪needs sage.modules
sage: for l in Q.linear_extensions():                                         #␣
↪needs sage.modules sage.rings.finite_rings
....:     if not l.is_supergreedy():
....:         print(l)
[0, 2, 1, 3, 4]
```

```
>>> from sage.all import *
>>> X = [Integer(0),Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6)]
>>> Y = [[Integer(0),Integer(5)],[Integer(1),Integer(4)],[Integer(1),
↪Integer(5)],[Integer(3),Integer(6)],[Integer(4),Integer(3)],[Integer(5),
↪Integer(6)],[Integer(6),Integer(2)]]
>>> P = Poset((X,Y), cover_relations=True, facade=False)
>>> for l in P.linear_extensions():                                    #␣
↪needs sage.modules
...     if l.is_supergreedy():
...         print(l)
[1, 4, 3, 0, 5, 6, 2]
[0, 1, 4, 3, 5, 6, 2]
[0, 1, 5, 4, 3, 6, 2]

>>> Q = posets.PentagonPoset()                                         #␣
↪needs sage.modules
>>> for l in Q.linear_extensions():                                    #␣
↪needs sage.modules sage.rings.finite_rings
...     if not l.is_supergreedy():
...         print(l)
[0, 2, 1, 3, 4]
```

jump_count()

Return the number of jumps in the linear extension.

A *jump* in a linear extension $[e_1, e_2, \ldots, e_n]$ is a pair (e_i, e_{i+1}) such that e_{i+1} does not cover e_i.

- *sage.combinat.posets.posets.FinitePoset.jump_number()*

EXAMPLES:

```
sage: B3 = posets.BooleanLattice(3)
sage: l1 = B3.linear_extension((0, 1, 2, 3, 4, 5, 6, 7))
sage: l1.jump_count()
3
sage: l2 = B3.linear_extension((0, 1, 2, 4, 3, 5, 6, 7))
sage: l2.jump_count()
5
```

```
>>> from sage.all import *
>>> B3 = posets.BooleanLattice(Integer(3))
>>> l1 = B3.linear_extension((Integer(0), Integer(1), Integer(2), Integer(3),␣
↪Integer(4), Integer(5), Integer(6), Integer(7)))
>>> l1.jump_count()
3
>>> l2 = B3.linear_extension((Integer(0), Integer(1), Integer(2), Integer(4),␣
↪Integer(3), Integer(5), Integer(6), Integer(7)))
>>> l2.jump_count()
5
```

poset()

Return the underlying original poset.

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,2],[2,3],[1,4]]))
sage: p = P.linear_extension([1,2,4,3])
sage: p.poset()
Finite poset containing 4 elements
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4)], [[Integer(1),
↪Integer(2)],[Integer(2),Integer(3)],[Integer(1),Integer(4)]]))
>>> p = P.linear_extension([Integer(1),Integer(2),Integer(4),Integer(3)])
>>> p.poset()
Finite poset containing 4 elements
```

promotion(*i=1*)

Compute the (generalized) promotion on the linear extension of a poset.

INPUT:

- `i` – (default: 1) an integer between 1 and $n-1$, where n is the cardinality of the poset

The i-th generalized promotion operator ∂_i on a linear extension π is defined as $\pi\tau_i\tau_{i+1}\cdots\tau_{n-1}$, where n is the size of the linear extension (or size of the underlying poset).

For more details see [Stan2009].

See also

tau(), *evacuation()*

EXAMPLES:

```
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,
↪6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: q = p.promotion(4); q
[1, 2, 3, 5, 6, 4, 7]
sage: p.to_poset() == q.to_poset()
False
sage: p.to_poset().is_isomorphic(q.to_poset())
True
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
↪Integer(6),Integer(7)], [[Integer(1),Integer(2)],[Integer(1),Integer(4)],
↪[Integer(2),Integer(3)],[Integer(2),Integer(5)],[Integer(3),Integer(6)],
↪[Integer(4),Integer(7)],[Integer(5),Integer(6)]]))
>>> p = P.linear_extension([Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5),Integer(6),Integer(7)])
>>> q = p.promotion(Integer(4)); q
[1, 2, 3, 5, 6, 4, 7]
```

(continues on next page)

(continued from previous page)

```
>>> p.to_poset() == q.to_poset()
False
>>> p.to_poset().is_isomorphic(q.to_poset())
True
```

tau(i)

Return the operator τ_i on linear extensions `self` of a poset.

INPUT:

- `i` – integer between 1 and $n-1$, where n is the cardinality of the poset

The operator τ_i on a linear extension π of a poset P interchanges positions i and $i+1$ if the result is again a linear extension of P, and otherwise acts trivially. For more details, see [Stan2009].

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: l = L.an_element(); l
[1, 2, 3, 4]
sage: l.tau(1)
[2, 1, 3, 4]
sage: for p in L:                                                          #␣
↪needs sage.modules
....:     for i in range(1,4):
....:         print("{} {} {}".format(i, p, p.tau(i)))
1 [1, 2, 3, 4] [2, 1, 3, 4]
2 [1, 2, 3, 4] [1, 2, 3, 4]
3 [1, 2, 3, 4] [1, 2, 4, 3]
1 [2, 1, 3, 4] [1, 2, 3, 4]
2 [2, 1, 3, 4] [2, 1, 3, 4]
3 [2, 1, 3, 4] [2, 1, 4, 3]
1 [2, 1, 4, 3] [1, 2, 4, 3]
2 [2, 1, 4, 3] [2, 1, 4, 3]
3 [2, 1, 4, 3] [2, 1, 3, 4]
1 [1, 4, 2, 3] [1, 4, 2, 3]
2 [1, 4, 2, 3] [1, 2, 4, 3]
3 [1, 4, 2, 3] [1, 4, 2, 3]
1 [1, 2, 4, 3] [2, 1, 4, 3]
2 [1, 2, 4, 3] [1, 4, 2, 3]
3 [1, 2, 4, 3] [1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4)], [[Integer(1),
↪Integer(3)],[Integer(1),Integer(4)],[Integer(2),Integer(3)]]), linear_
↪extension=True)
>>> L = P.linear_extensions()
>>> l = L.an_element(); l
[1, 2, 3, 4]
>>> l.tau(Integer(1))
[2, 1, 3, 4]
>>> for p in L:                                                            #␣
↪needs sage.modules
```

(continues on next page)

(continued from previous page)

