sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3,4,1,2])
sage: G.Q_symbol().pp()
1 2
3 4
```

```
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> G = LLMS4([Integer(3),Integer(4),Integer(1),Integer(2)])
>>> G.Q_symbol().pp()
1 2
3 4
```

forward_rule(*y*, *e*, *t*, *f*, *x*, *content*)

Return the output path given two incident edges and the content.

See [LS2007] Section 3.4 and [LLMSSZ2013] Section 6.3.

INPUT:

- `y`, `e`, `t`, `f`, `x` – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
t f x
e
y
```

- `content` – 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition g, z, h according to LLMS insertion.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)

sage: Z = LLMS3.zero
sage: LLMS3.forward_rule(Z, None, Z, None, Z, 0)
(None, [], None)

sage: LLMS3.forward_rule(Z, None, Z, None, Z, 1)
(None, [1], 0)

sage: Y = Core([3,1,1], 3)
```

(continues on next page)

(continued from previous page)

```
sage: LLMS3.forward_rule(Y, None, Y, None, Y, 1)
(None, [4, 2, 1, 1], 3)
```

```
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))

>>> Z = LLMS3.zero
>>> LLMS3.forward_rule(Z, None, Z, None, Z, Integer(0))
(None, [], None)

>>> LLMS3.forward_rule(Z, None, Z, None, Z, Integer(1))
(None, [1], 0)

>>> Y = Core([Integer(3),Integer(1),Integer(1)], Integer(3))
>>> LLMS3.forward_rule(Y, None, Y, None, Y, Integer(1))
(None, [4, 2, 1, 1], 3)
```

if `x != y`:

```
sage: Y = Core([1,1], 3); T = Core([1], 3); X = Core([2], 3)
sage: LLMS3.forward_rule(Y, -1, T, None, X, 0)
(None, [2, 1, 1], -1)

sage: Y = Core([2], 4); T = Core([1], 4); X = Core([1,1], 4)
sage: LLMS4.forward_rule(Y, 1, T, None, X, 0)
(None, [2, 1], 1)

sage: Y = Core([2,1,1], 3); T = Core([2], 3); X = Core([3,1], 3)
sage: LLMS3.forward_rule(Y, -1, T, None, X, 0)
(None, [3, 1, 1], -2)

sage: LLMS3.forward_rule(Core([2], 3), 1, Core([1], 3), None, Core([1,1], 3),␣
↪0)
(None, [3, 1], 2)
```

```
>>> from sage.all import *
>>> Y = Core([Integer(1),Integer(1)], Integer(3)); T = Core([Integer(1)],␣
↪Integer(3)); X = Core([Integer(2)], Integer(3))
>>> LLMS3.forward_rule(Y, -Integer(1), T, None, X, Integer(0))
(None, [2, 1, 1], -1)

>>> Y = Core([Integer(2)], Integer(4)); T = Core([Integer(1)], Integer(4)); X␣

(None, [2, 1], 1)

>>> Y = Core([Integer(2),Integer(1),Integer(1)], Integer(3)); T =␣
↪Core([Integer(2)], Integer(3)); X = Core([Integer(3),Integer(1)],␣
↪Integer(3))
>>> LLMS3.forward_rule(Y, -Integer(1), T, None, X, Integer(0))
(None, [3, 1, 1], -2)
```

(continues on next page)

(continued from previous page)

```
>>> LLMS3.forward_rule(Core([Integer(2)], Integer(3)), Integer(1),␣
↪Core([Integer(1)], Integer(3)), None, Core([Integer(1),Integer(1)],␣
↪Integer(3)), Integer(0))
(None, [3, 1], 2)
```

if `x == y != t`:

```
sage: Y = Core([1], 3); T = Core([], 3); X = Core([1], 3)
sage: LLMS3.forward_rule(Y, 0, T, None, X, 0)
(None, [1, 1], -1)

sage: Y = Core([1], 4); T = Core([], 4); X = Core([1], 4)
sage: LLMS4.forward_rule(Y, 0, T, None, X, 0)
(None, [1, 1], -1)

sage: Y = Core([2,1], 4); T = Core([1,1], 4); X = Core([2,1], 4)
sage: LLMS4.forward_rule(Y, 1, T, None, X, 0)
(None, [2, 2], 0)
```

```
>>> from sage.all import *
>>> Y = Core([Integer(1)], Integer(3)); T = Core([], Integer(3)); X =␣
↪Core([Integer(1)], Integer(3))
>>> LLMS3.forward_rule(Y, Integer(0), T, None, X, Integer(0))
(None, [1, 1], -1)

>>> Y = Core([Integer(1)], Integer(4)); T = Core([], Integer(4)); X =␣
↪Core([Integer(1)], Integer(4))
>>> LLMS4.forward_rule(Y, Integer(0), T, None, X, Integer(0))
(None, [1, 1], -1)

>>> Y = Core([Integer(2),Integer(1)], Integer(4)); T = Core([Integer(1),
↪Integer(1)], Integer(4)); X = Core([Integer(2),Integer(1)], Integer(4))
>>> LLMS4.forward_rule(Y, Integer(1), T, None, X, Integer(0))
(None, [2, 2], 0)
```

has_multiple_edges = True

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

For two k-cores v and w containing v, there are as many edges as there are components in the skew partition w/v. These components are ribbons, and therefore contain a unique cell with maximal content. We index the edge with this content.

EXAMPLES:

```
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(2)[0]; v
[2]
sage: [(w, LLMS4.is_P_edge(v, w)) for w in LLMS4.vertices(3)]
[([3], [2]), ([2, 1], [-1]), ([1, 1, 1], [])]
sage: all(LLMS4.is_P_edge(v, w) == [] for w in LLMS4.vertices(4))
True
```

```
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> v = LLMS4.vertices(Integer(2))[Integer(0)]; v
[2]
>>> [(w, LLMS4.is_P_edge(v, w)) for w in LLMS4.vertices(Integer(3))]
[([3], [2]), ([2, 1], [-1]), ([1, 1, 1], [])]
>>> all(LLMS4.is_P_edge(v, w) == [] for w in LLMS4.vertices(Integer(4)))
True
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a Q-edge of `self`.

`(v, w)` is an edge if `w` is a weak cover of `v`, see *weak_covers()*.

EXAMPLES:

```
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(3)[1]; v
[2, 1]
sage: [w for w in LLMS4.vertices(4) if len(LLMS4.is_Q_edge(v, w)) > 0]
[[2, 2], [3, 1, 1]]
sage: all(LLMS4.is_Q_edge(v, w) == [] for w in LLMS4.vertices(5))
True
```

```
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> v = LLMS4.vertices(Integer(3))[Integer(1)]; v
[2, 1]
>>> [w for w in LLMS4.vertices(Integer(4)) if len(LLMS4.is_Q_edge(v, w)) >␣
↪Integer(0)]
[[2, 2], [3, 1, 1]]
>>> all(LLMS4.is_Q_edge(v, w) == [] for w in LLMS4.vertices(Integer(5)))
True
```

normalize_vertex(*v*)

Convert `v` to a k-core.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.normalize_vertex([3,1]).parent()
3-Cores of length 3
```

```
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS3.normalize_vertex([Integer(3),Integer(1)]).parent()
3-Cores of length 3
```

rank(*v*)

Return the rank of `v`: the length of the core.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.rank(LLMS3.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS3.rank(LLMS3.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level `n`.

EXAMPLES:

```
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.vertices(2)
3-Cores of length 2
```

```
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS3.vertices(Integer(2))
3-Cores of length 2
```

zero_edge = None

class sage.combinat.growth.**RuleLeftCompositions**

Bases: *RuleCompositions*

Dual graded graphs for (skew) quasisymmetric Schur functions.

These were introduced by Stephanie van Willigenburg in [vW2020], cf. [TvW2018]. This class implements Theorem 3.15 of [vW2020].

Currently, no backward rule is implemented. The forward rule implemented here seems to agree with Mason's insertion algorithm from Section 6.1 of [HLMvW2011].

The vertices of the dual graded graph are *Compositions*:

```
sage: L = GrowthDiagram.rules.LeftCompositions()
sage: L.vertices(3)
Compositions of 3
```

```
>>> from sage.all import *
>>> L = GrowthDiagram.rules.LeftCompositions()
>>> L.vertices(Integer(3))
Compositions of 3
```

A saturated chain in the *sage.combinat.growth.Rule.P_graph()* is a (skew) *CompositionTableau*:

```
sage: c = [[], [1], [2], [1, 2], [1, 1, 2], [1, 1, 3], [2, 1, 3], [1, 2, 1, 3]]
sage: L.P_symbol(c).pp()
1
4  2
5
7  6  3
```

```
>>> from sage.all import *
>>> c = [[], [Integer(1)], [Integer(2)], [Integer(1), Integer(2)], [Integer(1),␣
↪Integer(1), Integer(2)], [Integer(1), Integer(1), Integer(3)], [Integer(2),␣
↪Integer(1), Integer(3)], [Integer(1), Integer(2), Integer(1), Integer(3)]]
>>> L.P_symbol(c).pp()
1
4  2
5
7  6  3
```

The number of *CompositionTableau* is the same as the number of standard Young tableaux with one entry less:

```
sage: [len(L.P_graph(n).maximal_chains()) for n in range(1,8)]
[1, 1, 2, 4, 10, 26, 76]

sage: [StandardTableaux(n).cardinality() for n in range(7)]
[1, 1, 2, 4, 10, 26, 76]
```

```
>>> from sage.all import *
>>> [len(L.P_graph(n).maximal_chains()) for n in range(Integer(1),Integer(8))]
[1, 1, 2, 4, 10, 26, 76]

>>> [StandardTableaux(n).cardinality() for n in range(Integer(7))]
[1, 1, 2, 4, 10, 26, 76]
```

The saturated chains in the *sage.combinat.growth.Rule.Q_graph()* are not in the OEIS as of 2026:

```
sage: [len(L.Q_graph(n).maximal_chains()) for n in range(1,8)]
[1, 1, 2, 6, 19, 69, 285]
```

```
>>> from sage.all import *
>>> [len(L.Q_graph(n).maximal_chains()) for n in range(Integer(1),Integer(8))]
[1, 1, 2, 6, 19, 69, 285]
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a composition tableau.

EXAMPLES:

```
sage: L = GrowthDiagram.rules.LeftCompositions()
sage: c =  [[], [1], [2], [1, 2], [1, 1, 2], [1, 1, 3], [2, 1, 3], [1, 2, 1,␣
↪3]]
sage: L.P_symbol(c).pp()
1
4  2
5
7  6  3
```

```
>>> from sage.all import *
>>> L = GrowthDiagram.rules.LeftCompositions()
>>> c =  [[], [Integer(1)], [Integer(2)], [Integer(1), Integer(2)],␣
↪[Integer(1), Integer(1), Integer(2)], [Integer(1), Integer(1), Integer(3)],␣
↪[Integer(2), Integer(1), Integer(3)], [Integer(1), Integer(2), Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(3)]]
>>> L.P_symbol(c).pp()
1
4  2
5
7  6  3
```

We obtain all standard composition tableaux:

```
sage: n = 5
sage: C1 = [T for T in CompositionTableaux(n) if T.is_standard()]
sage: C2 = [L.P_symbol(c) for c in L.P_graph(n+1).maximal_chains()]
sage: sorted(C1) == sorted(C2)
True
```

```
>>> from sage.all import *
>>> n = Integer(5)
>>> C1 = [T for T in CompositionTableaux(n) if T.is_standard()]
>>> C2 = [L.P_symbol(c) for c in L.P_graph(n+Integer(1)).maximal_chains()]
>>> sorted(C1) == sorted(C2)
True
```

There should be a descent set preserving bijection:

```
sage: n = 4
sage: P = L.P_graph(n+1); Q = L.Q_graph(n+1).hasse_diagram()
sage: d1 = sorted([L.P_symbol(T).descent_set() for T in P.maximal_chains()␣
↪for i in range(len(Q.all_paths(L.zero, T[-1])))])
sage: d2 = sorted([pi.descents(from_zero=False) for pi in Permutations(n)])
sage: d1 == d2
True
```

```
>>> from sage.all import *
>>> n = Integer(4)
>>> P = L.P_graph(n+Integer(1)); Q = L.Q_graph(n+Integer(1)).hasse_diagram()
>>> d1 = sorted([L.P_symbol(T).descent_set() for T in P.maximal_chains() for␣
↪i in range(len(Q.all_paths(L.zero, T[-Integer(1)])))])
>>> d2 = sorted([pi.descents(from_zero=False) for pi in Permutations(n)])
>>> d1 == d2
True
```

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

Warning

This rule is still only conjectural.

INPUT:

- `y`, `t`, `x` – three compositions from a cell in a growth diagram, labelled as:

```
t x
y
```

- `content` – 0 or 1; the content of the cell

OUTPUT:

Conjecturally, the fourth partition according to Mason's insertion.

EXAMPLES:

```
sage: L = GrowthDiagram.rules.LeftCompositions()
sage: L([3,1,2]).out_labels()  # indirect doctest
[[], [1], [1, 1], [1, 2], [2], [1], []]
```

```
>>> from sage.all import *
>>> L = GrowthDiagram.rules.LeftCompositions()
>>> L([Integer(3),Integer(1),Integer(2)]).out_labels()  # indirect doctest
[[], [1], [1, 1], [1, 2], [2], [1], []]
```

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if any left most occurrence of a letter in `v` can be increased by one to obtain `w`.

class sage.combinat.growth.**RulePartitions**

Bases: *Rule*

A rule for growth diagrams on Young's lattice on integer partitions graded by size.

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.P_symbol().pp()
1  2  2
2
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = RuleRSK([[Integer(0),Integer(1),Integer(0)], [Integer(1),Integer(0),
↪Integer(2)]])
>>> G.P_symbol().pp()
1  2  2
2
```

Q_symbol(*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
```

(continues on next page)

(continued from previous page)

```
sage: G.Q_symbol().pp()
1  3  3
2
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = RuleRSK([[Integer(0),Integer(1),Integer(0)], [Integer(1),Integer(0),
↪Integer(2)]])
>>> G.Q_symbol().pp()
1  3  3
2
```

normalize_vertex(*v*)

Return v as a partition.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.normalize_vertex([3,1]).parent()
Partitions
```

```
>>> from sage.all import *
>>> RSK = GrowthDiagram.rules.RSK()
>>> RSK.normalize_vertex([Integer(3),Integer(1)]).parent()
Partitions
```

rank(*v*)

Return the rank of v: the size of the partition.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.rank(RSK.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> RSK = GrowthDiagram.rules.RSK()
>>> RSK.rank(RSK.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.vertices(3)
Partitions of the integer 3
```

```
>>> from sage.all import *
>>> RSK = GrowthDiagram.rules.RSK()
>>> RSK.vertices(Integer(3))
Partitions of the integer 3
```

zero = []

class sage.combinat.growth.**RuleRSK**

Bases: *RulePartitions*

A rule modelling Robinson-Schensted-Knuth insertion.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [3,2,1,2,3])
0  0  1  0  0
0  1  0  1  0
1  0  0  0  1
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> GrowthDiagram(RuleRSK, [Integer(3),Integer(2),Integer(1),Integer(2),
↪Integer(3)])
0  0  1  0  0
0  1  0  1  0
1  0  0  0  1
```

The vertices of the dual graded graph are integer partitions:

```
sage: RuleRSK.vertices(3)
Partitions of the integer 3
```

```
>>> from sage.all import *
>>> RuleRSK.vertices(Integer(3))
Partitions of the integer 3
```

The local rules implemented provide the RSK correspondence between matrices with nonnegative integer entries and pairs of semistandard tableaux, the *P_symbol()* and the *Q_symbol()*. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. For example:

```
sage: m = matrix([[0,0,0,0,1],[1,1,0,2,0], [0,3,0,0,0]])
sage: G = RuleRSK(m); G
0  0  0  0  1
1  1  0  2  0
0  3  0  0  0

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  2  2  3    1  2  2  2  2 ]
[   2  3             4  4          ]
[   3           ,    5             ]
```

```
>>> from sage.all import *
>>> m = matrix([[Integer(0),Integer(0),Integer(0),Integer(0),Integer(1)],
↪[Integer(1),Integer(1),Integer(0),Integer(2),Integer(0)], [Integer(0),
↪Integer(3),Integer(0),Integer(0),Integer(0)]])
>>> G = RuleRSK(m); G
```

(continues on next page)

(continued from previous page)

```
0  0  0  0  1
1  1  0  2  0
0  3  0  0  0

>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[   1  2  2  2  3    1  2  2  2  2 ]
[   2  3             4  4          ]
[   3           ,    5             ]
```

For rectangular fillings, the Kleitman-Greene invariant is the shape of the *P_symbol()* (or the *Q_symbol()*). Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the partition $(\mu_1, \ldots, \mu_n)$, where $\mu_1 + \cdots + \mu_i$ is the maximal sum of entries in a collection of i pairwise disjoint sequences of cells with weakly increasing coordinates.

For rectangular fillings, we could also use the (faster) implementation provided via *RSK()*. Because of the coordinate conventions in *RSK()*, we have to transpose matrices:

```
sage: [G.P_symbol(), G.Q_symbol()] == RSK(m.transpose())
True

sage: n = 5; l = [(pi, RuleRSK(pi)) for pi in Permutations(n)]
sage: all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True

sage: n = 5; l = [(w, RuleRSK(w)) for w in Words([1,2,3], 5)]
sage: all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True
```

```
>>> from sage.all import *
>>> [G.P_symbol(), G.Q_symbol()] == RSK(m.transpose())
True

>>> n = Integer(5); l = [(pi, RuleRSK(pi)) for pi in Permutations(n)]
>>> all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True

>>> n = Integer(5); l = [(w, RuleRSK(w)) for w in Words([Integer(1),Integer(2),
↪Integer(3)], Integer(5))]
>>> all([G.P_symbol(), G.Q_symbol()] == RSK(pi) for pi, G in l)
True
```

backward_rule(y, z, x)

Return the content and the input shape.

See [Kra2006] $(B^1 0) - (B^1 2)$.

INPUT:

- `y`, `z`, `x` – three partitions from a cell in a growth diagram, labelled as:

```
  x
y z
```

OUTPUT:

A pair `(t, content)` consisting of the shape of the fourth word according to the Robinson-Schensted-Knuth correspondence and the content of the cell.

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

See [Kra2006] $(F^1 0) - (F^1 2)$.

INPUT:

- `y`, `t`, `x` – three partitions from a cell in a growth diagram, labelled as:

```
t x
y
```

- `content` – nonnegative integer; the content of the cell

OUTPUT:

The fourth partition according to the Robinson-Schensted-Knuth correspondence.

EXAMPLES:

```
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: RuleRSK.forward_rule([2,1],[2,1],[2,1],1)
[3, 1]

sage: RuleRSK.forward_rule([1],[],[2],2)
[4, 1]
```

```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> RuleRSK.forward_rule([Integer(2),Integer(1)],[Integer(2),Integer(1)],
↪[Integer(2),Integer(1)],Integer(1))
[3, 1]

>>> RuleRSK.forward_rule([Integer(1)],[],[Integer(2)],Integer(2))
[4, 1]
```

class sage.combinat.growth.**RuleRightCompositions**

Bases: *RuleCompositions*

Dual graded graphs for (skew) quasisymmetric Schur functions.

These were introduced by Stephanie van Willigenburg in [vW2020], cf. [TvW2018]. This class implements Theorem 3.3 of [vW2020].

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

EXAMPLES:

Compare with Example 3.1 of [vW2020]:

```
sage: L = GrowthDiagram.rules.RightCompositions()
sage: L._P_out_edges(Composition([2,1,3]))  # indirect doctest
[([2, 1, 3], [1, 3, 3], 0),

```

class sage.combinat.growth.**RuleShiftedShapes**

Bases: *Rule*

A class modelling the Schensted correspondence for shifted shapes.

This agrees with Sagan [Sag1987] and Worley's [Wor1984], and Haiman's [Hai1989] insertion algorithms, see Proposition 4.5.2 of [Fom1995].

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: GrowthDiagram(Shifted, [3,1,2])
0  1  0
0  0  1
1  0  0
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> GrowthDiagram(Shifted, [Integer(3),Integer(1),Integer(2)])
0  1  0
0  0  1
1  0  0
```

The vertices of the dual graded graph are shifted shapes:

```
sage: Shifted.vertices(3)
Partitions of the integer 3 satisfying constraints max_slope=-1
```

```
>>> from sage.all import *
>>> Shifted.vertices(Integer(3))
Partitions of the integer 3 satisfying constraints max_slope=-1
```

Let us check the example just before Corollary 3.2 in [Sag1987]. Note that, instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams:

```
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.P_chain()
[[], 0, [1], 0, [2], 0, [3], 0, [3, 1], 0, [3, 2], 0, [4, 2], 0, [5, 2]]
sage: G.Q_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]
```

```
>>> from sage.all import *
>>> G = Shifted([Integer(2),Integer(6),Integer(5),Integer(1),Integer(7),
↪Integer(4),Integer(3)])
>>> G.P_chain()
[[], 0, [1], 0, [2], 0, [3], 0, [3, 1], 0, [3, 2], 0, [4, 2], 0, [5, 2]]
>>> G.Q_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a shifted tableau.

EXAMPLES:

Check the example just before Corollary 3.2 in [Sag1987]:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.P_symbol().pp()
1  2  3  6  7
   4  5
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> G = Shifted([Integer(2),Integer(6),Integer(5),Integer(1),Integer(7),
↪Integer(4),Integer(3)])
>>> G.P_symbol().pp()
1  2  3  6  7
   4  5
```

Check the example just before Corollary 8.2 in [SS1990]:

```
sage: T = ShiftedPrimedTableau([[4],[1],[5]], skew=[3,1])
sage: T.pp()
 .  .  .  4
    .  1
       5
sage: U = ShiftedPrimedTableau([[1],[3.5],[5]], skew=[3,1])
sage: U.pp()
 .  .  .  1
    .  4'
       5
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: labels = [mu if is_even(i) else 0
....:           for i, mu in enumerate(T.to_chain()[::-1])] + U.to_chain()[1:]
sage: G = Shifted({(1,2):1, (2,1):1}, shape=[5,5,5,5,5], labels=labels)
sage: G.P_symbol().pp()
 .  .  .  .  2
    .  .  1  3
       .  4  5
```

```
>>> from sage.all import *
>>> T = ShiftedPrimedTableau([[Integer(4)],[Integer(1)],[Integer(5)]],␣
↪skew=[Integer(3),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> T.pp()
 .  .  .  4
    .  1
       5
>>> U = ShiftedPrimedTableau([[Integer(1)],[RealNumber('3.5')],[Integer(5)]],␣
↪skew=[Integer(3),Integer(1)])
>>> U.pp()
 .  .  .  1
    .  4'
       5
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> labels = [mu if is_even(i) else Integer(0)
...           for i, mu in enumerate(T.to_chain()[::-Integer(1)])] + U.to_
↪chain()[Integer(1):]
>>> G = Shifted({(Integer(1),Integer(2)):Integer(1), (Integer(2),
↪Integer(1)):Integer(1)}, shape=[Integer(5),Integer(5),Integer(5),Integer(5),
↪Integer(5)], labels=labels)
>>> G.P_symbol().pp()
 .  .  .  .  2
    .  .  1  3
       .  4  5
```

Q_symbol(*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

EXAMPLES:

Check the example just before Corollary 3.2 in [Sag1987]:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.Q_symbol().pp()
1  2  4' 5  7'
   3  6'
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> G = Shifted([Integer(2),Integer(6),Integer(5),Integer(1),Integer(7),
↪Integer(4),Integer(3)])
>>> G.Q_symbol().pp()
1  2  4' 5  7'
   3  6'
```

Check the example just before Corollary 8.2 in [SS1990]:

```
sage: T = ShiftedPrimedTableau([[4],[1],[5]], skew=[3,1])
sage: T.pp()
 .  .  .  4
    .  1
       5
sage: U = ShiftedPrimedTableau([[1],[3.5],[5]], skew=[3,1])
sage: U.pp()
 .  .  .  1
```

(continues on next page)

(continued from previous page)

```
    .  4'
       5
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: labels = [mu if is_even(i) else 0
....:           for i, mu in enumerate(T.to_chain()[::-1])] + U.to_chain()[1:]
sage: G = Shifted({(1,2):1, (2,1):1}, shape=[5,5,5,5,5], labels=labels)
sage: G.Q_symbol().pp()
 .  .  .  .  2
    .  .  1  4'
       .  3' 5'
```

```
>>> from sage.all import *
>>> T = ShiftedPrimedTableau([[Integer(4)],[Integer(1)],[Integer(5)]],␣
↪skew=[Integer(3),Integer(1)])
>>> T.pp()
 .  .  .  4
    .  1
       5
>>> U = ShiftedPrimedTableau([[Integer(1)],[RealNumber('3.5')],[Integer(5)]],␣
↪skew=[Integer(3),Integer(1)])
>>> U.pp()
 .  .  .  1
    .  4'
       5
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> labels = [mu if is_even(i) else Integer(0)
...           for i, mu in enumerate(T.to_chain()[::-Integer(1)])] + U.to_
↪chain()[Integer(1):]
>>> G = Shifted({(Integer(1),Integer(2)):Integer(1), (Integer(2),
↪Integer(1)):Integer(1)}, shape=[Integer(5),Integer(5),Integer(5),Integer(5),
↪Integer(5)], labels=labels)
>>> G.Q_symbol().pp()
 .  .  .  .  2
    .  .  1  4'
       .  3' 5'
```

backward_rule(*y*, *g*, *z*, *h*, *x*)

Return the input path and the content given two incident edges.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

- `y`, `g`, `z`, `h`, `x` – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
   x
   h
y g z
```

OUTPUT:

A tuple `(e, t, f, content)` consisting of the shape `t` of the fourth word, the colours of the incident edges and the content of the cell according to Sagan - Worley insertion.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.backward_rule([], 1, [1], 0, [])
(0, [], 0, 1)

sage: Shifted.backward_rule([1], 2, [2], 0, [1])
(0, [1], 0, 1)
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.backward_rule([], Integer(1), [Integer(1)], Integer(0), [])
(0, [], 0, 1)

>>> Shifted.backward_rule([Integer(1)], Integer(2), [Integer(2)], Integer(0),␣
↪[Integer(1)])
(0, [1], 0, 1)
```

if `x != y`:

```
sage: Shifted.backward_rule([3], 1, [3, 1], 0, [2,1])
(0, [2], 1, 0)

sage: Shifted.backward_rule([2,1], 2, [3, 1], 0, [3])
(0, [2], 2, 0)
```

```
>>> from sage.all import *
>>> Shifted.backward_rule([Integer(3)], Integer(1), [Integer(3), Integer(1)],␣
↪Integer(0), [Integer(2),Integer(1)])
(0, [2], 1, 0)

>>> Shifted.backward_rule([Integer(2),Integer(1)], Integer(2), [Integer(3),␣
↪Integer(1)], Integer(0), [Integer(3)])
(0, [2], 2, 0)
```

if `x == y != t`:

```
sage: Shifted.backward_rule([3], 1, [3, 1], 0, [3])
(0, [2], 2, 0)

sage: Shifted.backward_rule([3,1], 2, [3, 2], 0, [3,1])
(0, [2, 1], 2, 0)

sage: Shifted.backward_rule([2,1], 3, [3, 1], 0, [2,1])
(0, [2], 1, 0)

sage: Shifted.backward_rule([3], 3, [4], 0, [3])
(0, [2], 3, 0)
```

```
>>> from sage.all import *
>>> Shifted.backward_rule([Integer(3)], Integer(1), [Integer(3), Integer(1)],␣
↪Integer(0), [Integer(3)])
(0, [2], 2, 0)
```

(continues on next page)

(continued from previous page)

```
>>> Shifted.backward_rule([Integer(3),Integer(1)], Integer(2), [Integer(3),␣
↪Integer(2)], Integer(0), [Integer(3),Integer(1)])
(0, [2, 1], 2, 0)

>>> Shifted.backward_rule([Integer(2),Integer(1)], Integer(3), [Integer(3),␣
↪Integer(1)], Integer(0), [Integer(2),Integer(1)])
(0, [2], 1, 0)

>>> Shifted.backward_rule([Integer(3)], Integer(3), [Integer(4)], Integer(0),␣
↪[Integer(3)])
(0, [2], 3, 0)
```

forward_rule(*y*, *e*, *t*, *f*, *x*, *content*)

Return the output path given two incident edges and the content.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

- `y`, `e`, `t`, `f`, `x` – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

```
t f x
e
y
```

- `content` – 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition `g`, `z`, `h` according to Sagan-Worley insertion.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.forward_rule([], 0, [], 0, [], 1)
(1, [1], 0)

sage: Shifted.forward_rule([1], 0, [1], 0, [1], 1)
(2, [2], 0)
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.forward_rule([], Integer(0), [], Integer(0), [], Integer(1))
(1, [1], 0)

>>> Shifted.forward_rule([Integer(1)], Integer(0), [Integer(1)], Integer(0),␣
↪[Integer(1)], Integer(1))
(2, [2], 0)
```

if `x != y`:

```
sage: Shifted.forward_rule([3], 0, [2], 1, [2,1], 0)
(1, [3, 1], 0)
```

(continues on next page)

(continued from previous page)

```
sage: Shifted.forward_rule([2,1], 0, [2], 2, [3], 0)
(2, [3, 1], 0)
```

```
>>> from sage.all import *
>>> Shifted.forward_rule([Integer(3)], Integer(0), [Integer(2)], Integer(1),␣
↪[Integer(2),Integer(1)], Integer(0))
(1, [3, 1], 0)

>>> Shifted.forward_rule([Integer(2),Integer(1)], Integer(0), [Integer(2)],␣
↪Integer(2), [Integer(3)], Integer(0))
(2, [3, 1], 0)
```

if `x == y != t`:

```
sage: Shifted.forward_rule([3], 0, [2], 2, [3], 0)
(1, [3, 1], 0)

sage: Shifted.forward_rule([3,1], 0, [2,1], 2, [3,1], 0)
(2, [3, 2], 0)

sage: Shifted.forward_rule([2,1], 0, [2], 1, [2,1], 0)
(3, [3, 1], 0)

sage: Shifted.forward_rule([3], 0, [2], 3, [3], 0)
(3, [4], 0)
```

```
>>> from sage.all import *
>>> Shifted.forward_rule([Integer(3)], Integer(0), [Integer(2)], Integer(2),␣
↪[Integer(3)], Integer(0))
(1, [3, 1], 0)

>>> Shifted.forward_rule([Integer(3),Integer(1)], Integer(0), [Integer(2),
↪Integer(1)], Integer(2), [Integer(3),Integer(1)], Integer(0))
(2, [3, 2], 0)

>>> Shifted.forward_rule([Integer(2),Integer(1)], Integer(0), [Integer(2)],␣
↪Integer(1), [Integer(2),Integer(1)], Integer(0))
(3, [3, 1], 0)

>>> Shifted.forward_rule([Integer(3)], Integer(0), [Integer(2)], Integer(3),␣
↪[Integer(3)], Integer(0))
(3, [4], 0)
```

has_multiple_edges = True

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `w` contains `v`.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: v = Shifted.vertices(2)[0]; v
[2]
sage: [w for w in Shifted.vertices(3) if Shifted.is_P_edge(v, w)]
[[3], [2, 1]]
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> v = Shifted.vertices(Integer(2))[Integer(0)]; v
[2]
>>> [w for w in Shifted.vertices(Integer(3)) if Shifted.is_P_edge(v, w)]
[[3], [2, 1]]
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a Q-edge of `self`.

`(v, w)` is an edge if `w` is obtained from `v` by adding a cell. It is a black (color 1) edge, if the cell is on the diagonal, otherwise it can be blue or red (color 2 or 3).

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: v = Shifted.vertices(2)[0]; v
[2]
sage: [(w, Shifted.is_Q_edge(v, w)) for w in Shifted.vertices(3)]
[([3], [2, 3]), ([2, 1], [1])]
sage: all(Shifted.is_Q_edge(v, w) == [] for w in Shifted.vertices(4))
True
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> v = Shifted.vertices(Integer(2))[Integer(0)]; v
[2]
>>> [(w, Shifted.is_Q_edge(v, w)) for w in Shifted.vertices(Integer(3))]
[([3], [2, 3]), ([2, 1], [1])]
>>> all(Shifted.is_Q_edge(v, w) == [] for w in Shifted.vertices(Integer(4)))
True
```

normalize_vertex(*v*)

Return `v` as a partition.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.normalize_vertex([3,1]).parent()
Partitions
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.normalize_vertex([Integer(3),Integer(1)]).parent()
Partitions
```

rank(*v*)

Return the rank of `v`: the size of the shifted partition.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.rank(Shifted.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.rank(Shifted.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level `n`.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.vertices(3)
Partitions of the integer 3 satisfying constraints max_slope=-1
```

```
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.vertices(Integer(3))
Partitions of the integer 3 satisfying constraints max_slope=-1
```

zero = []

class sage.combinat.growth.**RuleSylvester**

Bases: *Rule*

A rule modelling a Schensted-like correspondence for binary trees.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: GrowthDiagram(Sylvester, [3,1,2])
0  1  0
0  0  1
1  0  0
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> GrowthDiagram(Sylvester, [Integer(3),Integer(1),Integer(2)])
0  1  0
0  0  1
1  0  0
```

The vertices of the dual graded graph are *BinaryTrees*:

```
sage: Sylvester.vertices(3)
Binary trees of size 3
```

```
>>> from sage.all import *
>>> Sylvester.vertices(Integer(3))
Binary trees of size 3
```

The *P_graph()* is also known as the bracket tree, the *Q_graph()* is the lattice of finite order ideals of the infinite binary tree, see Example 2.4.6 in [Fom1994].

For a permutation, the *P_symbol()* is the binary search tree, the *Q_symbol()* is the increasing tree corresponding to the inverse permutation. Note that, instead of passing the rule to *GrowthDiagram*, we can also call the rule to create growth diagrams. From [Nze2007]:

```
sage: pi = Permutation([3,5,1,4,2,6]); G = Sylvester(pi); G
0  0  1  0  0  0
0  0  0  0  1  0
1  0  0  0  0  0
0  0  0  1  0  0
0  1  0  0  0  0
0  0  0  0  0  1
sage: ascii_art(G.P_symbol())
  __3__
 /     \
1       5
 \     / \
  2   4   6
sage: ascii_art(G.Q_symbol())
  __1__
 /     \
3       2
 \     / \
  5   4   6

sage: all(Sylvester(pi).P_symbol() == pi.binary_search_tree()
....:     for pi in Permutations(5))
True

sage: all(Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
....:     for pi in Permutations(5))
True
```

```
>>> from sage.all import *
>>> pi = Permutation([Integer(3),Integer(5),Integer(1),Integer(4),Integer(2),
↪Integer(6)]); G = Sylvester(pi); G
0  0  1  0  0  0
0  0  0  0  1  0
1  0  0  0  0  0
0  0  0  1  0  0
0  1  0  0  0  0
0  0  0  0  0  1
>>> ascii_art(G.P_symbol())
  __3__
 /     \
1       5
 \     / \
  2   4   6
>>> ascii_art(G.Q_symbol())
  __1__
 /     \
3       2
```

(continues on next page)

(continued from previous page)

```
 \     / \
  5   4   6

>>> all(Sylvester(pi).P_symbol() == pi.binary_search_tree()
...     for pi in Permutations(Integer(5)))
True

>>> all(Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
...     for pi in Permutations(Integer(5)))
True
```

P_symbol(*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the binary search tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).P_symbol())
  _2_
 /   \
1     4
     /
    3
sage: Sylvester(pi).P_symbol() == pi.binary_search_tree()
True
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> pi = Permutation([Integer(2),Integer(4),Integer(3),Integer(1)])
>>> ascii_art(Sylvester(pi).P_symbol())
  _2_
 /   \
1     4
     /
    3
>>> Sylvester(pi).P_symbol() == pi.binary_search_tree()
True
```

We can also do the skew version:

```
sage: B = BinaryTree; E = B(); N = B([])
sage: ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).P_
↪symbol())
  __1___
 /      \
None     3
        /
       2
```

```
>>> from sage.all import *
>>> B = BinaryTree; E = B(); N = B([])
>>> ascii_art(Sylvester([Integer(3),Integer(2)], shape=[Integer(3),Integer(3),
↪Integer(3)], labels=[N,N,N,E,E,E,N]).P_symbol())
  __1___
 /      \
None     3
        /
       2
```

Q_symbol(*Q_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the increasing tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).Q_symbol())
  _1_
 /   \
4     2
     /
    3
sage: Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
True
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> pi = Permutation([Integer(2),Integer(4),Integer(3),Integer(1)])
>>> ascii_art(Sylvester(pi).Q_symbol())
  _1_
 /   \
4     2
     /
    3
>>> Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree()
True
```

We can also do the skew version:

```
sage: B = BinaryTree; E = B(); N = B([])
sage: ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).Q_
↪symbol())
  _None_
 /      \
3        1
        /
       2
```

```
>>> from sage.all import *
>>> B = BinaryTree; E = B(); N = B([])
```

(continues on next page)

(continued from previous page)

```
>>> ascii_art(Sylvester([Integer(3),Integer(2)], shape=[Integer(3),Integer(3),
↪Integer(3)], labels=[N,N,N,E,E,E,N]).Q_symbol())
  _None_
 /      \
3        1
        /
       2
```

backward_rule(*y*, *z*, *x*)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

INPUT:

- `y`, `z`, `x` – three binary trees from a cell in a growth diagram, labelled as:

```
  x
y z
```

OUTPUT:

A pair `(t, content)` consisting of the shape of the fourth binary tree t and the content of the cell.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: B = BinaryTree; E = B(); N = B([]); L = B([[],None])
sage: R = B([None,[]]); T = B([[],[]])

sage: ascii_art(Sylvester.backward_rule(E, E, E))
( , 0 )
sage: ascii_art(Sylvester.backward_rule(N, N, N))
( o, 0 )
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> B = BinaryTree; E = B(); N = B([]); L = B([[],None])
>>> R = B([None,[]]); T = B([[],[]])

>>> ascii_art(Sylvester.backward_rule(E, E, E))
( , 0 )
>>> ascii_art(Sylvester.backward_rule(N, N, N))
( o, 0 )
```

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

INPUT:

- `y`, `t`, `x` – three binary trees from a cell in a growth diagram, labelled as:

```
t x
y
```

- `content` – 0 or 1; the content of the cell

OUTPUT: the fourth binary tree `z`

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: B = BinaryTree; E = B(); N = B([]); L = B([[],None])
sage: R = B([None,[]]); T = B([[],[]])

sage: ascii_art(Sylvester.forward_rule(E, E, E, 1))
o
sage: ascii_art(Sylvester.forward_rule(N, N, N, 1))
o
 \
  o
sage: ascii_art(Sylvester.forward_rule(L, L, L, 1))
  o
 / \
o   o
sage: ascii_art(Sylvester.forward_rule(R, R, R, 1))
o
 \
  o
   \
    o
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> B = BinaryTree; E = B(); N = B([]); L = B([[],None])
>>> R = B([None,[]]); T = B([[],[]])

>>> ascii_art(Sylvester.forward_rule(E, E, E, Integer(1)))
o
>>> ascii_art(Sylvester.forward_rule(N, N, N, Integer(1)))
o
 \
  o
>>> ascii_art(Sylvester.forward_rule(L, L, L, Integer(1)))
  o
 / \
o   o
>>> ascii_art(Sylvester.forward_rule(R, R, R, Integer(1)))
o
 \
  o
   \
    o
```

If `y != x`, obtain `z` from `y` adding a node such that deleting the right most gives `x`:

```
sage: ascii_art(Sylvester.forward_rule(R, N, L, 0))
  o
 / \
```

(continues on next page)

(continued from previous page)

```
o   o

sage: ascii_art(Sylvester.forward_rule(L, N, R, 0))
  o
 /
o
 \
  o
```

```
>>> from sage.all import *
>>> ascii_art(Sylvester.forward_rule(R, N, L, Integer(0)))
  o
 / \
o   o

>>> ascii_art(Sylvester.forward_rule(L, N, R, Integer(0)))
  o
 /
o
 \
  o
```

If `y == x != t`, obtain `z` from `x` by adding a node as left child to the right most node:

```
sage: ascii_art(Sylvester.forward_rule(N, E, N, 0))
  o
 /
o
sage: ascii_art(Sylvester.forward_rule(T, L, T, 0))
  _o_
 /   \
o     o
     /
    o
sage: ascii_art(Sylvester.forward_rule(L, N, L, 0))
    o
   /
  o
 /
o
sage: ascii_art(Sylvester.forward_rule(R, N, R, 0))
o
 \
  o
 /
o
```

```
>>> from sage.all import *
>>> ascii_art(Sylvester.forward_rule(N, E, N, Integer(0)))
  o
 /
o
```

(continues on next page)

(continued from previous page)

```
>>> ascii_art(Sylvester.forward_rule(T, L, T, Integer(0)))
  _o_
 /   \
o     o
     /
    o
>>> ascii_art(Sylvester.forward_rule(L, N, L, Integer(0)))
    o
   /
  o
 /
o
>>> ascii_art(Sylvester.forward_rule(R, N, R, Integer(0)))
o
 \
  o
 /
o
```

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `v` is obtained from `w` by deleting its right-most node.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
  o
 /
o

sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_P_edge(v,␣
↪w)])
[   o  ,     o ]
[  / \      /  ]
[ o   o    o   ]
[         /    ]
[        o     ]

sage: [w for w in Sylvester.vertices(4) if Sylvester.is_P_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> v = Sylvester.vertices(Integer(2))[Integer(1)]; ascii_art(v)
  o
 /
o

>>> ascii_art([w for w in Sylvester.vertices(Integer(3)) if Sylvester.is_P_
↪edge(v, w)])
[   o  ,     o ]
```

(continues on next page)

(continued from previous page)

```
[  / \      /  ]
[ o   o    o   ]
[         /    ]
[        o     ]

>>> [w for w in Sylvester.vertices(Integer(4)) if Sylvester.is_P_edge(v, w)]
[]
```

is_Q_edge(*v*, *w*)

Return whether `(v, w)` is a Q-edge of `self`.

`(v, w)` is an edge if `v` is a sub-tree of `w` with one node less.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
  o
 /
o
sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_Q_edge(v,␣
↪w)])
[   o  ,   o,     o ]
[  / \    /      /  ]
[ o   o  o      o   ]
[         \    /    ]
[          o  o     ]
sage: [w for w in Sylvester.vertices(4) if Sylvester.is_Q_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> v = Sylvester.vertices(Integer(2))[Integer(1)]; ascii_art(v)
  o
 /
o
>>> ascii_art([w for w in Sylvester.vertices(Integer(3)) if Sylvester.is_Q_
↪edge(v, w)])
[   o  ,   o,     o ]
[  / \    /      /  ]
[ o   o  o      o   ]
[         \    /    ]
[          o  o     ]
>>> [w for w in Sylvester.vertices(Integer(4)) if Sylvester.is_Q_edge(v, w)]
[]
```

normalize_vertex(*v*)

Return `v` as a binary tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.normalize_vertex([[],[]]).parent()
Binary trees
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.normalize_vertex([[],[]]).parent()
Binary trees
```

rank(*v*)

Return the rank of v: the number of nodes of the tree.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.rank(Sylvester.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.rank(Sylvester.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.vertices(3)
Binary trees of size 3
```

```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.vertices(Integer(3))
Binary trees of size 3
```

zero = .

class sage.combinat.growth.**RuleYoungFibonacci**

Bases: *Rule*

A rule modelling a Schensted-like correspondence for Young-Fibonacci-tableaux.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: GrowthDiagram(YF, [3,1,2])
0  1  0
0  0  1
1  0  0
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> GrowthDiagram(YF, [Integer(3),Integer(1),Integer(2)])
0  1  0
0  0  1
1  0  0
```

The vertices of the dual graded graph are Fibonacci words - compositions into parts of size at most two:

```
sage: YF.vertices(4)
[word: 22, word: 211, word: 121, word: 112, word: 1111]
```

```
>>> from sage.all import *
>>> YF.vertices(Integer(4))
[word: 22, word: 211, word: 121, word: 112, word: 1111]
```

Note that, instead of passing the rule to *GrowthDiagram*, we can also use call the rule to create growth diagrams. For example:

```
sage: G = YF([2, 3, 7, 4, 1, 6, 5]); G
0  0  0  0  1  0  0
1  0  0  0  0  0  0
0  1  0  0  0  0  0
0  0  0  1  0  0  0
0  0  0  0  0  0  1
0  0  0  0  0  1  0
0  0  1  0  0  0  0
```

```
>>> from sage.all import *
>>> G = YF([Integer(2), Integer(3), Integer(7), Integer(4), Integer(1),␣
↪Integer(6), Integer(5)]); G
0  0  0  0  1  0  0
1  0  0  0  0  0  0
0  1  0  0  0  0  0
0  0  0  1  0  0  0
0  0  0  0  0  0  1
0  0  0  0  0  1  0
0  0  1  0  0  0  0
```

The Kleitman Greene invariant is: take the last letter and the largest letter of the permutation and remove them. If they coincide write 1, otherwise write 2:

```
sage: G.P_chain()[-1]
word: 21211
```

```
>>> from sage.all import *
>>> G.P_chain()[-Integer(1)]
word: 21211
```

backward_rule(*y*, *z*, *x*)

Return the content and the input shape.

See [Fom1995] Lemma 4.4.1, page 35.

- `y`, `z`, `x` – three Fibonacci words from a cell in a growth diagram, labelled as:

```
  x
y z
```

OUTPUT:

A pair `(t, content)` consisting of the shape of the fourth word and the content of the cell.

forward_rule(*y*, *t*, *x*, *content*)

Return the output shape given three shapes and the content.

See [Fom1995] Lemma 4.4.1, page 35.

INPUT:

- `y`, `t`, `x` – three Fibonacci words from a cell in a growth diagram, labelled as:

```
t x
y
```

- `content` – 0 or 1; the content of the cell

OUTPUT: the fourth Fibonacci word

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()

sage: YF.forward_rule([], [], [], 1)
word: 1

sage: YF.forward_rule([1], [1], [1], 1)
word: 11

sage: YF.forward_rule([1,2], [1], [1,1], 0)
word: 21

sage: YF.forward_rule([1,1], [1], [1,1], 0)
word: 21
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()

>>> YF.forward_rule([], [], [], Integer(1))
word: 1

>>> YF.forward_rule([Integer(1)], [Integer(1)], [Integer(1)], Integer(1))
word: 11

>>> YF.forward_rule([Integer(1),Integer(2)], [Integer(1)], [Integer(1),
↪Integer(1)], Integer(0))
word: 21

>>> YF.forward_rule([Integer(1),Integer(1)], [Integer(1)], [Integer(1),
↪Integer(1)], Integer(0))
word: 21
```

is_P_edge(*v*, *w*)

Return whether `(v, w)` is a P-edge of `self`.