```
...     for i in range(Integer(1),Integer(4)):
...         print("{} {} {}".format(i, p, p.tau(i)))
1 [1, 2, 3, 4] [2, 1, 3, 4]
2 [1, 2, 3, 4] [1, 2, 3, 4]
3 [1, 2, 3, 4] [1, 2, 4, 3]
1 [2, 1, 3, 4] [1, 2, 3, 4]
2 [2, 1, 3, 4] [2, 1, 3, 4]
3 [2, 1, 3, 4] [2, 1, 4, 3]
1 [2, 1, 4, 3] [1, 2, 4, 3]
2 [2, 1, 4, 3] [2, 1, 4, 3]
3 [2, 1, 4, 3] [2, 1, 3, 4]
1 [1, 4, 2, 3] [1, 4, 2, 3]
2 [1, 4, 2, 3] [1, 2, 4, 3]
3 [1, 4, 2, 3] [1, 4, 2, 3]
1 [1, 2, 4, 3] [2, 1, 4, 3]
2 [1, 2, 4, 3] [1, 4, 2, 3]
3 [1, 2, 4, 3] [1, 2, 3, 4]
```

to_poset()

Return the poset associated to the linear extension `self`.

This method returns the poset obtained from the original poset P by relabelling the i-th element of `self` to the i-th element of the original poset, while keeping the linear extension of the original poset.

For a poset with default linear extension $1, \ldots, n$, `self` can be interpreted as a permutation, and the relabelling is done according to the inverse of this permutation.

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,2],[1,3],[3,4]]), linear_extension=True,␣
↪facade=False)
sage: p = P.linear_extension([1,3,4,2])
sage: Q = p.to_poset(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: P == Q
False
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4)], [[Integer(1),
↪Integer(2)],[Integer(1),Integer(3)],[Integer(3),Integer(4)]]), linear_
↪extension=True, facade=False)
>>> p = P.linear_extension([Integer(1),Integer(3),Integer(4),Integer(2)])
>>> Q = p.to_poset(); Q
Finite poset containing 4 elements with distinguished linear extension
>>> P == Q
False
```

The default linear extension remains the same:

```
sage: list(P)
[1, 2, 3, 4]
sage: list(Q)
[1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> list(P)
[1, 2, 3, 4]
>>> list(Q)
[1, 2, 3, 4]
```

But the relabelling can be seen on cover relations:

```
sage: P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
sage: Q.cover_relations()
[[1, 2], [1, 4], [2, 3]]

sage: p = P.linear_extension([1,2,3,4])
sage: Q = p.to_poset()
sage: P == Q
True
```

```
>>> from sage.all import *
>>> P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
>>> Q.cover_relations()
[[1, 2], [1, 4], [2, 3]]

>>> p = P.linear_extension([Integer(1),Integer(2),Integer(3),Integer(4)])
>>> Q = p.to_poset()
>>> P == Q
True
```

class sage.combinat.posets.linear_extensions.**LinearExtensionsOfForest**(*poset*, *facade*)

Bases: *LinearExtensionsOfPoset*

Linear extensions such that the poset is a forest.

cardinality()

Use Atkinson's algorithm to compute the number of linear extensions.

EXAMPLES:

```
sage: from sage.combinat.posets.forest import ForestPoset
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Poset({0: [2], 1: [2], 2: [3, 4], 3: [], 4: []})
sage: P.linear_extensions().cardinality()                                   #␣
↪needs sage.modules
4

sage: Q = Poset({0: [1], 1: [2, 3], 2: [], 3: [], 4: [5, 6], 5: [], 6: []})
sage: Q.linear_extensions().cardinality()                                   #␣
↪needs sage.modules
140
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.forest import ForestPoset

↪needs sage.modules
140
```

class sage.combinat.posets.linear_extensions.**LinearExtensionsOfMobile**(*poset*, *facade*)

Bases: *LinearExtensionsOfPoset*

Linear extensions for a mobile poset.

cardinality()

Return the number of linear extensions by using the determinant formula for counting linear extensions of mobiles.

EXAMPLES:

```
sage: from sage.combinat.posets.mobile import MobilePoset
sage: M = MobilePoset(DiGraph([[0,1,2,3,4,5,6,7,8], [(1,0),(3,0),(2,1),(2,3),
↪(4,
....: 3), (5,4),(5,6),(7,4),(7,8)]]))
sage: M.linear_extensions().cardinality()                                  #␣
↪needs sage.modules
1098

sage: M1 = posets.RibbonPoset(6, [1,3])
sage: M1.linear_extensions().cardinality()                                 #␣
↪needs sage.modules
61

361628701868606400
```

class sage.combinat.posets.linear_extensions.**LinearExtensionsOfPoset**(*poset*, *facade*)

Bases: UniqueRepresentation, Parent

The set of all linear extensions of a finite poset.