`(v, w)` is an edge if `v` is obtained from `w` by deleting a `1` or replacing the left-most `2` by a `1`.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: v = YF.vertices(5)[5]; v
word: 1121
sage: [w for w in YF.vertices(6) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
sage: [w for w in YF.vertices(7) if YF.is_P_edge(v, w)]
[]
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> v = YF.vertices(Integer(5))[Integer(5)]; v
word: 1121
>>> [w for w in YF.vertices(Integer(6)) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
>>> [w for w in YF.vertices(Integer(7)) if YF.is_P_edge(v, w)]
[]
```

is_Q_edge(*v*, *w*)

alias of *is_P_edge()*.

normalize_vertex(*v*)

Return v as a word with letters 1 and 2.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.normalize_vertex([1,2,1]).parent()
Finite words over {1, 2}
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> YF.normalize_vertex([Integer(1),Integer(2),Integer(1)]).parent()
Finite words over {1, 2}
```

rank(*v*)

Return the rank of v: the size of the corresponding composition.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.rank(YF.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> YF.rank(YF.vertices(Integer(3))[Integer(0)])
3
```

vertices(*n*)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.vertices(3)
[word: 21, word: 12, word: 111]
```

```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> YF.vertices(Integer(3))
[word: 21, word: 12, word: 111]
```

Hall polynomials

sage.combinat.hall_polynomial.**hall_polynomial**(*nu*, *mu*, *la*, *q=None*)

Return the (classical) Hall polynomial $P^{\nu}_{\mu,\lambda}$ (where ν, μ and λ are the inputs `nu`, `mu` and `la`).

Let ν, μ, λ be partitions. The Hall polynomial $P^{\nu}_{\mu,\lambda}(q)$ (in the indeterminate q) is defined as follows: Specialize q to a prime power, and consider the category of $\mathbf{F}_q$-vector spaces with a distinguished nilpotent endomorphism. The morphisms in this category shall be the linear maps commuting with the distinguished endomorphisms. The *type* of an object in the category will be the Jordan type of the distinguished endomorphism; this is a partition. Now, if N is any fixed object of type ν in this category, then the polynomial $P^{\nu}_{\mu,\lambda}(q)$ specialized at the prime power q counts the number of subobjects L of N having type λ such that the quotient object N/L has type μ. This determines the

values of the polynomial $P^{\nu}_{\mu,\lambda}$ at infinitely many points (namely, at all prime powers), and hence $P^{\nu}_{\mu,\lambda}$ is uniquely determined. The degree of this polynomial is at most $n(\nu) - n(\lambda) - n(\mu)$, where $n(\kappa) = \sum_i (i-1)\kappa_i$ for every partition κ. (If this is negative, then the polynomial is zero.)

These are the structure coefficients of the `(classical) Hall algebra`.

If $|\nu| \neq |\mu| + |\lambda|$, then we have $P^{\nu}_{\mu,\lambda} = 0$. More generally, if the Littlewood-Richardson coefficient $c^{\nu}_{\mu,\lambda}$ vanishes, then $P^{\nu}_{\mu,\lambda} = 0$.

The Hall polynomials satisfy the symmetry property $P^{\nu}_{\mu,\lambda} = P^{\nu}_{\lambda,\mu}$.

ALGORITHM:

If $\lambda = (1^r)$ and $|\nu| = |\mu| + |\lambda|$, then we compute $P^{\nu}_{\mu,\lambda}$ as follows (cf. Example 2.4 in [Sch2006]):

First, write $\nu = (1^{l_1}, 2^{l_2}, \ldots, n^{l_n})$, and define a sequence $r = r_0 \geq r_1 \geq \cdots \geq r_n$ such that

$$\mu = \left(1^{l_1 - r_0 + 2r_1 - r_2}, 2^{l_2 - r_1 + 2r_2 - r_3}, \ldots, (n-1)^{l_{n-1} - r_{n-2} + 2r_{n-1} - r_n}, n^{l_n - r_{n-1} + r_n}\right).$$

Thus if $\mu = (1^{m_1}, \ldots, n^{m_n})$, we have the following system of equations:

$$\begin{aligned} m_1 &= l_1 - r + 2r_1 - r_2, \\ m_2 &= l_2 - r_1 + 2r_2 - r_3, \\ &\vdots, \\ m_{n-1} &= l_{n-1} - r_{n-2} + 2r_{n-1} - r_n, \\ m_n &= l_n - r_{n-1} + r_n \end{aligned}$$

and solving for r_i and back substituting we obtain the equations:

$$\begin{aligned} r_n &= r_{n-1} + m_n - l_n, \\ r_{n-1} &= r_{n-2} + m_{n-1} - l_{n-1} + m_n - l_n, \\ &\vdots, \\ r_1 &= r + \sum_{k=1}^{n} (m_k - l_k), \end{aligned}$$

or in general we have the recursive equation:

$$r_i = r_{i-1} + \sum_{k=i}^{n} (m_k - l_k).$$

This, combined with the condition that $r_0 = r$, determines the r_i uniquely (recursively). Next we define

$$t = (r_{n-2} - r_{n-1})(l_n - r_{n-1}) + (r_{n-3} - r_{n-2})(l_{n-1} + l_n - r_{n-2}) + \cdots + (r_0 - r_1)(l_2 + \cdots + l_n - r_1),$$

and with these notations we have

$$P^{\nu}_{\mu,(1^r)} = q^t \binom{l_n}{r_{n-1}}_q \binom{l_{n-1}}{r_{n-2} - r_{n-1}}_q \cdots \binom{l_1}{r_0 - r_1}_q.$$

To compute $P^{\nu}_{\mu,\lambda}$ in general, we compute the product $I_\mu I_\lambda$ in the Hall algebra and return the coefficient of I_ν.

EXAMPLES:

```
sage: from sage.combinat.hall_polynomial import hall_polynomial
sage: hall_polynomial([1,1],[1],[1])
q + 1
sage: hall_polynomial([2],[1],[1])
1
sage: hall_polynomial([2,1],[2],[1])
q
sage: hall_polynomial([2,2,1],[2,1],[1,1])
q^2 + q
sage: hall_polynomial([2,2,2,1],[2,2,1],[1,1])
q^4 + q^3 + q^2
sage: hall_polynomial([3,2,2,1], [3,2], [2,1])
q^6 + q^5
sage: hall_polynomial([4,2,1,1], [3,1,1], [2,1])
2*q^3 + q^2 - q - 1
sage: hall_polynomial([4,2], [2,1], [2,1], 0)
1
```

```
>>> from sage.all import *
>>> from sage.combinat.hall_polynomial import hall_polynomial
>>> hall_polynomial([Integer(1),Integer(1)],[Integer(1)],[Integer(1)])
q + 1
>>> hall_polynomial([Integer(2)],[Integer(1)],[Integer(1)])
1
>>> hall_polynomial([Integer(2),Integer(1)],[Integer(2)],[Integer(1)])
q
>>> hall_polynomial([Integer(2),Integer(2),Integer(1)],[Integer(2),Integer(1)],
↪[Integer(1),Integer(1)])
q^2 + q
>>> hall_polynomial([Integer(2),Integer(2),Integer(2),Integer(1)],[Integer(2),
↪Integer(2),Integer(1)],[Integer(1),Integer(1)])
q^4 + q^3 + q^2
>>> hall_polynomial([Integer(3),Integer(2),Integer(2),Integer(1)], [Integer(3),
↪Integer(2)], [Integer(2),Integer(1)])
q^6 + q^5
>>> hall_polynomial([Integer(4),Integer(2),Integer(1),Integer(1)], [Integer(3),
↪Integer(1),Integer(1)], [Integer(2),Integer(1)])
2*q^3 + q^2 - q - 1
>>> hall_polynomial([Integer(4),Integer(2)], [Integer(2),Integer(1)], [Integer(2),
↪Integer(1)], Integer(0))
1
```

Integer compositions

A composition c of a nonnegative integer n is a list of positive integers (the *parts* of the composition) with total sum n.

This module provides tools for manipulating compositions and enumerated sets of compositions.

EXAMPLES:

```
sage: Composition([5, 3, 1, 3])
[5, 3, 1, 3]
sage: list(Compositions(4))
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

```
>>> from sage.all import *
>>> Composition([Integer(5), Integer(3), Integer(1), Integer(3)])
[5, 3, 1, 3]
>>> list(Compositions(Integer(4)))
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

class sage.combinat.composition.**Composition**(*parent*, *lst*)

Bases: *CombinatorialElement*

Integer compositions.

A composition of a nonnegative integer n is a list $(i_1, \ldots, i_k)$ of positive integers with total sum n.

EXAMPLES:

The simplest way to create a composition is by specifying its entries as a list, tuple (or other iterable):

```
sage: Composition([3,1,2])
[3, 1, 2]
sage: Composition((3,1,2))
[3, 1, 2]
sage: Composition(i for i in range(2,5))
[2, 3, 4]
```

```
>>> from sage.all import *
>>> Composition([Integer(3),Integer(1),Integer(2)])
[3, 1, 2]
>>> Composition((Integer(3),Integer(1),Integer(2)))
[3, 1, 2]
>>> Composition(i for i in range(Integer(2),Integer(5)))
[2, 3, 4]
```

You can also create a composition from its code. The *code* of a composition $(i_1, i_2, \ldots, i_k)$ of n is a list of length n that consists of a 1 followed by $i_1 - 1$ zeros, then a 1 followed by $i_2 - 1$ zeros, and so on.

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Composition(code=_)
[4, 1, 2, 3, 5]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Composition(code=_)
[3, 1, 2, 3, 5]
```

```
>>> from sage.all import *
>>> Composition([Integer(4),Integer(1),Integer(2),Integer(3),Integer(5)]).to_
↪code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
```

(continues on next page)

(continued from previous page)

```
>>> Composition(code=_)
[4, 1, 2, 3, 5]
>>> Composition([Integer(3),Integer(1),Integer(2),Integer(3),Integer(5)]).to_
↪code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
>>> Composition(code=_)
[3, 1, 2, 3, 5]
```

You can also create the composition of n corresponding to a subset of $\{1, 2, \ldots, n-1\}$ under the bijection that maps the composition $(i_1, i_2, \ldots, i_k)$ of n to the subset $\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + \cdots + i_{k-1}\}$ (see `to_subset()`):

```
sage: Composition(from_subset=({1, 2, 4}, 5))
[1, 1, 2, 1]
sage: Composition([1, 1, 2, 1]).to_subset()
{1, 2, 4}
```

```
>>> from sage.all import *
>>> Composition(from_subset=({Integer(1), Integer(2), Integer(4)}, Integer(5)))
[1, 1, 2, 1]
>>> Composition([Integer(1), Integer(1), Integer(2), Integer(1)]).to_subset()
{1, 2, 4}
```

The following notation equivalently specifies the composition from the set $\{i_1 - 1, i_1 + i_2 - 1, i_1 + i_2 + i_3 - 1, \ldots, i_1 + \cdots + i_{k-1} - 1, n - 1\}$ or $\{i_1 - 1, i_1 + i_2 - 1, i_1 + i_2 + i_3 - 1, \ldots, i_1 + \cdots + i_{k-1} - 1\}$ and n. This provides compatibility with Python's 0-indexing.

```
sage: Composition(descents=[1,0,4,8,11])
[1, 1, 3, 4, 3]
sage: Composition(descents=[0,1,3,4])
[1, 1, 2, 1]
sage: Composition(descents=([0,1,3],5))
[1, 1, 2, 1]
sage: Composition(descents=({0,1,3},5))
[1, 1, 2, 1]
```

```
>>> from sage.all import *
>>> Composition(descents=[Integer(1),Integer(0),Integer(4),Integer(8),
↪Integer(11)])
[1, 1, 3, 4, 3]
>>> Composition(descents=[Integer(0),Integer(1),Integer(3),Integer(4)])
[1, 1, 2, 1]
>>> Composition(descents=([Integer(0),Integer(1),Integer(3)],Integer(5)))
[1, 1, 2, 1]
>>> Composition(descents=({Integer(0),Integer(1),Integer(3)},Integer(5)))
[1, 1, 2, 1]
```

An integer composition may be regarded as a sequence. Thus it is an instance of the Python abstract base class `Sequence` allows us to check if objects behave "like" sequences based on implemented methods. Note that `collections.abc.Sequence` is not the same as `sage.structure.sequence.Sequence()`:

```
sage: import collections.abc
sage: C = Composition([3,2,3])
sage: isinstance(C, collections.abc.Sequence)
True
sage: issubclass(C.__class__, collections.abc.Sequence)
True
```

```
>>> from sage.all import *
>>> import collections.abc
>>> C = Composition([Integer(3),Integer(2),Integer(3)])
>>> isinstance(C, collections.abc.Sequence)
True
>>> issubclass(C.__class__, collections.abc.Sequence)
True
```

Typically, instances of `collections.abc.Sequence` have a `.count` method. `Composition.count` counts the number of parts of a specified size:

```
sage: C.count(3)
2
```

```
>>> from sage.all import *
>>> C.count(Integer(3))
2
```

EXAMPLES:

```
sage: C = Composition([3,1,2])
sage: TestSuite(C).run()
```

```
>>> from sage.all import *
>>> C = Composition([Integer(3),Integer(1),Integer(2)])
>>> TestSuite(C).run()
```

complement()

Return the complement of the composition `self`.

The complement of a composition I is defined as follows:

If I is the empty composition, then the complement is the empty composition as well. Otherwise, let S be the descent set of I (that is, the subset $\{i_1, i_1 + i_2, \ldots, i_1 + i_2 + \cdots + i_{k-1}\}$ of $\{1, 2, \ldots, |I| - 1\}$, where I is written as $(i_1, i_2, \ldots, i_k)$). Then, the complement of I is defined as the composition of size $|I|$ whose descent set is $\{1, 2, \ldots, |I| - 1\} \setminus S$.

The complement of a composition I also is the reverse composition (*reversed()*) of the conjugate (*conjugate()*) of I.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
sage: Composition([1, 1, 3, 1, 2, 1, 3]).complement()
[3, 1, 3, 3, 1, 1]
```

```
>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),␣
↪Integer(1), Integer(3)]).conjugate()
[1, 1, 3, 3, 1, 3]
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),␣
↪Integer(1), Integer(3)]).complement()
[3, 1, 3, 3, 1, 1]
```

conjugate()

Return the conjugate of the composition `self`.

The conjugate of a composition I is defined as the complement (see *complement()*) of the reverse composition (see *reversed()*) of I.

An equivalent definition of the conjugate goes by saying that the ribbon shape of the conjugate of a composition I is the conjugate of the ribbon shape of I. (The ribbon shape of a composition is returned by *to_skew_partition()*.)

This implementation uses the algorithm from mupad-combinat.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).conjugate()
[1, 1, 3, 3, 1, 3]
```

```
>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),␣
↪Integer(1), Integer(3)]).conjugate()
[1, 1, 3, 3, 1, 3]
```

The ribbon shape of the conjugate of I is the conjugate of the ribbon shape of I:

```
sage: all( I.conjugate().to_skew_partition()                                #␣
↪needs sage.combinat
....:      == I.to_skew_partition().conjugate()
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( I.conjugate().to_skew_partition()                                  #␣
↪needs sage.combinat
...       == I.to_skew_partition().conjugate()
...       for I in Compositions(Integer(4)) )
True
```

count(n)

Return the number of parts of size `n`.

EXAMPLES:

```
sage: C = Composition([3,2,3])
sage: C.count(3)
2
sage: C.count(2)
1
```

(continues on next page)

(continued from previous page)

```
sage: C.count(1)
0
```

```
>>> from sage.all import *
>>> C = Composition([Integer(3),Integer(2),Integer(3)])
>>> C.count(Integer(3))
2
>>> C.count(Integer(2))
1
>>> C.count(Integer(1))
0
```

descents(*final_descent=False*)

This gives one fewer than the partial sums of the composition.

This is here to maintain some sort of backward compatibility, even through the original implementation was broken (it gave the wrong answer). The same information can be found in *partial_sums()*.

See also

partial_sums()

INPUT:

- `final_descent` – boolean (default: `False`)

OUTPUT:

- the list of partial sums of `self` with each part decremented by 1. This includes the sum of all entries when `final_descent` is `True`.

EXAMPLES:

```
sage: c = Composition([2,1,3,2])
sage: c.descents()
[1, 2, 5]
sage: c.descents(final_descent=True)
[1, 2, 5, 7]
```

```
>>> from sage.all import *
>>> c = Composition([Integer(2),Integer(1),Integer(3),Integer(2)])
>>> c.descents()
[1, 2, 5]
>>> c.descents(final_descent=True)
[1, 2, 5, 7]
```

fatten(*grouping*)

Return the composition fatter than `self`, obtained by grouping together consecutive parts according to `grouping`.

INPUT:

- `grouping` – a composition whose sum is the length of `self`

EXAMPLES:

Let us start with the composition:

```
sage: c = Composition([4,5,2,7,1])
```

```
>>> from sage.all import *
>>> c = Composition([Integer(4),Integer(5),Integer(2),Integer(7),Integer(1)])
```

With `grouping` equal to $(1, \ldots, 1)$, c is left unchanged:

```
sage: c.fatten(Composition([1,1,1,1,1]))
[4, 5, 2, 7, 1]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1)]))
[4, 5, 2, 7, 1]
```

With `grouping` equal to (ℓ) where ℓ is the length of c, this yields the coarsest composition above c:

```
sage: c.fatten(Composition([5]))
[19]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(5)]))
[19]
```

Other values for `grouping` yield (all the) other compositions coarser than c:

```
sage: c.fatten(Composition([2,1,2]))
[9, 2, 8]
sage: c.fatten(Composition([3,1,1]))
[11, 7, 1]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(2),Integer(1),Integer(2)]))
[9, 2, 8]
>>> c.fatten(Composition([Integer(3),Integer(1),Integer(1)]))
[11, 7, 1]
```

fatter()

Return the set of compositions which are fatter than `self`.

Complexity for generation: $O(|c|)$ memory, $O(|r|)$ time where $|c|$ is the size of `self` and r is the result.

EXAMPLES:

```
sage: C = Composition([4,5,2]).fatter()
sage: C.cardinality()
4
sage: list(C)
[[4, 5, 2], [4, 7], [9, 2], [11]]
```

```
>>> from sage.all import *
>>> C = Composition([Integer(4),Integer(5),Integer(2)]).fatter()
>>> C.cardinality()
4
>>> list(C)
[[4, 5, 2], [4, 7], [9, 2], [11]]
```

Some extreme cases:

```
sage: list(Composition([5]).fatter())
[[5]]
sage: list(Composition([]).fatter())
[[]]
sage: list(Composition([1,1,1,1]).fatter()) == list(Compositions(4))
True
```

```
>>> from sage.all import *
>>> list(Composition([Integer(5)]).fatter())
[[5]]
>>> list(Composition([]).fatter())
[[]]
>>> list(Composition([Integer(1),Integer(1),Integer(1),Integer(1)]).fatter())␣
↪== list(Compositions(Integer(4)))
True
```

finer()

Return the set of compositions which are finer than `self`.

EXAMPLES:

```
sage: C = Composition([3,2]).finer()
sage: C.cardinality()
8
sage: C.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 2, 1, 1], [1, 2, 2], [2, 1, 1, 1], [2, 1,␣
↪2], [3, 1, 1], [3, 2]]

sage: Composition([]).finer()
{[]}
```

```
>>> from sage.all import *
>>> C = Composition([Integer(3),Integer(2)]).finer()
>>> C.cardinality()
8
>>> C.list()
[[1, 1, 1, 1, 1], [1, 1, 1, 2], [1, 2, 1, 1], [1, 2, 2], [2, 1, 1, 1], [2, 1,␣
↪2], [3, 1, 1], [3, 2]]

>>> Composition([]).finer()
{[]}
```

inf(*other*, *check=True*)

alias of *meet()*.

is_finer(*co2*)

Return `True` if the composition `self` is finer than the composition `co2`; otherwise, return `False`.

EXAMPLES:

```
sage: Composition([4,1,2]).is_finer([3,1,3])
False
sage: Composition([3,1,3]).is_finer([4,1,2])
False
sage: Composition([1,2,2,1,1,2]).is_finer([5,1,3])
True
sage: Composition([2,2,2]).is_finer([4,2])
True
```

```
>>> from sage.all import *
>>> Composition([Integer(4),Integer(1),Integer(2)]).is_finer([Integer(3),
↪Integer(1),Integer(3)])
False
>>> Composition([Integer(3),Integer(1),Integer(3)]).is_finer([Integer(4),
↪Integer(1),Integer(2)])
False
>>> Composition([Integer(1),Integer(2),Integer(2),Integer(1),Integer(1),
↪Integer(2)]).is_finer([Integer(5),Integer(1),Integer(3)])
True
>>> Composition([Integer(2),Integer(2),Integer(2)]).is_finer([Integer(4),
↪Integer(2)])
True
```

join(*other*, *check=True*)

Return the join of `self` with a composition `other` of the same size.

The join of two compositions I and J of size n is the coarsest composition of n which refines each of I and J. It can be described as the composition whose descent set is the union of the descent sets of I and J. It is also the concatenation of $I_1, I_2, \cdots, I_m$, where $I = I_1 \bullet I_2 \bullet \ldots \bullet I_m$ is the ribbon decomposition of I with respect to J (see *ribbon_decomposition()*).

INPUT:

- `other` – composition of same size as `self`
- `check` – boolean (default: `True`); whether to check the input compositions for having the same size

OUTPUT: the join of the compositions `self` and `other`

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).join([4, 3, 2])
[3, 1, 1, 2, 1, 1]
sage: Composition([9, 6]).join([1, 3, 6, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([9, 6]).join([1, 3, 5, 1, 3, 2])
[1, 3, 5, 1, 3, 2]
sage: Composition([1, 1, 1, 1, 1]).join([3, 2])
[1, 1, 1, 1, 1]
sage: Composition([4, 2]).join([3, 3])
[3, 1, 2]
```

(continues on next page)

(continued from previous page)

```
sage: Composition([]).join([])
[]
```

```
>>> from sage.all import *
>>> Composition([Integer(3), Integer(1), Integer(1), Integer(3), Integer(1)]).
↪join([Integer(4), Integer(3), Integer(2)])
[3, 1, 1, 2, 1, 1]
>>> Composition([Integer(9), Integer(6)]).join([Integer(1), Integer(3),␣
↪Integer(6), Integer(3), Integer(2)])
[1, 3, 5, 1, 3, 2]
>>> Composition([Integer(9), Integer(6)]).join([Integer(1), Integer(3),␣
↪Integer(5), Integer(1), Integer(3), Integer(2)])
[1, 3, 5, 1, 3, 2]
>>> Composition([Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)]).
↪join([Integer(3), Integer(2)])
[1, 1, 1, 1, 1]
>>> Composition([Integer(4), Integer(2)]).join([Integer(3), Integer(3)])
[3, 1, 2]
>>> Composition([]).join([])
[]
```

Let us verify on small examples that the join of I and J refines both of I and J:

```
sage: all( all( I.join(J).is_finer(I) and
....:           I.join(J).is_finer(J)
....:           for J in Compositions(4) )
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( all( I.join(J).is_finer(I) and
...           I.join(J).is_finer(J)
...           for J in Compositions(Integer(4)) )
...      for I in Compositions(Integer(4)) )
True
```

and is the coarsest composition to do so:

```
sage: all( all( all( K.is_finer(I.join(J))
....:                for K in I.finer()
....:                if K.is_finer(J) )
....:           for J in Compositions(3) )
....:      for I in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> all( all( all( K.is_finer(I.join(J))
...                for K in I.finer()
...                if K.is_finer(J) )
...           for J in Compositions(Integer(3)) )
...      for I in Compositions(Integer(3)) )
True
```

Let us check that the join of I and J is indeed the concatenation of $I_1, I_2, \cdots, I_m$, where $I = I_1 \bullet I_2 \bullet \ldots \bullet I_m$ is the ribbon decomposition of I with respect to J:

```
sage: all( all( Composition.sum(I.ribbon_decomposition(J)[0])
....:           == I.join(J) for J in Compositions(4) )
....:       for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( all( Composition.sum(I.ribbon_decomposition(J)[Integer(0)])
...            == I.join(J) for J in Compositions(Integer(4)) )
...       for I in Compositions(Integer(4)) )
True
```

Also, the descent set of the join of I and J is the union of the descent sets of I and J:

```
sage: all( all( I.to_subset().union(J.to_subset())
....:           == I.join(J).to_subset()
....:           for J in Compositions(4) )
....:       for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( all( I.to_subset().union(J.to_subset())
...           == I.join(J).to_subset()
...           for J in Compositions(Integer(4)) )
...       for I in Compositions(Integer(4)) )
True
```

See also

meet(), *ribbon_decomposition()*

AUTHORS:

- Darij Grinberg (2013-09-05)

major_index()

Return the major index of `self`. The major index is defined as the sum of the descents.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).major_index()
31
```

```
>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),␣
↪Integer(1), Integer(3)]).major_index()
31
```

meet(*other*, *check=True*)

Return the meet of `self` with a composition `other` of the same size.

The meet of two compositions I and J of size n is the finest composition of n which is coarser than each of I and J. It can be described as the composition whose descent set is the intersection of the descent sets of I and J.

INPUT:

- `other` – composition of same size as `self`
- `check` – boolean (default: `True`); whether to check the input compositions for having the same size

OUTPUT: the meet of the compositions `self` and `other`

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).meet([4, 3, 2])
[4, 5]
sage: Composition([9, 6]).meet([1, 3, 6, 3, 2])
[15]
sage: Composition([9, 6]).meet([1, 3, 5, 1, 3, 2])
[9, 6]
sage: Composition([1, 1, 1, 1, 1]).meet([3, 2])
[3, 2]
sage: Composition([4, 2]).meet([3, 3])
[6]
sage: Composition([]).meet([])
[]
sage: Composition([1]).meet([1])
[1]
```

```
>>> from sage.all import *
>>> Composition([Integer(3), Integer(1), Integer(1), Integer(3), Integer(1)]).
↪meet([Integer(4), Integer(3), Integer(2)])
[4, 5]
>>> Composition([Integer(9), Integer(6)]).meet([Integer(1), Integer(3),␣
↪Integer(6), Integer(3), Integer(2)])
[15]
>>> Composition([Integer(9), Integer(6)]).meet([Integer(1), Integer(3),␣
↪Integer(5), Integer(1), Integer(3), Integer(2)])
[9, 6]
>>> Composition([Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)]).
↪meet([Integer(3), Integer(2)])
[3, 2]
>>> Composition([Integer(4), Integer(2)]).meet([Integer(3), Integer(3)])
[6]
>>> Composition([]).meet([])
[]
>>> Composition([Integer(1)]).meet([Integer(1)])
[1]
```

Let us verify on small examples that the meet of I and J is coarser than both of I and J:

```
sage: all( all( I.is_finer(I.meet(J)) and
....:           J.is_finer(I.meet(J))
....:           for J in Compositions(4) )
....:      for I in Compositions(4) )
True
```

```
>>> from sage.all import *
>>> all( all( I.is_finer(I.meet(J)) and
...           J.is_finer(I.meet(J))
...           for J in Compositions(Integer(4)) )
...      for I in Compositions(Integer(4)) )
True
```

and is the finest composition to do so:

```
sage: all( all( all( I.meet(J).is_finer(K)
....:                for K in I.fatter()
....:                if J.is_finer(K) )
....:           for J in Compositions(3) )
....:      for I in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> all( all( all( I.meet(J).is_finer(K)
...                for K in I.fatter()
...                if J.is_finer(K) )
...           for J in Compositions(Integer(3)) )
...      for I in Compositions(Integer(3)) )
True
```

The descent set of the meet of I and J is the intersection of the descent sets of I and J:

```
sage: def test_meet(n):
....:     return all( all( I.to_subset().intersection(J.to_subset())
....:                      == I.meet(J).to_subset()
....:                      for J in Compositions(n) )
....:                 for I in Compositions(n) )
sage: all( test_meet(n) for n in range(1, 5) )
True
```

```
>>> from sage.all import *
>>> def test_meet(n):
...     return all( all( I.to_subset().intersection(J.to_subset())
...                      == I.meet(J).to_subset()
...                      for J in Compositions(n) )
...                 for I in Compositions(n) )
>>> all( test_meet(n) for n in range(Integer(1), Integer(5)) )
True
```

join()

AUTHORS:

- Darij Grinberg (2013-09-05)

near_concatenation(*other*)

Return the near-concatenation of two nonempty compositions `self` and `other`.

The near-concatenation $I \odot J$ of two nonempty compositions I and J is defined as the composition $(i_1, i_2, \ldots, i_{n-1}, i_n + j_1, j_2, j_3, \ldots, j_m)$, where $(i_1, i_2, \ldots, i_n) = I$ and $(j_1, j_2, \ldots, j_m) = J$.

This method returns `None` if one of the two input compositions is empty.

EXAMPLES:

```
sage: Composition([1, 1, 3]).near_concatenation(Composition([4, 1, 2]))
[1, 1, 7, 1, 2]
sage: Composition([6]).near_concatenation(Composition([1, 5]))
[7, 5]
sage: Composition([1, 5]).near_concatenation(Composition([6]))
[1, 11]
```

```
>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3)]).near_
↪concatenation(Composition([Integer(4), Integer(1), Integer(2)]))
[1, 1, 7, 1, 2]
>>> Composition([Integer(6)]).near_concatenation(Composition([Integer(1),␣
↪Integer(5)]))
[7, 5]
>>> Composition([Integer(1), Integer(5)]).near_
↪concatenation(Composition([Integer(6)]))
[1, 11]
```

partial_sums(*final=True*)

The partial sums of the sequence defined by the entries of the composition.

If $I = (i_1, \ldots, i_m)$ is a composition, then the partial sums of the entries of the composition are $[i_1, i_1 + i_2, \ldots, i_1 + i_2 + \cdots + i_m]$.

INPUT:

- `final` – boolean (default: `True`); whether or not to include the final partial sum, which is always the size of the composition

See also

to_subset()

EXAMPLES:

```
sage: Composition([1,1,3,1,2,1,3]).partial_sums()
[1, 2, 5, 6, 8, 9, 12]
```

```
>>> from sage.all import *
>>> Composition([Integer(1),Integer(1),Integer(3),Integer(1),Integer(2),
↪Integer(1),Integer(3)]).partial_sums()
[1, 2, 5, 6, 8, 9, 12]
```

With `final = False`, the last partial sum is not included:

```
sage: Composition([1,1,3,1,2,1,3]).partial_sums(final=False)
[1, 2, 5, 6, 8, 9]
```

```
>>> from sage.all import *
>>> Composition([Integer(1),Integer(1),Integer(3),Integer(1),Integer(2),
↪Integer(1),Integer(3)]).partial_sums(final=False)
[1, 2, 5, 6, 8, 9]
```

peaks()

Return a list of the peaks of the composition `self`.

The peaks of a composition are the descents which do not immediately follow another descent.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).peaks()
[4, 7]
```

```
>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),␣
↪Integer(1), Integer(3)]).peaks()
[4, 7]
```

refinement_splitting(J)

Return the refinement splitting of `self` according to `J`.

INPUT:

- `J` – a composition such that `self` is finer than `J`

OUTPUT:

- the unique list of compositions $(I^{(p)})_{p=1,\dots,m}$, obtained by splitting I, such that $|I^{(p)}| = J_p$ for all $p = 1, \dots, m$.

See also

refinement_splitting_lengths()

EXAMPLES:

```
sage: Composition([1,2,2,1,1,2]).refinement_splitting([5,1,3])
[[1, 2, 2], [1], [1, 2]]
sage: Composition([]).refinement_splitting([])
[]
sage: Composition([3]).refinement_splitting([2])
Traceback (most recent call last):
...
ValueError: compositions self (= [3]) and J (= [2]) must be of the same size
sage: Composition([2,1]).refinement_splitting([1,2])
Traceback (most recent call last):
...
ValueError: composition J (= [2, 1]) does not refine self (= [1, 2])
```

```
>>> from sage.all import *
>>> Composition([Integer(1),Integer(2),Integer(2),Integer(1),Integer(1),
↪Integer(2)]).refinement_splitting([Integer(5),Integer(1),Integer(3)])
```

(continues on next page)

(continued from previous page)

```
[[1, 2, 2], [1], [1, 2]]
>>> Composition([]).refinement_splitting([])
[]
>>> Composition([Integer(3)]).refinement_splitting([Integer(2)])
Traceback (most recent call last):
...
ValueError: compositions self (= [3]) and J (= [2]) must be of the same size
>>> Composition([Integer(2),Integer(1)]).refinement_splitting([Integer(1),
↪Integer(2)])
Traceback (most recent call last):
...
ValueError: composition J (= [2, 1]) does not refine self (= [1, 2])
```

refinement_splitting_lengths(*J*)

Return the lengths of the compositions in the refinement splitting of `self` according to `J`.

See also

refinement_splitting() for the definition of refinement splitting

EXAMPLES:

```
sage: Composition([1,2,2,1,1,2]).refinement_splitting_lengths([5,1,3])
[3, 1, 2]
sage: Composition([]).refinement_splitting_lengths([])
[]
sage: Composition([3]).refinement_splitting_lengths([2])
Traceback (most recent call last):
...
ValueError: compositions self (= [3]) and J (= [2]) must be of the same size
sage: Composition([2,1]).refinement_splitting_lengths([1,2])
Traceback (most recent call last):
...
ValueError: composition J (= [2, 1]) does not refine self (= [1, 2])
```

```
>>> from sage.all import *
>>> Composition([Integer(1),Integer(2),Integer(2),Integer(1),Integer(1),
↪Integer(2)]).refinement_splitting_lengths([Integer(5),Integer(1),
↪Integer(3)])
[3, 1, 2]
>>> Composition([]).refinement_splitting_lengths([])
[]
>>> Composition([Integer(3)]).refinement_splitting_lengths([Integer(2)])
Traceback (most recent call last):
...
ValueError: compositions self (= [3]) and J (= [2]) must be of the same size
>>> Composition([Integer(2),Integer(1)]).refinement_splitting_
↪lengths([Integer(1),Integer(2)])
Traceback (most recent call last):
...
ValueError: composition J (= [2, 1]) does not refine self (= [1, 2])
```

reversed()

Return the reverse composition of `self`.

The reverse composition of a composition $(i_1, i_2, \ldots, i_k)$ is defined as the composition $(i_k, i_{k-1}, \ldots, i_1)$.

EXAMPLES:

```
sage: Composition([1, 1, 3, 1, 2, 1, 3]).reversed()
[3, 1, 2, 1, 3, 1, 1]
```

```
>>> from sage.all import *
>>> Composition([Integer(1), Integer(1), Integer(3), Integer(1), Integer(2),␣
↪Integer(1), Integer(3)]).reversed()
[3, 1, 2, 1, 3, 1, 1]
```

ribbon_decomposition(*other*, *check=True*)

Return a pair describing the ribbon decomposition of a composition `self` with respect to a composition `other` of the same size.

If I and J are two compositions of the same nonzero size, then the ribbon decomposition of I with respect to J is defined as follows: Write I and J as $I = (i_1, i_2, \ldots, i_n)$ and $J = (j_1, j_2, \ldots, j_m)$. Then, the equality $I = I_1 \bullet I_2 \bullet \ldots \bullet I_m$ holds for a unique m-tuple $(I_1, I_2, \ldots, I_m)$ of compositions such that each I_k has size j_k and for a unique choice of $m - 1$ signs $\bullet$ each of which is either the concatenation sign $\cdot$ or the near-concatenation sign $\odot$ (see `__add__` and *near_concatenation()* for the definitions of these two signs). This m-tuple and this choice of signs together are said to form the ribbon decomposition of I with respect to J. If I and J are empty, then the same definition applies, except that there are 0 rather than $m - 1$ signs.

See Section 4.8 of [NCSF1].

INPUT:

- `other` – composition of same size as `self`
- `check` – boolean (default: `True`); whether to check the input compositions for having the same size

OUTPUT:

- a pair `(u, v)`, where `u` is a tuple of compositions (corresponding to the m-tuple $(I_1, I_2, \ldots, I_m)$ in the above definition), and `v` is a tuple of 0`s and 1`s (encoding the choice of signs`$\bullet$ in the above definition, with a 0 standing for $\cdot$ and a 1 standing for $\odot$).

EXAMPLES:

```
sage: Composition([3, 1, 1, 3, 1]).ribbon_decomposition([4, 3, 2])
(([3, 1], [1, 2], [1, 1]), (0, 1))
sage: Composition([9, 6]).ribbon_decomposition([1, 3, 6, 3, 2])
(([1], [3], [5, 1], [3], [2]), (1, 1, 1, 1))
sage: Composition([9, 6]).ribbon_decomposition([1, 3, 5, 1, 3, 2])
(([1], [3], [5], [1], [3], [2]), (1, 1, 0, 1, 1))
sage: Composition([1, 1, 1, 1, 1]).ribbon_decomposition([3, 2])
(([1, 1, 1], [1, 1]), (0,))
sage: Composition([4, 2]).ribbon_decomposition([6])
(([4, 2],), ())
sage: Composition([]).ribbon_decomposition([])
((), ())
```

```
>>> from sage.all import *
>>> Composition([Integer(3), Integer(1), Integer(1), Integer(3), Integer(1)]).
↪ribbon_decomposition([Integer(4), Integer(3), Integer(2)])
(([3, 1], [1, 2], [1, 1]), (0, 1))
>>> Composition([Integer(9), Integer(6)]).ribbon_decomposition([Integer(1),␣
↪Integer(3), Integer(6), Integer(3), Integer(2)])
(([1], [3], [5, 1], [3], [2]), (1, 1, 1, 1))
>>> Composition([Integer(9), Integer(6)]).ribbon_decomposition([Integer(1),␣
↪Integer(3), Integer(5), Integer(1), Integer(3), Integer(2)])
(([1], [3], [5], [1], [3], [2]), (1, 1, 0, 1, 1))
>>> Composition([Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)]).
↪ribbon_decomposition([Integer(3), Integer(2)])
(([1, 1, 1], [1, 1]), (0,))
>>> Composition([Integer(4), Integer(2)]).ribbon_decomposition([Integer(6)])
(([4, 2],), ())
>>> Composition([]).ribbon_decomposition([])
((), ())
```

Let us check that the defining property $I = I_1 \bullet I_2 \bullet \ldots \bullet I_m$ is satisfied:

```
sage: def compose_back(u, v):
....:     comp = u[0]
....:     r = len(v)
....:     if len(u) != r + 1:
....:         raise ValueError("something is wrong")
....:     for i in range(r):
....:         if v[i] == 0:
....:             comp += u[i + 1]
....:         else:
....:             comp = comp.near_concatenation(u[i + 1])
....:     return comp
sage: all( all( all( compose_back(*(I.ribbon_decomposition(J))) == I
....:                for J in Compositions(n) )
....:           for I in Compositions(n) )
....:      for n in range(1, 5) )
True
```

```
>>> from sage.all import *
>>> def compose_back(u, v):
...     comp = u[Integer(0)]
...     r = len(v)
...     if len(u) != r + Integer(1):
...         raise ValueError("something is wrong")
...     for i in range(r):
...         if v[i] == Integer(0):
...             comp += u[i + Integer(1)]
...         else:
...             comp = comp.near_concatenation(u[i + Integer(1)])
...     return comp
>>> all( all( all( compose_back(*(I.ribbon_decomposition(J))) == I
...                for J in Compositions(n) )
...           for I in Compositions(n) )
...      for n in range(Integer(1), Integer(5)) )
```

(continues on next page)

(continued from previous page)

```
True
```

shuffle_product(*other*, *overlap=False*)

The (overlapping) shuffles of `self` and `other`.

Suppose $I = (i_1, \ldots, i_k)$ and $J = (j_1, \ldots, j_l)$ are two compositions. A *shuffle* of I and J is a composition of length $k + l$ that contains both I and J as subsequences.

More generally, an *overlapping shuffle* of I and J is obtained by distributing the elements of I and J (preserving the relative ordering of these elements) among the positions of an empty list; an element of I and an element of J are permitted to share the same position, in which case they are replaced by their sum. In particular, a shuffle of I and J is an overlapping shuffle of I and J.

INPUT:

- `other` – composition
- `overlap` – boolean (default: `False`); if `True`, the overlapping shuffle product is returned

OUTPUT:

An enumerated set (allowing for multiplicities)

EXAMPLES:

The shuffle product of $[2, 2]$ and $[1, 1, 3]$:

```
sage: alph = Composition([2,2])
sage: beta = Composition([1,1,3])
sage: S = alph.shuffle_product(beta); S                                    #␣
↪needs sage.combinat
Shuffle product of [2, 2] and [1, 1, 3]
sage: S.list()                                                             #␣
↪needs sage.combinat
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2],
 [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3],
 [1, 1, 2, 3, 2], [1, 1, 3, 2, 2]]
```