INPUT:

- `poset` – a poset P of size n
- `facade` – boolean (default: `False`)

See also

- *sage.combinat.posets.posets.FinitePoset.linear_extensions()*

EXAMPLES:

```
sage: elms = [1,2,3,4]
sage: rels = [[1,3],[1,4],[2,3]]
sage: P = Poset((elms, rels), linear_extension=True)
sage: L = P.linear_extensions(); L
The set of all linear extensions of
 Finite poset containing 4 elements with distinguished linear extension
sage: L.cardinality()
5
sage: L.list()                                                              #␣
↪needs sage.modules
[[1, 2, 3, 4], [2, 1, 3, 4], [2, 1, 4, 3], [1, 4, 2, 3], [1, 2, 4, 3]]
sage: L.an_element()
[1, 2, 3, 4]
```

(continues on next page)

(continued from previous page)

```
sage: L.poset()
Finite poset containing 4 elements with distinguished linear extension
```

```
>>> from sage.all import *
>>> elms = [Integer(1),Integer(2),Integer(3),Integer(4)]
>>> rels = [[Integer(1),Integer(3)],[Integer(1),Integer(4)],[Integer(2),
↪Integer(3)]]
>>> P = Poset((elms, rels), linear_extension=True)
>>> L = P.linear_extensions(); L
The set of all linear extensions of
 Finite poset containing 4 elements with distinguished linear extension
>>> L.cardinality()
5
>>> L.list()                                                                  #␣
↪needs sage.modules
[[1, 2, 3, 4], [2, 1, 3, 4], [2, 1, 4, 3], [1, 4, 2, 3], [1, 2, 4, 3]]
>>> L.an_element()
[1, 2, 3, 4]
>>> L.poset()
Finite poset containing 4 elements with distinguished linear extension
```

Element

alias of *LinearExtensionOfPoset*

cardinality()

Return the number of linear extensions.

EXAMPLES:

```
sage: N = Poset({0: [2, 3], 1: [3]})
sage: N.linear_extensions().cardinality()
5
```

```
>>> from sage.all import *
>>> N = Poset({Integer(0): [Integer(2), Integer(3)], Integer(1): [Integer(3)]}
↪)
>>> N.linear_extensions().cardinality()
5
```

markov_chain_digraph(*action='promotion'*, *labeling='identity'*)

Return the digraph of the action of generalized promotion or tau on `self`.

INPUT:

- `action` – 'promotion' or 'tau' (default: `'promotion'`)
- `labeling` – 'identity' or 'source' (default: `'identity'`)

Todo

- generalize this feature by accepting a family of operators as input
- move up in some appropriate category

This method creates a graph with vertices being the linear extensions of a given finite poset and an edge from π to π' if $\pi' = \pi\partial_i$ where ∂_i is the promotion operator (see *promotion()*) if `action` is set to `promotion` and τ_i (see *tau()*) if `action` is set to `tau`. The label of the edge is i (resp. π_i) if `labeling` is set to `identity` (resp. `source`).

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: G = L.markov_chain_digraph(); G
Looped multi-digraph on 5 vertices
sage: G.vertices(sort=True, key=repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: G.edges(sort=True, key=repr)
[([1, 2, 3, 4], [1, 2, 3, 4], 4), ([1, 2, 3, 4], [1, 2, 4, 3], 2), ([1, 2, 3,␣
↪4], [1, 2, 4, 3], 3),
 ([1, 2, 3, 4], [2, 1, 4, 3], 1), ([1, 2, 4, 3], [1, 2, 3, 4], 3), ([1, 2, 4,␣
↪3], [1, 2, 4, 3], 4),
 ([1, 2, 4, 3], [1, 4, 2, 3], 2), ([1, 2, 4, 3], [2, 1, 3, 4], 1), ([1, 4, 2,␣
↪3], [1, 2, 3, 4], 1),
 ([1, 4, 2, 3], [1, 2, 3, 4], 2), ([1, 4, 2, 3], [1, 4, 2, 3], 3), ([1, 4, 2,␣
↪3], [1, 4, 2, 3], 4),
 ([2, 1, 3, 4], [1, 2, 4, 3], 1), ([2, 1, 3, 4], [2, 1, 3, 4], 4), ([2, 1, 3,␣
↪4], [2, 1, 4, 3], 2),
 ([2, 1, 3, 4], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [1, 4, 2, 3], 1), ([2, 1, 4,␣

↪3], [2, 1, 3, 4], 1),
 ([2, 1, 4, 3], [2, 1, 3, 4], 4), ([2, 1, 4, 3], [2, 1, 4, 3], 3)]
```

The edges of the graph are by default colored using blue for edge 1, red for edge 2, green for edge 3, and yellow for edge 4:

```
sage: view(G) # optional - dot2tex graphviz, not tested (opens external␣
↪window)
```

```
>>> from sage.all import *
>>> view(G) # optional - dot2tex graphviz, not tested (opens external window)
```

Alternatively, one may get the graph of the action of the `tau` operator:

```
sage: G = L.markov_chain_digraph(action='tau'); G
Looped multi-digraph on 5 vertices
sage: G.vertices(sort=True, key=repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: G.edges(sort=True, key=repr)
[([1, 2, 3, 4], [1, 2, 3, 4], 2), ([1, 2, 3, 4], [1, 2, 4, 3], 3), ([1, 2, 3,␣
↪4], [2, 1, 3, 4], 1),
```

markov_chain_transition_matrix(), *promotion()*, *tau()*

markov_chain_transition_matrix(*action='promotion'*, *labeling='identity'*)

Return the transition matrix of the Markov chain for the action of generalized promotion or tau on `self`.

INPUT:

- `action` – `'promotion'` or `'tau'` (default: `'promotion'`)
- `labeling` – `'identity'` or `'source'` (default: `'identity'`)

This method yields the transition matrix of the Markov chain defined by the action of the generalized promotion operator ∂_i (resp. τ_i) on the set of linear extensions of a finite poset. Here the transition from the linear extension π to π', where $\pi' = \pi\partial_i$ (resp. $\pi' = \pi\tau_i$) is counted with weight x_i (resp. x_{π_i} if `labeling` is set to `source`).

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,3],[1,4],[2,3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: L.markov_chain_transition_matrix()                                    #␣
↪needs sage.modules

See also

markov_chain_digraph(), *promotion()*, *tau()*

poset()

Return the underlying original poset.

EXAMPLES:

```
sage: P = Poset(([1,2,3,4], [[1,2],[2,3],[1,4]]))
sage: L = P.linear_extensions()
sage: L.poset()
Finite poset containing 4 elements
```

```
>>> from sage.all import *
>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4)], [[Integer(1),
↪Integer(2)],[Integer(2),Integer(3)],[Integer(1),Integer(4)]]))
>>> L = P.linear_extensions()
>>> L.poset()
Finite poset containing 4 elements
```

class sage.combinat.posets.linear_extensions.**LinearExtensionsOfPosetWithHooks**(*poset*, *facade*)

Bases: *LinearExtensionsOfPoset*

Linear extensions such that the poset has well-defined hook lengths (i.e., d-complete).

cardinality()

Count the number of linear extensions using a hook-length formula.

EXAMPLES:

```
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Posets.YoungDiagramPoset(Partition([3,2]), dual=True)             #␣
↪needs sage.combinat sage.modules
sage: P.linear_extensions().cardinality()                                   #␣
```

5
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.poset_examples import Posets
>>> P = Posets.YoungDiagramPoset(Partition([Integer(3),Integer(2)]),␣
↪dual=True)             # needs sage.combinat sage.modules
>>> P.linear_extensions().cardinality()                                    #␣
↪needs sage.combinat sage.modules
5
```

Mobile posets

class sage.combinat.posets.mobile.**MobilePoset**(*hasse_diagram*, *elements*, *category*, *facade*, *key*, *ribbon=None*, *check=True*)

Bases: *FinitePoset*

A mobile poset.

Mobile posets are an extension of d-complete posets which permit a determinant formula for counting linear extensions. They are formed by having a ribbon poset with d-complete posets 'hanging' below it and at most one d-complete poset above it, known as the anchor. See [GGMM2020] for the definition.

EXAMPLES:

```
sage: P = posets.MobilePoset(posets.RibbonPoset(7, [1,3]),                  #␣
↪needs sage.combinat sage.modules
....:                        {1: [posets.YoungDiagramPoset([3, 2], dual=True)],
....:                         3: [posets.DoubleTailedDiamond(6)]},
....:                        anchor=(4, 2, posets.ChainPoset(6)))
sage: len(P._ribbon)                                                         #␣
↪needs sage.combinat sage.modules
8
sage: P._anchor                                                              #␣
↪needs sage.combinat sage.modules
(4, 5)
```

```
>>> from sage.all import *
>>> P = posets.MobilePoset(posets.RibbonPoset(Integer(7), [Integer(1),
↪Integer(3)]),                       # needs sage.combinat sage.modules
...                         {Integer(1): [posets.YoungDiagramPoset([Integer(3),␣
↪Integer(2)], dual=True)],
...                          Integer(3): [posets.DoubleTailedDiamond(Integer(6))]},
...                         anchor=(Integer(4), Integer(2), posets.
↪ChainPoset(Integer(6))))
>>> len(P._ribbon)                                                           #␣
↪needs sage.combinat sage.modules
8
>>> P._anchor                                                                #␣
↪needs sage.combinat sage.modules
(4, 5)
```

This example is Example 5.9 in [GGMM2020]:

```
sage: P1 = posets.MobilePoset(posets.RibbonPoset(8, [2,3,4]),
....:                         {4: [posets.ChainPoset(1)]},
....:                         anchor=(3, 0, posets.ChainPoset(1)))
sage: sorted([P1._element_to_vertex(i) for i in P1._ribbon])
[0, 1, 2, 6, 7, 9]
sage: P1._anchor
(3, 2)

sage: P2 = posets.MobilePoset(posets.RibbonPoset(15, [1,3,5,7,9,11,13]),
....:                         {}, anchor=(8, 0, posets.ChainPoset(1)))
sage: sorted(P2._ribbon)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13]
sage: P2._anchor
(8, (8, 0))
sage: P2.linear_extensions().cardinality()                                  #␣

>>> EP = posets.MobilePoset(posets.ChainPoset(Integer(0)), {})
Traceback (most recent call last):
...
ValueError: the empty poset is not a mobile poset
```

anchor()

Return the anchor of the mobile poset.

EXAMPLES:

```
sage: from sage.combinat.posets.mobile import MobilePoset
sage: M2 = MobilePoset(Poset([[0,1,2,3,4,5,6,7,8],
....:           [(1,0),(3,0),(2,1),(2,3),(4,3),(5,4),(7,4),(7,8)]]))
sage: M2.anchor()
(4, 3)
sage: M3 = MobilePoset(Posets.RibbonPoset(5, [1,2]))
sage: M3.anchor() is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.mobile import MobilePoset
>>> M2 = MobilePoset(Poset([[Integer(0),Integer(1),Integer(2),Integer(3),
↪Integer(4),Integer(5),Integer(6),Integer(7),Integer(8)],
...           [(Integer(1),Integer(0)),(Integer(3),Integer(0)),(Integer(2),
↪Integer(1)),(Integer(2),Integer(3)),(Integer(4),Integer(3)),(Integer(5),
↪Integer(4)),(Integer(7),Integer(4)),(Integer(7),Integer(8))]]))
>>> M2.anchor()
(4, 3)
>>> M3 = MobilePoset(Posets.RibbonPoset(Integer(5), [Integer(1),Integer(2)]))
>>> M3.anchor() is None
True
```

ribbon()

Return the ribbon of the mobile poset.

EXAMPLES:

```
sage: from sage.combinat.posets.mobile import MobilePoset
sage: M3 = MobilePoset(Posets.RibbonPoset(5, [1,2]))
sage: sorted(M3.ribbon())
[1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.mobile import MobilePoset
>>> M3 = MobilePoset(Posets.RibbonPoset(Integer(5), [Integer(1),Integer(2)]))
>>> sorted(M3.ribbon())
[1, 2, 3, 4]
```

Möbius algebras

class sage.combinat.posets.moebius_algebra.**BasisAbstract**(*R*, *basis_keys=None*, *element_class=None*, *category=None*, *prefix=None*, *names=None*, ***kwds*)

Bases: *CombinatorialFreeModule*, BindableClass

Abstract base class for a basis.

class sage.combinat.posets.moebius_algebra.**MoebiusAlgebra**(*R*, *L*)

Bases: Parent, UniqueRepresentation

The Möbius algebra of a lattice.

Let L be a lattice. The *Möbius algebra* M_L was originally constructed by Solomon [Solomon67] and has a natural basis $\{E_x \mid x \in L\}$ with multiplication given by $E_x \cdot E_y = E_{x \vee y}$. Moreover this has a basis given by orthogonal

idempotents $\{I_x \mid x \in L\}$ (so $I_x I_y = \delta_{xy} I_x$ where δ is the Kronecker delta) related to the natural basis by

$$I_x = \sum_{x \leq y} \mu_L(x, y) E_y,$$

where μ_L is the Möbius function of L.

Note

We use the join $\vee$ for our multiplication, whereas [Greene73] and [Etienne98] define the Möbius algebra using the meet $\wedge$. This is done for compatibility with *QuantumMoebiusAlgebra*.

REFERENCES:

class E(*M*, *prefix='E'*)

Bases: *BasisAbstract*

The natural basis of a Möbius algebra.

Let E_x and E_y be basis elements of M_L for some lattice L. Multiplication is given by $E_x E_y = E_{x \vee y}$.

one()

Return the element `1` of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.moebius_algebra(QQ).E()
sage: E.one()
E[0]
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> E = L.moebius_algebra(QQ).E()
>>> E.one()
E[0]
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.moebius_algebra(QQ).E()
sage: E.product_on_basis(5, 14)
E[15]
sage: E.product_on_basis(2, 8)
E[10]
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> E = L.moebius_algebra(QQ).E()
>>> E.product_on_basis(Integer(5), Integer(14))
E[15]
>>> E.product_on_basis(Integer(2), Integer(8))
E[10]
```

class I(*M*, *prefix='I'*)

Bases: *BasisAbstract*

The (orthogonal) idempotent basis of a Möbius algebra.

Let I_x and I_y be basis elements of M_L for some lattice L. Multiplication is given by $I_x I_y = \delta_{xy} I_x$ where δ_{xy} is the Kronecker delta.

one()

Return the element `1` of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: I = L.moebius_algebra(QQ).I()
sage: I.one()
I[0] + I[1] + I[2] + I[3] + I[4] + I[5] + I[6] + I[7] + I[8]
 + I[9] + I[10] + I[11] + I[12] + I[13] + I[14] + I[15]
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> I = L.moebius_algebra(QQ).I()
>>> I.one()
I[0] + I[1] + I[2] + I[3] + I[4] + I[5] + I[6] + I[7] + I[8]
 + I[9] + I[10] + I[11] + I[12] + I[13] + I[14] + I[15]
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: I = L.moebius_algebra(QQ).I()
sage: I.product_on_basis(5, 14)
0
sage: I.product_on_basis(2, 2)
I[2]
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> I = L.moebius_algebra(QQ).I()
>>> I.product_on_basis(Integer(5), Integer(14))
0
>>> I.product_on_basis(Integer(2), Integer(2))
I[2]
```

a_realization()

Return a particular realization of `self` (the B-basis).

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.a_realization()
Moebius algebra of Finite lattice containing 16 elements
 over Rational Field in the natural basis
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> M = L.moebius_algebra(QQ)
>>> M.a_realization()
Moebius algebra of Finite lattice containing 16 elements
 over Rational Field in the natural basis
```

idempotent

alias of *I*

lattice()

Return the defining lattice of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> M = L.moebius_algebra(QQ)
>>> M.lattice()
Finite lattice containing 16 elements
>>> M.lattice() == L
True
```

natural

alias of *E*

class sage.combinat.posets.moebius_algebra.**MoebiusAlgebraBases**(*parent_with_realization*)

Bases: `Category_realization_of_parent`

The category of bases of a Möbius algebra.