```
>>> from sage.all import *
>>> alph = Composition([Integer(2),Integer(2)])
>>> beta = Composition([Integer(1),Integer(1),Integer(3)])
>>> S = alph.shuffle_product(beta); S                                      #␣
↪needs sage.combinat
Shuffle product of [2, 2] and [1, 1, 3]
>>> S.list()                                                               #␣
↪needs sage.combinat
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2],
 [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3],
 [1, 1, 2, 3, 2], [1, 1, 3, 2, 2]]
```

The *overlapping* shuffle product of $[2, 2]$ and $[1, 1, 3]$:

```
sage: alph = Composition([2,2])
sage: beta = Composition([1,1,3])
sage: O = alph.shuffle_product(beta, overlap=True); O                          #␣
↪needs sage.combinat
Overlapping shuffle product of [2, 2] and [1, 1, 3]
sage: O.list()                                                                 #␣
↪needs sage.combinat
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2],
 [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3],
 [1, 1, 2, 3, 2], [1, 1, 3, 2, 2],
 [3, 2, 1, 3], [2, 3, 1, 3], [3, 1, 2, 3], [2, 1, 3, 3], [3, 1, 3, 2],
 [2, 1, 1, 5], [1, 3, 2, 3], [1, 2, 3, 3], [1, 3, 3, 2], [1, 2, 1, 5],
 [1, 1, 5, 2], [1, 1, 2, 5],
 [3, 3, 3], [3, 1, 5], [1, 3, 5]]
```

```
>>> from sage.all import *
>>> alph = Composition([Integer(2),Integer(2)])
>>> beta = Composition([Integer(1),Integer(1),Integer(3)])
>>> O = alph.shuffle_product(beta, overlap=True); O                            #␣
↪needs sage.combinat
Overlapping shuffle product of [2, 2] and [1, 1, 3]
>>> O.list()                                                                   #␣
↪needs sage.combinat
[[2, 2, 1, 1, 3], [2, 1, 2, 1, 3], [2, 1, 1, 2, 3], [2, 1, 1, 3, 2],
 [1, 2, 2, 1, 3], [1, 2, 1, 2, 3], [1, 2, 1, 3, 2], [1, 1, 2, 2, 3],
 [1, 1, 2, 3, 2], [1, 1, 3, 2, 2],
 [3, 2, 1, 3], [2, 3, 1, 3], [3, 1, 2, 3], [2, 1, 3, 3], [3, 1, 3, 2],
 [2, 1, 1, 5], [1, 3, 2, 3], [1, 2, 3, 3], [1, 3, 3, 2], [1, 2, 1, 5],
 [1, 1, 5, 2], [1, 1, 2, 5],
 [3, 3, 3], [3, 1, 5], [1, 3, 5]]
```

Note that the shuffle product of two compositions can include the same composition more than once since a composition can be a shuffle of two compositions in several ways. For example:

```
sage: # needs sage.combinat
sage: w1 = Composition([1])
sage: S = w1.shuffle_product(w1); S
Shuffle product of [1] and [1]
sage: S.list()
[[1, 1], [1, 1]]
sage: O = w1.shuffle_product(w1, overlap=True); O
Overlapping shuffle product of [1] and [1]
sage: O.list()
[[1, 1], [1, 1], [2]]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> w1 = Composition([Integer(1)])
>>> S = w1.shuffle_product(w1); S
Shuffle product of [1] and [1]
>>> S.list()
[[1, 1], [1, 1]]
```

(continues on next page)

(continued from previous page)

```
>>> O = w1.shuffle_product(w1, overlap=True); O
Overlapping shuffle product of [1] and [1]
>>> O.list()
[[1, 1], [1, 1], [2]]
```

size()

Return the size of `self`, that is the sum of its parts.

EXAMPLES:

```
sage: Composition([7,1,3]).size()
11
```

```
>>> from sage.all import *
>>> Composition([Integer(7),Integer(1),Integer(3)]).size()
11
```

specht_module(*base_ring=None*)

Return the Specht module corresponding to `self`.

EXAMPLES:

```
sage: SM = Composition([1,2,2]).specht_module(QQ); SM                          #␣
↪needs sage.combinat sage.modules
Specht module of [(0, 0), (1, 0), (1, 1), (2, 0), (2, 1)] over Rational Field
sage: s = SymmetricFunctions(QQ).s()                                           #␣
↪needs sage.combinat sage.modules
sage: s(SM.frobenius_image())                                                  #␣
↪needs sage.combinat sage.modules
s[2, 2, 1]
```

```
>>> from sage.all import *
>>> SM = Composition([Integer(1),Integer(2),Integer(2)]).specht_module(QQ);␣
↪SM                        # needs sage.combinat sage.modules
Specht module of [(0, 0), (1, 0), (1, 1), (2, 0), (2, 1)] over Rational Field
>>> s = SymmetricFunctions(QQ).s()                                             #␣
↪needs sage.combinat sage.modules
>>> s(SM.frobenius_image())                                                    #␣
↪needs sage.combinat sage.modules
s[2, 2, 1]
```

specht_module_dimension(*base_ring=None*)

Return the dimension of the Specht module corresponding to `self`.

INPUT:

- `base_ring` – (default: $\mathbf{Q}$) the base ring

EXAMPLES:

```
sage: Composition([1,2,2]).specht_module_dimension()                           #␣
↪needs sage.combinat sage.modules
5
sage: Composition([1,2,2]).specht_module_dimension(GF(2))                      #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat sage.modules sage.rings.finite_rings
5
```

```
>>> from sage.all import *
>>> Composition([Integer(1),Integer(2),Integer(2)]).specht_module_dimension()␣
↪                      # needs sage.combinat sage.modules
5
>>> Composition([Integer(1),Integer(2),Integer(2)]).specht_module_
↪dimension(GF(Integer(2)))                    # needs sage.combinat sage.
↪modules sage.rings.finite_rings
5
```

static sum(*compositions*)

Return the concatenation of the given compositions.

INPUT:

- `compositions` – list (or iterable) of compositions

EXAMPLES:

```
sage: Composition.sum([Composition([1, 1, 3]), Composition([4, 1, 2]),␣
↪Composition([3,1])])
[1, 1, 3, 4, 1, 2, 3, 1]
```

```
>>> from sage.all import *
>>> Composition.sum([Composition([Integer(1), Integer(1), Integer(3)]),␣
↪Composition([Integer(4), Integer(1), Integer(2)]), Composition([Integer(3),
↪Integer(1)])])
[1, 1, 3, 4, 1, 2, 3, 1]
```

Any iterable can be provided as input:

```
sage: Composition.sum([Composition([i,i]) for i in [4,1,3]])
[4, 4, 1, 1, 3, 3]
```

```
>>> from sage.all import *
>>> Composition.sum([Composition([i,i]) for i in [Integer(4),Integer(1),
↪Integer(3)]])
[4, 4, 1, 1, 3, 3]
```

Empty inputs are handled gracefully:

```
sage: Composition.sum([]) == Composition([])
True
```

```
>>> from sage.all import *
>>> Composition.sum([]) == Composition([])
True
```

sup(*other*, *check=True*)

alias of *join()*.

to_code()

Return the code of the composition `self`.

The code of a composition I is a list of length size(I) of 1s and 0s such that there is a 1 wherever a new part starts. (Exceptional case: When the composition is empty, the code is `[0]`.)

EXAMPLES:

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> Composition([Integer(4),Integer(1),Integer(2),Integer(3),Integer(5)]).to_
↪code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
```

to_partition()

Return the partition obtained by sorting `self` into decreasing order.

EXAMPLES:

```
sage: Composition([2,1,3]).to_partition()                                   #␣
↪needs sage.combinat
[3, 2, 1]
sage: Composition([4,2,2]).to_partition()                                   #␣
↪needs sage.combinat
[4, 2, 2]
sage: Composition([]).to_partition()                                        #␣
↪needs sage.combinat
[]
```

```
>>> from sage.all import *
>>> Composition([Integer(2),Integer(1),Integer(3)]).to_partition()          ␣
↪                        # needs sage.combinat
[3, 2, 1]
>>> Composition([Integer(4),Integer(2),Integer(2)]).to_partition()          ␣
↪                        # needs sage.combinat
[4, 2, 2]
>>> Composition([]).to_partition()                                         #␣
↪needs sage.combinat
[]
```

to_skew_partition(*overlap=1*)

Return the skew partition obtained from `self`.

This is a skew partition whose rows have the entries of `self` as their length, taken in reverse order (so the first entry of `self` is the length of the lowermost row, etc.). The parameter `overlap` indicates the number of cells on each row that are directly below cells of the previous row. When it is set to 1 (its default value), the result is the ribbon shape of `self`.

EXAMPLES:

```
sage: # needs sage.combinat
sage: Composition([3,4,1]).to_skew_partition()
[6, 6, 3] / [5, 2]
```

(continues on next page)

(continued from previous page)

```
sage: Composition([3,4,1]).to_skew_partition(overlap=0)
[8, 7, 3] / [7, 3]
sage: Composition([]).to_skew_partition()
[] / []
sage: Composition([1,2]).to_skew_partition()
[2, 1] / []
sage: Composition([2,1]).to_skew_partition()
[2, 2] / [1]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> Composition([Integer(3),Integer(4),Integer(1)]).to_skew_partition()
[6, 6, 3] / [5, 2]
>>> Composition([Integer(3),Integer(4),Integer(1)]).to_skew_
↪partition(overlap=Integer(0))
[8, 7, 3] / [7, 3]
>>> Composition([]).to_skew_partition()
[] / []
>>> Composition([Integer(1),Integer(2)]).to_skew_partition()
[2, 1] / []
>>> Composition([Integer(2),Integer(1)]).to_skew_partition()
[2, 2] / [1]
```

to_subset (*final=False*)

The subset corresponding to `self` under the bijection (see below) between compositions of n and subsets of $\{1, 2, \ldots, n-1\}$.

The bijection maps a composition $(i_1, \ldots, i_k)$ of n to $\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + \cdots + i_{k-1}\}$.

INPUT:

- `final` – boolean (default: `False`); whether or not to include the final partial sum, which is always the size of the composition

See also

partial_sums()

EXAMPLES:

```
sage: Composition([1,1,3,1,2,1,3]).to_subset()
{1, 2, 5, 6, 8, 9}
sage: for I in Compositions(3): print(I.to_subset())
{1, 2}
{1}
{2}
{}
```

```
>>> from sage.all import *
>>> Composition([Integer(1),Integer(1),Integer(3),Integer(1),Integer(2),
↪Integer(1),Integer(3)]).to_subset()
{1, 2, 5, 6, 8, 9}
```

(continues on next page)

(continued from previous page)

```
>>> for I in Compositions(Integer(3)): print(I.to_subset())
{1, 2}
{1}
{2}
{}
```

With `final=True`, the sum of all the elements of the composition is included in the subset:

```
sage: Composition([1,1,3,1,2,1,3]).to_subset(final=True)
{1, 2, 5, 6, 8, 9, 12}
```

```
>>> from sage.all import *
>>> Composition([Integer(1),Integer(1),Integer(3),Integer(1),Integer(2),
↪Integer(1),Integer(3)]).to_subset(final=True)
{1, 2, 5, 6, 8, 9, 12}
```

wll_gt(*co2*)

Return `True` if the composition `self` is greater than the composition `co2` with respect to the wll-ordering; otherwise, return `False`.

The wll-ordering is a total order on the set of all compositions defined as follows: A composition I is greater than a composition J if and only if one of the following conditions holds:

- The size of I is greater than the size of J.
- The size of I equals the size of J, but the length of I is greater than the length of J.
- The size of I equals the size of J, and the length of I equals the length of J, but I is lexicographically greater than J.

("wll-ordering" is short for "weight, length, lexicographic ordering".)

EXAMPLES:

```
sage: Composition([4,1,2]).wll_gt([3,1,3])
True
sage: Composition([7]).wll_gt([4,1,2])
False
sage: Composition([8]).wll_gt([4,1,2])
True
sage: Composition([3,2,2,2]).wll_gt([5,2])
True
sage: Composition([]).wll_gt([3])
False
sage: Composition([2,1]).wll_gt([2,1])
False
sage: Composition([2,2,2]).wll_gt([4,2])
True
sage: Composition([4,2]).wll_gt([2,2,2])
False
sage: Composition([1,1,2]).wll_gt([2,2])
True
sage: Composition([2,2]).wll_gt([1,3])
True
```

(continues on next page)

(continued from previous page)

```
sage: Composition([2,1,2]).wll_gt([])
True
```

```
>>> from sage.all import *
>>> Composition([Integer(4),Integer(1),Integer(2)]).wll_gt([Integer(3),
↪Integer(1),Integer(3)])
True
>>> Composition([Integer(7)]).wll_gt([Integer(4),Integer(1),Integer(2)])
False
>>> Composition([Integer(8)]).wll_gt([Integer(4),Integer(1),Integer(2)])
True
>>> Composition([Integer(3),Integer(2),Integer(2),Integer(2)]).wll_
↪gt([Integer(5),Integer(2)])
True
>>> Composition([]).wll_gt([Integer(3)])
False
>>> Composition([Integer(2),Integer(1)]).wll_gt([Integer(2),Integer(1)])
False
>>> Composition([Integer(2),Integer(2),Integer(2)]).wll_gt([Integer(4),
↪Integer(2)])
True
>>> Composition([Integer(4),Integer(2)]).wll_gt([Integer(2),Integer(2),
↪Integer(2)])
False
>>> Composition([Integer(1),Integer(1),Integer(2)]).wll_gt([Integer(2),
↪Integer(2)])
True
>>> Composition([Integer(2),Integer(2)]).wll_gt([Integer(1),Integer(3)])
True
>>> Composition([Integer(2),Integer(1),Integer(2)]).wll_gt([])
True
```

class sage.combinat.composition.**Compositions**(*is_infinite=False*, *category=None*)

Bases: UniqueRepresentation, Parent

Set of integer compositions.

A composition c of a nonnegative integer n is a list of positive integers with total sum n.

See also

- *Composition*
- *Partitions*
- *IntegerVectors*

EXAMPLES:

There are 8 compositions of 4:

```
sage: Compositions(4).cardinality()
8
```

```
>>> from sage.all import *
>>> Compositions(Integer(4)).cardinality()
8
```

Here is the list of them:

```
sage: Compositions(4).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4)).list()
[[1, 1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 3], [2, 1, 1], [2, 2], [3, 1], [4]]
```

You can use the `.first()` method to get the 'first' composition of a number:

```
sage: Compositions(4).first()
[1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4)).first()
[1, 1, 1, 1]
```

You can also calculate the 'next' composition given the current one:

```
sage: Compositions(4).next([1,1,2])
[1, 2, 1]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4)).next([Integer(1),Integer(1),Integer(2)])
[1, 2, 1]
```

If n is not specified, this returns the combinatorial class of all (nonnegative) integer compositions:

```
sage: Compositions()
Compositions of nonnegative integers
sage: [] in Compositions()
True
sage: [2,3,1] in Compositions()
True
sage: [-2,3,1] in Compositions()
False
```

```
>>> from sage.all import *
>>> Compositions()
Compositions of nonnegative integers
>>> [] in Compositions()
True
>>> [Integer(2),Integer(3),Integer(1)] in Compositions()
True
>>> [-Integer(2),Integer(3),Integer(1)] in Compositions()
False
```

If n is specified, it returns the class of compositions of n:

```
sage: Compositions(3)
Compositions of 3
sage: list(Compositions(3))
[[1, 1, 1], [1, 2], [2, 1], [3]]
sage: Compositions(3).cardinality()
4
```

```
>>> from sage.all import *
>>> Compositions(Integer(3))
Compositions of 3
>>> list(Compositions(Integer(3)))
[[1, 1, 1], [1, 2], [2, 1], [3]]
>>> Compositions(Integer(3)).cardinality()
4
```

The following examples show how to test whether or not an object is a composition:

```
sage: [3,4] in Compositions()
True
sage: [3,4] in Compositions(7)
True
sage: [3,4] in Compositions(5)
False
```

```
>>> from sage.all import *
>>> [Integer(3),Integer(4)] in Compositions()
True
>>> [Integer(3),Integer(4)] in Compositions(Integer(7))
True
>>> [Integer(3),Integer(4)] in Compositions(Integer(5))
False
```

Similarly, one can check whether or not an object is a composition which satisfies further constraints:

```
sage: [4,2] in Compositions(6, inner=[2,2])
True
sage: [4,2] in Compositions(6, inner=[2,3])
False
sage: [4,1] in Compositions(5, inner=[2,1], max_slope = 0)
True
```

```
>>> from sage.all import *
>>> [Integer(4),Integer(2)] in Compositions(Integer(6), inner=[Integer(2),
↪Integer(2)])
True
>>> [Integer(4),Integer(2)] in Compositions(Integer(6), inner=[Integer(2),
↪Integer(3)])
False
>>> [Integer(4),Integer(1)] in Compositions(Integer(5), inner=[Integer(2),
↪Integer(1)], max_slope = Integer(0))
True
```

An example with incompatible constraints:

```
sage: [4,2] in Compositions(6, inner=[2,2], min_part=3)
False
```

```
>>> from sage.all import *
>>> [Integer(4),Integer(2)] in Compositions(Integer(6), inner=[Integer(2),
↪Integer(2)], min_part=Integer(3))
False
```

The options `length`, `min_length`, and `max_length` can be used to set length constraints on the compositions. For example, the compositions of 4 of length equal to, at least, and at most 2 are given by:

```
sage: Compositions(4, length=2).list()
[[3, 1], [2, 2], [1, 3]]
sage: Compositions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
sage: Compositions(4, max_length=2).list()
[[4], [3, 1], [2, 2], [1, 3]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4), length=Integer(2)).list()
[[3, 1], [2, 2], [1, 3]]
>>> Compositions(Integer(4), min_length=Integer(2)).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
>>> Compositions(Integer(4), max_length=Integer(2)).list()
[[4], [3, 1], [2, 2], [1, 3]]
```

Setting both `min_length` and `max_length` to the same value is equivalent to setting `length` to this value:

```
sage: Compositions(4, min_length=2, max_length=2).list()
[[3, 1], [2, 2], [1, 3]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4), min_length=Integer(2), max_length=Integer(2)).list()
[[3, 1], [2, 2], [1, 3]]
```

The options `inner` and `outer` can be used to set part-by-part containment constraints. The list of compositions of 4 bounded above by `[3,1,2]` is given by:

```
sage: list(Compositions(4, outer=[3,1,2]))
[[3, 1], [2, 1, 1], [1, 1, 2]]
```

```
>>> from sage.all import *
>>> list(Compositions(Integer(4), outer=[Integer(3),Integer(1),Integer(2)]))
[[3, 1], [2, 1, 1], [1, 1, 2]]
```

`outer` sets `max_length` to the length of its argument. Moreover, the parts of `outer` may be infinite to clear the constraint on specific parts. This is the list of compositions of 4 of length at most 3 such that the first and third parts are at most 1:

```
sage: Compositions(4, outer=[1,oo,1]).list()
[[1, 3], [1, 2, 1]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4), outer=[Integer(1),oo,Integer(1)]).list()
[[1, 3], [1, 2, 1]]
```

This is the list of compositions of 4 bounded below by `[1,1,1]`:

```
sage: Compositions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4), inner=[Integer(1),Integer(1),Integer(1)]).list()
[[2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

The options `min_slope` and `max_slope` can be used to set constraints on the slope, that is the difference `p[i+1]-p[i]` of two consecutive parts. The following is the list of weakly increasing compositions of 4:

```
sage: Compositions(4, min_slope=0).list()
[[4], [2, 2], [1, 3], [1, 1, 2], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4), min_slope=Integer(0)).list()
[[4], [2, 2], [1, 3], [1, 1, 2], [1, 1, 1, 1]]
```

Here are the weakly decreasing ones:

```
sage: Compositions(4, max_slope=0).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4), max_slope=Integer(0)).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The following is the list of compositions of 4 such that two consecutive parts differ by at most one:

```
sage: Compositions(4, min_slope=-1, max_slope=1).list()
[[4], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(4), min_slope=-Integer(1), max_slope=Integer(1)).list()
[[4], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

The constraints can be combined together in all reasonable ways. This is the list of compositions of 5 of length between 2 and 4 such that the difference between consecutive parts is between -2 and 1:

```
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4).
↪list()
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2], [2, 1, 1, 1], [1, 2, 2], [1, 2,␣
↪1, 1], [1, 1, 2, 1], [1, 1, 1, 2]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(5), max_slope=Integer(1), min_slope=-Integer(2), min_
↪length=Integer(2), max_length=Integer(4)).list()
```

(continues on next page)

(continued from previous page)

```
[[3, 2], [3, 1, 1], [2, 3], [2, 2, 1], [2, 1, 2], [2, 1, 1, 1], [1, 2, 2], [1, 2,␣
↪1, 1], [1, 1, 2, 1], [1, 1, 1, 2]]
```

We can do the same thing with an outer constraint:

```
sage: Compositions(5, max_slope=1, min_slope=-2, min_length=2, max_length=4,␣
↪outer=[2,5,2]).list()
[[2, 3], [2, 2, 1], [2, 1, 2], [1, 2, 2]]
```

```
>>> from sage.all import *
>>> Compositions(Integer(5), max_slope=Integer(1), min_slope=-Integer(2), min_
↪length=Integer(2), max_length=Integer(4), outer=[Integer(2),Integer(5),
↪Integer(2)]).list()
[[2, 3], [2, 2, 1], [2, 1, 2], [1, 2, 2]]
```

However, providing incoherent constraints may yield strange results. It is up to the user to ensure that the inner and outer compositions themselves satisfy the parts and slope constraints.

Note that setting `min_part=0` is not allowed:

```
sage: Compositions(2, length=3, min_part=0)
Traceback (most recent call last):
...
ValueError: setting min_part=0 is not allowed for Compositions
```

```
>>> from sage.all import *
>>> Compositions(Integer(2), length=Integer(3), min_part=Integer(0))
Traceback (most recent call last):
...
ValueError: setting min_part=0 is not allowed for Compositions
```

Instead you must use `IntegerVectors`:

```
sage: list(IntegerVectors(2, 3))
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

```
>>> from sage.all import *
>>> list(IntegerVectors(Integer(2), Integer(3)))
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

The generation algorithm is constant amortized time, and handled by the generic tool *IntegerListsLex*.

Element

alias of *Composition*

from_code(*code*)

Return the composition from its code. The code of a composition I is a list of length size(I) consisting of 1s and 0s such that there is a 1 wherever a new part starts. (Exceptional case: When the composition is empty, the code is `[0]`.)

EXAMPLES:

```
sage: Composition([4,1,2,3,5]).to_code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Compositions().from_code(_)
[4, 1, 2, 3, 5]
sage: Composition([3,1,2,3,5]).to_code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
sage: Compositions().from_code(_)
[3, 1, 2, 3, 5]
```

```
>>> from sage.all import *
>>> Composition([Integer(4),Integer(1),Integer(2),Integer(3),Integer(5)]).to_
↪code()
[1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
>>> Compositions().from_code(_)
[4, 1, 2, 3, 5]
>>> Composition([Integer(3),Integer(1),Integer(2),Integer(3),Integer(5)]).to_
↪code()
[1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0]
>>> Compositions().from_code(_)
[3, 1, 2, 3, 5]
```

from_descents(*descents*, *nps=None*)

Return a composition from the list of descents.

INPUT:

- `descents` – an iterable
- `nps` – integer or `None` (default: `None`)

OUTPUT:

- The composition of `nps` whose descents are listed in `descents`, assuming that `nps` is not `None` (otherwise, the last element of `descents` is removed from `descents`, and `nps` is set to be this last element plus 1).

EXAMPLES:

```
sage: [x-1 for x in Composition([1, 1, 3, 4, 3]).to_subset()]
[0, 1, 4, 8]
sage: Compositions().from_descents([1,0,4,8],12)
[1, 1, 3, 4, 3]
sage: Compositions().from_descents([1,0,4,8,11])
[1, 1, 3, 4, 3]
```

```
>>> from sage.all import *
>>> [x-Integer(1) for x in Composition([Integer(1), Integer(1), Integer(3),␣
↪Integer(4), Integer(3)]).to_subset()]
[0, 1, 4, 8]
>>> Compositions().from_descents([Integer(1),Integer(0),Integer(4),
↪Integer(8)],Integer(12))
[1, 1, 3, 4, 3]
>>> Compositions().from_descents([Integer(1),Integer(0),Integer(4),Integer(8),
↪Integer(11)])
[1, 1, 3, 4, 3]
```

from_subset(*S*, *n*)

The composition of n corresponding to the subset `S` of $\{1, 2, \ldots, n-1\}$ under the bijection that maps the composition $(i_1, i_2, \ldots, i_k)$ of n to the subset $\{i_1, i_1+i_2, i_1+i_2+i_3, \ldots, i_1+\cdots+i_{k-1}\}$ (see *Composition.to_subset()*).

INPUT:

- `S` – an iterable, a subset of $\{1, 2, \ldots, n-1\}$
- `n` – integer

EXAMPLES:

```
sage: Compositions().from_subset([2,1,5,9], 12)
[1, 1, 3, 4, 3]
sage: Compositions().from_subset({2,1,5,9}, 12)
[1, 1, 3, 4, 3]

sage: Compositions().from_subset([], 12)
[12]
sage: Compositions().from_subset([], 0)
[]
```

```
>>> from sage.all import *
>>> Compositions().from_subset([Integer(2),Integer(1),Integer(5),Integer(9)],␣
↪Integer(12))
[1, 1, 3, 4, 3]
>>> Compositions().from_subset({Integer(2),Integer(1),Integer(5),Integer(9)},␣
↪Integer(12))
[1, 1, 3, 4, 3]

>>> Compositions().from_subset([], Integer(12))
[12]
>>> Compositions().from_subset([], Integer(0))
[]
```

class sage.combinat.composition.**Compositions_all**

Bases: *Compositions*

Class of all compositions.

subset(*size=None*)

Return the set of compositions of the given size.

EXAMPLES:

```
sage: C = Compositions()
sage: C.subset(4)
Compositions of 4
sage: C.subset(size=3)
Compositions of 3
```

```
>>> from sage.all import *
>>> C = Compositions()
>>> C.subset(Integer(4))
Compositions of 4
```

(continues on next page)

(continued from previous page)

```
>>> C.subset(size=Integer(3))
Compositions of 3
```

zero()

Return the zero of the additive monoid.

This is the empty composition.

EXAMPLES:

```
sage: C = Compositions()
sage: C.zero()
[]
```

```
>>> from sage.all import *
>>> C = Compositions()
>>> C.zero()
[]
```

class sage.combinat.composition.**Compositions_constraints**(**args*, ***kwds*)

Bases: *IntegerListsLex*

class sage.combinat.composition.**Compositions_n**(n)

Bases: *Compositions*

Class of compositions of a fixed n.

cardinality()

Return the number of compositions of n.

random_element()

Return a random `Composition` with uniform probability.

This method generates a random binary word starting with a 1 and then uses the bijection between compositions and their code.

EXAMPLES:

```
sage: Compositions(5).random_element() # random
[2, 1, 1, 1]
sage: Compositions(0).random_element()
[]
sage: Compositions(1).random_element()
[1]
```

```
>>> from sage.all import *
>>> Compositions(Integer(5)).random_element() # random
[2, 1, 1, 1]
>>> Compositions(Integer(0)).random_element()
[]
>>> Compositions(Integer(1)).random_element()
[1]
```

sage.combinat.composition.**composition_iterator_fast**(n)

Iterator over compositions of n yielded as lists.

Integer partitions

A partition p of a nonnegative integer n is a non-increasing list of positive integers (the *parts* of the partition) with total sum n.

A partition can be depicted by a diagram made of rows of cells, where the number of cells in the i-th row starting from the top is the i-th part of the partition.

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition $[5, 3, 1]$ are $[[0, 4], [1, 2], [2, 0]]$.

For display options, see `Partitions.options`.

Note

- Boxes is a synonym for cells. All methods will use 'cell' and 'cells' instead of 'box' and 'boxes'.
- Partitions are 0 based with coordinates in the form of (row-index, column-index).
- If given coordinates of the form `(r, c)`, then use Python's *-operator.
- Throughout this documentation, for a partition λ we will denote its conjugate partition by λ'. For more on conjugate partitions, see `Partition.conjugate()`.
- The comparisons on partitions use lexicographic order.

Note

We use the convention that lexicographic ordering is read from left-to-right. That is to say $[1, 3, 7]$ is smaller than $[2, 3, 4]$.

AUTHORS:

- Mike Hansen (2007): initial version
- Dan Drake (2009-03-28): deprecate RestrictedPartitions and implement Partitions_parts_in
- Travis Scrimshaw (2012-01-12): Implemented latex function to Partition_class
- Travis Scrimshaw (2012-05-09): Fixed Partitions(-1).list() infinite recursion loop by saying Partitions_n is the empty set.
- Travis Scrimshaw (2012-05-11): Fixed bug in inner where if the length was longer than the length of the inner partition, it would include 0's.
- Andrew Mathas (2012-06-01): Removed deprecated functions and added compatibility with the PartitionTuple classes. See Issue #13072
- Travis Scrimshaw (2012-10-12): Added options. Made `Partition_class` to the element `Partition`. `Partitions*` are now all in the category framework except `PartitionsRestricted` (which will eventually be removed). Cleaned up documentation.
- Matthew Lancellotti (2018-09-14): Added a bunch of "k" methods to Partition.

EXAMPLES:

There are 5 partitions of the integer 4:

```
sage: Partitions(4).cardinality()                                              #␣
↪needs sage.libs.flint
5
sage: Partitions(4).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).cardinality()                                       ␣
↪     # needs sage.libs.flint
5
>>> Partitions(Integer(4)).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

We can use the method `.first()` to get the 'first' partition of a number:

```
sage: Partitions(4).first()
[4]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).first()
[4]
```

Using the method `.next(p)`, we can calculate the 'next' partition after p. When we are at the last partition, `None` will be returned:

```
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) is None
True
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).next([Integer(4)])
[3, 1]
>>> Partitions(Integer(4)).next([Integer(1),Integer(1),Integer(1),Integer(1)]) is None
True
```

We can use `iter` to get an object which iterates over the partitions one by one to save memory. Note that when we do something like `for part in Partitions(4)` this iterator is used in the background:

```
sage: g = iter(Partitions(4))
sage: next(g)
[4]
sage: next(g)
[3, 1]
sage: next(g)
[2, 2]
sage: for p in Partitions(4): print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> g = iter(Partitions(Integer(4)))
>>> next(g)
[4]
>>> next(g)
[3, 1]
>>> next(g)
[2, 2]
>>> for p in Partitions(Integer(4)): print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
```

We can add constraints to the type of partitions we want. For example, to get all of the partitions of 4 of length 2, we'd do the following:

```
sage: Partitions(4, length=2).list()
[[3, 1], [2, 2]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), length=Integer(2)).list()
[[3, 1], [2, 2]]
```

Here is the list of partitions of length at least 2 and the list of ones with length at most 2:

```
sage: Partitions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: Partitions(4, max_length=2).list()
[[4], [3, 1], [2, 2]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), min_length=Integer(2)).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
>>> Partitions(Integer(4), max_length=Integer(2)).list()
[[4], [3, 1], [2, 2]]
```

The options `min_part` and `max_part` can be used to set constraints on the sizes of all parts. Using `max_part`, we can select partitions having only 'small' entries. The following is the list of the partitions of 4 with parts at most 2:

```
sage: Partitions(4, max_part=2).list()
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), max_part=Integer(2)).list()
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The `min_part` options is complementary to `max_part` and selects partitions having only 'large' parts. Here is the list of all partitions of 4 with each part at least 2:

```
sage: Partitions(4, min_part=2).list()
[[4], [2, 2]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), min_part=Integer(2)).list()
[[4], [2, 2]]
```

The options `inner` and `outer` can be used to set part-by-part constraints. This is the list of partitions of 4 with `[3, 1, 1]` as an outer bound (that is, partitions of 4 contained in the partition `[3, 1, 1]`):

```
sage: Partitions(4, outer=[3,1,1]).list()
[[3, 1], [2, 1, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), outer=[Integer(3),Integer(1),Integer(1)]).list()
[[3, 1], [2, 1, 1]]
```

`outer` sets `max_length` to the length of its argument. Moreover, the parts of `outer` may be infinite to clear constraints on specific parts. Here is the list of the partitions of 4 of length at most 3 such that the second and third part are 1 when they exist:

```
sage: Partitions(4, outer=[oo,1,1]).list()
[[4], [3, 1], [2, 1, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), outer=[oo,Integer(1),Integer(1)]).list()
[[4], [3, 1], [2, 1, 1]]
```

Finally, here are the partitions of 4 with `[1,1,1]` as an inner bound (i. e., the partitions of 4 containing the partition `[1,1,1]`). Note that `inner` sets `min_length` to the length of its argument, interpreted as a partition:

```
sage: Partitions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), inner=[Integer(1),Integer(1),Integer(1)]).list()
[[2, 1, 1], [1, 1, 1, 1]]
```

The options `min_slope` and `max_slope` can be used to set constraints on the slope, that is on the difference `p[i+1]-p[i]` of two consecutive parts. Here is the list of the strictly decreasing partitions of 4:

```
sage: Partitions(4, max_slope=-1).list()
[[4], [3, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), max_slope=-Integer(1)).list()
[[4], [3, 1]]
```

The constraints can be combined together in all reasonable ways. Here are all the partitions of 11 of length between 2 and 4 such that the difference between two consecutive parts is between -3 and -1:

```
sage: Partitions(11, min_slope=-3, max_slope=-1, min_length=2, max_length=4).list()
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(11), min_slope=-Integer(3), max_slope=-Integer(1), min_
↪length=Integer(2), max_length=Integer(4)).list()
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
```

Partition objects can also be created individually with *Partition*:

```
sage: Partition([2,1])
[2, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1)])
[2, 1]
```

Once we have a partition object, then there are a variety of methods that we can use. For example, we can get the conjugate of a partition. Geometrically, the conjugate of a partition is the reflection of that partition through its main diagonal. Of course, this operation is an involution:

```
sage: Partition([4,1]).conjugate()
[2, 1, 1, 1]
sage: Partition([4,1]).conjugate().conjugate()
[4, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(1)]).conjugate()
[2, 1, 1, 1]
>>> Partition([Integer(4),Integer(1)]).conjugate().conjugate()
[4, 1]
```

If we create a partition with extra zeros at the end, they will be dropped:

```
sage: Partition([4,1,0,0])
[4, 1]
sage: Partition([0])
[]
sage: Partition([0,0])
[]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(1),Integer(0),Integer(0)])
[4, 1]
>>> Partition([Integer(0)])
[]
>>> Partition([Integer(0),Integer(0)])
[]
```

The idea of a partition being followed by infinitely many parts of size 0 is consistent with the `get_part` method:

```
sage: p = Partition([5, 2])
sage: p.get_part(0)
5
sage: p.get_part(10)
0
```

```
>>> from sage.all import *
>>> p = Partition([Integer(5), Integer(2)])
>>> p.get_part(Integer(0))
5
>>> p.get_part(Integer(10))
0
```

We can go back and forth between the standard and the exponential notations of a partition. The exponential notation can be padded with extra zeros:

```
sage: Partition([6,4,4,2,1]).to_exp()
[1, 1, 0, 2, 0, 1]
sage: Partition(exp=[1,1,0,2,0,1])
[6, 4, 4, 2, 1]
sage: Partition([6,4,4,2,1]).to_exp(5)
[1, 1, 0, 2, 0, 1]
sage: Partition([6,4,4,2,1]).to_exp(7)
[1, 1, 0, 2, 0, 1, 0]
sage: Partition([6,4,4,2,1]).to_exp(10)
[1, 1, 0, 2, 0, 1, 0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> Partition([Integer(6),Integer(4),Integer(4),Integer(2),Integer(1)]).to_exp()
[1, 1, 0, 2, 0, 1]
>>> Partition(exp=[Integer(1),Integer(1),Integer(0),Integer(2),Integer(0),Integer(1)])
[6, 4, 4, 2, 1]
>>> Partition([Integer(6),Integer(4),Integer(4),Integer(2),Integer(1)]).to_
↪exp(Integer(5))
[1, 1, 0, 2, 0, 1]
>>> Partition([Integer(6),Integer(4),Integer(4),Integer(2),Integer(1)]).to_
↪exp(Integer(7))
[1, 1, 0, 2, 0, 1, 0]
>>> Partition([Integer(6),Integer(4),Integer(4),Integer(2),Integer(1)]).to_
↪exp(Integer(10))
[1, 1, 0, 2, 0, 1, 0, 0, 0, 0]
```

We can get the (zero-based!) coordinates of the corners of a partition:

```
sage: Partition([4,3,1]).corners()
[(0, 3), (1, 2), (2, 0)]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(1)]).corners()
[(0, 3), (1, 2), (2, 0)]
```

We can compute the core and quotient of a partition and build the partition back up from them:

```
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([7,7,5,3,3,3,1]).quotient(3)
([2], [1], [2, 2, 2])
sage: p = Partition([11,5,5,3,2,2,2])
sage: p.core(3)
```

(continues on next page)

(continued from previous page)

```
[]
sage: p.quotient(3)
([2, 1], [4], [1, 1, 1])
sage: Partition(core=[],quotient=([2, 1], [4], [1, 1, 1]))
[11, 5, 5, 3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> Partition([Integer(6),Integer(3),Integer(2),Integer(2)]).core(Integer(3))
[2, 1, 1]
>>> Partition([Integer(7),Integer(7),Integer(5),Integer(3),Integer(3),Integer(3),
↪Integer(1)]).quotient(Integer(3))
([2], [1], [2, 2, 2])
>>> p = Partition([Integer(11),Integer(5),Integer(5),Integer(3),Integer(2),Integer(2),
↪Integer(2)])
>>> p.core(Integer(3))
[]
>>> p.quotient(Integer(3))
([2, 1], [4], [1, 1, 1])
>>> Partition(core=[],quotient=([Integer(2), Integer(1)], [Integer(4)], [Integer(1),␣
↪Integer(1), Integer(1)]))
[11, 5, 5, 3, 2, 2, 2]
```

We can compute the $0-1$ sequence and go back and forth:

```
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
sage: all(Partitions().from_zero_one(mu.zero_one_sequence())
....:     == mu for n in range(5) for mu in Partitions(n))
True
```

```
>>> from sage.all import *
>>> Partitions().from_zero_one([Integer(1), Integer(1), Integer(1), Integer(1),␣
↪Integer(0), Integer(1), Integer(0)])
[5, 4]
>>> all(Partitions().from_zero_one(mu.zero_one_sequence())
...     == mu for n in range(Integer(5)) for mu in Partitions(n))
True
```

We can compute the Frobenius coordinates and go back and forth:

```
sage: Partition([7,3,1]).frobenius_coordinates()
([6, 1], [2, 0])
sage: Partition(frobenius_coordinates=([6,1],[2,0]))
[7, 3, 1]
sage: all(mu == Partition(frobenius_coordinates=mu.frobenius_coordinates())
....:     for n in range(12) for mu in Partitions(n))
True
```

```
>>> from sage.all import *
>>> Partition([Integer(7),Integer(3),Integer(1)]).frobenius_coordinates()
([6, 1], [2, 0])
>>> Partition(frobenius_coordinates=([Integer(6),Integer(1)],[Integer(2),Integer(0)]))
```

(continues on next page)

(continued from previous page)

```
[7, 3, 1]
>>> all(mu == Partition(frobenius_coordinates=mu.frobenius_coordinates())
...     for n in range(Integer(12)) for mu in Partitions(n))
True
```

We use the lexicographic ordering:

```
sage: pl = Partition([4,1,1])
sage: ql = Partitions()([3,3])
sage: pl > ql
True
sage: PL = Partitions()
sage: pl = PL([4,1,1])
sage: ql = PL([3,3])
sage: pl > ql
True
```

```
>>> from sage.all import *
>>> pl = Partition([Integer(4),Integer(1),Integer(1)])
>>> ql = Partitions()([Integer(3),Integer(3)])
>>> pl > ql
True
>>> PL = Partitions()
>>> pl = PL([Integer(4),Integer(1),Integer(1)])
>>> ql = PL([Integer(3),Integer(3)])
>>> pl > ql
True
```

class sage.combinat.partition.**OrderedPartitions**(n, k)

Bases: *Partitions*

The class of ordered partitions of n. If k is specified, then this contains only the ordered partitions of length k.

An *ordered partition* of a nonnegative integer n means a list of positive integers whose sum is n. This is the same as a composition of n.

Note

It is recommended that you use *Compositions()* instead as *OrderedPartitions()* wraps GAP.

EXAMPLES:

```
sage: OrderedPartitions(3)
Ordered partitions of 3
sage: OrderedPartitions(3).list()                                          #␣
↪needs sage.libs.gap
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2)
Ordered partitions of 3 of length 2
sage: OrderedPartitions(3,2).list()                                        #␣
↪needs sage.libs.gap
[[2, 1], [1, 2]]
```

(continues on next page)

(continued from previous page)

```
sage: OrderedPartitions(10, k=2).list()                                    #␣
↪needs sage.libs.gap
[[9, 1], [8, 2], [7, 3], [6, 4], [5, 5], [4, 6], [3, 7], [2, 8], [1, 9]]
sage: OrderedPartitions(4).list()                                          #␣
↪needs sage.libs.gap
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> OrderedPartitions(Integer(3))
Ordered partitions of 3
>>> OrderedPartitions(Integer(3)).list()                                   ␣
↪     # needs sage.libs.gap
[[3], [2, 1], [1, 2], [1, 1, 1]]
>>> OrderedPartitions(Integer(3),Integer(2))
Ordered partitions of 3 of length 2
>>> OrderedPartitions(Integer(3),Integer(2)).list()                        ␣
↪              # needs sage.libs.gap
[[2, 1], [1, 2]]

>>> OrderedPartitions(Integer(10), k=Integer(2)).list()                    ␣
↪              # needs sage.libs.gap
[[9, 1], [8, 2], [7, 3], [6, 4], [5, 5], [4, 6], [3, 7], [2, 8], [1, 9]]
>>> OrderedPartitions(Integer(4)).list()                                   ␣
↪     # needs sage.libs.gap
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: # needs sage.libs.gap
sage: OrderedPartitions(3).cardinality()
4
sage: OrderedPartitions(3,2).cardinality()
2
sage: OrderedPartitions(10,2).cardinality()
9
sage: OrderedPartitions(15).cardinality()
16384
```

```
>>> from sage.all import *
>>> # needs sage.libs.gap
>>> OrderedPartitions(Integer(3)).cardinality()
4
>>> OrderedPartitions(Integer(3),Integer(2)).cardinality()
2
>>> OrderedPartitions(Integer(10),Integer(2)).cardinality()
9
>>> OrderedPartitions(Integer(15)).cardinality()
16384
```

list()

Return a list of partitions in `self`.

EXAMPLES:

```
sage: OrderedPartitions(3).list()                                          #␣
↪needs sage.libs.gap
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2).list()                                        #␣
↪needs sage.libs.gap
[[2, 1], [1, 2]]
```

```
>>> from sage.all import *
>>> OrderedPartitions(Integer(3)).list()                                   ␣
↪     # needs sage.libs.gap
[[3], [2, 1], [1, 2], [1, 1, 1]]
>>> OrderedPartitions(Integer(3),Integer(2)).list()                        ␣
↪              # needs sage.libs.gap
[[2, 1], [1, 2]]
```

class sage.combinat.partition.**Partition**(*parent*, *mu*)

Bases: *CombinatorialElement*

A partition p of a nonnegative integer n is a non-increasing list of positive integers (the *parts* of the partition) with total sum n.

A partition is often represented as a diagram consisting of **cells**, or **boxes**, placed in rows on top of each other such that the number of cells in the i-th row, reading from top to bottom, is the i-th part of the partition. The rows are left-justified (and become shorter and shorter the farther down one goes). This diagram is called the **Young diagram** of the partition, or more precisely its Young diagram in English notation. (French and Russian notations are variations on this representation.)

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition `[5, 3, 1]` are `[[0,4], [1,2], [2,0]]`.

For display options, see *Partitions.options()*.

Note

Partitions are 0 based with coordinates in the form of (row-index, column-index). For example consider the partition `mu=Partition([4,3,2,2])`, the first part is `mu[0]` (which is 4), the second is `mu[1]`, and so on, and the upper-left cell in English convention is `(0, 0)`.

A partition can be specified in one of the following ways:

- a list (the default)
- using exponential notation
- by Frobenius coordinates
- specifying its $0-1$ sequence
- specifying the core and the quotient

See the examples below.

EXAMPLES:

Creating partitions though parents:

```
sage: mu = Partitions(8)([3,2,1,1,1]); mu
[3, 2, 1, 1, 1]
sage: nu = Partition([3,2,1,1,1]); nu
[3, 2, 1, 1, 1]
sage: mu == nu
True
sage: mu is nu
False
sage: mu in Partitions()
True
sage: mu.parent()
Partitions of the integer 8
sage: mu.size()
8
sage: mu.category()
Category of elements of Partitions of the integer 8
sage: nu.parent()
Partitions
sage: nu.category()
Category of elements of Partitions
sage: mu[0]
3
sage: mu[1]
2
sage: mu[2]
1
sage: mu.pp()
***

```

Creating partitions using `Partition`:

```
sage: Partition([3,2,1])
[3, 2, 1]
sage: Partition(exp=[2,1,1])
[3, 2, 1, 1]
sage: Partition(core=[2,1], quotient=[[2,1],[3],[1,1,1]])
```

(continues on next page)

(continued from previous page)

```
[11, 5, 5, 3, 2, 2, 2]
sage: Partition(frobenius_coordinates=([3,2],[4,0]))
[4, 4, 1, 1, 1]
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
sage: [2,1] in Partitions()
True
sage: [2,1,0] in Partitions()
True
sage: Partition([1,2,3])
Traceback (most recent call last):
...
ValueError: [1, 2, 3] is not an element of Partitions
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)])
[3, 2, 1]
>>> Partition(exp=[Integer(2),Integer(1),Integer(1)])
[3, 2, 1, 1]
>>> Partition(core=[Integer(2),Integer(1)], quotient=[[Integer(2),Integer(1)],
↪[Integer(3)],[Integer(1),Integer(1),Integer(1)]])
[11, 5, 5, 3, 2, 2, 2]
>>> Partition(frobenius_coordinates=([Integer(3),Integer(2)],[Integer(4),
↪Integer(0)]))
[4, 4, 1, 1, 1]
>>> Partitions().from_zero_one([Integer(1), Integer(1), Integer(1), Integer(1),␣
↪Integer(0), Integer(1), Integer(0)])
[5, 4]
>>> [Integer(2),Integer(1)] in Partitions()

>>> [Integer(2),Integer(1),Integer(0)] in Partitions()
True
>>> Partition([Integer(1),Integer(2),Integer(3)])
Traceback (most recent call last):
...
ValueError: [1, 2, 3] is not an element of Partitions
```

Sage ignores trailing zeros at the end of partitions:

```
sage: Partition([3,2,1,0])
[3, 2, 1]
sage: Partitions()([3,2,1,0])
[3, 2, 1]
sage: Partitions(6)([3,2,1,0])
[3, 2, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1),Integer(0)])
[3, 2, 1]
>>> Partitions()([Integer(3),Integer(2),Integer(1),Integer(0)])
[3, 2, 1]
>>> Partitions(Integer(6))([Integer(3),Integer(2),Integer(1),Integer(0)])
```

(continues on next page)

(continued from previous page)

```
[3, 2, 1]
```

add_cell(*i*, *j=None*)

Return a partition corresponding to `self` with a cell added in row `i`. (This does not change `self`.)

EXAMPLES:

```
sage: Partition([3, 2, 1, 1]).add_cell(0)
[4, 2, 1, 1]
sage: cell = [4, 0]; Partition([3, 2, 1, 1]).add_cell(*cell)
[3, 2, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(3), Integer(2), Integer(1), Integer(1)]).add_
↪cell(Integer(0))
[4, 2, 1, 1]
>>> cell = [Integer(4), Integer(0)]; Partition([Integer(3), Integer(2),␣
↪Integer(1), Integer(1)]).add_cell(*cell)
[3, 2, 1, 1, 1]
```

add_horizontal_border_strip(*k*)

Return a list of all the partitions that can be obtained by adding a horizontal border strip of length `k` to `self`.

EXAMPLES:

```
sage: Partition([]).add_horizontal_border_strip(0)
[[]]
sage: Partition([3,2,1]).add_horizontal_border_strip(0)
[[3, 2, 1]]
sage: Partition([]).add_horizontal_border_strip(2)
[[2]]
sage: Partition([2,2]).add_horizontal_border_strip(2)
[[4, 2], [3, 2, 1], [2, 2, 2]]
sage: Partition([3,2,2]).add_horizontal_border_strip(2)
[[5, 2, 2], [4, 3, 2], [4, 2, 2, 1], [3, 3, 2, 1], [3, 2, 2, 2]]
```

```
>>> from sage.all import *
>>> Partition([]).add_horizontal_border_strip(Integer(0))
[[]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).add_horizontal_border_
↪strip(Integer(0))
[[3, 2, 1]]
>>> Partition([]).add_horizontal_border_strip(Integer(2))
[[2]]
>>> Partition([Integer(2),Integer(2)]).add_horizontal_border_strip(Integer(2))
[[4, 2], [3, 2, 1], [2, 2, 2]]
>>> Partition([Integer(3),Integer(2),Integer(2)]).add_horizontal_border_
↪strip(Integer(2))
[[5, 2, 2], [4, 3, 2], [4, 2, 2, 1], [3, 3, 2, 1], [3, 2, 2, 2]]
```

add_vertical_border_strip(*k*)

Return a list of all the partitions that can be obtained by adding a vertical border strip of length `k` to `self`.

EXAMPLES:

```
sage: Partition([]).add_vertical_border_strip(0)
[[]]
sage: Partition([3,2,1]).add_vertical_border_strip(0)
[[3, 2, 1]]
sage: Partition([]).add_vertical_border_strip(2)
[[1, 1]]
sage: Partition([2,2]).add_vertical_border_strip(2)
[[3, 3], [3, 2, 1], [2, 2, 1, 1]]
sage: Partition([3,2,2]).add_vertical_border_strip(2)
[[4, 3, 2], [4, 2, 2, 1], [3, 3, 3], [3, 3, 2, 1], [3, 2, 2, 1, 1]]
```

```
>>> from sage.all import *
>>> Partition([]).add_vertical_border_strip(Integer(0))
[[]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).add_vertical_border_
↪strip(Integer(0))
[[3, 2, 1]]
>>> Partition([]).add_vertical_border_strip(Integer(2))
[[1, 1]]
>>> Partition([Integer(2),Integer(2)]).add_vertical_border_strip(Integer(2))
[[3, 3], [3, 2, 1], [2, 2, 1, 1]]
>>> Partition([Integer(3),Integer(2),Integer(2)]).add_vertical_border_
↪strip(Integer(2))
[[4, 3, 2], [4, 2, 2, 1], [3, 3, 3], [3, 3, 2, 1], [3, 2, 2, 1, 1]]
```

addable_cells()

alias of *outside_corners()*.

addable_cells_residue(i, l)

alias of *outside_corners_residue()*.

arm_cells(i, j)

Return the list of the cells of the arm of cell (i, j) in `self`.

The arm of cell $c = (i, j)$ is the boxes that appear to the right of c.

The cell coordinates are zero-based, i. e., the northwesternmost cell is $(0, 0)$.

INPUT:

- `i`, `j` – two integers

OUTPUT: list of pairs of integers

EXAMPLES:

```
sage: Partition([4,4,3,1]).arm_cells(1,1)
[(1, 2), (1, 3)]

sage: Partition([]).arm_cells(0,0)
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(4),Integer(3),Integer(1)]).arm_
```

(continues on next page)

(continued from previous page)

```
↪cells(Integer(1),Integer(1))
[(1, 2), (1, 3)]

>>> Partition([]).arm_cells(Integer(0),Integer(0))
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
```

arm_length(*i*, *j*)

Return the length of the arm of cell (i, j) in `self`.

The arm of cell (i, j) is the cells that appear to the right of cell (i, j).

The cell coordinates are zero-based, i. e., the northwesternmost cell is $(0, 0)$.

INPUT:

- `i`, `j` – two integers

OUTPUT: integer or a `ValueError`

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.arm_length(0, 0)
1
sage: p.arm_length(0, 1)
0
sage: p.arm_length(2, 0)
0
sage: Partition([3,3]).arm_length(0, 0)
2
sage: Partition([3,3]).arm_length(*[0,0])
2
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(2),Integer(1)])
>>> p.arm_length(Integer(0), Integer(0))
1
>>> p.arm_length(Integer(0), Integer(1))
0
>>> p.arm_length(Integer(2), Integer(0))
0
>>> Partition([Integer(3),Integer(3)]).arm_length(Integer(0), Integer(0))
2
>>> Partition([Integer(3),Integer(3)]).arm_length(*[Integer(0),Integer(0)])
2
```

arm_lengths(*flat=False*)

Return a tableau of shape `self` where each cell is filled with its arm length.

The optional boolean parameter `flat` provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).arm_lengths()
[[1, 0], [1, 0], [0]]
sage: Partition([2,2,1]).arm_lengths(flat=True)
[1, 0, 1, 0, 0]
sage: Partition([3,3]).arm_lengths()
[[2, 1, 0], [2, 1, 0]]
sage: Partition([3,3]).arm_lengths(flat=True)
[2, 1, 0, 2, 1, 0]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(1)]).arm_lengths()
[[1, 0], [1, 0], [0]]
>>> Partition([Integer(2),Integer(2),Integer(1)]).arm_lengths(flat=True)
[1, 0, 1, 0, 0]
>>> Partition([Integer(3),Integer(3)]).arm_lengths()
[[2, 1, 0], [2, 1, 0]]
>>> Partition([Integer(3),Integer(3)]).arm_lengths(flat=True)
[2, 1, 0, 2, 1, 0]
```

arms_legs_coeff(i, j)

This is a statistic on a cell $c = (i, j)$ in the diagram of partition p given by

$$\frac{1 - q^a \cdot t^{\ell+1}}{1 - q^{a+1} \cdot t^{\ell}}$$

where a is the arm length of c and ℓ is the leg length of c.

The coordinates `i` and `j` of the cell are understood to be 0-based, so that `(0, 0)` is the northwesternmost cell (in English notation).

EXAMPLES:

```
sage: Partition([3,2,1]).arms_legs_coeff(1,1)
(-t + 1)/(-q + 1)
sage: Partition([3,2,1]).arms_legs_coeff(0,0)
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
sage: Partition([3,2,1]).arms_legs_coeff(*[0,0])
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).arms_legs_coeff(Integer(1),
↪Integer(1))
(-t + 1)/(-q + 1)
>>> Partition([Integer(3),Integer(2),Integer(1)]).arms_legs_coeff(Integer(0),
↪Integer(0))
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
>>> Partition([Integer(3),Integer(2),Integer(1)]).arms_legs_
↪coeff(*[Integer(0),Integer(0)])
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
```

atom()

Return a list of the standard tableaux of size `self.size()` whose atom is equal to `self`.

EXAMPLES:

```
sage: Partition([2,1]).atom()
[[1, 2], [3]]
sage: Partition([3,2,1]).atom()
[[1, 2, 3, 6], [4, 5]], [[1, 2, 3], [4, 5], [6]]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1)]).atom()
[[1, 2], [3]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).atom()
[[1, 2, 3, 6], [4, 5]], [[1, 2, 3], [4, 5], [6]]
```

attacking_pairs()

Return a list of the attacking pairs of the Young diagram of `self`.

A pair of cells (c, d) of a Young diagram (in English notation) is said to be attacking if one of the following conditions holds:

1. c and d lie in the same row with c strictly to the west of d.
2. c is in the row immediately to the south of d, and c lies strictly east of d.

This particular method returns each pair (c, d) as a tuple, where each of c and d is given as a tuple (i, j) with i and j zero-based (so $i = 0$ means that the cell lies in the topmost row).

EXAMPLES:

```
sage: p = Partition([3, 2])
sage: p.attacking_pairs()
[((0, 0), (0, 1)),
 ((0, 0), (0, 2)),
 ((0, 1), (0, 2)),
 ((1, 0), (1, 1)),
 ((1, 1), (0, 0))]
sage: Partition([]).attacking_pairs()
[]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(3), Integer(2)])
>>> p.attacking_pairs()
[((0, 0), (0, 1)),
 ((0, 0), (0, 2)),
 ((0, 1), (0, 2)),
 ((1, 0), (1, 1)),
 ((1, 1), (0, 0))]
>>> Partition([]).attacking_pairs()
[]
```

aut(*t=0*, *q=0*)

alias of *centralizer_size()*.

beta_numbers(*length=None*)

Return the set of beta numbers corresponding to `self`.

The optional argument `length` specifies the length of the beta set (which must be at least the length of `self`).

For more on beta numbers, see *frobenius_coordinates()*.

EXAMPLES:

```
sage: Partition([4,3,2]).beta_numbers()
[6, 4, 2]
sage: Partition([4,3,2]).beta_numbers(5)
[8, 6, 4, 1, 0]
sage: Partition([]).beta_numbers()
[]
sage: Partition([]).beta_numbers(3)
[2, 1, 0]
sage: Partition([6,4,1,1]).beta_numbers()
[9, 6, 2, 1]
sage: Partition([6,4,1,1]).beta_numbers(6)
[11, 8, 4, 3, 1, 0]
sage: Partition([1,1,1]).beta_numbers()
[3, 2, 1]
sage: Partition([1,1,1]).beta_numbers(4)
[4, 3, 2, 0]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(2)]).beta_numbers()
[6, 4, 2]
>>> Partition([Integer(4),Integer(3),Integer(2)]).beta_numbers(Integer(5))
[8, 6, 4, 1, 0]
>>> Partition([]).beta_numbers()
[]
>>> Partition([]).beta_numbers(Integer(3))
[2, 1, 0]
>>> Partition([Integer(6),Integer(4),Integer(1),Integer(1)]).beta_numbers()
[9, 6, 2, 1]
>>> Partition([Integer(6),Integer(4),Integer(1),Integer(1)]).beta_
↪numbers(Integer(6))
[11, 8, 4, 3, 1, 0]
>>> Partition([Integer(1),Integer(1),Integer(1)]).beta_numbers()
[3, 2, 1]
>>> Partition([Integer(1),Integer(1),Integer(1)]).beta_numbers(Integer(4))
[4, 3, 2, 0]
```

block(*e*, *multicharge=(0,)*)

Return a dictionary β that determines the block associated to the partition `self` and the *quantum_characteristic()* `e`.

INPUT:

- `e` – the quantum characteristic
- `multicharge` – the multicharge (default: $(0,)$)

OUTPUT:

- A dictionary giving the multiplicities of the residues in the partition tuple `self`

In more detail, the value `beta[i]` is equal to the number of nodes of residue `i`. This corresponds to the positive root

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+,$$

a element of the positive root lattice of the corresponding Kac-Moody algebra. See [DJM1998] and [BK2009] for more details.

This is a useful statistics because two Specht modules for a Hecke algebra of type A belong to the same block if and only if they correspond to same element β of the root lattice, given above.

We return a dictionary because when the quantum characteristic is 0, the Cartan type is A_∞, in which case the simple roots are indexed by the integers.

EXAMPLES:

```
sage: Partition([4,3,2]).block(0)
{-2: 1, -1: 2, 0: 2, 1: 2, 2: 1, 3: 1}
sage: Partition([4,3,2]).block(2)
{0: 4, 1: 5}
sage: Partition([4,3,2]).block(2, multicharge=(1,))
{0: 5, 1: 4}
sage: Partition([4,3,2]).block(3)
{0: 3, 1: 3, 2: 3}
sage: Partition([4,3,2]).block(4)
{0: 2, 1: 2, 2: 2, 3: 3}
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(0))
{-2: 1, -1: 2, 0: 2, 1: 2, 2: 1, 3: 1}
>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(2))
{0: 4, 1: 5}
>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(2),␣
↪multicharge=(Integer(1),))
{0: 5, 1: 4}
>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(3))
{0: 3, 1: 3, 2: 3}
>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(4))
{0: 2, 1: 2, 2: 2, 3: 3}
```

boundary()

Return the integer coordinates of points on the boundary of `self`.

For the following description, picture the Ferrer's diagram of `self` using the French convention. Recall that the French convention puts the longest row on the bottom and the shortest row on the top. In addition, interpret the Ferrer's diagram as 1 x 1 cells in the Euclidean plane. So if `self` was the partition [3, 1], the lower-left vertices of the 1 x 1 cells in the Ferrer's diagram would be (0, 0), (1, 0), (2, 0), and (0, 1).

The boundary of a partition is the set $\{\text{NE}(d) \mid \forall d \text{ diagonal}\}$. That is, for every diagonal line $y = x + b$ where $b \in \mathbb{Z}$, we find the northeasternmost (NE) point on that diagonal which is also in the Ferrer's diagram.

The boundary will go from bottom-right to top-left.

EXAMPLES:

Consider the partition (1) depicted as a square on a cartesian plane with vertices (0, 0), (1, 0), (1, 1), and (0, 1). Three of those vertices in the appropriate order form the boundary:

```
sage: Partition([1]).boundary()
[(1, 0), (1, 1), (0, 1)]
```

```
>>> from sage.all import *
>>> Partition([Integer(1)]).boundary()
[(1, 0), (1, 1), (0, 1)]
```

The partition (3, 1) can be visualized as three squares on a cartesian plane. The coordinates of the appropriate vertices form the boundary:

```
sage: Partition([3, 1]).boundary()
[(3, 0), (3, 1), (2, 1), (1, 1), (1, 2), (0, 2)]
```

```
>>> from sage.all import *
>>> Partition([Integer(3), Integer(1)]).boundary()
[(3, 0), (3, 1), (2, 1), (1, 1), (1, 2), (0, 2)]
```

See also

k_rim(). You might have been looking for *k_boundary()* instead.

cell_poset(*orientation='SE'*)

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to `'SE'`). Concretely, `orientation` has to be specified to one of the strings `'NW'`, `'NE'`, `'SW'`, and `'SE'`, standing for "northwest", "northeast", "southwest" and "southeast", respectively. If `orientation` is `'SE'`, then the order relation of the poset is such that a cell u is greater or equal to a cell v in the poset if and only if u lies weakly southeast of v (this means that u can be reached from v by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of `self`, written as tuples of zero-based coordinates (so that $(3, 7)$ stands for the 8-th cell of the 4-th row, etc.).

EXAMPLES:

```
sage: # needs sage.graphs
sage: p = Partition([3,3,1])
sage: Q = p.cell_poset(); Q
Finite poset containing 7 elements
sage: sorted(Q)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: Q.minimal_elements()
[(0, 0)]
sage: sorted(Q.upper_covers((1, 0)))
[(1, 1), (2, 0)]
sage: Q.upper_covers((1, 1))
[(1, 2)]

sage: # needs sage.graphs
sage: P = p.cell_poset(orientation="NW"); P
```

(continues on next page)

(continued from previous page)

```
Finite poset containing 7 elements
sage: sorted(P)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: P.maximal_elements()
[(0, 0)]
sage: P.upper_covers((2, 0))
[(1, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]
sage: sorted(P.upper_covers((1, 1)))
[(0, 1), (1, 0)]
sage: sorted([len(P.upper_covers(v)) for v in P])
[0, 1, 1, 1, 1, 2, 2]

sage: # needs sage.graphs
sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 7 elements
sage: sorted(R)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()

[(0, 2)]
>>> R.minimal_elements()
[(2, 0)]
>>> sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1, 1, 2, 2]
>>> R.is_isomorphic(P)
False
>>> R.is_isomorphic(P.dual())
False
```

Linear extensions of `p.cell_poset()` are in 1-to-1 correspondence with standard Young tableaux of shape *p*:

```
sage: all( len(p.cell_poset().linear_extensions())                              #␣
↪needs sage.graphs
....:      == len(p.standard_tableaux())
....:      for n in range(8) for p in Partitions(n) )
True
```

```
>>> from sage.all import *
>>> all( len(p.cell_poset().linear_extensions())                                #␣
↪needs sage.graphs
...       == len(p.standard_tableaux())
...       for n in range(Integer(8)) for p in Partitions(n) )
True
```

This is not the case for northeast orientation:

```
sage: q = Partition([3, 1])
sage: q.cell_poset(orientation="NE").is_chain()                                 #␣
↪needs sage.graphs
True
```

```
>>> from sage.all import *
>>> q = Partition([Integer(3), Integer(1)])
>>> q.cell_poset(orientation="NE").is_chain()                                  #␣
↪needs sage.graphs
True
```

cells()

Return the coordinates of the cells of `self`.

EXAMPLES:

```
sage: Partition([2,2]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: Partition([3,2]).cells()
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1)]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
>>> Partition([Integer(3),Integer(2)]).cells()
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1)]
```

centralizer_size(*t=0*, *q=0*)

Return the size of the centralizer of any permutation of cycle type `self`.

If m_i is the multiplicity of i as a part of p, this is given by

$$\prod_i m_i! i^{m_i}.$$

Including the optional parameters t and q gives the q, t analog, which is the former product times

$$\prod_{i=1}^{\text{length}(p)} \frac{1-q^{p_i}}{1-t^{p_i}}.$$

See Section 1.3, p. 24, in [Ke1991].

EXAMPLES:

```
sage: Partition([2,2,1]).centralizer_size()
8
sage: Partition([2,2,2]).centralizer_size()
48
sage: Partition([2,2,1]).centralizer_size(q=2, t=3)
9/16
sage: Partition([]).centralizer_size()
1
sage: Partition([]).centralizer_size(q=2, t=4)
1
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(1)]).centralizer_size()
8
>>> Partition([Integer(2),Integer(2),Integer(2)]).centralizer_size()
```

(continues on next page)

(continued from previous page)

```
48
>>> Partition([Integer(2),Integer(2),Integer(1)]).centralizer_
↪size(q=Integer(2), t=Integer(3))
9/16
>>> Partition([]).centralizer_size()
1
>>> Partition([]).centralizer_size(q=Integer(2), t=Integer(4))
1
```

character_polynomial()

Return the character polynomial associated to the partition `self`.

The character polynomial q_μ associated to a partition μ is defined by

$$q_\mu(x_1, x_2, \ldots, x_k) = \downarrow \sum_{\alpha \vdash k} \frac{\chi^\mu_\alpha}{1^{a_1} 2^{a_2} \cdots k^{a_k} a_1! a_2! \cdots a_k!} \prod_{i=1}^{k} (i x_i - 1)^{a_i}$$

where k is the size of μ, and a_i is the multiplicity of i in α.

It is computed in the following manner:

1. Expand the Schur function s_μ in the power-sum basis,
2. Replace each p_i with $i x_i - 1$,
3. Apply the umbral operator $\downarrow$ to the resulting polynomial.

EXAMPLES:

```
sage: Partition([1]).character_polynomial()                                #␣
↪needs sage.modules
x - 1
sage: Partition([1,1]).character_polynomial()                              #␣
↪needs sage.modules
1/2*x0^2 - 3/2*x0 - x1 + 1
sage: Partition([2,1]).character_polynomial()                              #␣
↪needs sage.modules
1/3*x0^3 - 2*x0^2 + 8/3*x0 - x2
```

```
>>> from sage.all import *
>>> Partition([Integer(1)]).character_polynomial()                         ␣
↪     # needs sage.modules
x - 1
>>> Partition([Integer(1),Integer(1)]).character_polynomial()              ␣
↪              # needs sage.modules
1/2*x0^2 - 3/2*x0 - x1 + 1
>>> Partition([Integer(2),Integer(1)]).character_polynomial()              ␣
↪              # needs sage.modules
1/3*x0^3 - 2*x0^2 + 8/3*x0 - x2
```

components()

Return a list containing the shape of `self`.

This method exists only for compatibility with *PartitionTuples*.

EXAMPLES:

```
sage: Partition([3,2]).components()
[[3, 2]]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2)]).components()
[[3, 2]]
```

conjugacy_class_size()

Return the size of the conjugacy class of the symmetric group indexed by `self`.

EXAMPLES:

```
sage: Partition([2,2,2]).conjugacy_class_size()
15
sage: Partition([2,2,1]).conjugacy_class_size()
15
sage: Partition([2,1,1]).conjugacy_class_size()
6
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(2)]).conjugacy_class_size()
15
>>> Partition([Integer(2),Integer(2),Integer(1)]).conjugacy_class_size()
15
>>> Partition([Integer(2),Integer(1),Integer(1)]).conjugacy_class_size()
6
```

conjugate()

Return the conjugate partition of the partition `self`.

This is also called the associated partition or the transpose in the literature.

EXAMPLES:

```
sage: Partition([2,2]).conjugate()
[2, 2]
sage: Partition([6,3,1]).conjugate()
[3, 2, 2, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).conjugate()
[2, 2]
>>> Partition([Integer(6),Integer(3),Integer(1)]).conjugate()
[3, 2, 2, 1, 1, 1]
```

The conjugate partition is obtained by transposing the Ferrers diagram of the partition (see *ferrers_diagram()*):

```
sage: print(Partition([6,3,1]).ferrers_diagram())
******
***
*
sage: print(Partition([6,3,1]).conjugate().ferrers_diagram())
```

(continues on next page)

(continued from previous page)

```
***
**
**
*
*
*
```

```
>>> from sage.all import *
>>> print(Partition([Integer(6),Integer(3),Integer(1)]).ferrers_diagram())
******
***
*
>>> print(Partition([Integer(6),Integer(3),Integer(1)]).conjugate().ferrers_
↪diagram())
***
**
**
*
*
*
```

contains(x)

Return `True` if `x` is a partition whose Ferrers diagram is contained in the Ferrers diagram of `self`.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.contains([2,1])
True
sage: all(p.contains(mu) for mu in Partitions(3))
True
sage: all(p.contains(mu) for mu in Partitions(4))
False
```

```
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2),Integer(1)])
>>> p.contains([Integer(2),Integer(1)])
True
>>> all(p.contains(mu) for mu in Partitions(Integer(3)))
True
>>> all(p.contains(mu) for mu in Partitions(Integer(4)))
False
```

content(r, c, *multicharge=(0,)*)

Return the content of the cell at row r and column c.

The content of a cell is $c - r$.

For consistency with partition tuples there is also an optional `multicharge` argument which is an offset to the usual content. By setting the `multicharge` equal to the 0-element of the ring $\mathbf{Z}/e\mathbf{Z}$, the corresponding e-residue will be returned. This is the content modulo e.

The content (and residue) do not strictly depend on the partition, however, this method is included because it is often useful in the context of partitions.

EXAMPLES:

```
sage: Partition([2,1]).content(1,0)
-1
sage: p = Partition([3,2])
sage: sum([p.content(*c) for c in p.cells()])
2
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1)]).content(Integer(1),Integer(0))
-1
>>> p = Partition([Integer(3),Integer(2)])
>>> sum([p.content(*c) for c in p.cells()])
2
```

and now we return the 3-residue of a cell:

```
sage: Partition([2,1]).content(1,0, multicharge=[IntegerModRing(3)(0)])
2
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1)]).content(Integer(1),Integer(0),␣
↪multicharge=[IntegerModRing(Integer(3))(Integer(0))])
2
```

contents_tableau(*multicharge=(0,)*)

Return the tableau which has `(k,r,c)`-th cell equal to the content `multicharge[k] - r + c` of the cell.

EXAMPLES:

```
sage: Partition([2,1]).contents_tableau()
[[0, 1], [-1]]
sage: Partition([3,2,1,1]).contents_tableau().pp()
    0  1  2
    -1  0
    -2
    -3
sage: Partition([3,2,1,1]).contents_tableau([ IntegerModRing(3)(0)] ).pp()
    0  1  2
    2  0
    1
    0
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1)]).contents_tableau()
[[0, 1], [-1]]
>>> Partition([Integer(3),Integer(2),Integer(1),Integer(1)]).contents_
↪tableau().pp()
    0  1  2
    -1  0
    -2
    -3
>>> Partition([Integer(3),Integer(2),Integer(1),Integer(1)]).contents_
```

(continues on next page)

(continued from previous page)

```
↪tableau([ IntegerModRing(Integer(3))(Integer(0))] ).pp()
   0  1  2
   2  0
   1
   0
```

core(*length*)

Return the `length`-core of the partition – in the literature the core is commonly referred to as the k-core, p-core, r-core, ...

The r-core of a partition λ can be obtained by repeatedly removing rim hooks of size r from (the Young diagram of) λ until this is no longer possible. The remaining partition is the core.

EXAMPLES:

```
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([]).core(3)
[]
sage: Partition([8,7,7,4,1,1,1,1,1]).core(3)
[2, 1, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(6),Integer(3),Integer(2),Integer(2)]).core(Integer(3))
[2, 1, 1]
>>> Partition([]).core(Integer(3))
[]
>>> Partition([Integer(8),Integer(7),Integer(7),Integer(4),Integer(1),
↪Integer(1),Integer(1),Integer(1),Integer(1)]).core(Integer(3))
[2, 1, 1]
```

corners()

Return a list of the corners of the partition `self`.

A corner of a partition λ is a cell of the Young diagram of λ which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

Note

This is referred to as an "inner corner" in [Sag2001].

EXAMPLES:

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners()
[(0, 2), (1, 1), (2, 0)]
>>> Partition([Integer(3),Integer(3),Integer(1)]).corners()
[(1, 2), (2, 0)]
>>> Partition([]).corners()
[]
```

corners_residue(i, l)

Return a list of the corners of the partition `self` having `l`-residue `i`.

A corner of a partition λ is a cell of the Young diagram of λ which can be removed from the Young diagram while still leaving a straight shape behind. See *residue()* for the definition of the `l`-residue.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners_residue(Integer(0),␣
↪Integer(3))
[(1, 1)]
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners_residue(Integer(1),␣
↪Integer(3))
[(2, 0)]
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners_residue(Integer(2),␣
↪Integer(3))
[(0, 2)]
```

crank()

Return the Dyson crank of `self`.

The Dyson crank of a partition λ is defined as follows: If λ contains at least one 1, then the crank is $\mu(\lambda) - \omega(\lambda)$, where $\omega(\lambda)$ is the number of 1`$sin$`λ, and $\mu(\lambda)$ is the number of parts of λ larger than $\omega(\lambda)$. If λ contains no 1, then the crank is simply the largest part of λ.

REFERENCES:

- [AG1988]

EXAMPLES:

```
sage: Partition([]).crank()
0
sage: Partition([3,2,2]).crank()
3
sage: Partition([5,4,2,1,1]).crank()
0
```

↪Integer(1)]).crank()
-6
```

defect(*e*, *multicharge=(0,)*)

Return the `e`-defect or the `e`-weight of `self`.

The e-defect is the number of (connected) e-rim hooks that can be removed from the partition.

The defect of a partition is given by

$$\text{defect}(\beta) = (\Lambda, \beta) - \tfrac{1}{2}(\beta, \beta),$$

where $\Lambda = \sum_r \Lambda_{\kappa_r}$ for the multicharge $(\kappa_1, \ldots, \kappa_\ell)$ and $\beta = \sum_{(r,c)} \alpha_{(c-r) \pmod e}$, with the sum being over the cells in the partition.

INPUT:

- `e` – the quantum characteristic
- `multicharge` – the multicharge (default: $(0,)$)

OUTPUT: nonnegative integer, which is the defect of the block containing the partition `self`

EXAMPLES:

```
sage: Partition([4,3,2]).defect(2)
3
sage: Partition([0]).defect(2)
0
sage: Partition([3]).defect(2)
1
sage: Partition([6]).defect(2)
3
sage: Partition([9]).defect(2)
4
sage: Partition([12]).defect(2)
6
sage: Partition([4,3,2]).defect(3)
3
sage: Partition([0]).defect(3)
0
sage: Partition([3]).defect(3)
```

(continues on next page)

(continued from previous page)

```
1
sage: Partition([6]).defect(3)
2
sage: Partition([9]).defect(3)
3
sage: Partition([12]).defect(3)
4
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(2)]).defect(Integer(2))
3
>>> Partition([Integer(0)]).defect(Integer(2))
0
>>> Partition([Integer(3)]).defect(Integer(2))
1
>>> Partition([Integer(6)]).defect(Integer(2))
3
>>> Partition([Integer(9)]).defect(Integer(2))
4
>>> Partition([Integer(12)]).defect(Integer(2))
6
>>> Partition([Integer(4),Integer(3),Integer(2)]).defect(Integer(3))
3
>>> Partition([Integer(0)]).defect(Integer(3))
0
>>> Partition([Integer(3)]).defect(Integer(3))
1
>>> Partition([Integer(6)]).defect(Integer(3))
2
>>> Partition([Integer(9)]).defect(Integer(3))
3
>>> Partition([Integer(12)]).defect(Integer(3))
4
```

degree(*e*)

Return the `e`-th degree of `self`.

The e-th degree of a partition λ is the sum of the e-th degrees of the standard tableaux of shape λ. The e-th degree is the exponent of $\Phi_e(q)$ in the Gram determinant of the Specht module for a semisimple Iwahori-Hecke algebra of type A with parameter q.

INPUT:

- `e` – an integer $e > 1$

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: Partition([4,3]).degree(2)
28
sage: Partition([4,3]).degree(3)
15
sage: Partition([4,3]).degree(4)
```

(continues on next page)

(continued from previous page)

```
8
sage: Partition([4,3]).degree(5)
13
sage: Partition([4,3]).degree(6)
0
sage: Partition([4,3]).degree(7)
0
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3)]).degree(Integer(2))
28
>>> Partition([Integer(4),Integer(3)]).degree(Integer(3))
15
>>> Partition([Integer(4),Integer(3)]).degree(Integer(4))
8
>>> Partition([Integer(4),Integer(3)]).degree(Integer(5))
13
>>> Partition([Integer(4),Integer(3)]).degree(Integer(6))
0
>>> Partition([Integer(4),Integer(3)]).degree(Integer(7))
0
```

Therefore, the Gram determinant of $S(5,3)$ when the Hecke parameter q is "generic" is

$$q^N \Phi_2(q)^{28} \Phi_3(q)^{15} \Phi_4(q)^8 \Phi_5(q)^{13}$$

for some integer N. Compare with *prime_degree()*.

dimension(*smaller=None*, *k=1*)

Return the number of paths from the `smaller` partition to the partition `self`, where each step consists of adding a k-ribbon while keeping a partition.

Note that a 1-ribbon is just a single cell, so this counts paths in the Young graph when $k = 1$.

Note also that the default case ($k = 1$ and `smaller = []`) gives the dimension of the irreducible representation of the symmetric group corresponding to `self`.

INPUT:

- `smaller` – a partition (default: an empty list `[]`)
- `k` – positive integer (default: 1)

OUTPUT: the number of such paths

EXAMPLES:

Looks at the number of ways of getting from `[5,4]` to the empty partition, removing one cell at a time:

```
sage: mu = Partition([5,4])
sage: mu.dimension()
42
```

```
>>> from sage.all import *
>>> mu = Partition([Integer(5),Integer(4)])
>>> mu.dimension()
42
```

Same, but removing one 3-ribbon at a time. Note that the 3-core of `mu` is empty:

```
sage: mu.dimension(k=3)
3
```

```
>>> from sage.all import *
>>> mu.dimension(k=Integer(3))
3
```

The 2-core of `mu` is not the empty partition:

```
sage: mu.dimension(k=2)
0
```

```
>>> from sage.all import *
>>> mu.dimension(k=Integer(2))
0
```

Indeed, the 2-core of `mu` is `[1]`:

```
sage: mu.dimension(Partition([1]),k=2)
2
```

```
>>> from sage.all import *
>>> mu.dimension(Partition([Integer(1)]),k=Integer(2))
2
```

ALGORITHM:

Depending on the parameters given, different simplifications occur. When $k = 1$ and `smaller` is empty, this function uses the hook formula. When $k = 1$ and `smaller` is not empty, it uses a formula from [ORV].

When $k \neq 1$, we first check that both `self` and `smaller` have the same k-core, then use the k-quotients and the same algorithm on each of the k-quotients.

AUTHORS:

- Paul-Olivier Dehaye (2011-06-07)

dominated_partitions(*rows=None*)

Return a list of the partitions dominated by n. If `rows` is specified, then it only returns the ones whose number of rows is at most `rows`.

EXAMPLES:

```
sage: Partition([3,2,1]).dominated_partitions()
[[3, 2, 1], [3, 1, 1, 1], [2, 2, 2], [2, 2, 1, 1], [2, 1, 1, 1, 1], [1, 1, 1,␣
↪1, 1, 1]]
sage: Partition([3,2,1]).dominated_partitions(rows=3)
[[3, 2, 1], [2, 2, 2]]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).dominated_partitions()
[[3, 2, 1], [3, 1, 1, 1], [2, 2, 2], [2, 2, 1, 1], [2, 1, 1, 1, 1], [1, 1, 1,␣
↪1, 1, 1]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).dominated_
```

(continues on next page)

(continued from previous page)

```
↪partitions(rows=Integer(3))
[[3, 2, 1], [2, 2, 2]]
```

dominates(*p2*)

Return `True` if `self` dominates the partition `p2`. Otherwise it returns `False`.

EXAMPLES:

```
sage: p = Partition([3,2])
sage: p.dominates([3,1])
True
sage: p.dominates([2,2])
True
sage: p.dominates([2,1,1])
True
sage: p.dominates([3,3])
False
sage: p.dominates([4])
False
sage: Partition([4]).dominates(p)
False
sage: Partition([]).dominates([1])
False
sage: Partition([]).dominates([])
True
sage: Partition([1]).dominates([])
True
```

```
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2)])
>>> p.dominates([Integer(3),Integer(1)])
True
>>> p.dominates([Integer(2),Integer(2)])
True
>>> p.dominates([Integer(2),Integer(1),Integer(1)])
True
>>> p.dominates([Integer(3),Integer(3)])
False
>>> p.dominates([Integer(4)])
False
>>> Partition([Integer(4)]).dominates(p)
False
>>> Partition([]).dominates([Integer(1)])
False
>>> Partition([]).dominates([])
True
>>> Partition([Integer(1)]).dominates([])
True
```

down()

Return a generator for partitions that can be obtained from `self` by removing a cell.

EXAMPLES:

```
sage: [p for p in Partition([2,1,1]).down()]
[[1, 1, 1], [2, 1]]
sage: [p for p in Partition([3,2]).down()]
[[2, 2], [3, 1]]
sage: [p for p in Partition([3,2,1]).down()]
[[2, 2, 1], [3, 1, 1], [3, 2]]
```

```
>>> from sage.all import *
>>> [p for p in Partition([Integer(2),Integer(1),Integer(1)]).down()]
[[1, 1, 1], [2, 1]]
>>> [p for p in Partition([Integer(3),Integer(2)]).down()]
[[2, 2], [3, 1]]
>>> [p for p in Partition([Integer(3),Integer(2),Integer(1)]).down()]
[[2, 2, 1], [3, 1, 1], [3, 2]]
```

down_list()

Return a list of the partitions that can be obtained from `self` by removing a cell.

EXAMPLES:

```
sage: Partition([2,1,1]).down_list()
[[1, 1, 1], [2, 1]]
sage: Partition([3,2]).down_list()
[[2, 2], [3, 1]]
sage: Partition([3,2,1]).down_list()
[[2, 2, 1], [3, 1, 1], [3, 2]]
sage: Partition([]).down_list()  #checks :issue:`11435`
[]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1),Integer(1)]).down_list()
[[1, 1, 1], [2, 1]]
>>> Partition([Integer(3),Integer(2)]).down_list()
[[2, 2], [3, 1]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).down_list()
[[2, 2, 1], [3, 1, 1], [3, 2]]
>>> Partition([]).down_list()  #checks :issue:`11435`
[]
```

dual_equivalence_graph(*directed=False*, *coloring=None*)

Return the dual equivalence graph of `self`.

Two permutations p and q in the symmetric group S_n differ by an *i-elementary dual equivalence (or dual Knuth) relation* (where i is an integer with $1 < i < n$) when the following two conditions are satisfied:

- In the one-line notation of the permutation p, the letter i does not appear between $i-1$ and $i+1$.
- The permutation q is obtained from p by switching two of the three letters $i-1, i, i+1$ (in its one-line notation) – namely, the leftmost and the rightmost one in order of their appearance in p.

Notice that this is equivalent to the statement that the permutations p^{-1} and q^{-1} differ by an elementary Knuth equivalence at positions $i-1, i, i+1$.

Two standard Young tableaux of shape λ differ by an i-elementary dual equivalence relation (of color i), if their reading words differ by an i-elementary dual equivalence relation.

The *dual equivalence graph* of the partition λ is the edge-colored graph whose vertices are the standard Young tableaux of shape λ, and whose edges colored by i are given by the i-elementary dual equivalences.

INPUT:

- `directed` – boolean (default: `False`); whether to have the dual equivalence graph be directed (where we have a directed edge $S \to T$ if i appears to the left of $i+1$ in the reading word of T; otherwise we have the directed edge $T \to S$)
- `coloring` – (optional) a function which sends each integer $i > 1$ to a color (as a string, e.g., `'red'` or `'black'`) to be used when visually representing the resulting graph using dot2tex; the default choice is `2 -> 'red', 3 -> 'blue', 4 -> 'green', 5 -> 'purple', 6 -> 'brown', 7 -> 'orange', 8 -> 'yellow', anything greater than 8 -> 'black'`.

 ([[1, 3, 5], [2], [4]], [[1, 2, 5], [3], [4]], 2),
```

(continues on next page)

(continued from previous page)

```
 ([[1, 3, 5], [2], [4]], [[1, 3, 4], [2], [5]], 4),
 ([[1, 4, 5], [2], [3]], [[1, 3, 5], [2], [4]], 3)]
```

evaluation()

Return the evaluation of `self`.

The **commutative evaluation**, often shortened to **evaluation**, of a word (we think of a partition as a word in $\{1, 2, 3, \ldots\}$) is its image in the free commutative monoid. In other words, this counts how many occurrences there are of each letter.

This is also is known as **Parikh vector** and **abelianization** and has the same output as *to_exp()*.

EXAMPLES:

```
sage: Partition([4,3,1,1]).evaluation()
[2, 0, 1, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(1),Integer(1)]).evaluation()
[2, 0, 1, 1]
```

ferrers_diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: mu = Partition([5,5,2,1])
sage: Partitions.options(diagram_str='*', convention='english')
sage: print(mu.ferrers_diagram())
*****
*****
**
*
sage: Partitions.options(diagram_str='')
sage: print(mu.ferrers_diagram())
■■■■■
■■■■■
■■
■
sage: Partitions.options.convention="french"
sage: print(mu.ferrers_diagram())
■
■■
■■■■■
■■■■■
sage: print(Partition([]).ferrers_diagram())
-
sage: Partitions.options(diagram_str='-')
sage: print(Partition([]).ferrers_diagram())
(/)
sage: Partitions.options._reset()
```

```
>>> from sage.all import *
>>> mu = Partition([Integer(5),Integer(5),Integer(2),Integer(1)])
>>> Partitions.options(diagram_str='*', convention='english')
>>> print(mu.ferrers_diagram())
*****
*****
**
*
>>> Partitions.options(diagram_str='')
>>> print(mu.ferrers_diagram())
```

```
>>> Partitions.options.convention="french"
>>> print(mu.ferrers_diagram())
```

```
>>> print(Partition([]).ferrers_diagram())
-
>>> Partitions.options(diagram_str='-')
>>> print(Partition([]).ferrers_diagram())
(/)
>>> Partitions.options._reset()
```

frobenius_coordinates()

Return a pair of sequences of Frobenius coordinates aka beta numbers of the partition.

These are two strictly decreasing sequences of nonnegative integers of the same length.

EXAMPLES:

```
sage: Partition([]).frobenius_coordinates()
([], [])
sage: Partition([1]).frobenius_coordinates()
([0], [0])
sage: Partition([3,3,3]).frobenius_coordinates()
([2, 1, 0], [2, 1, 0])
sage: Partition([9,1,1,1,1,1,1]).frobenius_coordinates()
([8], [6])
```

```
>>> from sage.all import *
>>> Partition([]).frobenius_coordinates()
([], [])
>>> Partition([Integer(1)]).frobenius_coordinates()
([0], [0])
>>> Partition([Integer(3),Integer(3),Integer(3)]).frobenius_coordinates()
([2, 1, 0], [2, 1, 0])
>>> Partition([Integer(9),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1),Integer(1)]).frobenius_coordinates()
([8], [6])
```

frobenius_rank()

Return the Frobenius rank of the partition `self`.

The Frobenius rank of a partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \cdots)$ is defined to be the largest i such that $\lambda_i \geq i$. In other words, it is the number of cells on the main diagonal of λ. In yet other words, it is the size of the largest square fitting into the Young diagram of λ.

EXAMPLES:

```
sage: Partition([]).frobenius_rank()
0
sage: Partition([1]).frobenius_rank()
1
sage: Partition([3,3,3]).frobenius_rank()
3
sage: Partition([9,1,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,1,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,2,1,1,1,1]).frobenius_rank()
2
sage: Partition([3,2]).frobenius_rank()
2
sage: Partition([3,2,2]).frobenius_rank()
2
sage: Partition([8,4,4,4,4]).frobenius_rank()
4
sage: Partition([8,4,1]).frobenius_rank()
2
sage: Partition([3,3,1]).frobenius_rank()
2
```

```
>>> from sage.all import *
>>> Partition([]).frobenius_rank()
0
>>> Partition([Integer(1)]).frobenius_rank()
1
>>> Partition([Integer(3),Integer(3),Integer(3)]).frobenius_rank()
3
>>> Partition([Integer(9),Integer(1),Integer(1),Integer(1),Integer(1),
...Integer(1)]).frobenius_rank()
1
>>> Partition([Integer(2),Integer(1),Integer(1),Integer(1),Integer(1),
...Integer(1)]).frobenius_rank()
1
>>> Partition([Integer(2),Integer(2),Integer(1),Integer(1),Integer(1),
...Integer(1)]).frobenius_rank()
2
>>> Partition([Integer(3),Integer(2)]).frobenius_rank()
2
>>> Partition([Integer(3),Integer(2),Integer(2)]).frobenius_rank()
2
>>> Partition([Integer(8),Integer(4),Integer(4),Integer(4),Integer(4)]).
...frobenius_rank()
```

(continues on next page)

(continued from previous page)

```
4
>>> Partition([Integer(8),Integer(4),Integer(1)]).frobenius_rank()
2
>>> Partition([Integer(3),Integer(3),Integer(1)]).frobenius_rank()
2
```

from_kbounded_to_grassmannian(k)

Map a k-bounded partition to a Grassmannian element in the affine Weyl group of type $A_k^{(1)}$.

For details, see the documentation of the method *from_kbounded_to_reduced_word()* .

EXAMPLES:

```
sage: p = Partition([2,1,1])
sage: p.from_kbounded_to_grassmannian(2)                                    #␣
↪needs sage.modules
[-1  1  1]
[-2  2  1]
[-2  1  2]
sage: p = Partition([])
sage: p.from_kbounded_to_grassmannian(2)                                    #␣
↪needs sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1),Integer(1)])
>>> p.from_kbounded_to_grassmannian(Integer(2))                             ␣
↪     # needs sage.modules
[-1  1  1]
[-2  2  1]
[-2  1  2]
>>> p = Partition([])
>>> p.from_kbounded_to_grassmannian(Integer(2))                             ␣
↪     # needs sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
```

from_kbounded_to_reduced_word(k)

Map a k-bounded partition to a reduced word for an element in the affine permutation group.

This uses the fact that there is a bijection between k-bounded partitions and $(k+1)$-cores and an action of the affine nilCoxeter algebra of type $A_k^{(1)}$ on $(k+1)$-cores as described in [LM2006b].

EXAMPLES:

```
sage: p = Partition([2,1,1])
sage: p.from_kbounded_to_reduced_word(2)
[2, 1, 2, 0]
sage: p = Partition([3,1])
sage: p.from_kbounded_to_reduced_word(3)
```

(continues on next page)

(continued from previous page)

```
[3, 2, 1, 0]
sage: p.from_kbounded_to_reduced_word(2)
Traceback (most recent call last):
...
ValueError: the partition must be 2-bounded
sage: p = Partition([])
sage: p.from_kbounded_to_reduced_word(2)
[]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1),Integer(1)])
>>> p.from_kbounded_to_reduced_word(Integer(2))
[2, 1, 2, 0]
>>> p = Partition([Integer(3),Integer(1)])
>>> p.from_kbounded_to_reduced_word(Integer(3))
[3, 2, 1, 0]
>>> p.from_kbounded_to_reduced_word(Integer(2))
Traceback (most recent call last):
...
ValueError: the partition must be 2-bounded
>>> p = Partition([])
>>> p.from_kbounded_to_reduced_word(Integer(2))
[]
```

garnir_tableau(**cell*)

Return the Garnir tableau of shape `self` corresponding to the cell `cell`. If `cell` $= (a, c)$ then $(a + 1, c)$ must belong to the diagram of `self`.

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules over an arbitrary ring.

The Garnir tableaux are the "first" non-standard tableaux which arise when you act by simple transpositions. If (a, c) is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers $1, 2, \ldots, n$ entered in order from left to right along the rows of the diagram up to the cell $(a, c - 1)$, then along the cells $(a + 1, 1)$ to $(a + 1, c)$, then (a, c) until the end of row a and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

Note

The function also sets `g._garnir_cell`, where `g` is the resulting Garnir tableau, equal to `cell` which is used by some other functions.

EXAMPLES:

```
sage: g = Partition([5,3,3,2]).garnir_tableau((0,2)); g.pp()
  1  2  6  7  8
  3  4  5
  9 10 11
 12 13
sage: g.is_row_strict(); g.is_column_strict()
True
```

(continues on next page)

(continued from previous page)

```
False

sage: Partition([5,3,3,2]).garnir_tableau(0,2).pp()
  1  2  6  7  8
  3  4  5
  9 10 11
 12 13
sage: Partition([5,3,3,2]).garnir_tableau(2,1).pp()
  1  2  3  4  5
  6  7  8
  9 12 13
 10 11
sage: Partition([5,3,3,2]).garnir_tableau(2,2).pp()
Traceback (most recent call last):
...
ValueError: (row+1, col) must be inside the diagram
```

```
>>> from sage.all import *
>>> g = Partition([Integer(5),Integer(3),Integer(3),Integer(2)]).garnir_
↪tableau((Integer(0),Integer(2))); g.pp()
  1  2  6  7  8
  3  4  5
  9 10 11
 12 13
>>> g.is_row_strict(); g.is_column_strict()
True
False

>>> Partition([Integer(5),Integer(3),Integer(3),Integer(2)]).garnir_
↪tableau(Integer(0),Integer(2)).pp()
  1  2  6  7  8
  3  4  5
  9 10 11
 12 13
>>> Partition([Integer(5),Integer(3),Integer(3),Integer(2)]).garnir_
↪tableau(Integer(2),Integer(1)).pp()
  1  2  3  4  5
  6  7  8
  9 12 13
 10 11
>>> Partition([Integer(5),Integer(3),Integer(3),Integer(2)]).garnir_
↪tableau(Integer(2),Integer(2)).pp()
Traceback (most recent call last):
...
ValueError: (row+1, col) must be inside the diagram
```

See also

- *top_garnir_tableau()*

garsia_procesi_module(*base_ring=None*)

Return the *Garsia-Procesi module* corresponding to `self`.

INPUT:

- `base_ring` – (default: **Q**) the base ring

EXAMPLES:

```
sage: GP = Partition([3,2,1]).garsia_procesi_module(QQ); GP
Garsia-Procesi module of shape [3, 2, 1] over Rational Field
sage: GP.graded_frobenius_image()
q^4*s[3, 2, 1] + q^3*s[3, 3] + q^3*s[4, 1, 1] + (q^3+q^2)*s[4, 2]
 + (q^2+q)*s[5, 1] + s[6]

sage: Partition([3,2,1]).garsia_procesi_module(GF(3))
Garsia-Procesi module of shape [3, 2, 1] over Finite Field of size 3
```

```
>>> from sage.all import *
>>> GP = Partition([Integer(3),Integer(2),Integer(1)]).garsia_procesi_
↪module(QQ); GP
Garsia-Procesi module of shape [3, 2, 1] over Rational Field
>>> GP.graded_frobenius_image()
q^4*s[3, 2, 1] + q^3*s[3, 3] + q^3*s[4, 1, 1] + (q^3+q^2)*s[4, 2]
 + (q^2+q)*s[5, 1] + s[6]

>>> Partition([Integer(3),Integer(2),Integer(1)]).garsia_procesi_
↪module(GF(Integer(3)))
Garsia-Procesi module of shape [3, 2, 1] over Finite Field of size 3
```

generalized_pochhammer_symbol(*a*, *alpha*)

Return the generalized Pochhammer symbol $(a)^{(\alpha)}_{self}$. This is the product over all cells (i, j) in `self` of $a - (i - 1)/\alpha + j - 1$.

EXAMPLES:

```
sage: Partition([2,2]).generalized_pochhammer_symbol(2,1)
12
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).generalized_pochhammer_
↪symbol(Integer(2),Integer(1))
12
```

get_part(*i*, *default=0*)

Return the i-th part of `self`, or `default` if it does not exist.

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.get_part(0), p.get_part(1), p.get_part(2)
(2, 1, 0)
sage: p.get_part(10,-1)
-1
sage: Partition([]).get_part(0)
0
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1)])
>>> p.get_part(Integer(0)), p.get_part(Integer(1)), p.get_part(Integer(2))
(2, 1, 0)
>>> p.get_part(Integer(10),-Integer(1))
-1
>>> Partition([]).get_part(Integer(0))
0
```

glaisher_franklin(*s*)

Apply the Glaisher-Franklin bijection to `self`.

The Franklin-Glaisher bijection, with parameter s, returns a partition whose set of parts that are repeated at least s times equals the set of parts divisible by s in `self`, after dividing each part by s.

INPUT:

- `s` – positive integer

EXAMPLES:

```
sage: Partition([4, 3, 2, 2, 1]).glaisher_franklin(2)
[3, 2, 2, 1, 1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(4), Integer(3), Integer(2), Integer(2), Integer(1)]).
↪glaisher_franklin(Integer(2))
[3, 2, 2, 1, 1, 1, 1, 1]
```

glaisher_franklin_inverse(*s*)

Apply the inverse of the Glaisher-Franklin bijection to `self`.

The inverse of the Franklin-Glaisher bijection, with parameter s, returns a partition whose set of parts that are divisible by s, after dividing each by s, equals the equals the set of parts repeated at least s times in `self`.

INPUT:

- `s` – positive integer

EXAMPLES:

```
sage: Partition([4, 3, 2, 2, 1]).glaisher_franklin(2)
[3, 2, 2, 1, 1, 1, 1, 1]
sage: Partition([3, 2, 2, 1, 1, 1, 1, 1]).glaisher_franklin_inverse(2)
[4, 3, 2, 2, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(4), Integer(3), Integer(2), Integer(2), Integer(1)]).
```

(continues on next page)

(continued from previous page)

```
↪glaisher_franklin(Integer(2))
[3, 2, 2, 1, 1, 1, 1, 1]
>>> Partition([Integer(3), Integer(2), Integer(2), Integer(1), Integer(1),␣
↪Integer(1), Integer(1), Integer(1)]).glaisher_franklin_inverse(Integer(2))
[4, 3, 2, 2, 1]
```

has_k_rectangle(k)

Return `True` if the Ferrer's diagram of `self` contains $k - i + 1$ rows (*or more*) of length i (*exactly*) for any i in $[1, k]$.

This is mainly a helper function for *is_k_reducible()* and *is_k_irreducible()*, the only difference between this function and *is_k_reducible()* being that this function allows any partition as input while *is_k_reducible()* requires the input to be k-bounded.

EXAMPLES:

The partition [1, 1, 1] has at least 2 rows of length 1:

```
sage: Partition([1, 1, 1]).has_k_rectangle(2)
True
```

```
>>> from sage.all import *
>>> Partition([Integer(1), Integer(1), Integer(1)]).has_k_
↪rectangle(Integer(2))
True
```

The partition [1, 1, 1] does *not* have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```
sage: Partition([1, 1, 1]).has_k_rectangle(4)
False
```

```
>>> from sage.all import *
>>> Partition([Integer(1), Integer(1), Integer(1)]).has_k_
↪rectangle(Integer(4))
False
```

See also

is_k_irreducible(), *is_k_reducible()*, *has_rectangle()*

has_rectangle(h, w)

Return `True` if the Ferrer's diagram of `self` has `h` (*or more*) rows of length `w` (*exactly*).

INPUT:

- `h` – integer $h \geq 1$; the (*minimum*) height of the rectangle
- `w` – integer $w \geq 1$; the width of the rectangle

EXAMPLES:

```
sage: Partition([3, 3, 3, 3]).has_rectangle(2, 3)
True
```

(continues on next page)

(continued from previous page)

```
sage: Partition([3, 3]).has_rectangle(2, 3)
True
sage: Partition([4, 3]).has_rectangle(2, 3)
False
sage: Partition([3]).has_rectangle(2, 3)
False
```

```
>>> from sage.all import *
>>> Partition([Integer(3), Integer(3), Integer(3), Integer(3)]).has_
↪rectangle(Integer(2), Integer(3))
True
>>> Partition([Integer(3), Integer(3)]).has_rectangle(Integer(2), Integer(3))
True
>>> Partition([Integer(4), Integer(3)]).has_rectangle(Integer(2), Integer(3))
False
>>> Partition([Integer(3)]).has_rectangle(Integer(2), Integer(3))
False
```

See also

has_k_rectangle()

hook_length(i, j)

Return the length of the hook of cell (i, j) in `self`.

The (length of the) hook of cell (i, j) of a partition λ is

$$\lambda_i + \lambda'_j - i - j + 1$$

where λ' is the conjugate partition. In English convention, the hook length is the number of cells horizontally to the right and vertically below the cell (i, j) (including that cell).

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.hook_length(0, 0)
4
sage: p.hook_length(0, 1)
2
sage: p.hook_length(2, 0)
1
sage: Partition([3,3]).hook_length(0, 0)
4
sage: cell = [0,0]; Partition([3,3]).hook_length(*cell)
4
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(2),Integer(1)])
>>> p.hook_length(Integer(0), Integer(0))
4
>>> p.hook_length(Integer(0), Integer(1))
```

(continues on next page)

(continued from previous page)

```
2
>>> p.hook_length(Integer(2), Integer(0))
1
>>> Partition([Integer(3),Integer(3)]).hook_length(Integer(0), Integer(0))
4
>>> cell = [Integer(0),Integer(0)]; Partition([Integer(3),Integer(3)]).hook_
↪length(*cell)
4
```

hook_lengths()

Return a tableau of shape `self` with the cells filled in with the hook lengths.

In each cell, put the sum of one plus the number of cells horizontally to the right and vertically below the cell (the hook length).

For example, consider the partition `[3,2,1]` of 6 with Ferrers diagram:

```
# # #
# #
#
```

When we fill in the cells with the hook lengths, we obtain:

```
5 3 1
3 1
1
```

EXAMPLES:

```
sage: Partition([2,2,1]).hook_lengths()
[[4, 2], [3, 1], [1]]
sage: Partition([3,3]).hook_lengths()
[[4, 3, 2], [3, 2, 1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: Partition([2,2]).hook_lengths()
[[3, 2], [2, 1]]
sage: Partition([5]).hook_lengths()
[[5, 4, 3, 2, 1]]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(1)]).hook_lengths()
[[4, 2], [3, 1], [1]]
>>> Partition([Integer(3),Integer(3)]).hook_lengths()
[[4, 3, 2], [3, 2, 1]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
>>> Partition([Integer(2),Integer(2)]).hook_lengths()
[[3, 2], [2, 1]]
>>> Partition([Integer(5)]).hook_lengths()
[[5, 4, 3, 2, 1]]
```

REFERENCES:

- http://mathworld.wolfram.com/HookLengthFormula.html

hook_polynomial(*q*, *t*)

Return the two-variable hook polynomial.

EXAMPLES:

```
sage: R.<q,t> = PolynomialRing(QQ)
sage: a = Partition([2,2]).hook_polynomial(q,t)
sage: a == (1 - t)*(1 - q*t)*(1 - t^2)*(1 - q*t^2)
True
sage: a = Partition([3,2,1]).hook_polynomial(q,t)
sage: a == (1 - t)^3*(1 - q*t^2)^2*(1 - q^2*t^3)
True
```

```
>>> from sage.all import *
>>> R = PolynomialRing(QQ, names=('q', 't',)); (q, t,) = R._first_ngens(2)
>>> a = Partition([Integer(2),Integer(2)]).hook_polynomial(q,t)
>>> a == (Integer(1) - t)*(Integer(1) - q*t)*(Integer(1) -␣
↪t**Integer(2))*(Integer(1) - q*t**Integer(2))
True
>>> a = Partition([Integer(3),Integer(2),Integer(1)]).hook_polynomial(q,t)
>>> a == (Integer(1) - t)**Integer(3)*(Integer(1) -␣
↪q*t**Integer(2))**Integer(2)*(Integer(1) - q**Integer(2)*t**Integer(3))
True
```

hook_product(*a*)

Return the Jack hook-product.

EXAMPLES:

```
sage: Partition([3,2,1]).hook_product(x)                                    #␣
↪needs sage.symbolic
(2*x + 3)*(x + 2)^2
sage: Partition([2,2]).hook_product(x)                                      #␣
↪needs sage.symbolic
2*(x + 2)*(x + 1)
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).hook_product(x)           ␣
↪                        # needs sage.symbolic
(2*x + 3)*(x + 2)^2
>>> Partition([Integer(2),Integer(2)]).hook_product(x)                      ␣
↪              # needs sage.symbolic
2*(x + 2)*(x + 1)
```

hooks()

Return a sorted list of the hook lengths in `self`.

EXAMPLES:

```
sage: Partition([3,2,1]).hooks()
[5, 3, 3, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).hooks()
[5, 3, 3, 1, 1, 1]
```

horizontal_border_strip_cells(k)

Return a list of all the horizontal border strips of length `k` which can be added to `self`, where each horizontal border strip is a `generator` of cells.

EXAMPLES:

```
sage: list(Partition([]).horizontal_border_strip_cells(0))
[]
sage: list(Partition([3,2,1]).horizontal_border_strip_cells(0))
[]
sage: list(Partition([]).horizontal_border_strip_cells(2))
[[(0, 0), (0, 1)]]
sage: list(Partition([2,2]).horizontal_border_strip_cells(2))
[[(0, 2), (0, 3)], [(0, 2), (2, 0)], [(2, 0), (2, 1)]]
sage: list(Partition([3,2,2]).horizontal_border_strip_cells(2))
[[(0, 3), (0, 4)],
 [(0, 3), (1, 2)],
 [(0, 3), (3, 0)],
 [(1, 2), (3, 0)],
 [(3, 0), (3, 1)]]
```

```
>>> from sage.all import *
>>> list(Partition([]).horizontal_border_strip_cells(Integer(0)))
[]
>>> list(Partition([Integer(3),Integer(2),Integer(1)]).horizontal_border_
↪strip_cells(Integer(0)))
[]
>>> list(Partition([]).horizontal_border_strip_cells(Integer(2)))
[[(0, 0), (0, 1)]]
>>> list(Partition([Integer(2),Integer(2)]).horizontal_border_strip_
↪cells(Integer(2)))
[[(0, 2), (0, 3)], [(0, 2), (2, 0)], [(2, 0), (2, 1)]]
>>> list(Partition([Integer(3),Integer(2),Integer(2)]).horizontal_border_
↪strip_cells(Integer(2)))
[[(0, 3), (0, 4)],
 [(0, 3), (1, 2)],
 [(0, 3), (3, 0)],
 [(1, 2), (3, 0)],
 [(3, 0), (3, 1)]]
```

initial_column_tableau()

Return the initial column tableau of shape `self`.

The initial column tableau of shape `self` is the standard tableau that has the numbers 1 to n, where n is the *size()* of `self`, entered in order from top to bottom and then left to right down the columns of `self`.

EXAMPLES:

```
sage: Partition([3,2]).initial_column_tableau()
[[1, 3, 5], [2, 4]]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2)]).initial_column_tableau()
[[1, 3, 5], [2, 4]]
```

initial_tableau()

Return the *standard tableau* which has the numbers $1, 2, \ldots, n$ where n is the *size()* of `self` entered in order from left to right along the rows of each component, where the components are ordered from left to right.

EXAMPLES:

```
sage: Partition([3,2,2]).initial_tableau()
[[1, 2, 3], [4, 5], [6, 7]]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(2)]).initial_tableau()
[[1, 2, 3], [4, 5], [6, 7]]
```

inside_corners()

alias of *corners()*.

inside_corners_residue(i, l)

alias of *corners_residue()*.

is_core(k)

Return `True` if the Partition `self` is a `k`-core.

A partition is said to be a *`k`-core* if it has no hooks of length k. Equivalently, a partition is said to be a k-core if it is its own k-core (where the latter is defined as in *core()*).

Visually, this can be checked by trying to remove border strips of size k from `self`. If this is not possible, then `self` is a k-core.

EXAMPLES:

In the partition (2, 1), a hook length of 2 does not occur, but a hook length of 3 does:

```
sage: p = Partition([2, 1])
sage: p.is_core(2)
True
sage: p.is_core(3)
False

sage: q = Partition([12, 8, 5, 5, 2, 2, 1])
sage: q.is_core(4)
False
sage: q.is_core(5)
True
sage: q.is_core(0)
True
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2), Integer(1)])
>>> p.is_core(Integer(2))
True
```

(continues on next page)

(continued from previous page)

```
>>> p.is_core(Integer(3))
False

>>> q = Partition([Integer(12), Integer(8), Integer(5), Integer(5),␣
↪Integer(2), Integer(2), Integer(1)])
>>> q.is_core(Integer(4))
False
>>> q.is_core(Integer(5))
True
>>> q.is_core(Integer(0))
True
```

See also

core(), *Core*

is_empty()

Return `True` if `self` is the empty partition.

EXAMPLES:

```
sage: Partition([]).is_empty()
True
sage: Partition([2,1,1]).is_empty()
False
```

```
>>> from sage.all import *
>>> Partition([]).is_empty()
True
>>> Partition([Integer(2),Integer(1),Integer(1)]).is_empty()
False
```

is_k_bounded(k)

Return `True` if the partition `self` is bounded by `k`.

EXAMPLES:

```
sage: Partition([4, 3, 1]).is_k_bounded(4)
True
sage: Partition([4, 3, 1]).is_k_bounded(7)
True
sage: Partition([4, 3, 1]).is_k_bounded(3)
False
```

```
>>> from sage.all import *
>>> Partition([Integer(4), Integer(3), Integer(1)]).is_k_bounded(Integer(4))
True
>>> Partition([Integer(4), Integer(3), Integer(1)]).is_k_bounded(Integer(7))
True
>>> Partition([Integer(4), Integer(3), Integer(1)]).is_k_bounded(Integer(3))
False
```

is_k_irreducible(k)

Return `True` if the partition `self` is `k`-irreducible.

A k-bounded partition is *k-irreducible* if its Ferrer's diagram does *not* contain $k - i + 1$ rows (or more) of length i (exactly) for every $i \in [1, k]$.

(Also, a k-bounded partition is k-irreducible if and only if it is not k-reducible.)

EXAMPLES:

The partition [1, 1, 1] has at least 2 rows of length 1:

```
sage: Partition([1, 1, 1]).is_k_irreducible(2)
False
```

```
>>> from sage.all import *
>>> Partition([Integer(1), Integer(1), Integer(1)]).is_k_
↪irreducible(Integer(2))
False
```

The partition [1, 1, 1] does *not* have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```
sage: Partition([1, 1, 1]).is_k_irreducible(4)
True
```

```
>>> from sage.all import *
>>> Partition([Integer(1), Integer(1), Integer(1)]).is_k_
↪irreducible(Integer(4))
True
```

See also

is_k_reducible(), has_k_rectangle()

is_k_reducible(k)

Return `True` if the partition `self` is `k`-reducible.

A k-bounded partition is *k-reducible* if its Ferrer's diagram contains $k - i + 1$ rows (or more) of length i (exactly) for some $i \in [1, k]$.

(Also, a k-bounded partition is k-reducible if and only if it is not k-irreducible.)

EXAMPLES:

The partition [1, 1, 1] has at least 2 rows of length 1:

```
sage: Partition([1, 1, 1]).is_k_reducible(2)
True
```

```
>>> from sage.all import *
>>> Partition([Integer(1), Integer(1), Integer(1)]).is_k_reducible(Integer(2))
True
```

The partition [1, 1, 1] does *not* have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```
sage: Partition([1, 1, 1]).is_k_reducible(4)
False
```

```
>>> from sage.all import *
>>> Partition([Integer(1), Integer(1), Integer(1)]).is_k_reducible(Integer(4))
False
```

See also

is_k_irreducible(), *has_k_rectangle()*

is_regular(*e*, *multicharge=(0,)*)

Return `True` is this is an `e`-regular partition.

A partition is e-regular if it does not have e equal nonzero parts.

EXAMPLES:

```
sage: Partition([4,3,3,3]).is_regular(2)
False
sage: Partition([4,3,3,3]).is_regular(3)
False
sage: Partition([4,3,3,3]).is_regular(4)
True
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(3)]).is_
↪regular(Integer(2))
False
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(3)]).is_
↪regular(Integer(3))
False
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(3)]).is_
↪regular(Integer(4))
True
```

is_restricted(*e*, *multicharge=(0,)*)

Return `True` is this is an `e`-restricted partition.

An e-restricted partition is a partition such that the difference of consecutive parts is always strictly less than e, where partitions are considered to have an infinite number of 0 parts. I.e., the last part must be strictly less than e.

EXAMPLES:

```
sage: Partition([4,3,3,2]).is_restricted(2)
False
sage: Partition([4,3,3,2]).is_restricted(3)
True
sage: Partition([4,3,3,2]).is_restricted(4)
True
sage: Partition([4]).is_restricted(4)
False
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(2)]).is_
↪restricted(Integer(2))
False
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(2)]).is_
↪restricted(Integer(3))
True
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(2)]).is_
↪restricted(Integer(4))
True
>>> Partition([Integer(4)]).is_restricted(Integer(4))
False
```

is_symmetric()

Return `True` if the partition `self` equals its own transpose.

EXAMPLES:

```
sage: Partition([2, 1]).is_symmetric()
True
sage: Partition([3, 1]).is_symmetric()
False
```

```
>>> from sage.all import *
>>> Partition([Integer(2), Integer(1)]).is_symmetric()
True
>>> Partition([Integer(3), Integer(1)]).is_symmetric()
False
```

jacobi_trudi()

Return the Jacobi-Trudi matrix of `self` thought of as a skew partition. See *SkewPartition.jacobi_trudi()*.

EXAMPLES:

```
sage: # needs sage.modules
sage: part = Partition([3,2,1])
sage: jt = part.jacobi_trudi(); jt
[h[3] h[1]    0]
[h[4] h[2]  h[]]
[h[5] h[3] h[1]]
sage: s = SymmetricFunctions(QQ).schur()
sage: h = SymmetricFunctions(QQ).homogeneous()
sage: h( s(part) )
h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]
sage: jt.det()
h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> part = Partition([Integer(3),Integer(2),Integer(1)])
>>> jt = part.jacobi_trudi(); jt
[h[3] h[1]    0]
```

(continues on next page)

(continued from previous page)

```
[h[4] h[2]  h[]]
[h[5] h[3] h[1]]
>>> s = SymmetricFunctions(QQ).schur()
>>> h = SymmetricFunctions(QQ).homogeneous()
>>> h( s(part) )
h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]
>>> jt.det()
h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]
```

k_atom(k)

Return a list of the standard tableaux of size `self.size()` whose `k`-atom is equal to `self`.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.k_atom(1)
[]
sage: p.k_atom(3)
[[[1, 1, 1, 2, 3], [2]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1], [2, 2], [3]]]
sage: Partition([3,2,1]).k_atom(4)
[[[1, 1, 1, 3], [2, 2]], [[1, 1, 1], [2, 2], [3]]]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2),Integer(1)])
>>> p.k_atom(Integer(1))
[]
>>> p.k_atom(Integer(3))
[[[1, 1, 1, 2, 3], [2]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2], [2], [3]],
 [[1, 1, 1], [2, 2], [3]]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).k_atom(Integer(4))
[[[1, 1, 1, 3], [2, 2]], [[1, 1, 1], [2, 2], [3]]]
```

k_boundary(k)

Return the skew partition formed by removing the cells of the `k`-interior, see *k_interior()*.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.k_boundary(2)
[3, 2, 1] / [2, 1]
sage: p.k_boundary(3)
[3, 2, 1] / [1]

sage: p = Partition([12,8,5,5,2,2,1])
sage: p.k_boundary(4)
[12, 8, 5, 5, 2, 2, 1] / [8, 5, 2, 2]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2),Integer(1)])
>>> p.k_boundary(Integer(2))
[3, 2, 1] / [2, 1]
>>> p.k_boundary(Integer(3))
[3, 2, 1] / [1]

>>> p = Partition([Integer(12),Integer(8),Integer(5),Integer(5),Integer(2),
↪Integer(2),Integer(1)])
>>> p.k_boundary(Integer(4))
[12, 8, 5, 5, 2, 2, 1] / [8, 5, 2, 2]
```

k_column_lengths(k)

Return the k-column-shape of the partition self.

This is the 'column' analog of *k_row_lengths()*.

EXAMPLES:

```
sage: Partition([6, 1]).k_column_lengths(2)
[1, 0, 0, 0, 1, 1]

sage: Partition([4, 4, 4, 3, 2]).k_column_lengths(2)
[1, 1, 1, 2]
```

```
>>> from sage.all import *
>>> Partition([Integer(6), Integer(1)]).k_column_lengths(Integer(2))
[1, 0, 0, 0, 1, 1]

>>> Partition([Integer(4), Integer(4), Integer(4), Integer(3), Integer(2)]).k_
↪column_lengths(Integer(2))
[1, 1, 1, 2]
```

See also

k_row_lengths(), *k_boundary()*, *SkewPartition.row_lengths()*, *SkewPartition.column_lengths()*

k_conjugate(k)

Return the k-conjugate of self.

The k-conjugate is the partition that is given by the columns of the k-skew diagram of the partition.

We can also define the k-conjugate in the following way. Let P denote the bijection from $(k+1)$-cores to k-bounded partitions. The k-conjugate of a $(k+1)$-core λ is

$$\lambda^{(k)} = P^{-1}\left((P(\lambda))'\right).$$

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_conjugate(4)
[3, 2, 2, 1, 1, 1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(3),Integer(2),Integer(2),Integer(1),
↪Integer(1)])
>>> p.k_conjugate(Integer(4))
[3, 2, 2, 1, 1, 1, 1, 1, 1]
```

k_interior(k)

Return the partition consisting of the cells of `self` whose hook lengths are greater than `k`.

EXAMPLES:

```
sage: p = Partition([3,2,1])
sage: p.hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: p.k_interior(2)
[2, 1]
sage: p.k_interior(3)
[1]

sage: p = Partition([])
sage: p.k_interior(3)
[]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2),Integer(1)])
>>> p.hook_lengths()
[[5, 3, 1], [3, 1], [1]]
>>> p.k_interior(Integer(2))
[2, 1]
>>> p.k_interior(Integer(3))
[1]

>>> p = Partition([])
>>> p.k_interior(Integer(3))
[]
```

k_irreducible(k)

Return the partition with all $r \times (k+1-r)$ rectangles removed.

If `self` is a k-bounded partition, then this method will return the partition where all rectangles of dimension $r \times (k+1-r)$ for $1 \leq r \leq k$ have been deleted.

If `self` is not a k-bounded partition then the method will raise an error.

INPUT:

- `k` – nonnegative integer

OUTPUT: a partition

EXAMPLES:

```
sage: Partition([3,2,2,1,1,1]).k_irreducible(4)
[3, 2, 2, 1, 1, 1]
sage: Partition([3,2,2,1,1,1]).k_irreducible(3)
[]
```

(continues on next page)

(continued from previous page)

```
sage: Partition([3,3,3,2,2,2,2,2,1,1,1,1]).k_irreducible(3)
[2, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1),Integer(1),
↪Integer(1)]).k_irreducible(Integer(4))
[3, 2, 2, 1, 1, 1]
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1),Integer(1),
↪Integer(1)]).k_irreducible(Integer(3))
[]
>>> Partition([Integer(3),Integer(3),Integer(3),Integer(2),Integer(2),
↪Integer(2),Integer(2),Integer(2),Integer(1),Integer(1),Integer(1),
↪Integer(1)]).k_irreducible(Integer(3))
[2, 1]
```

k_rim(k)

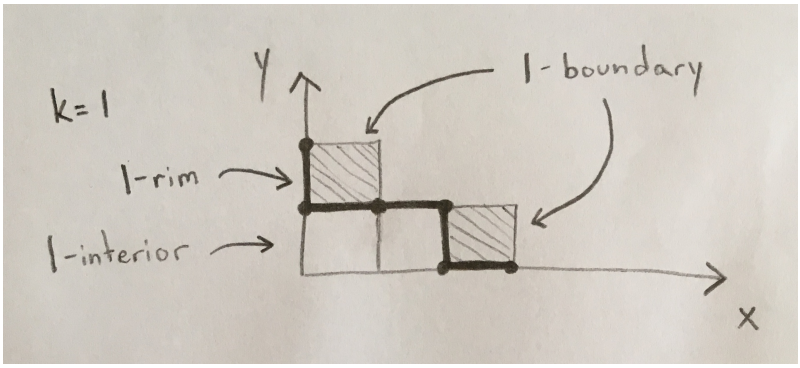
Return the `k`-rim of `self` as a list of integer coordinates.

The k-rim of a partition is the "line between" (or "intersection of") the k-boundary and the k-interior. (Section 2.3 of [HM2011])

It will be output as an ordered list of integer coordinates, where the origin is $(0, 0)$. It will start at the top-left of the k-rim (using French convention) and end at the bottom-right.

EXAMPLES:

Consider the partition (3, 1) split up into its 1-interior and 1-boundary:



The line shown in bold is the 1-rim, and that information is equivalent to the integer coordinates of the points that occur along that line:

```
sage: Partition([3, 1]).k_rim(1)
[(3, 0), (2, 0), (2, 1), (1, 1), (0, 1), (0, 2)]
```

```
>>> from sage.all import *
>>> Partition([Integer(3), Integer(1)]).k_rim(Integer(1))
[(3, 0), (2, 0), (2, 1), (1, 1), (0, 1), (0, 2)]
```

See also

k_interior(), k_boundary(), boundary()

k_row_lengths(k)

Return the k-row-shape of the partition self.

This is equivalent to taking the k-boundary of the partition and then returning the row-shape of that. We do *not* discard rows of length 0. (Section 2.2 of [LLMS2013])

EXAMPLES:

```
sage: Partition([6, 1]).k_row_lengths(2)
[2, 1]

sage: Partition([4, 4, 4, 3, 2]).k_row_lengths(2)
[0, 1, 1, 1, 2]
```

```
>>> from sage.all import *
>>> Partition([Integer(6), Integer(1)]).k_row_lengths(Integer(2))
[2, 1]

>>> Partition([Integer(4), Integer(4), Integer(4), Integer(3), Integer(2)]).k_
↪row_lengths(Integer(2))
[0, 1, 1, 1, 2]
```

See also

k_column_lengths(), *k_boundary()*, *SkewPartition.row_lengths()*, *SkewPartition.column_lengths()*

k_size(k)

Given a partition self and a k, return the size of the k-boundary.

This is the same as the length method *sage.combinat.core.Core.length()* of the *sage.combinat.core.Core* object, with the exception that here we don't require self to be a $k+1$-core.

EXAMPLES:

```
sage: Partition([2, 1, 1]).k_size(1)
2
sage: Partition([2, 1, 1]).k_size(2)
3
sage: Partition([2, 1, 1]).k_size(3)
3
sage: Partition([2, 1, 1]).k_size(4)
4
```

```
>>> from sage.all import *
>>> Partition([Integer(2), Integer(1), Integer(1)]).k_size(Integer(1))
2
>>> Partition([Integer(2), Integer(1), Integer(1)]).k_size(Integer(2))
3
>>> Partition([Integer(2), Integer(1), Integer(1)]).k_size(Integer(3))
3
>>> Partition([Integer(2), Integer(1), Integer(1)]).k_size(Integer(4))
4
```

> **See also**
>
> *k_boundary()*, *SkewPartition.size()*

k_skew(k)

Return the k-skew partition.

The k-skew diagram of a k-bounded partition is the skew diagram denoted $\lambda/^k$ satisfying the conditions:

1. row i of $\lambda/^k$ has length λ_i,
2. no cell in $\lambda/^k$ has hook-length exceeding k,
3. every square above the diagram of $\lambda/^k$ has hook length exceeding k.

REFERENCES:

- [LM2004]

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_skew(4)
[9, 5, 3, 2, 1, 1] / [5, 2, 1]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(3),Integer(2),Integer(2),Integer(1),
↪Integer(1)])
>>> p.k_skew(Integer(4))
[9, 5, 3, 2, 1, 1] / [5, 2, 1]
```

k_split(k)

Return the k-split of `self`.

EXAMPLES:

```
sage: Partition([4,3,2,1]).k_split(3)
[]
sage: Partition([4,3,2,1]).k_split(4)
[[4], [3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(5)
[[4, 3], [2, 1]]
sage: Partition([4,3,2,1]).k_split(6)
[[4, 3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(7)
[[4, 3, 2, 1]]
sage: Partition([4,3,2,1]).k_split(8)
[[4, 3, 2, 1]]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_
↪split(Integer(3))
[]
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_
↪split(Integer(4))
[[4], [3, 2], [1]]
```

(continues on next page)

(continued from previous page)

```
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_
↪split(Integer(5))
[[4, 3], [2, 1]]
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_
↪split(Integer(6))
[[4, 3, 2], [1]]
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_
↪split(Integer(7))
[[4, 3, 2, 1]]
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_
↪split(Integer(8))
[[4, 3, 2, 1]]
```

ladder_tableau(*e*, *ladder_lengths=False*)

Return the ladder tableau of shape `self`.

The *e-ladder tableau* is the standard Young tableau obtained by reading the *ladders*, the set of cells (i, j) that differ from $(i + e - 1, j - 1)$, of the partition λ from left-to-right.

INPUT:

- `e` – nonnegative integer; 0 is considered as ∞ (analogous to the characteristic of a ring)
- `ladder_sizes` – boolean (default: `False`); if `True`, also return the sizes of the ladders

See also

ladders()

EXAMPLES:

```
sage: la = Partition([6, 5, 3, 1])
sage: ascii_art(la.ladder_tableau(3))
  1  2  3  5  7 10
  4  6  8 11 13
  9 12 14
 15
sage: la.ladder_tableau(3, ladder_lengths=True)[1]
[1, 1, 2, 2, 3, 3, 3]

sage: ascii_art(la.ladder_tableau(0))
  1  2  3  4  5  6
  7  8  9 10 11
 12 13 14
 15
sage: all(ll == 1 for ll in la.ladder_tableau(0, ladder_lengths=True)[1])
True
```

```
>>> from sage.all import *
>>> la = Partition([Integer(6), Integer(5), Integer(3), Integer(1)])
>>> ascii_art(la.ladder_tableau(Integer(3)))
  1  2  3  5  7 10
  4  6  8 11 13
```

(continues on next page)

(continued from previous page)

```
  9 12 14
 15
>>> la.ladder_tableau(Integer(3), ladder_lengths=True)[Integer(1)]
[1, 1, 2, 2, 3, 3, 3]

>>> ascii_art(la.ladder_tableau(Integer(0)))
  1  2  3  4  5  6
  7  8  9 10 11
 12 13 14
 15
>>> all(ll == Integer(1) for ll in la.ladder_tableau(Integer(0), ladder_
↪lengths=True)[Integer(1)])
True
```

ladders(*e*)

Return a dictionary containing the ladders in the diagram of `self`.

For $e > 0$, a node (i, j) in a partition belongs to the l-th e-ladder if $l = (e-1)r + c$.

INPUT:

- `e` – nonnegative integer; if `0`, then we set `e = self.size() + 1`

EXAMPLES:

```
sage: Partition([3, 2]).ladders(3)
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2), (1, 0)], 3: [(1, 1)]}
```

```
>>> from sage.all import *
>>> Partition([Integer(3), Integer(2)]).ladders(Integer(3))
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2), (1, 0)], 3: [(1, 1)]}
```

When `e` is `0`, the cells are in bijection with the ladders, but the index of the ladder depends on the size of the partition:

```
sage: Partition([3, 2]).ladders(0)
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 5: [(1, 0)], 6: [(1, 1)]}
sage: Partition([3, 2, 1]).ladders(0)
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 6: [(1, 0)], 7: [(1, 1)],
 12: [(2, 0)]}
sage: Partition([3, 1, 1]).ladders(0)
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 5: [(1, 0)], 10: [(2, 0)]}
sage: Partition([1, 1, 1]).ladders(0)
{0: [(0, 0)], 3: [(1, 0)], 6: [(2, 0)]}
```

```
>>> from sage.all import *
>>> Partition([Integer(3), Integer(2)]).ladders(Integer(0))
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 5: [(1, 0)], 6: [(1, 1)]}
>>> Partition([Integer(3), Integer(2), Integer(1)]).ladders(Integer(0))
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 6: [(1, 0)], 7: [(1, 1)],
 12: [(2, 0)]}
>>> Partition([Integer(3), Integer(1), Integer(1)]).ladders(Integer(0))
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 5: [(1, 0)], 10: [(2, 0)]}
```

(continues on next page)

(continued from previous page)

```
>>> Partition([Integer(1), Integer(1), Integer(1)]).ladders(Integer(0))
{0: [(0, 0)], 3: [(1, 0)], 6: [(2, 0)]}
```

larger_lex(*rhs*)

Return `True` if `self` is larger than `rhs` in lexicographic order. Otherwise return `False`.

EXAMPLES:

```
sage: p = Partition([3,2])
sage: p.larger_lex([3,1])
True
sage: p.larger_lex([1,4])
True
sage: p.larger_lex([3,2,1])
False
sage: p.larger_lex([3])
True
sage: p.larger_lex([5])
False
sage: p.larger_lex([3,1,1,1,1,1,1,1])
True
```

```
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2)])
>>> p.larger_lex([Integer(3),Integer(1)])
True
>>> p.larger_lex([Integer(1),Integer(4)])
True
>>> p.larger_lex([Integer(3),Integer(2),Integer(1)])
False
>>> p.larger_lex([Integer(3)])
True
>>> p.larger_lex([Integer(5)])
False
>>> p.larger_lex([Integer(3),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1),Integer(1),Integer(1)])
True
```

leg_cells(i, j)

Return the list of the cells of the leg of cell (i, j) in `self`.

The leg of cell $c = (i, j)$ is defined to be the cells below c (in English convention).

The cell coordinates are zero-based, i. e., the northwesternmost cell is $(0, 0)$.

INPUT:

- `i`, `j` – two integers

OUTPUT: list of pairs of integers

EXAMPLES:

```
sage: Partition([4,4,3,1]).leg_cells(1,1)
[(2, 1)]
```

(continues on next page)

(continued from previous page)

```
sage: Partition([4,4,3,1]).leg_cells(0,1)
[(1, 1), (2, 1)]

sage: Partition([]).leg_cells(0,0)
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(4),Integer(3),Integer(1)]).leg_
↪cells(Integer(1),Integer(1))
[(2, 1)]
>>> Partition([Integer(4),Integer(4),Integer(3),Integer(1)]).leg_
↪cells(Integer(0),Integer(1))
[(1, 1), (2, 1)]

>>> Partition([]).leg_cells(Integer(0),Integer(0))
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
```

leg_length(i, j)

Return the length of the leg of cell (i, j) in `self`.

The leg of cell $c = (i, j)$ is defined to be the cells below c (in English convention).

The cell coordinates are zero-based, i. e., the northwesternmost cell is $(0, 0)$.

INPUT:

- `i`, `j` – two integers

OUTPUT: integer or a `ValueError`

EXAMPLES:

```
sage: p = Partition([2,2,1])
sage: p.leg_length(0, 0)
2
sage: p.leg_length(0,1)
1
sage: p.leg_length(2,0)
0
sage: Partition([3,3]).leg_length(0, 0)
1
sage: cell = [0,0]; Partition([3,3]).leg_length(*cell)
1
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(2),Integer(1)])
>>> p.leg_length(Integer(0), Integer(0))
2
>>> p.leg_length(Integer(0),Integer(1))
1
```

(continues on next page)

(continued from previous page)

```
>>> p.leg_length(Integer(2),Integer(0))
0
>>> Partition([Integer(3),Integer(3)]).leg_length(Integer(0), Integer(0))
1
>>> cell = [Integer(0),Integer(0)]; Partition([Integer(3),Integer(3)]).leg_
↪length(*cell)
1
```

leg_lengths(*flat=False*)

Return a tableau of shape `self` with each cell filled in with its leg length. The optional boolean parameter `flat` provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).leg_lengths()
[[2, 1], [1, 0], [0]]
sage: Partition([2,2,1]).leg_lengths(flat=True)
[2, 1, 1, 0, 0]
sage: Partition([3,3]).leg_lengths()
[[1, 1, 1], [0, 0, 0]]
sage: Partition([3,3]).leg_lengths(flat=True)
[1, 1, 1, 0, 0, 0]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(1)]).leg_lengths()
[[2, 1], [1, 0], [0]]
>>> Partition([Integer(2),Integer(2),Integer(1)]).leg_lengths(flat=True)
[2, 1, 1, 0, 0]
>>> Partition([Integer(3),Integer(3)]).leg_lengths()
[[1, 1, 1], [0, 0, 0]]
>>> Partition([Integer(3),Integer(3)]).leg_lengths(flat=True)
[1, 1, 1, 0, 0, 0]
```

length()

Return the number of parts in `self`.