INPUT:

- `base` – a Möbius algebra

class ElementMethods

Bases: `object`

class ParentMethods

Bases: `object`

one()

Return the element `1` of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: all(C.one() * b == b for b in C.basis())
True
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> C = L.quantum_moebius_algebra().C()
>>> all(C.one() * b == b for b in C.basis())
True
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: C.product_on_basis(5, 14)
q^3*C[15]
sage: C.product_on_basis(2, 8)
q^4*C[10]
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> C = L.quantum_moebius_algebra().C()
>>> C.product_on_basis(Integer(5), Integer(14))
q^3*C[15]
>>> C.product_on_basis(Integer(2), Integer(8))
q^4*C[10]
```

super_categories()

The super categories of `self`.

EXAMPLES:

```
sage: from sage.combinat.posets.moebius_algebra import MoebiusAlgebraBases
sage: M = posets.BooleanLattice(4).moebius_algebra(QQ)
sage: bases = MoebiusAlgebraBases(M)
sage: bases.super_categories()
[Category of finite dimensional commutative algebras with basis over Rational␣
↪Field,
 Category of realizations of Moebius algebra of Finite lattice
    containing 16 elements over Rational Field]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.moebius_algebra import MoebiusAlgebraBases
>>> M = posets.BooleanLattice(Integer(4)).moebius_algebra(QQ)
>>> bases = MoebiusAlgebraBases(M)
>>> bases.super_categories()
[Category of finite dimensional commutative algebras with basis over Rational␣
↪Field,
 Category of realizations of Moebius algebra of Finite lattice
    containing 16 elements over Rational Field]
```

class sage.combinat.posets.moebius_algebra.**QuantumMoebiusAlgebra**(*L*, *q=None*)

Bases: `Parent`, `UniqueRepresentation`

The quantum Möbius algebra of a lattice.

Let L be a lattice, and we define the *quantum Möbius algebra* $M_L(q)$ as the algebra with basis $\{E_x \mid x \in L\}$ with multiplication given by

$$E_x E_y = \sum_{z \geq a \geq x \vee y} \mu_L(a, z) q^{\mathrm{crk}\, a} E_z,$$

where μ_L is the Möbius function of L and crk is the corank function (i.e., $\mathrm{crk}\, a = \mathrm{rank}\, L - \mathrm{rank}\ a$). At $q = 1$, this reduces to the multiplication formula originally given by Solomon.

class C(*M*, *prefix='C'*)

Bases: *BasisAbstract*

The characteristic basis of a quantum Möbius algebra.

The characteristic basis $\{C_x \mid x \in L\}$ of M_L for some lattice L is defined by

$$C_x = \sum_{a \geq x} P(F^x; q) E_a,$$

where $F^x = \{y \in L \mid y \geq x\}$ is the principal order filter of x and $P(F^x; q)$ is the characteristic polynomial of the (sub)poset F^x.

class E(*M*, *prefix='E'*)

Bases: *BasisAbstract*

The natural basis of a quantum Möbius algebra.

Let E_x and E_y be basis elements of M_L for some lattice L. Multiplication is given by

$$E_x E_y = \sum_{z \geq a \geq x \vee y} \mu_L(a, z) q^{\mathrm{crk}\, a} E_z,$$

where μ_L is the Möbius function of L and crk is the corank function (i.e., $\mathrm{crk}\, a = \mathrm{rank}\, L - \mathrm{rank}\ a$).

one()

Return the element `1` of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: all(E.one() * b == b for b in E.basis())
True
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> E = L.quantum_moebius_algebra().E()
>>> all(E.one() * b == b for b in E.basis())
True
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: E.product_on_basis(5, 14)
```

(continues on next page)

(continued from previous page)

```
E[15]
sage: E.product_on_basis(2, 8)
q^2*E[10] + (q-q^2)*E[11] + (q-q^2)*E[14] + (1-2*q+q^2)*E[15]
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> E = L.quantum_moebius_algebra().E()
>>> E.product_on_basis(Integer(5), Integer(14))
E[15]
>>> E.product_on_basis(Integer(2), Integer(8))
q^2*E[10] + (q-q^2)*E[11] + (q-q^2)*E[14] + (1-2*q+q^2)*E[15]
```

class KL(*M*, *prefix='KL'*)

Bases: *BasisAbstract*

The Kazhdan-Lusztig basis of a quantum Möbius algebra.

The Kazhdan-Lusztig basis $\{B_x \mid x \in L\}$ of M_L for some lattice L is defined by

$$B_x = \sum_{y \geq x} P_{x,y}(q) E_a,$$

where $P_{x,y}(q)$ is the Kazhdan-Lusztig polynomial of L, following the definition given in [EPW14].

EXAMPLES:

We construct some examples of Proposition 4.5 of [EPW14]:

```
sage: M = posets.BooleanLattice(4).quantum_moebius_algebra()
sage: KL = M.KL()
sage: KL[4] * KL[5]
(q^2+q^3)*KL[5] + (q+2*q^2+q^3)*KL[7] + (q+2*q^2+q^3)*KL[13]
 + (1+3*q+3*q^2+q^3)*KL[15]
sage: KL[4] * KL[15]
(1+3*q+3*q^2+q^3)*KL[15]
sage: KL[4] * KL[10]
(q+3*q^2+3*q^3+q^4)*KL[14] + (1+4*q+6*q^2+4*q^3+q^4)*KL[15]
```

```
>>> from sage.all import *
>>> M = posets.BooleanLattice(Integer(4)).quantum_moebius_algebra()
>>> KL = M.KL()
>>> KL[Integer(4)] * KL[Integer(5)]
(q^2+q^3)*KL[5] + (q+2*q^2+q^3)*KL[7] + (q+2*q^2+q^3)*KL[13]
 + (1+3*q+3*q^2+q^3)*KL[15]
>>> KL[Integer(4)] * KL[Integer(15)]
(1+3*q+3*q^2+q^3)*KL[15]
>>> KL[Integer(4)] * KL[Integer(10)]
(q+3*q^2+3*q^3+q^4)*KL[14] + (1+4*q+6*q^2+4*q^3+q^4)*KL[15]
```

a_realization()

Return a particular realization of `self` (the B-basis).