EXAMPLES:

```
sage: Partition([3,2]).length()
2
sage: Partition([2,2,1]).length()
3
sage: Partition([]).length()
0
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2)]).length()
2
>>> Partition([Integer(2),Integer(2),Integer(1)]).length()
3
>>> Partition([]).length()
0
```

level()

Return the level of `self`, which is always 1.

This method exists only for compatibility with *PartitionTuples*.

EXAMPLES:

```
sage: Partition([4,3,2]).level()
1
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(2)]).level()
1
```

lower_hook(*i*, *j*, *alpha*)

Return the lower hook length of the cell (i, j) in `self`. When `alpha = 1`, this is just the normal hook length.

The lower hook length of a cell (i, j) in a partition κ is defined by

$$h_*^\kappa(i,j) = \kappa'_j - i + 1 + \alpha(\kappa_i - j).$$

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.lower_hook(0,0,1)
3
sage: p.hook_length(0,0)
3
sage: [ p.lower_hook(i,j,x) for i,j in p.cells() ]                              #␣
↪needs sage.symbolic
[x + 2, 1, 1]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1)])
>>> p.lower_hook(Integer(0),Integer(0),Integer(1))
3
>>> p.hook_length(Integer(0),Integer(0))
3
>>> [ p.lower_hook(i,j,x) for i,j in p.cells() ]                                #␣
↪needs sage.symbolic
[x + 2, 1, 1]
```

lower_hook_lengths(*alpha*)

Return a tableau of shape `self` with the cells filled in with the lower hook lengths. When `alpha = 1`, these are just the normal hook lengths.

The lower hook length of a cell (i, j) in a partition κ is defined by

$$h_*^\kappa(i,j) = \kappa'_j - i + 1 + \alpha(\kappa_i - j).$$

EXAMPLES:

```
sage: Partition([3,2,1]).lower_hook_lengths(x)                                  #␣
↪needs sage.symbolic
```

(continues on next page)

(continued from previous page)

```
[[2*x + 3, x + 2, 1], [x + 2, 1], [1]]
sage: Partition([3,2,1]).lower_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).lower_hook_lengths(x)
↪                        # needs sage.symbolic
[[2*x + 3, x + 2, 1], [x + 2, 1], [1]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).lower_hook_
↪lengths(Integer(1))
[[5, 3, 1], [3, 1], [1]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

next()

Return the partition that lexicographically follows `self`, of the same size. If `self` is the last partition, then return `False`.

EXAMPLES:

```
sage: next(Partition([4]))
[3, 1]
sage: next(Partition([1,1,1,1]))
False
```

```
>>> from sage.all import *
>>> next(Partition([Integer(4)]))
[3, 1]
>>> next(Partition([Integer(1),Integer(1),Integer(1),Integer(1)]))
False
```

next_within_bounds(*min=[]*, *max=None*, *partition_type=None*)

Get the next partition lexicographically that contains `min` and is contained in `max`.

INPUT:

- `min` – (default: `[]`, the empty partition) the 'minimum partition' that `next_within_bounds(self)` must contain
- `max` – (default: `None`) the 'maximum partition' that `next_within_bounds(self)` must be contained in; if set to `None`, then there is no restriction
- `partition_type` – (default: `None`) the type of partitions allowed; for example, 'strict' for strictly decreasing partitions, or `None` to allow any valid partition

EXAMPLES:

```
sage: m = [1, 1]
sage: M = [3, 2, 1]
sage: Partition([1, 1]).next_within_bounds(min=m, max=M)
[1, 1, 1]
sage: Partition([1, 1, 1]).next_within_bounds(min=m, max=M)
```

(continues on next page)

(continued from previous page)

```
[2, 1]
sage: Partition([2, 1]).next_within_bounds(min=m, max=M)
[2, 1, 1]
sage: Partition([2, 1, 1]).next_within_bounds(min=m, max=M)
[2, 2]
sage: Partition([2, 2]).next_within_bounds(min=m, max=M)
[2, 2, 1]
sage: Partition([2, 2, 1]).next_within_bounds(min=m, max=M)
[3, 1]
sage: Partition([3, 1]).next_within_bounds(min=m, max=M)
[3, 1, 1]
sage: Partition([3, 1, 1]).next_within_bounds(min=m, max=M)
[3, 2]
sage: Partition([3, 2]).next_within_bounds(min=m, max=M)
[3, 2, 1]
sage: Partition([3, 2, 1]).next_within_bounds(min=m, max=M) == None
True
```

```
>>> from sage.all import *
>>> m = [Integer(1), Integer(1)]
>>> M = [Integer(3), Integer(2), Integer(1)]
>>> Partition([Integer(1), Integer(1)]).next_within_bounds(min=m, max=M)
[1, 1, 1]
>>> Partition([Integer(1), Integer(1), Integer(1)]).next_within_bounds(min=m,␣
↪max=M)
[2, 1]
>>> Partition([Integer(2), Integer(1)]).next_within_bounds(min=m, max=M)
[2, 1, 1]
>>> Partition([Integer(2), Integer(1), Integer(1)]).next_within_bounds(min=m,␣
↪max=M)
[2, 2]
>>> Partition([Integer(2), Integer(2)]).next_within_bounds(min=m, max=M)
[2, 2, 1]
>>> Partition([Integer(2), Integer(2), Integer(1)]).next_within_bounds(min=m,␣
↪max=M)
[3, 1]
>>> Partition([Integer(3), Integer(1)]).next_within_bounds(min=m, max=M)
[3, 1, 1]
>>> Partition([Integer(3), Integer(1), Integer(1)]).next_within_bounds(min=m,␣
↪max=M)
[3, 2]
>>> Partition([Integer(3), Integer(2)]).next_within_bounds(min=m, max=M)
[3, 2, 1]
>>> Partition([Integer(3), Integer(2), Integer(1)]).next_within_bounds(min=m,␣
↪max=M) == None
True
```

See also

next()

outer_rim()

Return the outer rim of `self`.

The outer rim of a partition λ is defined as the cells which do not belong to λ and which are adjacent to cells in λ.

EXAMPLES:

The outer rim of the partition $[4, 1]$ consists of the cells marked with `#` below:

```
****#
*####
##
```

```
sage: Partition([4,1]).outer_rim()
[(2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]

sage: Partition([2,2,1]).outer_rim()
[(3, 0), (3, 1), (2, 1), (2, 2), (1, 2), (0, 2)]
sage: Partition([2,2]).outer_rim()
[(2, 0), (2, 1), (2, 2), (1, 2), (0, 2)]
sage: Partition([6,3,3,1,1]).outer_rim()
[(5, 0), (5, 1), (4, 1), (3, 1), (3, 2), (3, 3), (2, 3), (1, 3), (1, 4), (1,␣
↪5), (1, 6), (0, 6)]
sage: Partition([]).outer_rim()
[(0, 0)]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(1)]).outer_rim()
[(2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]

>>> Partition([Integer(2),Integer(2),Integer(1)]).outer_rim()
[(3, 0), (3, 1), (2, 1), (2, 2), (1, 2), (0, 2)]
>>> Partition([Integer(2),Integer(2)]).outer_rim()
[(2, 0), (2, 1), (2, 2), (1, 2), (0, 2)]
>>> Partition([Integer(6),Integer(3),Integer(3),Integer(1),Integer(1)]).outer_
↪rim()
[(5, 0), (5, 1), (4, 1), (3, 1), (3, 2), (3, 3), (2, 3), (1, 3), (1, 4), (1,␣
↪5), (1, 6), (0, 6)]
>>> Partition([]).outer_rim()
[(0, 0)]
```

outline(*variable=None*)

Return the outline of the partition `self`.

This is a piecewise linear function, normalized so that the area under the partition `[1]` is 2.

INPUT:

- `variable` – a variable (default: `'x'` in the symbolic ring)

EXAMPLES:

```
sage: # needs sage.symbolic
sage: [Partition([5,4]).outline()(x=i) for i in range(-10, 11)]
[10, 9, 8, 7, 6, 5, 6, 5, 6, 5, 4, 3, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

(continues on next page)

(continued from previous page)

```
sage: Partition([]).outline()
abs(x)
sage: Partition([1]).outline()
abs(x + 1) + abs(x - 1) - abs(x)
sage: y = SR.var("y")
sage: Partition([6,5,1]).outline(variable=y)
abs(y + 6) - abs(y + 5) + abs(y + 4) - abs(y + 3)
 + abs(y - 1) - abs(y - 2) + abs(y - 3)
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> [Partition([Integer(5),Integer(4)]).outline()(x=i) for i in range(-
↪Integer(10), Integer(11))]
[10, 9, 8, 7, 6, 5, 6, 5, 6, 5, 4, 3, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> Partition([]).outline()
abs(x)
>>> Partition([Integer(1)]).outline()
abs(x + 1) + abs(x - 1) - abs(x)
>>> y = SR.var("y")
>>> Partition([Integer(6),Integer(5),Integer(1)]).outline(variable=y)
abs(y + 6) - abs(y + 5) + abs(y + 4) - abs(y + 3)
 + abs(y - 1) - abs(y - 2) + abs(y - 3)
```

outside_corners()

Return a list of the outside corners of the partition `self`.

An outside corner (also called a cocorner) of a partition λ is a cell on $\mathbf{Z}^2$ which does not belong to the Young diagram of λ but can be added to this Young diagram to still form a straight-shape Young diagram.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

Note

These are called "outer corners" in [Sag2001].

EXAMPLES:

```
sage: Partition([2,2,1]).outside_corners()
[(0, 2), (2, 1), (3, 0)]
sage: Partition([2,2]).outside_corners()
[(0, 2), (2, 0)]
sage: Partition([6,3,3,1,1,1]).outside_corners()
[(0, 6), (1, 3), (3, 1), (6, 0)]
sage: Partition([]).outside_corners()
[(0, 0)]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(1)]).outside_corners()
[(0, 2), (2, 1), (3, 0)]
>>> Partition([Integer(2),Integer(2)]).outside_corners()
```

(continues on next page)

(continued from previous page)

```
[(0, 2), (2, 0)]
>>> Partition([Integer(6),Integer(3),Integer(3),Integer(1),Integer(1),
↪Integer(1)]).outside_corners()
[(0, 6), (1, 3), (3, 1), (6, 0)]
>>> Partition([]).outside_corners()
[(0, 0)]
```

outside_corners_residue(*i*, *l*)

Return a list of the outside corners of the partition `self` having `l`-residue `i`.

An outside corner (also called a cocorner) of a partition λ is a cell on $\mathbf{Z}^2$ which does not belong to the Young diagram of λ but can be added to this Young diagram to still form a straight-shape Young diagram. See *residue()* for the definition of the `l`-residue.

The entries of the list returned are pairs of the form (i, j), where i and j are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).outside_corners_residue(0, 3)
[(0, 3), (3, 0)]
sage: Partition([3,2,1]).outside_corners_residue(1, 3)
[(1, 2)]
sage: Partition([3,2,1]).outside_corners_residue(2, 3)
[(2, 1)]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).outside_corners_
↪residue(Integer(0), Integer(3))
[(0, 3), (3, 0)]
>>> Partition([Integer(3),Integer(2),Integer(1)]).outside_corners_
↪residue(Integer(1), Integer(3))
[(1, 2)]
>>> Partition([Integer(3),Integer(2),Integer(1)]).outside_corners_
↪residue(Integer(2), Integer(3))
[(2, 1)]
```

plancherel_measure()

Return the probability of `self` under the Plancherel probability measure on partitions of the same size.

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See Wikipedia article Plancherel_measure and *Partitions_n.random_element_plancherel()*.

EXAMPLES:

```
sage: Partition([]).plancherel_measure()
1
sage: Partition([1]).plancherel_measure()
1
sage: Partition([2]).plancherel_measure()
1/2
sage: [mu.plancherel_measure() for mu in Partitions(3)]
[1/6, 2/3, 1/6]
```

(continues on next page)

(continued from previous page)

```
sage: Partition([5,4]).plancherel_measure()
7/1440
```

```
>>> from sage.all import *
>>> Partition([]).plancherel_measure()
1
>>> Partition([Integer(1)]).plancherel_measure()
1
>>> Partition([Integer(2)]).plancherel_measure()
1/2
>>> [mu.plancherel_measure() for mu in Partitions(Integer(3))]
[1/6, 2/3, 1/6]
>>> Partition([Integer(5),Integer(4)]).plancherel_measure()
7/1440
```

power(k)

Return the cycle type of the k-th power of any permutation with cycle type `self` (thus describes the powermap of symmetric groups).

Equivalent to GAP's `PowerPartition`.

EXAMPLES:

```
sage: p = Partition([5,3])
sage: p.power(1)
[5, 3]
sage: p.power(2)
[5, 3]
sage: p.power(3)
[5, 1, 1, 1]
sage: p.power(4)
[5, 3]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(5),Integer(3)])
>>> p.power(Integer(1))
[5, 3]
>>> p.power(Integer(2))
[5, 3]
>>> p.power(Integer(3))
[5, 1, 1, 1]
>>> p.power(Integer(4))
[5, 3]
```

Now let us compare this to the power map on S_8:

```
sage: # needs sage.groups
sage: G = SymmetricGroup(8)
sage: g = G([(1,2,3,4,5),(6,7,8)]); g
(1,2,3,4,5)(6,7,8)
sage: g^2
(1,3,5,2,4)(6,8,7)
sage: g^3
```

(continues on next page)

(continued from previous page)

```
(1,4,2,5,3)
sage: g^4
(1,5,4,3,2)(6,7,8)
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> G = SymmetricGroup(Integer(8))
>>> g = G([(Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)),
↪(Integer(6),Integer(7),Integer(8))]); g
(1,2,3,4,5)(6,7,8)
>>> g**Integer(2)
(1,3,5,2,4)(6,8,7)
>>> g**Integer(3)
(1,4,2,5,3)
>>> g**Integer(4)
(1,5,4,3,2)(6,7,8)
```

```
sage: Partition([3,2,1]).power(3)
[2, 1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).power(Integer(3))
[2, 1, 1, 1, 1]
```

pp()

Print the Ferrers diagram.

See *ferrers_diagram()* for more on the Ferrers diagram.

EXAMPLES:

```
sage: Partition([5,5,2,1]).pp()
*****
*****
**
*
sage: Partitions.options.convention='French'
sage: Partition([5,5,2,1]).pp()
*
**
*****
*****
sage: Partitions.options._reset()
```

```
>>> from sage.all import *
>>> Partition([Integer(5),Integer(5),Integer(2),Integer(1)]).pp()
*****
*****
**
*
>>> Partitions.options.convention='French'
>>> Partition([Integer(5),Integer(5),Integer(2),Integer(1)]).pp()
```

(continues on next page)

(continued from previous page)

```
*
**
*****
*****
>>> Partitions.options._reset()
```

prime_degree(*p*)

Return the prime degree for the prime integer``p`` for `self`.

INPUT:

- `p` – prime integer

OUTPUT: nonnegative integer

The degree of a partition λ is the sum of the e-*degree()* of the standard tableaux of shape λ, for e a power of the prime p. The prime degree gives the exponent of p in the Gram determinant of the integral Specht module of the symmetric group.

EXAMPLES:

```
sage: Partition([4,3]).prime_degree(2)
36
sage: Partition([4,3]).prime_degree(3)
15
sage: Partition([4,3]).prime_degree(5)
13
sage: Partition([4,3]).prime_degree(7)
0
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3)]).prime_degree(Integer(2))
36
>>> Partition([Integer(4),Integer(3)]).prime_degree(Integer(3))
15
>>> Partition([Integer(4),Integer(3)]).prime_degree(Integer(5))
13
>>> Partition([Integer(4),Integer(3)]).prime_degree(Integer(7))
0
```

Therefore, the Gram determinant of $S(5,3)$ when $q=1$ is $2^{36}3^{15}5^{13}$. Compare with *degree()*.

quotient(*length*)

Return the quotient of the partition – in the literature the quotient is commonly referred to as the k-quotient, p-quotient, r-quotient, ...

The r-quotient of a partition λ is a list of r partitions (labelled from 0 to $r-1$), constructed in the following way. Label each cell in the Young diagram of λ with its content modulo r. Let R_i be the set of rows ending in a cell labelled i, and C_i be the set of columns ending in a cell labelled i. Then the j-th component of the quotient of λ is the partition defined by intersecting R_j with C_{j+1}. (See Theorem 2.7.37 in [JK1981].)

EXAMPLES:

```
sage: Partition([7,7,5,3,3,3,1]).quotient(3)
([2], [1], [2, 2, 2])
```

```
>>> from sage.all import *
>>> Partition([Integer(7),Integer(7),Integer(5),Integer(3),Integer(3),
↪Integer(3),Integer(1)]).quotient(Integer(3))
([2], [1], [2, 2, 2])
```

reading_tableau()

Return the RSK recording tableau of the reading word of the (standard) tableau T labeled down (in English convention) each column to the shape of `self`.

For an example of the tableau T, consider the partition $\lambda = (3, 2, 1)$, then we have:

```
1 4 6
2 5
3
```

For more, see *RSK()*.

EXAMPLES:

```
sage: Partition([3,2,1]).reading_tableau()
[[1, 3, 6], [2, 5], [4]]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).reading_tableau()
[[1, 3, 6], [2, 5], [4]]
```

removable_cells()

alias of *corners()*.

removable_cells_residue(*i*, *l*)

alias of *corners_residue()*.

remove_cell(*i*, *j=None*)

Return the partition obtained by removing a cell at the end of row `i` of `self`.

EXAMPLES:

```
sage: Partition([2,2]).remove_cell(1)
[2, 1]
sage: Partition([2,2,1]).remove_cell(2)
[2, 2]
sage: #Partition([2,2]).remove_cell(0)
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).remove_cell(Integer(1))
[2, 1]
>>> Partition([Integer(2),Integer(2),Integer(1)]).remove_cell(Integer(2))
[2, 2]
>>> #Partition([2,2]).remove_cell(0)
```

```
sage: Partition([2,2]).remove_cell(1,1)
[2, 1]
sage: #Partition([2,2]).remove_cell(1,0)
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).remove_cell(Integer(1),Integer(1))
[2, 1]
>>> #Partition([2,2]).remove_cell(1,0)
```

remove_horizontal_border_strip(*k*)

Return the partitions obtained from `self` by removing an horizontal border strip of length `k`.

EXAMPLES:

```
sage: Partition([5,3,1]).remove_horizontal_border_strip(0).list()
[[5, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(1).list()
[[5, 3], [5, 2, 1], [4, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(2).list()
[[5, 2], [5, 1, 1], [4, 3], [4, 2, 1], [3, 3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(3).list()
[[5, 1], [4, 2], [4, 1, 1], [3, 3], [3, 2, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(4).list()
[[4, 1], [3, 2], [3, 1, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(5).list()
[[3, 1]]
sage: Partition([5,3,1]).remove_horizontal_border_strip(6).list()
[]
```

```
>>> from sage.all import *
>>> Partition([Integer(5),Integer(3),Integer(1)]).remove_horizontal_border_
↪strip(Integer(0)).list()
[[5, 3, 1]]
>>> Partition([Integer(5),Integer(3),Integer(1)]).remove_horizontal_border_
↪strip(Integer(1)).list()
[[5, 3], [5, 2, 1], [4, 3, 1]]
>>> Partition([Integer(5),Integer(3),Integer(1)]).remove_horizontal_border_
↪strip(Integer(2)).list()
[[5, 2], [5, 1, 1], [4, 3], [4, 2, 1], [3, 3, 1]]
>>> Partition([Integer(5),Integer(3),Integer(1)]).remove_horizontal_border_
↪strip(Integer(3)).list()
[[5, 1], [4, 2], [4, 1, 1], [3, 3], [3, 2, 1]]
>>> Partition([Integer(5),Integer(3),Integer(1)]).remove_horizontal_border_
↪strip(Integer(4)).list()
[[4, 1], [3, 2], [3, 1, 1]]
>>> Partition([Integer(5),Integer(3),Integer(1)]).remove_horizontal_border_
↪strip(Integer(5)).list()
[[3, 1]]
>>> Partition([Integer(5),Integer(3),Integer(1)]).remove_horizontal_border_
↪strip(Integer(6)).list()
[]
```

The result is returned as an instance of *Partitions_with_constraints*:

```
sage: Partition([5,3,1]).remove_horizontal_border_strip(5)
The subpartitions of [5, 3, 1] obtained by removing a horizontal border strip␣
↪of length 5
```

```
>>> from sage.all import *
>>> Partition([Integer(5),Integer(3),Integer(1)]).remove_horizontal_border_
↪strip(Integer(5))
The subpartitions of [5, 3, 1] obtained by removing a horizontal border strip␣
↪of length 5
```

residue(r, c, l)

Return the `l`-residue of the cell at row `r` and column `c`.

The ℓ-residue of a cell is $c - r$ modulo ℓ.

This does not strictly depend upon the partition, however, this method is included because it is often useful in the context of partitions.

EXAMPLES:

```
sage: Partition([2,1]).residue(1, 0, 3)
2
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1)]).residue(Integer(1), Integer(0),␣
↪Integer(3))
2
```

rim()

Return the rim of `self`.

The rim of a partition λ is defined as the cells which belong to λ and which are adjacent to cells not in λ.

EXAMPLES:

The rim of the partition $[5, 5, 2, 1]$ consists of the cells marked with `#` below:

```
****#
*####
##
#

sage: Partition([5,5,2,1]).rim()
[(3, 0), (2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]

sage: Partition([2,2,1]).rim()
[(2, 0), (1, 0), (1, 1), (0, 1)]
sage: Partition([2,2]).rim()
[(1, 0), (1, 1), (0, 1)]
sage: Partition([6,3,3,1,1]).rim()
[(4, 0), (3, 0), (2, 0), (2, 1), (2, 2), (1, 2), (0, 2), (0, 3), (0, 4), (0,␣
↪5)]
sage: Partition([]).rim()
[]
```

row_standard_tableaux()

Return the *row standard tableaux* of shape `self`.

EXAMPLES:

```
sage: Partition([3,2,2,1]).row_standard_tableaux()
Row standard tableaux of shape [3, 2, 2, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1)]).row_standard_
↪tableaux()
Row standard tableaux of shape [3, 2, 2, 1]
```

sign()

Return the sign of any permutation with cycle type `self`.

This function corresponds to a homomorphism from the symmetric group S_n into the cyclic group of order 2, whose kernel is exactly the alternating group A_n. Partitions of sign 1 are called even partitions while partitions of sign -1 are called odd.

EXAMPLES:

```
sage: Partition([5,3]).sign()
1
sage: Partition([5,2]).sign()
-1
```

```
>>> from sage.all import *
>>> Partition([Integer(5),Integer(3)]).sign()
1
>>> Partition([Integer(5),Integer(2)]).sign()
-1
```

Zolotarev's lemma states that the Legendre symbol $\left(\frac{a}{p}\right)$ for an integer $a \pmod p$ (p a prime number), can be computed as sign(p_a), where sign denotes the sign of a permutation and p_a the permutation of the residue classes $\pmod p$ induced by modular multiplication by a, provided p does not divide a.

We verify this in some examples.

```
sage: F = GF(11)                                                              #␣
↪needs sage.rings.finite_rings
sage: a = F.multiplicative_generator();a                                      #␣
↪needs sage.rings.finite_rings
2
sage: plist = [int(a*F(x)) for x in range(1,11)]; plist                       #␣
↪needs sage.rings.finite_rings
[2, 4, 6, 8, 10, 1, 3, 5, 7, 9]
```

```
>>> from sage.all import *
>>> F = GF(Integer(11))                                                       ␣
↪     # needs sage.rings.finite_rings
>>> a = F.multiplicative_generator();a                                      #␣
↪needs sage.rings.finite_rings
2
>>> plist = [int(a*F(x)) for x in range(Integer(1),Integer(11))]; plist      ␣
↪              # needs sage.rings.finite_rings
[2, 4, 6, 8, 10, 1, 3, 5, 7, 9]
```

This corresponds to the permutation (1, 2, 4, 8, 5, 10, 9, 7, 3, 6) (acting the set $\{1, 2, ..., 10\}$) and to the partition [10].

```
sage: p = PermutationGroupElement('(1, 2, 4, 8, 5, 10, 9, 7, 3, 6)')          #␣
↪needs sage.groups
sage: p.sign()                                                                 #␣
↪needs sage.groups
-1
sage: Partition([10]).sign()
-1
sage: kronecker_symbol(11,2)
-1
```

```
>>> from sage.all import *
>>> p = PermutationGroupElement('(1, 2, 4, 8, 5, 10, 9, 7, 3, 6)')          #␣
↪needs sage.groups
>>> p.sign()                                                                 #␣
↪needs sage.groups
-1
>>> Partition([Integer(10)]).sign()
-1
>>> kronecker_symbol(Integer(11),Integer(2))
-1
```

Now replace 2 by 3:

```
sage: plist = [int(F(3*x)) for x in range(1,11)]; plist                        #␣
↪needs sage.rings.finite_rings
[3, 6, 9, 1, 4, 7, 10, 2, 5, 8]
sage: list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: p = PermutationGroupElement('(3,4,8,7,9)')                               #␣
↪needs sage.groups
sage: p.sign()                                                                 #␣
↪needs sage.groups
1
sage: kronecker_symbol(3,11)
1
sage: Partition([5,1,1,1,1,1]).sign()
1
```

```
>>> from sage.all import *
>>> plist = [int(F(Integer(3)*x)) for x in range(Integer(1),Integer(11))];␣
↪plist                      # needs sage.rings.finite_rings
[3, 6, 9, 1, 4, 7, 10, 2, 5, 8]
>>> list(range(Integer(1), Integer(11)))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> p = PermutationGroupElement('(3,4,8,7,9)')                                 #␣
↪needs sage.groups
>>> p.sign()                                                                   #␣
↪needs sage.groups
1
>>> kronecker_symbol(Integer(3),Integer(11))
```

(continues on next page)

(continued from previous page)

```
1
>>> Partition([Integer(5),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1)]).sign()
1
```

In both cases, Zolotarev holds.

REFERENCES:

- Wikipedia article Zolotarev%27s_lemma

simple_module_dimension(*base_ring=None*)

Return the dimension of the simple module corresponding to `self`.

When the base ring is a field of characteristic 0, this is equal to the dimension of the Specht module.

INPUT:

- `base_ring` – (default: **Q**) the base ring

EXAMPLES:

```
sage: Partition([2,2,1]).simple_module_dimension()
5
sage: Partition([2,2,1]).specht_module_dimension(GF(3))                    #␣
↪needs sage.rings.finite_rings
5
sage: Partition([2,2,1]).simple_module_dimension(GF(3))                    #␣
↪needs sage.rings.finite_rings
4

sage: for la in Partitions(6, regular=3):
....:     print(la, la.specht_module_dimension(), la.simple_module_
↪dimension(GF(3)))
[6] 1 1
[5, 1] 5 4
[4, 2] 9 9
[4, 1, 1] 10 6
[3, 3] 5 1
[3, 2, 1] 16 4
[2, 2, 1, 1] 9 9
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(1)]).simple_module_dimension()
5
>>> Partition([Integer(2),Integer(2),Integer(1)]).specht_module_
↪dimension(GF(Integer(3)))                    # needs sage.rings.finite_
↪rings
5
>>> Partition([Integer(2),Integer(2),Integer(1)]).simple_module_
↪dimension(GF(Integer(3)))                    # needs sage.rings.finite_
↪rings
4

>>> for la in Partitions(Integer(6), regular=Integer(3)):
```

(continues on next page)

(continued from previous page)

```
...     print(la, la.specht_module_dimension(), la.simple_module_
↪dimension(GF(Integer(3))))
[6] 1 1
[5, 1] 5 4
[4, 2] 9 9
[4, 1, 1] 10 6
[3, 3] 5 1
[3, 2, 1] 16 4
[2, 2, 1, 1] 9 9
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: Partition([2,2]).size()
4
sage: Partition([3,2,1]).size()
6
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).size()
4
>>> Partition([Integer(3),Integer(2),Integer(1)]).size()
6
```

specht_module(*base_ring=None*)

Return the Specht module corresponding to `self`.

EXAMPLES:

```
sage: SM = Partition([2,2,1]).specht_module(QQ); SM                    #␣
↪needs sage.modules
Specht module of [2, 2, 1] over Rational Field
sage: SM.frobenius_image()                                             #␣
↪needs sage.modules
s[2, 2, 1]
```

```
>>> from sage.all import *
>>> SM = Partition([Integer(2),Integer(2),Integer(1)]).specht_module(QQ); SM ␣
↪                      # needs sage.modules
Specht module of [2, 2, 1] over Rational Field
>>> SM.frobenius_image()                                               #␣
↪needs sage.modules
s[2, 2, 1]
```

specht_module_dimension(*base_ring=None*)

Return the dimension of the Specht module corresponding to `self`.

This is equal to the number of standard tableaux of shape `self` when over a field of characteristic 0.

INPUT:

- `base_ring` – (default: **Q**) the base ring

EXAMPLES:

```
sage: Partition([2,2,1]).specht_module_dimension()
5
sage: Partition([2,2,1]).specht_module_dimension(GF(2))                    #␣
↪needs sage.rings.finite_rings
5
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(1)]).specht_module_dimension()
5
>>> Partition([Integer(2),Integer(2),Integer(1)]).specht_module_
↪dimension(GF(Integer(2)))                    # needs sage.rings.finite_
↪rings
5
```

standard_tableaux()

Return the *standard tableaux* of shape `self`.

EXAMPLES:

```
sage: Partition([3,2,2,1]).standard_tableaux()
Standard tableaux of shape [3, 2, 2, 1]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1)]).standard_
↪tableaux()
Standard tableaux of shape [3, 2, 2, 1]
```

stretch(*k*)

Return the partition obtained by multiplying each part with the given number.

EXAMPLES:

```
sage: p = Partition([4,2,2,1,1])
sage: p.stretch(3)
[12, 6, 6, 3, 3]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(2),Integer(2),Integer(1),Integer(1)])
>>> p.stretch(Integer(3))
[12, 6, 6, 3, 3]
```

suter_diagonal_slide(*n*, *exp=1*)

Return the image of `self` in Y_n under Suter's diagonal slide σ_n, where the notations used are those defined in [Sut2002].

The set Y_n is defined as the set of all partitions λ such that the hook length of the $(0,0)$-cell (i.e. the north-western most cell in English notation) of λ is less than n, including the empty partition.

The map σ_n sends a partition (with nonzero entries) $(\lambda_1, \lambda_2, \ldots, \lambda_m) \in Y_n$ to the partition $(\lambda_2 + 1, \lambda_3 + 1, \ldots, \lambda_m + 1, \underbrace{1, 1, \ldots, 1}_{n-m-\lambda_1 \text{ ones}})$. In other words, it pads the partition with trailing zeroes until it has length $n - \lambda_1$, then removes its first part, and finally adds 1 to each part.

By Theorem 2.1 of [Sut2002], the dihedral group D_n with $2n$ elements acts on Y_n by letting the primitive rotation act as σ_n and the reflection act as conjugation of partitions (*conjugate()*). This action is faithful if $n \geq 3$.

INPUT:

- `n` – nonnegative integer
- `exp` – (default: 1) how many times σ_n should be applied

OUTPUT:

The result of applying Suter's diagonal slide σ_n to `self`, assuming that `self` lies in Y_n. If the optional argument `exp` is set, then the slide σ_n is applied not just once, but `exp` times (note that `exp` is allowed to be negative, since the slide has finite order).

EXAMPLES:

```
sage: Partition([5,4,1]).suter_diagonal_slide(8)
[5, 2]
sage: Partition([5,4,1]).suter_diagonal_slide(9)
[5, 2, 1]
sage: Partition([]).suter_diagonal_slide(7)
[1, 1, 1, 1, 1, 1]
sage: Partition([]).suter_diagonal_slide(1)
[]
sage: Partition([]).suter_diagonal_slide(7, exp=-1)
[6]
sage: Partition([]).suter_diagonal_slide(1, exp=-1)
[]
sage: P7 = Partitions(7)
sage: all( p == p.suter_diagonal_slide(9, exp=-1).suter_diagonal_slide(9)
....:      for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=3)
....:            .suter_diagonal_slide(9, exp=3)
....:            .suter_diagonal_slide(9, exp=3)
....:      for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=6)
....:            .suter_diagonal_slide(9, exp=6)
....:            .suter_diagonal_slide(9, exp=6)
....:      for p in P7 )
True
sage: all( p == p.suter_diagonal_slide(9, exp=-1)
....:            .suter_diagonal_slide(9, exp=1)
....:      for p in P7 )
True
```

```
>>> from sage.all import *
>>> Partition([Integer(5),Integer(4),Integer(1)]).suter_diagonal_
↪slide(Integer(8))
[5, 2]
>>> Partition([Integer(5),Integer(4),Integer(1)]).suter_diagonal_
↪slide(Integer(9))
[5, 2, 1]
```

(continues on next page)

(continued from previous page)

```
>>> Partition([]).suter_diagonal_slide(Integer(7))
[1, 1, 1, 1, 1, 1]
>>> Partition([]).suter_diagonal_slide(Integer(1))
[]
>>> Partition([]).suter_diagonal_slide(Integer(7), exp=-Integer(1))
[6]
>>> Partition([]).suter_diagonal_slide(Integer(1), exp=-Integer(1))
[]
>>> P7 = Partitions(Integer(7))
>>> all( p == p.suter_diagonal_slide(Integer(9), exp=-Integer(1)).suter_
↪diagonal_slide(Integer(9))
...       for p in P7 )
True
>>> all( p == p.suter_diagonal_slide(Integer(9), exp=Integer(3))
...             .suter_diagonal_slide(Integer(9), exp=Integer(3))
...             .suter_diagonal_slide(Integer(9), exp=Integer(3))
...       for p in P7 )
True
>>> all( p == p.suter_diagonal_slide(Integer(9), exp=Integer(6))
...             .suter_diagonal_slide(Integer(9), exp=Integer(6))
...             .suter_diagonal_slide(Integer(9), exp=Integer(6))
...       for p in P7 )
True
>>> all( p == p.suter_diagonal_slide(Integer(9), exp=-Integer(1))
...             .suter_diagonal_slide(Integer(9), exp=Integer(1))
...       for p in P7 )
True
```

Check of the assertion in [Sut2002] that $\sigma_n\big(\sigma_n(\lambda')'\big) = \lambda$:

```
sage: all( p.suter_diagonal_slide(8).conjugate()
....:      == p.conjugate().suter_diagonal_slide(8, exp=-1)
....:      for p in P7 )
True
```

```
>>> from sage.all import *
>>> all( p.suter_diagonal_slide(Integer(8)).conjugate()
...       == p.conjugate().suter_diagonal_slide(Integer(8), exp=-Integer(1))
...       for p in P7 )
True
```

Check of Claim 1 in [Sut2002]:

```
sage: P5 = Partitions(5)
sage: all( all( (p.suter_diagonal_slide(6) in q.suter_diagonal_slide(6).
↪down())
....:            or (q.suter_diagonal_slide(6) in p.suter_diagonal_slide(6).
↪down())
....:            for p in q.down() )
....:      for q in P5 )
True
```

```
>>> from sage.all import *
>>> P5 = Partitions(Integer(5))
>>> all( all( (p.suter_diagonal_slide(Integer(6)) in q.suter_diagonal_
↪slide(Integer(6)).down())
...           or (q.suter_diagonal_slide(Integer(6)) in p.suter_diagonal_
↪slide(Integer(6)).down())
...           for p in q.down() )
...      for q in P5 )
True
```

t_completion(*t*)

Return the `t`-completion of the partition `self`.

If $\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$ is a partition and t is an integer greater or equal to $|\lambda| + \lambda_1$, then the *t-completion of* λ is defined as the partition $(t - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots)$ of t. This partition is denoted by $\lambda[t]$ in [BOR2009], by $\lambda_{[t]}$ in [BdVO2012], and by $\lambda(t)$ in [CO2010].

EXAMPLES:

```
sage: Partition([]).t_completion(0)
[]
sage: Partition([]).t_completion(1)
[1]
sage: Partition([]).t_completion(2)
[2]
sage: Partition([]).t_completion(3)
[3]
sage: Partition([2, 1]).t_completion(5)
[2, 2, 1]
sage: Partition([2, 1]).t_completion(6)
[3, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(13)
[4, 4, 2, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(19)
[10, 4, 2, 2, 1]
sage: Partition([4, 2, 2, 1]).t_completion(10)
Traceback (most recent call last):
...
ValueError: 10-completion is not defined
sage: Partition([4, 2, 2, 1]).t_completion(5)
Traceback (most recent call last):
...
ValueError: 5-completion is not defined
```

```
>>> from sage.all import *
>>> Partition([]).t_completion(Integer(0))
[]
>>> Partition([]).t_completion(Integer(1))
[1]
>>> Partition([]).t_completion(Integer(2))
[2]
>>> Partition([]).t_completion(Integer(3))
[3]
```

(continues on next page)

(continued from previous page)

```
>>> Partition([Integer(2), Integer(1)]).t_completion(Integer(5))
[2, 2, 1]
>>> Partition([Integer(2), Integer(1)]).t_completion(Integer(6))
[3, 2, 1]
>>> Partition([Integer(4), Integer(2), Integer(2), Integer(1)]).t_
↪completion(Integer(13))
[4, 4, 2, 2, 1]
>>> Partition([Integer(4), Integer(2), Integer(2), Integer(1)]).t_
↪completion(Integer(19))
[10, 4, 2, 2, 1]
>>> Partition([Integer(4), Integer(2), Integer(2), Integer(1)]).t_
↪completion(Integer(10))
Traceback (most recent call last):
...
ValueError: 10-completion is not defined
>>> Partition([Integer(4), Integer(2), Integer(2), Integer(1)]).t_
↪completion(Integer(5))
Traceback (most recent call last):
...
ValueError: 5-completion is not defined
```

tabloid_module(*base_ring=None*)

Return the tabloid module corresponding to `self`.

EXAMPLES:

```
sage: TM = Partition([2,2,1]).tabloid_module(QQ); TM
Tabloid module of [2, 2, 1] over Rational Field
sage: TM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

```
>>> from sage.all import *
>>> TM = Partition([Integer(2),Integer(2),Integer(1)]).tabloid_module(QQ); TM
Tabloid module of [2, 2, 1] over Rational Field
>>> TM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

to_core(k)

Map the k-bounded partition `self` to its corresponding $k+1$-core.

See also *k_skew()*.

EXAMPLES:

```
sage: p = Partition([4,3,2,2,1,1])
sage: c = p.to_core(4); c
[9, 5, 3, 2, 1, 1]
sage: type(c)
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: c.to_bounded_partition() == p
True
```

```
>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(3),Integer(2),Integer(2),Integer(1),
↪Integer(1)])
>>> c = p.to_core(Integer(4)); c
[9, 5, 3, 2, 1, 1]
>>> type(c)
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
>>> c.to_bounded_partition() == p
True
```

to_dyck_word(*n=None*)

Return the `n`-Dyck word whose corresponding partition is `self` (or, if `n` is not specified, the n-Dyck word with smallest n to satisfy this property).

If w is an n-Dyck word (that is, a Dyck word with n open symbols and n close symbols), then the Dyck path corresponding to w can be regarded as a lattice path in the northeastern half of an $n \times n$-square. The region to the northeast of this Dyck path can be regarded as a partition. It is called the partition corresponding to the Dyck word w. (See *to_partition()*.)

For every partition λ and every nonnegative integer n, there exists at most one n-Dyck word w such that the partition corresponding to w is λ (in fact, such w exists if and only if $\lambda_i + i \leq n$ for every i, where λ is written in the form $(\lambda_1, \lambda_2, \ldots, \lambda_k)$ with $\lambda_k > 0$). This method computes this w for a given λ and n. If n is not specified, this method computes the w for the smallest possible n for which such an w exists. (The minimality of n means that the partition demarcated by the Dyck path touches the diagonal.)

EXAMPLES:

```
sage: Partition([2,2]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(4)
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(5)
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
sage: Partition([6,3,1]).to_dyck_word()
[1, 1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0]
sage: Partition([]).to_dyck_word()
[]
sage: Partition([]).to_dyck_word(3)
[1, 1, 1, 0, 0, 0]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 0]
>>> Partition([Integer(2),Integer(2)]).to_dyck_word(Integer(4))
[1, 1, 0, 0, 1, 1, 0, 0]
>>> Partition([Integer(2),Integer(2)]).to_dyck_word(Integer(5))
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
>>> Partition([Integer(6),Integer(3),Integer(1)]).to_dyck_word()
[1, 1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0]
>>> Partition([]).to_dyck_word()
[]
>>> Partition([]).to_dyck_word(Integer(3))
[1, 1, 1, 0, 0, 0]
```

The partition corresponding to `self.dyck_word()` is `self` indeed:

```
sage: all( p.to_dyck_word().to_partition() == p
....:      for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> all( p.to_dyck_word().to_partition() == p
...      for p in Partitions(Integer(5)) )
True
```

to_exp(*k=0*)

Return a list of the multiplicities of the parts of a partition. Use the optional parameter `k` to get a return list of length at least `k`.

EXAMPLES:

```
sage: Partition([3,2,2,1]).to_exp()
[1, 2, 1]
sage: Partition([3,2,2,1]).to_exp(5)
[1, 2, 1, 0, 0]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1)]).to_exp()
[1, 2, 1]
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1)]).to_
↪exp(Integer(5))
[1, 2, 1, 0, 0]
```

to_exp_dict()

Return a dictionary containing the multiplicities of the parts of `self`.