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.a_realization()
Quantum Moebius algebra of Finite lattice containing 16 elements
 with q=q over Univariate Laurent Polynomial Ring in q
 over Integer Ring in the natural basis
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> M = L.quantum_moebius_algebra()
>>> M.a_realization()
Quantum Moebius algebra of Finite lattice containing 16 elements
 with q=q over Univariate Laurent Polynomial Ring in q
 over Integer Ring in the natural basis
```

characteristic_basis

alias of *C*

kazhdan_lusztig

alias of *KL*

lattice()

Return the defining lattice of `self`.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

```
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> M = L.quantum_moebius_algebra()
>>> M.lattice()
Finite lattice containing 16 elements
>>> M.lattice() == L
True
```

natural

alias of *E*

Lattices of sashes

These lattices were introduced by S. Law in [Law2014]. They are lattice quotients of the weak order on the symmetric groups. This implies that they are congruence-uniform.

There is a lattice of sashes Σ_n for every integer $n \geq 1$. The underlying set of Σ_n is the set of words of length n in the letters □, ▨ and ■■ of respective lengths $1, 1$ and 2.

The cardinalities of the lattices Σ_n are therefore given by the Pell numbers (OEIS sequence A000129).

The implementation describes sashes as tuples of strings.

This file also implements the polytopes known as pellytopes, and their fans. The skeletons of pellytopes are isomorphic to the undirected Hasse diagrams of the lattices of sashes.

REFERENCES:

- [Law2014]

sage.combinat.posets.sashes.**cover_relations**(*s*)

Iterate over the cover relations of the given sash.

INPUT:

- s – sash, as a tuple of strings

EXAMPLES:

```
sage: from sage.combinat.posets.sashes import cover_relations
sage: s = ('□', '⧄', '⧄')
sage: [''.join(t) for t in cover_relations(s)]
['□□⧄', '□⧄□']
sage: s = ('□', '■■', '⧄')
sage: [''.join(t) for t in cover_relations(s)]
['□□□⧄', '□■■□']
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.sashes import cover_relations
>>> s = ('□', '⧄', '⧄')
>>> [''.join(t) for t in cover_relations(s)]
['□□⧄', '□⧄□']
>>> s = ('□', '■■', '⧄')
>>> [''.join(t) for t in cover_relations(s)]
['□□□⧄', '□■■□']
```

sage.combinat.posets.sashes.**lattice_of_sashes**(*n*)

Return the lattice of sashes of length n.

INPUT:

- n – positive integer

EXAMPLES:

```
sage: L = posets.Sashes(4); L
Finite lattice containing 29 elements
sage: L.hasse_diagram().to_undirected().is_regular(4)
True
```

```
>>> from sage.all import *
>>> L = posets.Sashes(Integer(4)); L
Finite lattice containing 29 elements
>>> L.hasse_diagram().to_undirected().is_regular(Integer(4))
True
```

sage.combinat.posets.sashes.**pellytope**(*n*)

Return the pellytope of dimension n.

This is defined as a Minkowski sum of the unit volume n dimensional hypercube in the positive orthant and the triangles with vertices $(0, e_i, e_i + e_{i+1})$ for all $1 \leq i < n$.

INPUT:

- n – integer

EXAMPLES:

```
sage: P3 = polytopes.pellytope(3); P3
A 3-dimensional polyhedron in ZZ^3 defined as
the convex hull of 12 vertices
sage: P3.f_vector()
(1, 12, 18, 8, 1)
```

```
>>> from sage.all import *
>>> P3 = polytopes.pellytope(Integer(3)); P3
A 3-dimensional polyhedron in ZZ^3 defined as
the convex hull of 12 vertices
>>> P3.f_vector()
(1, 12, 18, 8, 1)
```

REFERENCES:

- [BTTM2024]

sage.combinat.posets.sashes.**pellytope_fan**()

Return the fan of the pellytope of dimension n.

This is defined by induction.

INPUT:

- n – integer

EXAMPLES:

```
sage: from sage.combinat.posets.sashes import pellytope_fan
sage: pellytope_fan(3).f_vector()
(1, 8, 18, 12)
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.sashes import pellytope_fan
>>> pellytope_fan(Integer(3)).f_vector()
(1, 8, 18, 12)
```

REFERENCES:

- [BTTM2024]

sage.combinat.posets.sashes.**sashes**(*n*)

Iterate over the sashes of length n.

INPUT:

- n – nonnegative integer

EXAMPLES:

```
sage: from sage.combinat.posets.sashes import sashes
sage: [''.join(s) for s in sashes(2)]
['□□', '□⧄', '⧄□', '⧄⧄', '■■']
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.sashes import sashes
>>> [''.join(s) for s in sashes(Integer(2))]
['□□', '□▨', '▨□', '▨▨', '■■']
```

Posets

Common posets can be accessed through `posets.<tab>` and are listed in the posets catalog:

- *Catalog of posets and lattices*

Poset-related classes:

- *Finite posets*
- *Finite lattices and semilattices*
- *Linear extensions of posets*
- *D-complete posets*
- *Forest posets*
- *Mobile posets*
- *Incidence algebras*
- *Cartesian products of posets*
- *Möbius algebras*
- *Generalized Tamari lattices*
- *Tamari Interval-posets*
- *Shard intersection order*

If you are looking for Poset-related `categories`, see `Posets`, `FinitePosets`, `LatticePosets` and `FiniteLatticePosets`.

Some fast computations for finite posets

class sage.combinat.posets.hasse_cython.**IncreasingChains**(*positions*, *element_constructor*, *exclude*, *conversion=None*)

Bases: `RecursivelyEnumeratedSet_forest`

The enumerated set of increasing chains.

INPUT:

- `positions` – list of sets of integers describing the poset, as given by the lazy attribute `_leq_storage` of Hasse diagrams
- `element_constructor` – used to determine the type of chains, for example `list` or `tuple`
- `exclude` – list of integers that should not belong to the chains
- `conversion` – (optional) list of elements of the poset

If `conversion` is provided, it is used to convert chain elements to elements of this list.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_cython import IncreasingChains
sage: D = IncreasingChains([{0,1},{1}], list, []); D
An enumerated set with a forest structure
sage: D.cardinality()
4
sage: list(D)
[[], [0], [0, 1], [1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_cython import IncreasingChains
>>> D = IncreasingChains([{Integer(0),Integer(1)},{Integer(1)}], list, []); D
An enumerated set with a forest structure
>>> D.cardinality()
4
>>> list(D)
[[], [0], [0, 1], [1]]
```

children(*chain*)

Return the children of a chain, by adding one largest element.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_cython import IncreasingChains
sage: D = IncreasingChains([{0,1},{1}], list, [])
sage: D.children((0,))
[(0, 1)]

sage: P = Poset({'a':['b'],'b':[]})
sage: next(iter(P.chains()))
[]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_cython import IncreasingChains
>>> D = IncreasingChains([{Integer(0),Integer(1)},{Integer(1)}], list, [])
>>> D.children((Integer(0),))
[(0, 1)]

>>> P = Poset({'a':['b'],'b':[]})
>>> next(iter(P.chains()))
[]
```

post_process(*chain*)

Create a chain from the internal object.

If `conversion` was provided, it first converts elements of the chain to elements of this list.

Then the given `element_constructor` is applied to the chain.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_cython import IncreasingChains
sage: D = IncreasingChains([{0,1},{1}], list, [])
sage: D.post_process((0,1))
[0, 1]
```

(continues on next page)

(continued from previous page)

```
sage: P = Poset({'a':['b'],'b':[]})
sage: list(P.chains())
[[], ['a'], ['a', 'b'], ['b']]
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_cython import IncreasingChains
>>> D = IncreasingChains([{Integer(0),Integer(1)},{Integer(1)}], list, [])
>>> D.post_process((Integer(0),Integer(1)))
[0, 1]

>>> P = Poset({'a':['b'],'b':[]})
>>> list(P.chains())
[[], ['a'], ['a', 'b'], ['b']]
```

Some fast computations for finite posets using FLINT matrices

sage.combinat.posets.hasse_cython_flint.**chain_poly**(*positions*)

Return the chain polynomial of a poset.

INPUT:

- positions – a list of sets of integers describing the poset, as given by the lazy attribute _leq_storage of Hasse diagrams

OUTPUT: a Flint polynomial in one variable over **Z**.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_cython_flint import chain_poly
sage: D = [{0, 1}, {1}]
sage: chain_poly(D)
3  1 2 1
sage: P = posets.TamariLattice(5)
sage: H = P._hasse_diagram
sage: D = H._leq_storage
sage: chain_poly(D)
12  1 42 357 1385 3133 4635 4758 3468 1778 612 127 12
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_cython_flint import chain_poly
>>> D = [{Integer(0), Integer(1)}, {Integer(1)}]
>>> chain_poly(D)
3  1 2 1
>>> P = posets.TamariLattice(Integer(5))
>>> H = P._hasse_diagram
>>> D = H._leq_storage
>>> chain_poly(D)
12  1 42 357 1385 3133 4635 4758 3468 1778 612 127 12
```

sage.combinat.posets.hasse_cython_flint.**coxeter_matrix_fast**(*positions*)

Compute the Coxeter matrix of a poset by a specific algorithm.

INPUT:

- positions – a list of sets of integers describing the poset, as given by the lazy attribute _leq_storage of Hasse diagrams

OUTPUT: a dense matrix

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_cython_flint import coxeter_matrix_fast
sage: D = [{0,1},{1}]
sage: coxeter_matrix_fast(D)
[ 0 -1]
[ 1 -1]
sage: P = posets.TamariLattice(5)
sage: H = P._hasse_diagram
sage: D = H._leq_storage
sage: coxeter_matrix_fast(D)
42 x 42 dense matrix over Integer Ring (...)
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_cython_flint import coxeter_matrix_fast
>>> D = [{Integer(0),Integer(1)},{Integer(1)}]
>>> coxeter_matrix_fast(D)
[ 0 -1]
[ 1 -1]
>>> P = posets.TamariLattice(Integer(5))
>>> H = P._hasse_diagram
>>> D = H._leq_storage
>>> coxeter_matrix_fast(D)
42 x 42 dense matrix over Integer Ring (...)
```

sage.combinat.posets.hasse_cython_flint.**moebius_matrix_fast**(*positions*)