EXAMPLES:

```
sage: p = Partition([4,2,2,1])
sage: d = p.to_exp_dict()
sage: d[4]
1
sage: d[2]
2
sage: d[1]
1
sage: 5 in d
False
```

```
>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(2),Integer(2),Integer(1)])
>>> d = p.to_exp_dict()
>>> d[Integer(4)]
1
>>> d[Integer(2)]
2
>>> d[Integer(1)]
1
```

(continues on next page)

(continued from previous page)

```
>>> Integer(5) in d
False
```

to_list()

Return `self` as a list.

EXAMPLES:

```
sage: p = Partition([2,1]).to_list(); p
[2, 1]
sage: type(p)
<class 'list'>
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1)]).to_list(); p
[2, 1]
>>> type(p)
<class 'list'>
```

top_garnir_tableau(*e*, *cell*)

Return the most dominant *standard* tableau which dominates the corresponding Garnir tableau and has the same `e`-residue.

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules. The *top Garnir tableaux* arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR2012].

If the Garnir node is `cell=(r,c)` and m and M are the entries in the cells `(r,c)` and `(r+1,c)`, respectively, in the initial tableau then the top `e`-Garnir tableau is obtained by inserting the numbers $m, m+1, \ldots, M$ in order from left to right first in the cells in row `r+1` which are not in the `e`-Garnir belt, then in the cell in rows `r` and `r+1` which are in the Garnir belt and then, finally, in the remaining cells in row `r` which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If `e = 0`, or if there are no `e`-bricks in either row `r` or `r+1`, then the top Garnir tableau is the corresponding Garnir tableau.

EXAMPLES:

```
sage: Partition([5,4,3,2]).top_garnir_tableau(2,(0,2)).pp()
   1  2  4  5  8
   3  6  7  9
  10 11 12
  13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(3,(0,2)).pp()
   1  2  3  4  5
   6  7  8  9
  10 11 12
  13 14
sage: Partition([5,4,3,2]).top_garnir_tableau(4,(0,2)).pp()
   1  2  6  7  8
   3  4  5  9
  10 11 12
  13 14
```

(continues on next page)

(continued from previous page)

```
sage: Partition([5,4,3,2]).top_garnir_tableau(0,(0,2)).pp()
   1  2  6  7  8
   3  4  5  9
  10 11 12
  13 14
```

```
>>> from sage.all import *
>>> Partition([Integer(5),Integer(4),Integer(3),Integer(2)]).top_garnir_
↪tableau(Integer(2),(Integer(0),Integer(2))).pp()
   1  2  4  5  8
   3  6  7  9
  10 11 12
  13 14
>>> Partition([Integer(5),Integer(4),Integer(3),Integer(2)]).top_garnir_
↪tableau(Integer(3),(Integer(0),Integer(2))).pp()
   1  2  3  4  5
   6  7  8  9
  10 11 12
  13 14
>>> Partition([Integer(5),Integer(4),Integer(3),Integer(2)]).top_garnir_
↪tableau(Integer(4),(Integer(0),Integer(2))).pp()
   1  2  6  7  8
   3  4  5  9
  10 11 12
  13 14
>>> Partition([Integer(5),Integer(4),Integer(3),Integer(2)]).top_garnir_
↪tableau(Integer(0),(Integer(0),Integer(2))).pp()
   1  2  6  7  8
   3  4  5  9
  10 11 12
  13 14
```

REFERENCES:

- [KMR2012]

up()

Return a generator for partitions that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: list(Partition([2,1,1]).up())
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: list(Partition([3,2]).up())
[[4, 2], [3, 3], [3, 2, 1]]
sage: [p for p in Partition([]).up()]
[[1]]
```

```
>>> from sage.all import *
>>> list(Partition([Integer(2),Integer(1),Integer(1)]).up())
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
>>> list(Partition([Integer(3),Integer(2)]).up())
[[4, 2], [3, 3], [3, 2, 1]]
```

(continues on next page)

(continued from previous page)

```
>>> [p for p in Partition([]).up()]
[[1]]
```

up_list()

Return a list of the partitions that can be formed from `self` by adding a cell.

EXAMPLES:

```
sage: Partition([2,1,1]).up_list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: Partition([3,2]).up_list()
[[4, 2], [3, 3], [3, 2, 1]]
sage: Partition([]).up_list()
[[1]]
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1),Integer(1)]).up_list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
>>> Partition([Integer(3),Integer(2)]).up_list()
[[4, 2], [3, 3], [3, 2, 1]]
>>> Partition([]).up_list()
[[1]]
```

upper_hook(*i*, *j*, *alpha*)

Return the upper hook length of the cell (i, j) in `self`. When `alpha = 1`, this is just the normal hook length.

The upper hook length of a cell (i, j) in a partition κ is defined by

$$h^*_\kappa(i,j) = \kappa'_j - i + \alpha(\kappa_i - j + 1).$$

EXAMPLES:

```
sage: p = Partition([2,1])
sage: p.upper_hook(0,0,1)
3
sage: p.hook_length(0,0)
3
sage: [ p.upper_hook(i,j,x) for i,j in p.cells() ]                              #␣
↪needs sage.symbolic
[2*x + 1, x, x]
```

```
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1)])
>>> p.upper_hook(Integer(0),Integer(0),Integer(1))
3
>>> p.hook_length(Integer(0),Integer(0))
3
>>> [ p.upper_hook(i,j,x) for i,j in p.cells() ]                              #␣
↪needs sage.symbolic
[2*x + 1, x, x]
```

upper_hook_lengths(*alpha*)

Return a tableau of shape `self` with the cells filled in with the upper hook lengths. When `alpha = 1`, these are just the normal hook lengths.

The upper hook length of a cell (i, j) in a partition κ is defined by

$$h^*_\kappa(i,j) = \kappa'_j - i + \alpha(\kappa_i - j + 1).$$

EXAMPLES:

```
sage: Partition([3,2,1]).upper_hook_lengths(x)                                  #␣
↪needs sage.symbolic
[[3*x + 2, 2*x + 1, x], [2*x + 1, x], [x]]
sage: Partition([3,2,1]).upper_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).upper_hook_lengths(x)       ␣
↪                        # needs sage.symbolic
[[3*x + 2, 2*x + 1, x], [2*x + 1, x], [x]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).upper_hook_
↪lengths(Integer(1))
[[5, 3, 1], [3, 1], [1]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
```

vertical_border_strip_cells(*k*)

Return a list of all the vertical border strips of length `k` which can be added to `self`, where each horizontal border strip is a `generator` of cells.

EXAMPLES:

```
sage: list(Partition([]).vertical_border_strip_cells(0))
[]
sage: list(Partition([3,2,1]).vertical_border_strip_cells(0))
[]
sage: list(Partition([]).vertical_border_strip_cells(2))
[[(0, 0), (1, 0)]]
sage: list(Partition([2,2]).vertical_border_strip_cells(2))
[[(0, 2), (1, 2)],
 [(0, 2), (2, 0)],
 [(2, 0), (3, 0)]]
sage: list(Partition([3,2,2]).vertical_border_strip_cells(2))
[[(0, 3), (1, 2)],
 [(0, 3), (3, 0)],
 [(1, 2), (2, 2)],
 [(1, 2), (3, 0)],
 [(3, 0), (4, 0)]]
```

```
>>> from sage.all import *
>>> list(Partition([]).vertical_border_strip_cells(Integer(0)))
[]
```

(continues on next page)

(continued from previous page)

```
>>> list(Partition([Integer(3),Integer(2),Integer(1)]).vertical_border_strip_
↪cells(Integer(0)))
[]
>>> list(Partition([]).vertical_border_strip_cells(Integer(2)))
[[(0, 0), (1, 0)]]
>>> list(Partition([Integer(2),Integer(2)]).vertical_border_strip_
↪cells(Integer(2)))
[[(0, 2), (1, 2)],
 [(0, 2), (2, 0)],
 [(2, 0), (3, 0)]]
>>> list(Partition([Integer(3),Integer(2),Integer(2)]).vertical_border_strip_
↪cells(Integer(2)))
[[(0, 3), (1, 2)],
 [(0, 3), (3, 0)],
 [(1, 2), (2, 2)],
 [(1, 2), (3, 0)],
 [(3, 0), (4, 0)]]
```

weighted_size()

Return the weighted size of `self`.

The weighted size of a partition λ is

$$\sum_i i \cdot \lambda_i,$$

where $\lambda = (\lambda_0, \lambda_1, \lambda_2, \cdots)$.

This also the sum of the leg length of every cell in λ, or

$$\sum_i \binom{\lambda'_i}{2}$$

where λ' is the conjugate partition of λ.

EXAMPLES:

```
sage: Partition([2,2]).weighted_size()
2
sage: Partition([3,3,3]).weighted_size()
9
sage: Partition([5,2]).weighted_size()
2
sage: Partition([]).weighted_size()
0
```

```
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).weighted_size()
2
>>> Partition([Integer(3),Integer(3),Integer(3)]).weighted_size()
9
>>> Partition([Integer(5),Integer(2)]).weighted_size()
2
>>> Partition([]).weighted_size()
0
```

young_subgroup()

Return the corresponding Young, or parabolic, subgroup of the symmetric group.

The Young subgroup of a partition $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ of n is the group:

$$S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell}$$

embedded into S_n in the standard way (i.e., the S_{λ_i} factor acts on the numbers from $\lambda_1 + \lambda_2 + \cdots + \lambda_{i-1} + 1$ to $\lambda_1 + \lambda_2 + \cdots + \lambda_i$).

EXAMPLES:

```
sage: Partition([4,2]).young_subgroup()                                    #␣
↪needs sage.groups
Permutation Group with generators [(), (5,6), (3,4), (2,3), (1,2)]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(2)]).young_subgroup()                    ␣
↪              # needs sage.groups
Permutation Group with generators [(), (5,6), (3,4), (2,3), (1,2)]
```

young_subgroup_generators()

Return an indexing set for the generators of the corresponding Young subgroup. Here the generators correspond to the simple adjacent transpositions $s_i = (i\ i+1)$.

EXAMPLES:

```
sage: Partition([4,2]).young_subgroup_generators()
[1, 2, 3, 5]
sage: Partition([1,1,1]).young_subgroup_generators()
[]
sage: Partition([2,2]).young_subgroup_generators()
[1, 3]
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(2)]).young_subgroup_generators()
[1, 2, 3, 5]
>>> Partition([Integer(1),Integer(1),Integer(1)]).young_subgroup_generators()
[]
>>> Partition([Integer(2),Integer(2)]).young_subgroup_generators()
[1, 3]
```

See also

young_subgroup()

zero_one_sequence()

Compute the finite $0-1$ sequence of the partition.

The full $0-1$ sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.

Note that every full $0-1$ sequence starts with infinitely many 0s and ends with infinitely many 1s.

One place where these arise is in the affine symmetric group where one takes an affine permutation w and every i such that $w(i) \leq 0$ corresponds to a 1 and $w(i) > 0$ corresponds to a 0. See pages 24-25 of [LLMSSZ2013] for connections to affine Grassmannian elements (note there they use the French convention for their partitions).

These are also known as **path sequences**, **Maya diagrams**, **plus-minus diagrams**, **Comet code** [Sta-EC2], among others.

OUTPUT:

The finite $0-1$ sequence is obtained from the full $0-1$ sequence by omitting all heading 0s and trailing 1s. The output sequence is finite, starts with a 1 and ends with a 0 (unless it is empty, for the empty partition). Its length is the sum of the first part of the partition with the length of the partition.

EXAMPLES:

```
sage: Partition([5,4]).zero_one_sequence()
[1, 1, 1, 1, 0, 1, 0]
sage: Partition([]).zero_one_sequence()
[]
sage: Partition([2]).zero_one_sequence()
[1, 1, 0]
```

```
>>> from sage.all import *
>>> Partition([Integer(5),Integer(4)]).zero_one_sequence()
[1, 1, 1, 1, 0, 1, 0]
>>> Partition([]).zero_one_sequence()
[]
>>> Partition([Integer(2)]).zero_one_sequence()
[1, 1, 0]
```

class sage.combinat.partition.**Partitions**(*is_infinite=False*)

Bases: UniqueRepresentation, Parent

`Partitions(n, **kwargs)` returns the combinatorial class of integer partitions of n subject to the constraints given by the keywords.

Valid keywords are: `starting`, `ending`, `min_part`, `max_part`, `max_length`, `min_length`, `length`, `max_slope`, `min_slope`, `inner`, `outer`, `parts_in`, `regular`, and `restricted`. They have the following meanings:

- `starting=p` specifies that the partitions should all be less than or equal to p in lex order. This argument cannot be combined with any other (see Issue #15467).
- `ending=p` specifies that the partitions should all be greater than or equal to p in lex order. This argument cannot be combined with any other (see Issue #15467).
- `length=k` specifies that the partitions have exactly k parts.
- `min_length=k` specifies that the partitions have at least k parts.
- `min_part=k` specifies that all parts of the partitions are at least k.
- `inner=p` specifies that the partitions must contain the partition p.
- `outer=p` specifies that the partitions be contained inside the partition p.
- `min_slope=k` specifies that the partitions have slope at least k; the slope at position i is the difference between the $(i+1)$-th part and the i-th part.

- `parts_in=S` specifies that the partitions have parts in the set S, which can be any sequence of pairwise distinct positive integers. This argument cannot be combined with any other (see Issue #15467).
- `regular=ell` specifies that the partitions are ℓ-regular, and can only be combined with the `max_length` or `max_part`, but not both, keywords if n is not specified
- `restricted=ell` specifies that the partitions are ℓ-restricted, and cannot be combined with any other keywords

The `max_*` versions, along with `inner` and `ending`, work analogously.

Right now, the `parts_in`, `starting`, `ending`, `regular`, and `restricted` keyword arguments are mutually exclusive, both of each other and of other keyword arguments. If you specify, say, `parts_in`, all other keyword arguments will be ignored; `starting`, `ending`, `regular`, and `restricted` work the same way.

EXAMPLES:

If no arguments are passed, then the combinatorial class of all integer partitions is returned:

```
sage: Partitions()
Partitions
sage: [2,1] in Partitions()
True
```

```
>>> from sage.all import *
>>> Partitions()
Partitions
>>> [Integer(2),Integer(1)] in Partitions()
True
```

If an integer n is passed, then the combinatorial class of integer partitions of n is returned:

```
sage: Partitions(3)
Partitions of the integer 3
sage: Partitions(3).list()
[[3], [2, 1], [1, 1, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(3))
Partitions of the integer 3
>>> Partitions(Integer(3)).list()
[[3], [2, 1], [1, 1, 1]]
```

If `starting=p` is passed, then the combinatorial class of partitions greater than or equal to p in lexicographic order is returned:

```
sage: Partitions(3, starting=[2,1])
Partitions of the integer 3 starting with [2, 1]
sage: Partitions(3, starting=[2,1]).list()
[[2, 1], [1, 1, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(3), starting=[Integer(2),Integer(1)])
Partitions of the integer 3 starting with [2, 1]
>>> Partitions(Integer(3), starting=[Integer(2),Integer(1)]).list()
[[2, 1], [1, 1, 1]]
```

If `ending=p` is passed, then the combinatorial class of partitions at most p in lexicographic order is returned:

```
sage: Partitions(3, ending=[2,1])
Partitions of the integer 3 ending with [2, 1]
sage: Partitions(3, ending=[2,1]).list()
[[3], [2, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(3), ending=[Integer(2),Integer(1)])
Partitions of the integer 3 ending with [2, 1]
>>> Partitions(Integer(3), ending=[Integer(2),Integer(1)]).list()
[[3], [2, 1]]
```

Using `max_slope=-1` yields partitions into distinct parts – each part differs from the next by at least 1. Use a different `max_slope` to get parts that differ by, say, 2:

```
sage: Partitions(7, max_slope=-1).list()
[[7], [6, 1], [5, 2], [4, 3], [4, 2, 1]]
sage: Partitions(15, max_slope=-1).cardinality()
27
```

```
>>> from sage.all import *
>>> Partitions(Integer(7), max_slope=-Integer(1)).list()
[[7], [6, 1], [5, 2], [4, 3], [4, 2, 1]]
>>> Partitions(Integer(15), max_slope=-Integer(1)).cardinality()
27
```

The number of partitions of n into odd parts equals the number of partitions into distinct parts. Let's test that for n from 10 to 20:

```
sage: def test(n):
....:     return (Partitions(n, max_slope=-1).cardinality()
....:             == Partitions(n, parts_in=[1,3..n]).cardinality())
sage: all(test(n) for n in [10..20])                                          #␣
↪needs sage.libs.gap
True
```

```
>>> from sage.all import *
>>> def test(n):
...     return (Partitions(n, max_slope=-Integer(1)).cardinality()
...             == Partitions(n, parts_in=(ellipsis_range(Integer(1),Integer(3),
↪Ellipsis,n))).cardinality())
>>> all(test(n) for n in (ellipsis_range(Integer(10),Ellipsis,Integer(20))))     ␣
↪                                    # needs sage.libs.gap
True
```

The number of partitions of n into distinct parts that differ by at least 2 equals the number of partitions into parts that equal 1 or 4 modulo 5; this is one of the Rogers-Ramanujan identities:

```
sage: def test(n):
....:     return (Partitions(n, max_slope=-2).cardinality()
....:             == Partitions(n, parts_in=([1,6..n] + [4,9..n])).cardinality())
sage: all(test(n) for n in [10..20])                                          #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.libs.gap
True
```

```
>>> from sage.all import *
>>> def test(n):
...     return (Partitions(n, max_slope=-Integer(2)).cardinality()
...             == Partitions(n, parts_in=((ellipsis_range(Integer(1),Integer(6),
↪Ellipsis,n)) + (ellipsis_range(Integer(4),Integer(9),Ellipsis,n)))).
↪cardinality())
>>> all(test(n) for n in (ellipsis_range(Integer(10),Ellipsis,Integer(20))))     ␣
↪                                    # needs sage.libs.gap
True
```

Here are some more examples illustrating `min_part`, `max_part`, and `length`:

```
sage: Partitions(5, min_part=2)
Partitions of 5 whose parts are at least 2
sage: Partitions(5, min_part=2).list()
[[5], [3, 2]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(5), min_part=Integer(2))
Partitions of 5 whose parts are at least 2
>>> Partitions(Integer(5), min_part=Integer(2)).list()
[[5], [3, 2]]
```

```
sage: Partitions(3, max_length=2).list()
[[3], [2, 1]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(3), max_length=Integer(2)).list()
[[3], [2, 1]]
```

```
sage: Partitions(10, min_part=2, length=3).list()
[[6, 2, 2], [5, 3, 2], [4, 4, 2], [4, 3, 3]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(10), min_part=Integer(2), length=Integer(3)).list()
[[6, 2, 2], [5, 3, 2], [4, 4, 2], [4, 3, 3]]
```

Some examples using the `regular` keyword:

```
sage: Partitions(regular=4)
4-Regular Partitions
sage: Partitions(regular=4, max_length=3)
4-Regular Partitions with max length 3
sage: Partitions(regular=4, max_part=3)
4-Regular 3-Bounded Partitions
sage: Partitions(3, regular=4)
4-Regular Partitions of the integer 3
```

```
>>> from sage.all import *
>>> Partitions(regular=Integer(4))
4-Regular Partitions
>>> Partitions(regular=Integer(4), max_length=Integer(3))
4-Regular Partitions with max length 3
>>> Partitions(regular=Integer(4), max_part=Integer(3))
4-Regular 3-Bounded Partitions
>>> Partitions(Integer(3), regular=Integer(4))
4-Regular Partitions of the integer 3
```

Some examples using the `restricted` keyword:

```
sage: Partitions(restricted=4)
4-Restricted Partitions
sage: Partitions(3, restricted=4)
4-Restricted Partitions of the integer 3
```

```
>>> from sage.all import *
>>> Partitions(restricted=Integer(4))
4-Restricted Partitions
>>> Partitions(Integer(3), restricted=Integer(4))
4-Restricted Partitions of the integer 3
```

Here are some further examples using various constraints:

```
sage: [x for x in Partitions(4)]
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, length=2)]
[[3, 1], [2, 2]]
sage: [x for x in Partitions(4, min_length=2)]
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, max_length=2)]
[[4], [3, 1], [2, 2]]
sage: [x for x in Partitions(4, min_length=2, max_length=2)]
[[3, 1], [2, 2]]
sage: [x for x in Partitions(4, max_part=2)]
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, min_part=2)]
[[4], [2, 2]]
sage: [x for x in Partitions(4, outer=[3,1,1])]
[[3, 1], [2, 1, 1]]
sage: [x for x in Partitions(4, outer=[infinity, 1, 1])]
[[4], [3, 1], [2, 1, 1]]
sage: [x for x in Partitions(4, inner=[1,1,1])]
[[2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, max_slope=-1)]
[[4], [3, 1]]
sage: [x for x in Partitions(4, min_slope=-1)]
[[4], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_
↪length=4)]
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
sage: [x for x in Partitions(11, max_slope=-1, min_slope=-3, min_length=2, max_
```

(continues on next page)

(continued from previous page)

```
↪length=4, outer=[6,5,2])]
[[6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2]]
```

```
>>> from sage.all import *
>>> [x for x in Partitions(Integer(4))]
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
>>> [x for x in Partitions(Integer(4), length=Integer(2))]
[[3, 1], [2, 2]]
>>> [x for x in Partitions(Integer(4), min_length=Integer(2))]
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
>>> [x for x in Partitions(Integer(4), max_length=Integer(2))]
[[4], [3, 1], [2, 2]]
>>> [x for x in Partitions(Integer(4), min_length=Integer(2), max_
↪length=Integer(2))]
[[3, 1], [2, 2]]
>>> [x for x in Partitions(Integer(4), max_part=Integer(2))]
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
>>> [x for x in Partitions(Integer(4), min_part=Integer(2))]
[[4], [2, 2]]
>>> [x for x in Partitions(Integer(4), outer=[Integer(3),Integer(1),Integer(1)])]
[[3, 1], [2, 1, 1]]
>>> [x for x in Partitions(Integer(4), outer=[infinity, Integer(1), Integer(1)])]
[[4], [3, 1], [2, 1, 1]]
>>> [x for x in Partitions(Integer(4), inner=[Integer(1),Integer(1),Integer(1)])]
[[2, 1, 1], [1, 1, 1, 1]]
>>> [x for x in Partitions(Integer(4), max_slope=-Integer(1))]
[[4], [3, 1]]
>>> [x for x in Partitions(Integer(4), min_slope=-Integer(1))]
[[4], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
>>> [x for x in Partitions(Integer(11), max_slope=-Integer(1), min_slope=-
↪Integer(3), min_length=Integer(2), max_length=Integer(4))]
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
>>> [x for x in Partitions(Integer(11), max_slope=-Integer(1), min_slope=-
↪Integer(3), min_length=Integer(2), max_length=Integer(4), outer=[Integer(6),
↪Integer(5),Integer(2)])]
[[6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2]]
```

Note that if you specify `min_part=0`, then it will treat the minimum part as being 1 (see Issue #13605):

```
sage: [x for x in Partitions(4, length=3, min_part=0)]
[[2, 1, 1]]
sage: [x for x in Partitions(4, min_length=3, min_part=0)]
[[2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> [x for x in Partitions(Integer(4), length=Integer(3), min_part=Integer(0))]
[[2, 1, 1]]
>>> [x for x in Partitions(Integer(4), min_length=Integer(3), min_
↪part=Integer(0))]
[[2, 1, 1], [1, 1, 1, 1]]
```

Except for very special cases, counting is done by brute force iteration through all the partitions. However the iter-

ation itself has a reasonable complexity (see *IntegerListsLex*), which allows for manipulating large partitions:

```
sage: Partitions(1000, max_length=1).list()
[[1000]]
```

```
>>> from sage.all import *
>>> Partitions(Integer(1000), max_length=Integer(1)).list()
[[1000]]
```

In particular, getting the first element is also constant time:

```
sage: Partitions(30, max_part=29).first()
[29, 1]
```

```
>>> from sage.all import *
>>> Partitions(Integer(30), max_part=Integer(29)).first()
[29, 1]
```

Element

alias of *Partition*

options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast

subset(**args*, ***kwargs*)

Return `self` if no arguments are given.

Otherwise, it raises a `ValueError`.

EXAMPLES:

```
sage: P = Partitions(5, starting=[3,1]); P
Partitions of the integer 5 starting with [3, 1]
sage: P.subset()
Partitions of the integer 5 starting with [3, 1]
sage: P.subset(ending=[3,1])
Traceback (most recent call last):
...
ValueError: invalid combination of arguments
```

```
>>> from sage.all import *
>>> P = Partitions(Integer(5), starting=[Integer(3),Integer(1)]); P
Partitions of the integer 5 starting with [3, 1]
>>> P.subset()
Partitions of the integer 5 starting with [3, 1]
>>> P.subset(ending=[Integer(3),Integer(1)])
Traceback (most recent call last):
...
ValueError: invalid combination of arguments
```

class sage.combinat.partition.**PartitionsGreatestEQ**(n, k)

Bases: `UniqueRepresentation`, *IntegerListsLex*

The class of all (unordered) "restricted" partitions of the integer n having all its greatest parts equal to the integer k.

EXAMPLES:

```
sage: PartitionsGreatestEQ(10, 2)
Partitions of 10 having greatest part equal to 2
sage: PartitionsGreatestEQ(10, 2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestEQ(10, 2)
False
sage: [2,2,2,2,2] in PartitionsGreatestEQ(10, 2)
True
```

```
>>> from sage.all import *
>>> PartitionsGreatestEQ(Integer(10), Integer(2))
Partitions of 10 having greatest part equal to 2
>>> PartitionsGreatestEQ(Integer(10), Integer(2)).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1]]

>>> [Integer(4),Integer(3),Integer(2),Integer(1)] in␣
↪PartitionsGreatestEQ(Integer(10), Integer(2))
False
>>> [Integer(2),Integer(2),Integer(2),Integer(2),Integer(2)] in␣
↪PartitionsGreatestEQ(Integer(10), Integer(2))
True
```

The empty partition has no maximal part, but it is contained in the set of partitions with any specified maximal part:

```
sage: PartitionsGreatestEQ(0, 2).list()
[[]]
```

```
>>> from sage.all import *
>>> PartitionsGreatestEQ(Integer(0), Integer(2)).list()
[[]]
```

Element

alias of *Partition*

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: PartitionsGreatestEQ(10, 2).cardinality()
5
```

```
>>> from sage.all import *

5
```

options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast

class sage.combinat.partition.**PartitionsGreatestLE**(n, k)

Bases: UniqueRepresentation, *IntegerListsLex*

The class of all (unordered) "restricted" partitions of the integer n having parts less than or equal to the integer k.

EXAMPLES:

```
sage: PartitionsGreatestLE(10, 2)
Partitions of 10 having parts less than or equal to 2
sage: PartitionsGreatestLE(10, 2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1],
 [1, 1, 1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestLE(10, 2)
False
sage: [2,2,2,2,2] in PartitionsGreatestLE(10, 2)
True
sage: PartitionsGreatestLE(10, 2).first().parent()
Partitions...
```

```
>>> from sage.all import *
>>> PartitionsGreatestLE(Integer(10), Integer(2))
Partitions of 10 having parts less than or equal to 2
>>> PartitionsGreatestLE(Integer(10), Integer(2)).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1],
 [1, 1, 1, 1, 1, 1, 1, 1, 1, 1]]

>>> [Integer(4),Integer(3),Integer(2),Integer(1)] in␣
↪PartitionsGreatestLE(Integer(10), Integer(2))
False
>>> [Integer(2),Integer(2),Integer(2),Integer(2),Integer(2)] in␣
↪PartitionsGreatestLE(Integer(10), Integer(2))
True
>>> PartitionsGreatestLE(Integer(10), Integer(2)).first().parent()
Partitions...
```

Element

alias of *Partition*

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: PartitionsGreatestLE(9, 5).cardinality()                                #␣
↪needs sage.libs.gap
23
```

```
>>> from sage.all import *
>>> PartitionsGreatestLE(Integer(9), Integer(5)).cardinality()                ␣
↪              # needs sage.libs.gap
23
```

options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast

class sage.combinat.partition.**PartitionsInBox**(h, w)

Bases: *Partitions*

All partitions which fit in an $h \times w$ box.

EXAMPLES:

```
sage: PartitionsInBox(2, 2)
Integer partitions which fit in a 2 x 2 box
sage: PartitionsInBox(2, 2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]

sage: Partitions(max_part=2, max_length=3)
Integer partitions which fit in a 3 x 2 box
```

```
>>> from sage.all import *
>>> PartitionsInBox(Integer(2), Integer(2))
Integer partitions which fit in a 2 x 2 box
>>> PartitionsInBox(Integer(2), Integer(2)).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]

>>> Partitions(max_part=Integer(2), max_length=Integer(3))
Integer partitions which fit in a 3 x 2 box
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: PartitionsInBox(2, 3).cardinality()
10
```

```
>>> from sage.all import *
>>> PartitionsInBox(Integer(2), Integer(3)).cardinality()
10
```

list()

Return a list of all the partitions inside a box of height h and width w.

EXAMPLES:

```
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
sage: PartitionsInBox(2,3).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2], [3], [3, 1], [3, 2], [3, 3]]
```

```
>>> from sage.all import *
>>> PartitionsInBox(Integer(2),Integer(2)).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
>>> PartitionsInBox(Integer(2),Integer(3)).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2], [3], [3, 1], [3, 2], [3, 3]]
```

class sage.combinat.partition.**Partitions_all**

Bases: *Partitions*

Class of all partitions.

from_beta_numbers(*beta*)

Return a partition corresponding to a sequence of beta numbers.

A sequence of beta numbers is a strictly increasing sequence $0 \leq b_1 < \cdots < b_k$ of nonnegative integers. The corresponding partition $\mu = (\mu_k, \ldots, \mu_1)$ is given by $\mu_i = [1, i) \setminus \{b_1, \ldots, b_i\}$. This gives a bijection from the set of partitions with at most k nonzero parts to the set of strictly increasing sequences of nonnegative integers of length k.

EXAMPLES:

```
sage: Partitions().from_beta_numbers([0,1,2,4,5,8])
[3, 1, 1]
sage: Partitions().from_beta_numbers([0,2,3,6])
[3, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions().from_beta_numbers([Integer(0),Integer(1),Integer(2),
↪Integer(4),Integer(5),Integer(8)])
[3, 1, 1]
>>> Partitions().from_beta_numbers([Integer(0),Integer(2),Integer(3),
↪Integer(6)])
[3, 1, 1]
```

from_core_and_quotient(*core*, *quotient*)

Return a partition from its core and quotient.

Algorithm from mupad-combinat.

EXAMPLES:

```
sage: Partitions().from_core_and_quotient([2,1], [[2,1],[3],[1,1,1]])
[11, 5, 5, 3, 2, 2, 2]
```

```
>>> from sage.all import *
>>> Partitions().from_core_and_quotient([Integer(2),Integer(1)], [[Integer(2),
↪Integer(1)],[Integer(3)],[Integer(1),Integer(1),Integer(1)]])
[11, 5, 5, 3, 2, 2, 2]
```

from_exp(*exp*)

Return a partition from its list of multiplicities.

EXAMPLES:

```
sage: Partitions().from_exp([2,2,1])
[3, 2, 2, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions().from_exp([Integer(2),Integer(2),Integer(1)])
[3, 2, 2, 1, 1]
```

from_frobenius_coordinates(*frobenius_coordinates*)

Return a partition from a pair of sequences of Frobenius coordinates.

EXAMPLES:

```
sage: Partitions().from_frobenius_coordinates(([],[]))
[]
sage: Partitions().from_frobenius_coordinates(([0],[0]))
[1]
sage: Partitions().from_frobenius_coordinates(([1],[1]))
[2, 1]
sage: Partitions().from_frobenius_coordinates(([6,3,2],[4,1,0]))
[7, 5, 5, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions().from_frobenius_coordinates(([],[]))
[]
>>> Partitions().from_frobenius_coordinates(([Integer(0)],[Integer(0)]))
[1]
>>> Partitions().from_frobenius_coordinates(([Integer(1)],[Integer(1)]))
[2, 1]
>>> Partitions().from_frobenius_coordinates(([Integer(6),Integer(3),
↪Integer(2)],[Integer(4),Integer(1),Integer(0)]))
[7, 5, 5, 1, 1]
```

from_zero_one(*seq*)

Return a partition from its $0-1$ sequence.

The full $0-1$ sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.

Note that every full $0-1$ sequence starts with infinitely many 0s and ends with infinitely many 1s.

See also

Partition.zero_one_sequence()

INPUT:

The input should be a finite sequence of 0s and 1s. The heading 0s and trailing 1s will be discarded.

EXAMPLES:

```
sage: Partitions().from_zero_one([])
[]
sage: Partitions().from_zero_one([1,0])
[1]
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
```

```
>>> from sage.all import *
>>> Partitions().from_zero_one([])
[]
>>> Partitions().from_zero_one([Integer(1),Integer(0)])
[1]
>>> Partitions().from_zero_one([Integer(1), Integer(1), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(0)])
[5, 4]
```

Heading 0s and trailing 1s are correctly handled:

```
sage: Partitions().from_zero_one([0,0,1,1,1,1,0,1,0,1,1,1])
[5, 4]
```

```
>>> from sage.all import *
>>> Partitions().from_zero_one([Integer(0),Integer(0),Integer(1),Integer(1),
↪Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
↪Integer(1),Integer(1)])
[5, 4]
```

subset(*size=None*, ***kwargs*)

Return the subset of partitions of a given size and additional keyword arguments.

EXAMPLES:

```
sage: P = Partitions()
sage: P.subset(4)
Partitions of the integer 4
```

```
>>> from sage.all import *
>>> P = Partitions()
>>> P.subset(Integer(4))
Partitions of the integer 4
```

class sage.combinat.partition.**Partitions_all_bounded**(*k*)

Bases: *Partitions*

Partitions whose parts do not exceed a given bound.

class sage.combinat.partition.**Partitions_all_constrained**(***kwargs*)

Bases: *Partitions*

class sage.combinat.partition.**Partitions_ending**(*n*, *ending_partition*)

Bases: *Partitions*

All partitions with a given ending.

first()

Return the first partition in `self`.

EXAMPLES:

```
sage: Partitions(4, ending=[1,1,1,1]).first()
[4]
sage: Partitions(4, ending=[5]).first() is None
True
```

```
>>> from sage.all import *
>>> Partitions(Integer(4), ending=[Integer(1),Integer(1),Integer(1),
↪Integer(1)]).first()
[4]
>>> Partitions(Integer(4), ending=[Integer(5)]).first() is None
True
```

next(*part*)

Return the next partition after `part` in `self`.

EXAMPLES::

sage: Partitions(4, ending=[1,1,1,1,1]).next(Partition([4])) [3, 1] sage: Partitions(4, ending=[3,2]).next(Partition([3,1])) is None True sage: Partitions(4, ending=[1,1,1,1]).next(Partition([4])) [3, 1] sage: Partitions(4, ending=[1,1,1,1]).next(Partition([1,1,1,1])) is None True sage: Partitions(4, ending=[3]).next(Partition([3,1])) is None True

class sage.combinat.partition.**Partitions_length_and_parts_constrained**(*n*, *min_length*, *max_length*, *min_part*, *max_part*)

Bases: *Partitions*

The class of all integer partitions having parts and length in a given range.

This class is strictly more general than *PartitionsGreatestLE*, except that we insist that the size of the partition is positive and that neither the constraints on the parts nor on the length are contradictory.

INPUT:

- `n` – the size of the partition, positive
- `min_length` – the lower bound on the number of parts, between 1 and `n`
- `max_length` – the upper bound on the number of parts, between `min_length` and `n`
- `min_part` – the bound on the smallest part, between 1 and `n`
- `max_part` – the bound on the largest part, between `min_part` and `n`

EXAMPLES:

```
sage: from sage.combinat.partition import Partitions_length_and_parts_constrained
sage: Partitions_length_and_parts_constrained(10, 1, 10, 2, 5)
Partitions of 10 whose parts are between 2 and 5
sage: list(Partitions_length_and_parts_constrained(9, 3, 4, 2, 4))
[[4, 3, 2], [3, 3, 3], [3, 2, 2, 2]]

sage: [4,3,2,1] in Partitions_length_and_parts_constrained(10, 1, 10, 2, 10)
False
```

(continues on next page)

(continued from previous page)

```
sage: [2,2,2,2,2] in Partitions_length_and_parts_constrained(10, 1, 10, 2, 10)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition import Partitions_length_and_parts_constrained
>>> Partitions_length_and_parts_constrained(Integer(10), Integer(1), Integer(10),␣
↪Integer(2), Integer(5))
Partitions of 10 whose parts are between 2 and 5
>>> list(Partitions_length_and_parts_constrained(Integer(9), Integer(3),␣
↪Integer(4), Integer(2), Integer(4)))
[[4, 3, 2], [3, 3, 3], [3, 2, 2, 2]]

>>> [Integer(4),Integer(3),Integer(2),Integer(1)] in Partitions_length_and_parts_
↪constrained(Integer(10), Integer(1), Integer(10), Integer(2), Integer(10))
False
>>> [Integer(2),Integer(2),Integer(2),Integer(2),Integer(2)] in Partitions_length_
↪and_parts_constrained(Integer(10), Integer(1), Integer(10), Integer(2),␣
↪Integer(10))
True
```

Warning

If `min_length` and `min_part` equal 1 and `max_length` and `max_part` equal `n`, this class contains the same partitions as *`Partitions`*, but is different from that class.

```
sage: Partitions_length_and_parts_constrained(9, 1, 9, 1, 9)
Partitions of 9
sage: Partitions_length_and_parts_constrained(9, 1, 9, 1, 9) == Partitions(9)
False
```

```
>>> from sage.all import *
>>> Partitions_length_and_parts_constrained(Integer(9), Integer(1), Integer(9),␣
↪Integer(1), Integer(9))
Partitions of 9
>>> Partitions_length_and_parts_constrained(Integer(9), Integer(1), Integer(9),␣
↪Integer(1), Integer(9)) == Partitions(Integer(9))
False
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: from sage.combinat.partition import Partitions_length_and_parts_
↪constrained
sage: list(Partitions_length_and_parts_constrained(9, 1, 2, 3, 9))
[[9], [6, 3], [5, 4]]
sage: Partitions_length_and_parts_constrained(9, 1, 2, 3, 9).cardinality()
3
```

```
>>> from sage.all import *
>>> from sage.combinat.partition import Partitions_length_and_parts_
↪constrained
>>> list(Partitions_length_and_parts_constrained(Integer(9), Integer(1),␣
↪Integer(2), Integer(3), Integer(9)))
[[9], [6, 3], [5, 4]]
>>> Partitions_length_and_parts_constrained(Integer(9), Integer(1),␣
↪Integer(2), Integer(3), Integer(9)).cardinality()
3
```

class sage.combinat.partition.**Partitions_n**(*n*)

Bases: *Partitions*

Partitions of the integer n.

cardinality(*algorithm='flint'*)

Return the number of partitions of the specified size.

INPUT:

- `algorithm` – (default: `'flint'`)
  - `'flint'` – use FLINT (currently the fastest)
  - `'gap'` – use GAP (VERY *slow*)
  - `'pari'` – use PARI. Speed seems the same as GAP until n is in the thousands, in which case PARI is faster

It is possible to associate with every partition of the integer n a conjugacy class of permutations in the symmetric group on n points and vice versa. Therefore the number of partitions p_n is the number of conjugacy classes of the symmetric group on n points.

EXAMPLES:

```
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
sage: Partitions(5).cardinality(algorithm='gap')                              #␣
↪needs sage.libs.gap
7
```

```
>>> from sage.all import *
>>> v = Partitions(Integer(5)).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
>>> len(v)
7
>>> Partitions(Integer(5)).cardinality(algorithm='gap')                       ␣
↪     # needs sage.libs.gap
7
```

```
sage: # needs sage.libs.flint
sage: Partitions(3).cardinality()
3
sage: number_of_partitions(5, algorithm='flint')
```

(continues on next page)

(continued from previous page)

```
7
sage: Partitions(10).cardinality()
42
sage: Partitions(40).cardinality()
37338
sage: Partitions(100).cardinality()
190569292
```

```
>>> from sage.all import *
>>> # needs sage.libs.flint
>>> Partitions(Integer(3)).cardinality()
3
>>> number_of_partitions(Integer(5), algorithm='flint')
7
>>> Partitions(Integer(10)).cardinality()
42
>>> Partitions(Integer(40)).cardinality()
37338
>>> Partitions(Integer(100)).cardinality()
190569292
```

```
sage: # needs sage.libs.pari
sage: Partitions(3).cardinality(algorithm='pari')
3
sage: Partitions(5).cardinality(algorithm='pari')
7
sage: Partitions(10).cardinality(algorithm='pari')
42
```

```
>>> from sage.all import *
>>> # needs sage.libs.pari
>>> Partitions(Integer(3)).cardinality(algorithm='pari')
3
>>> Partitions(Integer(5)).cardinality(algorithm='pari')
7
>>> Partitions(Integer(10)).cardinality(algorithm='pari')
42
```

A generating function for p_n is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \frac{1}{1-x^k}.$$

We use Sage to verify that the first several coefficients do indeed agree:

```
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])  # partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [Partitions(k).cardinality() for k in range(2,10)]                    #␣
↪needs sage.libs.flint
[2, 3, 5, 7, 11, 15, 22, 30]
```

```
>>> from sage.all import *
>>> q = PowerSeriesRing(QQ, 'q', default_prec=Integer(9)).gen()
>>> prod([(Integer(1)-q**k)**(-Integer(1)) for k in range(Integer(1),
↪Integer(9))])  # partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
>>> [Partitions(k).cardinality() for k in range(Integer(2),Integer(10))]
↪              # needs sage.libs.flint
[2, 3, 5, 7, 11, 15, 22, 30]
```

Another consistency test for `n` up to 500:

```
sage: len([n for n in [1..500]                                                #␣
↪needs sage.libs.flint sage.libs.pari
....:     if Partitions(n).cardinality() != Partitions(n).
↪cardinality(algorithm='pari')])
0
```

```
>>> from sage.all import *
>>> len([n for n in (ellipsis_range(Integer(1),Ellipsis,Integer(500)))
↪                                    # needs sage.libs.flint sage.libs.pari
...     if Partitions(n).cardinality() != Partitions(n).cardinality(algorithm=
↪'pari')])
0
```

For negative inputs, the result is zero (the algorithm is ignored):

```
sage: Partitions(-5).cardinality()
0
```

```
>>> from sage.all import *
>>> Partitions(-Integer(5)).cardinality()
0
```

REFERENCES:

- Wikipedia article Partition_(number_theory)

first()

Return the lexicographically first partition of a positive integer n. This is the partition `[n]`.

EXAMPLES:

```
sage: Partitions(4).first()
[4]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).first()
[4]
```

last()

Return the lexicographically last partition of the positive integer n. This is the all-ones partition.

EXAMPLES:

```
sage: Partitions(4).last()
[1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).last()
[1, 1, 1, 1]
```

next(*p*)

Return the lexicographically next partition after the partition `p`.

EXAMPLES:

```
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1]) is None
True
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).next([Integer(4)])
[3, 1]
>>> Partitions(Integer(4)).next([Integer(1),Integer(1),Integer(1),
↪Integer(1)]) is None
True
```

prev(*p*)

Return the lexicographically previous partition before partition `p`.

EXAMPLES:

```
sage: Partitions(4).prev([3, 1])
[4]
sage: Partitions(4).prev([4]) is None
True
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).prev([Integer(3), Integer(1)])
[4]
>>> Partitions(Integer(4)).prev([Integer(4)]) is None
True
```

random_element(*measure='uniform'*)

Return a random partitions of n for the specified measure.

INPUT:

- `measure` – `'uniform'` or `'Plancherel'` (default: `'uniform'`)

See also

- *random_element_uniform()*
- *random_element_plancherel()*

EXAMPLES:

```
sage: Partitions(5).random_element()  # random                                #␣
↪needs sage.libs.flint
[2, 1, 1, 1]
sage: Partitions(5).random_element(measure='Plancherel')  # random           #␣
↪needs sage.libs.flint
[2, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions(Integer(5)).random_element()  # random                        ␣
↪     # needs sage.libs.flint
[2, 1, 1, 1]
>>> Partitions(Integer(5)).random_element(measure='Plancherel')  # random    ␣
↪     # needs sage.libs.flint
[2, 1, 1, 1]
```

random_element_plancherel()

Return a random partition of n (for the Plancherel measure).

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See Wikipedia article Plancherel_measure and *Partition.plancherel_measure()*.

EXAMPLES:

```
sage: Partitions(5).random_element_plancherel()   # random
[2, 1, 1, 1]
sage: Partitions(20).random_element_plancherel()  # random
[9, 3, 3, 2, 2, 1]
```

```
>>> from sage.all import *
>>> Partitions(Integer(5)).random_element_plancherel()   # random
[2, 1, 1, 1]
>>> Partitions(Integer(20)).random_element_plancherel()  # random
[9, 3, 3, 2, 2, 1]
```

ALGORITHM:

- insert by Robinson-Schensted a uniform random permutations of n and returns the shape of the resulting tableau. The complexity is $O(n \ln(n))$ which is likely optimal. However, the implementation could be optimized.

AUTHOR:

- Florent Hivert (2009-11-23)

random_element_uniform()

Return a random partition of n with uniform probability.

EXAMPLES:

```
sage: Partitions(5).random_element_uniform()  # random                        #␣
↪needs sage.libs.flint
[2, 1, 1, 1]
sage: Partitions(20).random_element_uniform()  # random                       #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.libs.flint
[9, 3, 3, 2, 2, 1]
```

```
>>> from sage.all import *
>>> Partitions(Integer(5)).random_element_uniform()  # random
↪     # needs sage.libs.flint
[2, 1, 1, 1]
>>> Partitions(Integer(20)).random_element_uniform()  # random
↪     # needs sage.libs.flint
[9, 3, 3, 2, 2, 1]
```

ALGORITHM:

- It is a python Implementation of RANDPAR, see [NW1978]. The complexity is unknown, there may be better algorithms.

  Todo

  Check in Knuth AOCP4.

- There is also certainly a lot of room for optimizations, see comments in the code.

AUTHOR:

- Florent Hivert (2009-11-23)

subset(***kwargs*)

Return a subset of `self` with the additional optional arguments.

EXAMPLES:

```
sage: P = Partitions(5); P
Partitions of the integer 5
sage: P.subset(starting=[3,1])
Partitions of the integer 5 starting with [3, 1]
```

```
>>> from sage.all import *
>>> P = Partitions(Integer(5)); P
Partitions of the integer 5
>>> P.subset(starting=[Integer(3),Integer(1)])
Partitions of the integer 5 starting with [3, 1]
```

class sage.combinat.partition.**Partitions_nk**(n, k)

Bases: *Partitions*

Partitions of the integer n of length equal to k.

cardinality(*algorithm='hybrid'*)

Return the number of partitions of the specified size with the specified length.

INPUT:

- `algorithm` – (default: `'hybrid'`) the algorithm to compute the cardinality and can be one of the following:
  - `'hybrid'` – use a hybrid algorithm which uses heuristics to reduce the complexity

– 'gap' – use GAP

EXAMPLES:

```
sage: v = Partitions(5, length=2).list(); v
[[4, 1], [3, 2]]
sage: len(v)
2
sage: Partitions(5, length=2).cardinality()
2
```

```
>>> from sage.all import *
>>> v = Partitions(Integer(5), length=Integer(2)).list(); v
[[4, 1], [3, 2]]
>>> len(v)
2
>>> Partitions(Integer(5), length=Integer(2)).cardinality()
2
```

More generally, the number of partitions of n of length 2 is $\left\lfloor \frac{n}{2} \right\rfloor$:

```
sage: all( Partitions(n, length=2).cardinality()
....:      == n // 2 for n in range(10) )
True
```

```
>>> from sage.all import *
>>> all( Partitions(n, length=Integer(2)).cardinality()
...      == n // Integer(2) for n in range(Integer(10)) )
True
```

The number of partitions of n of length 1 is 1 for n positive:

```
sage: all( Partitions(n, length=1).cardinality() == 1
....:      for n in range(1, 10) )
True
```

```
>>> from sage.all import *
>>> all( Partitions(n, length=Integer(1)).cardinality() == Integer(1)
...      for n in range(Integer(1), Integer(10)) )
True
```

Further examples:

```
sage: # needs sage.libs.flint
sage: Partitions(5, length=3).cardinality()
2
sage: Partitions(6, length=3).cardinality()
3
sage: Partitions(8, length=4).cardinality()
5
sage: Partitions(8, length=5).cardinality()
3
sage: Partitions(15, length=6).cardinality()
26
```

(continues on next page)

(continued from previous page)

```
sage: Partitions(0, length=0).cardinality()
1
sage: Partitions(0, length=1).cardinality()
0
sage: Partitions(1, length=0).cardinality()
0
sage: Partitions(1, length=4).cardinality()
0
```

```
>>> from sage.all import *
>>> # needs sage.libs.flint
>>> Partitions(Integer(5), length=Integer(3)).cardinality()
2
>>> Partitions(Integer(6), length=Integer(3)).cardinality()
3
>>> Partitions(Integer(8), length=Integer(4)).cardinality()
5
>>> Partitions(Integer(8), length=Integer(5)).cardinality()
3
>>> Partitions(Integer(15), length=Integer(6)).cardinality()
26
>>> Partitions(Integer(0), length=Integer(0)).cardinality()
1
>>> Partitions(Integer(0), length=Integer(1)).cardinality()
0
>>> Partitions(Integer(1), length=Integer(0)).cardinality()
0
>>> Partitions(Integer(1), length=Integer(4)).cardinality()
0
```

subset(***kwargs*)

Return a subset of `self` with the additional optional arguments.

EXAMPLES:

```
sage: P = Partitions(5, length=2); P
Partitions of the integer 5 of length 2
sage: P.subset(max_part=3)
Partitions of 5 having length 2 and whose parts are at most 3
```

```
>>> from sage.all import *
>>> P = Partitions(Integer(5), length=Integer(2)); P
Partitions of the integer 5 of length 2
>>> P.subset(max_part=Integer(3))
Partitions of 5 having length 2 and whose parts are at most 3
```

class sage.combinat.partition.**Partitions_parts_in**(*n*, *parts*)

Bases: *Partitions*

Partitions of n with parts in a given set S.

This is invoked indirectly when calling `Partitions(n, parts_in=parts)`, where `parts` is a list of pairwise distinct integers.

cardinality()

Return the number of partitions with parts in `self`. Wraps GAP's `NrRestrictedPartitions`.

EXAMPLES:

```
sage: Partitions(15, parts_in=[2,3,7]).cardinality()                    #␣
↪needs sage.libs.gap
5
```

```
>>> from sage.all import *
>>> Partitions(Integer(15), parts_in=[Integer(2),Integer(3),Integer(7)]).
↪cardinality()                          # needs sage.libs.gap
5
```

If you can use all parts 1 through n, we'd better get $p(n)$:

```
sage: (Partitions(20, parts_in=[1..20]).cardinality()                   #␣
↪needs sage.libs.gap
....:    == Partitions(20).cardinality())
True
```

```
>>> from sage.all import *
>>> (Partitions(Integer(20), parts_in=(ellipsis_range(Integer(1),Ellipsis,
↪Integer(20)))).cardinality()                          # needs sage.libs.gap
...    == Partitions(Integer(20)).cardinality())
True
```

first()

Return the lexicographically first partition of a positive integer n with the specified parts, or `None` if no such partition exists.

EXAMPLES:

```
sage: Partitions(9, parts_in=[3,4]).first()
[3, 3, 3]
sage: Partitions(6, parts_in=[1..6]).first()
[6]
sage: Partitions(30, parts_in=[4,7,8,10,11]).first()
[11, 11, 8]
```

```
>>> from sage.all import *
>>> Partitions(Integer(9), parts_in=[Integer(3),Integer(4)]).first()
[3, 3, 3]
>>> Partitions(Integer(6), parts_in=(ellipsis_range(Integer(1),Ellipsis,
↪Integer(6)))).first()
[6]
>>> Partitions(Integer(30), parts_in=[Integer(4),Integer(7),Integer(8),
↪Integer(10),Integer(11)]).first()
[11, 11, 8]
```

last()

Return the lexicographically last partition of the positive integer n with the specified parts, or `None` if no such partition exists.

EXAMPLES:

```
sage: Partitions(15, parts_in=[2,3]).last()
[3, 2, 2, 2, 2, 2, 2]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4, 4]
sage: Partitions(10, parts_in=[3,6]).last() is None
True
sage: Partitions(50, parts_in=[11,12,13]).last()
[13, 13, 12, 12]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4, 4]
```

```
>>> from sage.all import *
>>> Partitions(Integer(15), parts_in=[Integer(2),Integer(3)]).last()
[3, 2, 2, 2, 2, 2, 2]
>>> Partitions(Integer(30), parts_in=[Integer(4),Integer(7),Integer(8),
↪Integer(10),Integer(11)]).last()
[7, 7, 4, 4, 4, 4]
>>> Partitions(Integer(10), parts_in=[Integer(3),Integer(6)]).last() is None
True
>>> Partitions(Integer(50), parts_in=[Integer(11),Integer(12),Integer(13)]).
↪last()
[13, 13, 12, 12]
>>> Partitions(Integer(30), parts_in=[Integer(4),Integer(7),Integer(8),
↪Integer(10),Integer(11)]).last()
[7, 7, 4, 4, 4, 4]
```

class sage.combinat.partition.**Partitions_starting**(*n*, *starting_partition*)

Bases: *Partitions*

All partitions with a given start.

first()

Return the first partition in `self`.

EXAMPLES:

```
sage: Partitions(3, starting=[2,1]).first()
[2, 1]
sage: Partitions(3, starting=[1,1,1]).first()
[1, 1, 1]
sage: Partitions(3, starting=[1,1]).first()
False
sage: Partitions(3, starting=[3,1]).first()
[3]
sage: Partitions(3, starting=[2,2]).first()
[2, 1]
```

```
>>> from sage.all import *
>>> Partitions(Integer(3), starting=[Integer(2),Integer(1)]).first()
[2, 1]
>>> Partitions(Integer(3), starting=[Integer(1),Integer(1),Integer(1)]).
↪first()
[1, 1, 1]
```

(continues on next page)

(continued from previous page)

```
>>> Partitions(Integer(3), starting=[Integer(1),Integer(1)]).first()
False
>>> Partitions(Integer(3), starting=[Integer(3),Integer(1)]).first()
[3]
>>> Partitions(Integer(3), starting=[Integer(2),Integer(2)]).first()
[2, 1]
```

next(*part*)

Return the next partition after `part` in `self`.

EXAMPLES:

```
sage: Partitions(3, starting=[2,1]).next(Partition([2,1]))
[1, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions(Integer(3), starting=[Integer(2),Integer(1)]).
↪next(Partition([Integer(2),Integer(1)]))
[1, 1, 1]
```

class sage.combinat.partition.**Partitions_with_constraints**(**args*, ***kwds*)

Bases: *IntegerListsLex*

Partitions which satisfy a set of constraints.

EXAMPLES:

```
sage: P = Partitions(6, inner=[1,1], max_slope=-1)
sage: list(P)
[[5, 1], [4, 2], [3, 2, 1]]
```

```
>>> from sage.all import *
>>> P = Partitions(Integer(6), inner=[Integer(1),Integer(1)], max_slope=-
↪Integer(1))
>>> list(P)
[[5, 1], [4, 2], [3, 2, 1]]
```

Element

alias of *Partition*

options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast

class sage.combinat.partition.**RegularPartitions**(*ell*, *is_infinite=False*)

Bases: *Partitions*

Base class for ℓ-regular partitions.

Let ℓ be a positive integer. A partition λ is *ℓ-regular* if $m_i < \ell$ for all i, where m_i is the multiplicity of i in λ.

Note

This is conjugate to the notion of ℓ-*restricted* partitions, where the difference between any two consecutive parts is $< \ell$.

INPUT:

- `ell` – the positive integer ℓ
- `is_infinite` – boolean; if the subset of ℓ-regular partitions is infinite

ell()

Return the value ℓ.

EXAMPLES:

```
sage: P = Partitions(regular=2)
sage: P.ell()
2
```

```
>>> from sage.all import *
>>> P = Partitions(regular=Integer(2))
>>> P.ell()
2
```

class sage.combinat.partition.**RegularPartitions_all**(*ell*)

Bases: *RegularPartitions*

The class of all ℓ-regular partitions.

INPUT:

- `ell` – the positive integer ℓ

See also

RegularPartitions

class sage.combinat.partition.**RegularPartitions_bounded**(*ell*, *k*)

Bases: *RegularPartitions*

The class of ℓ-regular k-bounded partitions.

INPUT:

- `ell` – the integer ℓ
- `k` – integer; the value k

See also

RegularPartitions

class sage.combinat.partition.**RegularPartitions_n**(*n*, *ell*)

Bases: *RegularPartitions*, *Partitions_n*

The class of ℓ-regular partitions of n.

INPUT:

- `n` – the integer n to partition
- `ell` – the integer ℓ

See also

RegularPartitions

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Partitions(5, regular=3)
sage: P.cardinality()                                                       #␣
↪needs sage.libs.flint
5
sage: P = Partitions(5, regular=6)
sage: P.cardinality()                                                       #␣
↪needs sage.libs.flint
7
sage: P.cardinality() == Partitions(5).cardinality()                        #␣
↪needs sage.libs.flint
True
```

```
>>> from sage.all import *
>>> P = Partitions(Integer(5), regular=Integer(3))
>>> P.cardinality()                                                         #␣
↪needs sage.libs.flint
5
>>> P = Partitions(Integer(5), regular=Integer(6))
>>> P.cardinality()                                                         #␣
↪needs sage.libs.flint
7
>>> P.cardinality() == Partitions(Integer(5)).cardinality()                 ␣
↪     # needs sage.libs.flint
True
```

class sage.combinat.partition.**RegularPartitions_truncated**(*ell*, *max_len*)

Bases: *RegularPartitions*

The class of ℓ-regular partitions with max length k.

INPUT:

- `ell` – the integer ℓ
- `max_len` – integer; the maximum length

See also

RegularPartitions

max_length()

Return the maximum length of the partitions of `self`.

EXAMPLES:

```
sage: P = Partitions(regular=4, max_length=3)
sage: P.max_length()
3
```

```
>>> from sage.all import *
>>> P = Partitions(regular=Integer(4), max_length=Integer(3))
>>> P.max_length()
3
```

class sage.combinat.partition.**RestrictedPartitions_all**(*ell*)

Bases: *RestrictedPartitions_generic*

The class of all ℓ-restricted partitions.

INPUT:

- `ell` – the positive integer ℓ

See also

RestrictedPartitions_generic

class sage.combinat.partition.**RestrictedPartitions_generic**(*ell*, *is_infinite=False*)

Bases: *Partitions*

Base class for ℓ-restricted partitions.

Let ℓ be a positive integer. A partition λ is *ℓ-restricted* if $\lambda_i - \lambda_{i+1} < \ell$ for all i, including rows of length 0.

Note

This is conjugate to the notion of *ℓ-regular* partitions, where the multiplicity of any parts is at most ℓ.

INPUT:

- `ell` – the positive integer ℓ
- `is_infinite` – boolean; if the subset of ℓ-restricted partitions is infinite

ell()

Return the value ℓ.

EXAMPLES:

```
sage: P = Partitions(restricted=2)
sage: P.ell()
2
```

```
>>> from sage.all import *
>>> P = Partitions(restricted=Integer(2))
>>> P.ell()
2
```

class sage.combinat.partition.**RestrictedPartitions_n**(*n*, *ell*)

Bases: *RestrictedPartitions_generic*, *Partitions_n*

The class of ℓ-restricted partitions of n.

INPUT:

- `n` – the integer n to partition
- `ell` – the integer ℓ

See also

RestrictedPartitions_generic

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Partitions(5, restricted=3)
sage: P.cardinality()                                                       #␣
↪needs sage.libs.flint
5
sage: P = Partitions(5, restricted=6)
sage: P.cardinality()                                                       #␣
↪needs sage.libs.flint
7
sage: P.cardinality() == Partitions(5).cardinality()                        #␣
↪needs sage.libs.flint
True
```

```
>>> from sage.all import *
>>> P = Partitions(Integer(5), restricted=Integer(3))
>>> P.cardinality()                                                         #␣
↪needs sage.libs.flint
5
>>> P = Partitions(Integer(5), restricted=Integer(6))
>>> P.cardinality()                                                         #␣
↪needs sage.libs.flint
7
>>> P.cardinality() == Partitions(Integer(5)).cardinality()                 ␣
↪     # needs sage.libs.flint
True
```

sage.combinat.partition.**number_of_partitions**(*n*, *algorithm='default'*)

Return the number of partitions of n with, optionally, at most k parts.

The options of *number_of_partitions()* are being deprecated Issue #13072 in favour of *Partitions_n.cardinality()* so that *number_of_partitions()* can become a stripped down version of the fastest algorithm available (currently this is using FLINT).

INPUT:

- `n` – integer
- **`algorithm`** – **(default: `'default'`)**
  [Will be deprecated except in Partition().cardinality()]
  - **`'default'` – if `k` is not `None`, then use Gap (very slow);**
    if `k` is `None`, use FLINT
  - `'flint'` – use FLINT

EXAMPLES:

```
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
```

```
>>> from sage.all import *
>>> v = Partitions(Integer(5)).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
>>> len(v)
7
```

The input must be a nonnegative integer or a `ValueError` is raised.

```
sage: number_of_partitions(-5)
Traceback (most recent call last):
...
ValueError: n (=-5) must be a nonnegative integer
```

```
>>> from sage.all import *
>>> number_of_partitions(-Integer(5))
Traceback (most recent call last):
...
ValueError: n (=-5) must be a nonnegative integer
```

```

```

A generating function for the number of partitions p_n is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \left(\frac{1}{1-x^k}\right).$$

We use Sage to verify that the first several coefficients do instead agree:

```
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])  # partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [number_of_partitions(k) for k in range(2,10)]                    #␣
↪needs sage.libs.flint
[2, 3, 5, 7, 11, 15, 22, 30]
```

```
>>> from sage.all import *
>>> q = PowerSeriesRing(QQ, 'q', default_prec=Integer(9)).gen()
>>> prod([(Integer(1)-q**k)**(-Integer(1)) for k in range(Integer(1),
↪Integer(9))])  # partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
>>> [number_of_partitions(k) for k in range(Integer(2),Integer(10))]    ␣
↪              # needs sage.libs.flint
[2, 3, 5, 7, 11, 15, 22, 30]
```

sage.combinat.partition.**number_of_partitions_length**(*n*, *k*, *algorithm='hybrid'*)

Return the number of partitions of n with length k.

This is a wrapper for GAP's `NrPartitions` function.

EXAMPLES:

```
sage: # needs sage.libs.gap
sage: from sage.combinat.partition import number_of_partitions_length
sage: number_of_partitions_length(5, 2)
2
sage: number_of_partitions_length(10, 2)
5
sage: number_of_partitions_length(10, 4)
9
sage: number_of_partitions_length(10, 0)
0
sage: number_of_partitions_length(10, 1)
1
sage: number_of_partitions_length(0, 0)
1
sage: number_of_partitions_length(0, 1)
0
```

```
>>> from sage.all import *
>>> # needs sage.libs.gap
>>> from sage.combinat.partition import number_of_partitions_length
>>> number_of_partitions_length(Integer(5), Integer(2))
2
>>> number_of_partitions_length(Integer(10), Integer(2))
5
>>> number_of_partitions_length(Integer(10), Integer(4))
9
>>> number_of_partitions_length(Integer(10), Integer(0))
0
>>> number_of_partitions_length(Integer(10), Integer(1))
1
>>> number_of_partitions_length(Integer(0), Integer(0))
1
>>> number_of_partitions_length(Integer(0), Integer(1))
0
```

sage.combinat.partition.**number_of_partitions_max_length_max_part**(*k*, *b*)

Return the number of partitions of n with at most k parts, all of which are at most b.

EXAMPLES:

This could also be computed using the q-binomial coefficient:

```
sage: from sage.combinat.partition import number_of_partitions_max_length_max_
↪part as f
sage: all(f(n, k, b) == q_binomial(k + b, b)[n] for n in range(5) for k in␣
↪range(n+1) for b in range(n+1))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition import number_of_partitions_max_length_max_part␣
↪as f
>>> all(f(n, k, b) == q_binomial(k + b, b)[n] for n in range(Integer(5)) for k in␣
↪range(n+Integer(1)) for b in range(n+Integer(1)))
True
```

However, although the q-binomial coefficient is faster for individual invocations, it seems that the caching we use here is essential for some computations:

```
sage: def A(n):
....:     s1 = number_of_partitions(n)
....:     s2 = sum(Partitions(m, max_part=l, length=k).cardinality()
....:              * Partitions(n-m-l^2, min_length=k+2*l).cardinality()
....:              for l in range(1, (n+1).isqrt())
....:              for m in range((n-l^2-2*l)*l//(l+1)+1)
....:              for k in range(ceil(m/l), min(m, n-m-l^2-2*l)+1))
....:     return s1 + s2

sage: A(100)
10934714090
```

```
>>> from sage.all import *
>>> def A(n):
...     s1 = number_of_partitions(n)
...     s2 = sum(Partitions(m, max_part=l, length=k).cardinality()
...              * Partitions(n-m-l**Integer(2), min_length=k+Integer(2)*l).
↪cardinality()
...              for l in range(Integer(1), (n+Integer(1)).isqrt())
...              for m in range((n-l**Integer(2)-Integer(2)*l)*l//
↪(l+Integer(1))+Integer(1))
...              for k in range(ceil(m/l), min(m, n-m-l**Integer(2)-
↪Integer(2)*l)+Integer(1)))
...     return s1 + s2

>>> A(Integer(100))
10934714090
```

Integer vectors modulo the action of a permutation group

AUTHORS:

- Nicolas Borie (2010-2012) - original module
- Jukka Kohonen (2023) - fast cardinality method, Issue #36787, Issue #36681

class sage.combinat.integer_vectors_mod_permgroup.**IntegerVectorsModPermutationGroup**

Bases: UniqueRepresentation

Return an enumerated set containing integer vectors which are maximal in their orbit under the action of the permutation group G for the lexicographic order.

In Sage, a permutation group G is viewed as a subgroup of the symmetric group S_n of degree n and n is said to be the degree of G. Any integer vector v is said to be canonical if it is maximal in its orbit under the action of G. v

is canonical if and only if

$$v = \max_{\text{lex order}} \{g \cdot v | g \in G\}$$

The action of G is on position. This means for example that the simple transposition $s_1 = (1, 2)$ swaps the first and the second entries of any integer vector $v = [a_1, a_2, a_3, \ldots, a_n]$

$$s_1 \cdot v = [a_2, a_1, a_3, \ldots, a_n]$$

This function returns a parent which contains, from each orbit orbit under the action of the permutation group G, a single canonical vector. The canonical vector is the one that is maximal within the orbit according to lexicographic order.

INPUT:

- `G` – a permutation group
- `sum` – (default: `None`) - a nonnegative integer
- `max_part` – (default: `None`) - a nonnegative integer setting the maximum value for every element
- `sgs` – (default: `None`) - a strong generating system of the group G. If you do not provide it, it will be calculated at the creation of the parent

OUTPUT:

- If `sum` and `max_part` are None, it returns the infinite enumerated set of all integer vectors (lists of integers) maximal in their orbit for the lexicographic order. Exceptionally, if the domain of `G` is empty, the result is a finite enumerated set that contains one element, namely the empty vector.
- If `sum` is an integer, it returns a finite enumerated set containing all integer vectors maximal in their orbit for the lexicographic order and whose entries sum to `sum`.

EXAMPLES:

Here is the set enumerating integer vectors modulo the action of the cyclic group of 3 elements:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3)]]))
sage: I.category()
Category of infinite enumerated quotients of sets
sage: I.cardinality()
+Infinity
sage: I.list()
Traceback (most recent call last):
...
NotImplementedError: cannot list an infinite set
sage: p = iter(I)
sage: for i in range(10): next(p)
[0, 0, 0]
[1, 0, 0]
[2, 0, 0]
[1, 1, 0]
[3, 0, 0]
[2, 1, 0]
[2, 0, 1]
[1, 1, 1]
[4, 0, 0]
[3, 1, 0]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3))]]))
>>> I.category()
Category of infinite enumerated quotients of sets
>>> I.cardinality()
+Infinity
>>> I.list()
Traceback (most recent call last):
...
NotImplementedError: cannot list an infinite set
>>> p = iter(I)
>>> for i in range(Integer(10)): next(p)
[0, 0, 0]
[1, 0, 0]
[2, 0, 0]
[1, 1, 0]
[3, 0, 0]
[2, 1, 0]
[2, 0, 1]
[1, 1, 1]
[4, 0, 0]
[3, 1, 0]
```

The method *is_canonical()* tests if an integer vector is maximal in its orbit. This method is also used in the containment test:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.is_canonical([5,2,0,4])
True
sage: I.is_canonical([5,0,6,4])
False
sage: I.is_canonical([1,1,1,1])
True
sage: [2,3,1,0] in I
False
sage: [5,0,5,0] in I
True
sage: 'Bla' in I
False
sage: I.is_canonical('bla')
Traceback (most recent call last):
...
AssertionError: bla should be a list or an integer vector
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.is_canonical([Integer(5),Integer(2),Integer(0),Integer(4)])
True
>>> I.is_canonical([Integer(5),Integer(0),Integer(6),Integer(4)])
False
>>> I.is_canonical([Integer(1),Integer(1),Integer(1),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
True
>>> [Integer(2),Integer(3),Integer(1),Integer(0)] in I
False
>>> [Integer(5),Integer(0),Integer(5),Integer(0)] in I
True
>>> 'Bla' in I
False
>>> I.is_canonical('bla')
Traceback (most recent call last):
...
AssertionError: bla should be a list or an integer vector
```

If you give a value to the extra argument `sum`, the set returned will be a finite set containing only canonical vectors whose entries sum to `sum`.:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3)]]), sum=6)
sage: I.cardinality()
10
sage: I.list()
[[6, 0, 0], [5, 1, 0], [5, 0, 1], [4, 2, 0], [4, 1, 1],
 [4, 0, 2], [3, 3, 0], [3, 2, 1], [3, 1, 2], [2, 2, 2]]
sage: I.category()
Join of Category of finite enumerated sets
    and Category of subquotients of finite sets
    and Category of quotients of sets
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3))]]), sum=Integer(6))
>>> I.cardinality()
10
>>> I.list()
[[6, 0, 0], [5, 1, 0], [5, 0, 1], [4, 2, 0], [4, 1, 1],
 [4, 0, 2], [3, 3, 0], [3, 2, 1], [3, 1, 2], [2, 2, 2]]
>>> I.category()
Join of Category of finite enumerated sets
    and Category of subquotients of finite sets
    and Category of quotients of sets
```

To get the orbit of any integer vector v under the action of the group, use the method *orbit()*; we convert the returned set of vectors into a list in increasing lexicographic order, to get a reproducible test:

```
sage: sorted(I.orbit([6,0,0]))
[[0, 0, 6], [0, 6, 0], [6, 0, 0]]
sage: sorted(I.orbit([5,1,0]))
[[0, 5, 1], [1, 0, 5], [5, 1, 0]]
sage: I.orbit([2,2,2])
{[2, 2, 2]}
```

```
>>> from sage.all import *
>>> sorted(I.orbit([Integer(6),Integer(0),Integer(0)]))
[[0, 0, 6], [0, 6, 0], [6, 0, 0]]
```

(continues on next page)

(continued from previous page)

```
>>> sorted(I.orbit([Integer(5),Integer(1),Integer(0)]))
[[0, 5, 1], [1, 0, 5], [5, 1, 0]]
>>> I.orbit([Integer(2),Integer(2),Integer(2)])
{[2, 2, 2]}
```

Even without constraints, for an empty domain the result is a singleton set:

```
sage: G = PermutationGroup([], domain=[])
sage: sgs = tuple(tuple(s) for s in G.strong_generating_system())
sage: list(IntegerVectorsModPermutationGroup(G, sgs=sgs))
[[]]
```

```
>>> from sage.all import *
>>> G = PermutationGroup([], domain=[])
>>> sgs = tuple(tuple(s) for s in G.strong_generating_system())
>>> list(IntegerVectorsModPermutationGroup(G, sgs=sgs))
[[]]
```

Warning

Because of Issue #36527, permutation groups that have different domains but similar generators can be erroneously treated as the same group. This will silently produce erroneous results. To avoid this issue, compute a strong generating system for the group as:

```
sgs = tuple(tuple(s) for s in G.strong_generating_system())
```

and provide it as the optional `sgs` argument to the constructor.

class sage.combinat.integer_vectors_mod_permgroup.**IntegerVectorsModPermutationGroup_All**(*G*, *sgs=None*)

Bases: UniqueRepresentation, RecursivelyEnumeratedSet_forest

A class for integer vectors enumerated up to the action of a permutation group.

A Sage permutation group is viewed as a subgroup of the symmetric group S_n for a certain n. This group has a natural action by position on vectors of length n. This class implements a set which keeps a single vector for each orbit. We say that a vector is canonical if it is the maximum in its orbit under the action of the permutation group for the lexicographic order.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]])); I
Integer vectors of length 4 enumerated up to the action of
 Permutation Group with generators [(1,2,3,4)]
sage: I.cardinality()
+Infinity
sage: TestSuite(I).run()
sage: it = iter(I)
sage: [next(it), next(it), next(it), next(it), next(it)]
[[0, 0, 0, 0],
 [1, 0, 0, 0],
 [2, 0, 0, 0],
```

(continues on next page)

(continued from previous page)

```
 [1, 1, 0, 0],
 [1, 0, 1, 0]]
sage: x = next(it); x
[3, 0, 0, 0]
sage: I.first()
[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]])); I
Integer vectors of length 4 enumerated up to the action of
 Permutation Group with generators [(1,2,3,4)]
>>> I.cardinality()
+Infinity
>>> TestSuite(I).run()
>>> it = iter(I)
>>> [next(it), next(it), next(it), next(it), next(it)]
[[0, 0, 0, 0],
 [1, 0, 0, 0],
 [2, 0, 0, 0],
 [1, 1, 0, 0],
 [1, 0, 1, 0]]
>>> x = next(it); x
[3, 0, 0, 0]
>>> I.first()
[0, 0, 0, 0]
```

class Element

Bases: `ClonableIntArray`

Element class for the set of integer vectors of given sum enumerated modulo the action of a permutation group. These vectors are clonable lists of integers which must satisfy conditions coming from the parent appearing in the method `check()`.

check()

Check that `self` verify the invariants needed for living in `self.parent()`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,
↪4)]]))
sage: v = I.an_element()
sage: v.check()
sage: w = I([0,4,0,0], check=False); w
[0, 4, 0, 0]
sage: w.check()
Traceback (most recent call last):
...
AssertionError
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
```

(continues on next page)

(continued from previous page)

```
>>> v = I.an_element()
>>> v.check()
>>> w = I([Integer(0),Integer(4),Integer(0),Integer(0)], check=False); w
[0, 4, 0, 0]
>>> w.check()
Traceback (most recent call last):
...
AssertionError
```

ambient()

Return the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: S.ambient()
Integer vectors of length 4
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> S.ambient()
Integer vectors of length 4
```

children(x)

Return the list of children of the element `x`. This method is required to build the tree structure of `self` which inherits from the class `RecursivelyEnumeratedSet_forest`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.children(I([2,1,0,0], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.children(I([Integer(2),Integer(1),Integer(0),Integer(0)], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

is_canonical(v, *check=True*)

Return `True` if the integer list `v` is maximal in its orbit under the action of the permutation group given to define `self`. Such integer vectors are said to be canonical. A vector v is canonical if and only if

$$v = \max_{\text{lex order}} \{g \cdot v | g \in G\}$$

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.is_canonical([4,3,2,1])
True
sage: I.is_canonical([4,0,0,1])
True
```

(continues on next page)

(continued from previous page)

```
sage: I.is_canonical([4,0,3,3])
True
sage: I.is_canonical([4,0,4,4])
False
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.is_canonical([Integer(4),Integer(3),Integer(2),Integer(1)])
True
>>> I.is_canonical([Integer(4),Integer(0),Integer(0),Integer(1)])
True
>>> I.is_canonical([Integer(4),Integer(0),Integer(3),Integer(3)])
True
>>> I.is_canonical([Integer(4),Integer(0),Integer(4),Integer(4)])
False
```

lift(*elt*)

Lift the element `elt` inside the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: v = S.lift(S([4,3,0,1])); v
[4, 3, 0, 1]
sage: type(v)
<class 'list'>
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> v = S.lift(S([Integer(4),Integer(3),Integer(0),Integer(1)])); v
[4, 3, 0, 1]
>>> type(v)
<class 'list'>
```

orbit(*v*)

Return the orbit of the integer vector `v` under the action of the permutation group defining `self`. The result is a set.

EXAMPLES:

In order to get reproducible doctests, we convert the returned sets into lists in increasing lexicographic order:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: sorted(I.orbit([2,2,0,0]))
[[0, 0, 2, 2], [0, 2, 2, 0], [2, 0, 0, 2], [2, 2, 0, 0]]
sage: sorted(I.orbit([2,1,0,0]))
[[0, 0, 2, 1], [0, 2, 1, 0], [1, 0, 0, 2], [2, 1, 0, 0]]
sage: sorted(I.orbit([2,0,1,0]))
[[0, 1, 0, 2], [0, 2, 0, 1], [1, 0, 2, 0], [2, 0, 1, 0]]
sage: sorted(I.orbit([2,0,2,0]))
[[0, 2, 0, 2], [2, 0, 2, 0]]
```

(continues on next page)

(continued from previous page)

```
sage: I.orbit([1,1,1,1])
{[1, 1, 1, 1]}
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> sorted(I.orbit([Integer(2),Integer(2),Integer(0),Integer(0)]))
[[0, 0, 2, 2], [0, 2, 2, 0], [2, 0, 0, 2], [2, 2, 0, 0]]
>>> sorted(I.orbit([Integer(2),Integer(1),Integer(0),Integer(0)]))
[[0, 0, 2, 1], [0, 2, 1, 0], [1, 0, 0, 2], [2, 1, 0, 0]]
>>> sorted(I.orbit([Integer(2),Integer(0),Integer(1),Integer(0)]))
[[0, 1, 0, 2], [0, 2, 0, 1], [1, 0, 2, 0], [2, 0, 1, 0]]
>>> sorted(I.orbit([Integer(2),Integer(0),Integer(2),Integer(0)]))
[[0, 2, 0, 2], [2, 0, 2, 0]]
>>> I.orbit([Integer(1),Integer(1),Integer(1),Integer(1)])
{[1, 1, 1, 1]}
```

permutation_group()

Return the permutation group given to define `self`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.permutation_group()
Permutation Group with generators [(1,2,3,4)]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.permutation_group()
Permutation Group with generators [(1,2,3,4)]
```

retract(*elt*)

Return the canonical representative of the orbit of the integer `elt` under the action of the permutation group defining `self`.

If the element `elt` is already maximal in its orbit for the lexicographic order, `elt` is thus the good representative for its orbit.

EXAMPLES:

```
sage: [0,0,0,0] in IntegerVectors(0,4)
True
sage: [1,0,0,0] in IntegerVectors(1,4)
True
sage: [0,1,0,0] in IntegerVectors(1,4)
True
sage: [1,0,1,0] in IntegerVectors(2,4)
True
sage: [0,1,0,1] in IntegerVectors(2,4)
True
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: S.retract([0,0,0,0])
```

(continues on next page)

(continued from previous page)

```
[0, 0, 0, 0]
sage: S.retract([1,0,0,0])
[1, 0, 0, 0]
sage: S.retract([0,1,0,0])
[1, 0, 0, 0]
sage: S.retract([1,0,1,0])
[1, 0, 1, 0]
sage: S.retract([0,1,0,1])
[1, 0, 1, 0]
```

```
>>> from sage.all import *
>>> [Integer(0),Integer(0),Integer(0),Integer(0)] in␣
↪IntegerVectors(Integer(0),Integer(4))
True
>>> [Integer(1),Integer(0),Integer(0),Integer(0)] in␣
↪IntegerVectors(Integer(1),Integer(4))
True
>>> [Integer(0),Integer(1),Integer(0),Integer(0)] in␣
↪IntegerVectors(Integer(1),Integer(4))
True
>>> [Integer(1),Integer(0),Integer(1),Integer(0)] in␣
↪IntegerVectors(Integer(2),Integer(4))
True
>>> [Integer(0),Integer(1),Integer(0),Integer(1)] in␣
↪IntegerVectors(Integer(2),Integer(4))
True
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> S.retract([Integer(0),Integer(0),Integer(0),Integer(0)])
[0, 0, 0, 0]
>>> S.retract([Integer(1),Integer(0),Integer(0),Integer(0)])
[1, 0, 0, 0]
>>> S.retract([Integer(0),Integer(1),Integer(0),Integer(0)])
[1, 0, 0, 0]
>>> S.retract([Integer(1),Integer(0),Integer(1),Integer(0)])
[1, 0, 1, 0]
>>> S.retract([Integer(0),Integer(1),Integer(0),Integer(1)])
[1, 0, 1, 0]
```

roots()

Return the root of generation of `self`. This method is required to build the tree structure of `self` which inherits from the class `RecursivelyEnumeratedSet_forest`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.roots()
[[0, 0, 0, 0]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
```

(continues on next page)

(continued from previous page)

```
>>> I.roots()
[[0, 0, 0, 0]]
```

subset(*sum=None*, *max_part=None*)

Return the subset of `self` containing integer vectors whose entries sum to `sum`.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: S.subset(4)
Integer vectors of length 4 and of sum 4 enumerated up to
the action of Permutation Group with generators
[(1,2,3,4)]
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> S.subset(Integer(4))
Integer vectors of length 4 and of sum 4 enumerated up to
the action of Permutation Group with generators
[(1,2,3,4)]
```

class sage.combinat.integer_vectors_mod_permgroup.**IntegerVectorsModPermutationGroup_with_constraints**

Bases: `UniqueRepresentation`, `RecursivelyEnumeratedSet_forest`

This class models finite enumerated sets of integer vectors with constraint enumerated up to the action of a permutation group. Integer vectors are enumerated modulo the action of the permutation group. To implement that, we keep a single integer vector by orbit under the action of the permutation group. Elements chosen are vectors maximal in their orbit for the lexicographic order.

For more information see *IntegerVectorsModPermutationGroup*.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       max_part=1)
sage: I.list()
[[0, 0, 0, 0], [1, 0, 0, 0], [1, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 0],
 [1, 1, 1, 1]]
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       sum=6, max_part=4)
sage: I.list()
[[4, 2, 0, 0], [4, 1, 1, 0], [4, 1, 0, 1], [4, 0, 2, 0], [4, 0, 1, 1],
 [4, 0, 0, 2], [3, 3, 0, 0], [3, 2, 1, 0], [3, 2, 0, 1], [3, 1, 2, 0],
 [3, 1, 1, 1], [3, 1, 0, 2], [3, 0, 3, 0], [3, 0, 2, 1], [3, 0, 1, 2],
 [2, 2, 2, 0], [2, 2, 1, 1], [2, 1, 2, 1]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
```

(continues on next page)

(continued from previous page)

```
...                                          max_part=Integer(1))
>>> I.list()
[[0, 0, 0, 0], [1, 0, 0, 0], [1, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 0],
 [1, 1, 1, 1]]
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                          sum=Integer(6), max_part=Integer(4))
>>> I.list()
[[4, 2, 0, 0], [4, 1, 1, 0], [4, 1, 0, 1], [4, 0, 2, 0], [4, 0, 1, 1],
 [4, 0, 0, 2], [3, 3, 0, 0], [3, 2, 1, 0], [3, 2, 0, 1], [3, 1, 2, 0],
 [3, 1, 1, 1], [3, 1, 0, 2], [3, 0, 3, 0], [3, 0, 2, 1], [3, 0, 1, 2],
 [2, 2, 2, 0], [2, 2, 1, 1], [2, 1, 2, 1]]
```

Here is the enumeration of unlabeled graphs over 5 vertices:

```
sage: G = IntegerVectorsModPermutationGroup(TransitiveGroup(10,12), max_part=1)
sage: G.cardinality()
34
```

```
>>> from sage.all import *
>>> G = IntegerVectorsModPermutationGroup(TransitiveGroup(Integer(10),
↪Integer(12)), max_part=Integer(1))
>>> G.cardinality()
34
```

class Element

Bases: `ClonableIntArray`

Element class for the set of integer vectors with constraints enumerated modulo the action of a permutation group. These vectors are clonable lists of integers which must satisfy conditions coming from the parent as in the method *check()*.

check()

Check that `self` meets the constraints of being an element of `self.parent()`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,
↪4)]]), 4)
sage: v = I.an_element()
sage: v.check()
sage: w = I([0,4,0,0], check=False); w
[0, 4, 0, 0]
sage: w.check()
Traceback (most recent call last):
...
AssertionError
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]), Integer(4))
>>> v = I.an_element()
>>> v.check()
```

(continues on next page)

(continued from previous page)

```
>>> w = I([Integer(0),Integer(4),Integer(0),Integer(0)], check=False); w
[0, 4, 0, 0]
>>> w.check()
Traceback (most recent call last):
...
AssertionError
```

ambient()

Return the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),␣
↪6)
sage: S.ambient()
Integer vectors that sum to 6
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       6, max_part=12)
sage: S.ambient()
Integer vectors that sum to 6 with constraints: max_part=12
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       max_part=12)
sage: S.ambient()
Integer vectors with constraints: max_part=12
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]), Integer(6))
>>> S.ambient()
Integer vectors that sum to 6
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       Integer(6), max_part=Integer(12))
>>> S.ambient()
Integer vectors that sum to 6 with constraints: max_part=12
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       max_part=Integer(12))
>>> S.ambient()
Integer vectors with constraints: max_part=12
```

cardinality()

Return the number of integer vectors in the set.

The algorithm utilises Cycle Index Theorem, allowing for a faster than a plain enumeration computation.

EXAMPLES:

With a trivial group all vectors are canonical:

```
sage: G = PermutationGroup([], domain=[1,2,3])
sage: IntegerVectorsModPermutationGroup(G, 5).cardinality()
21
```

(continues on next page)

(continued from previous page)

```
sage: IntegerVectors(5, 3).cardinality()
21
```

```
>>> from sage.all import *
>>> G = PermutationGroup([], domain=[Integer(1),Integer(2),Integer(3)])
>>> IntegerVectorsModPermutationGroup(G, Integer(5)).cardinality()
21
>>> IntegerVectors(Integer(5), Integer(3)).cardinality()
21
```

With two interchangeable elements, the smaller one ranges from zero to `sum//2`:

```
sage: G = PermutationGroup([(1,2)])
sage: IntegerVectorsModPermutationGroup(G, 1000).cardinality()
501
```

```
>>> from sage.all import *
>>> G = PermutationGroup([(Integer(1),Integer(2))])
>>> IntegerVectorsModPermutationGroup(G, Integer(1000)).cardinality()
501
```

Binary vectors up to full symmetry are first some ones and then some zeros:

```
sage: G = SymmetricGroup(10)
sage: I = IntegerVectorsModPermutationGroup(G, max_part=1)
sage: I.cardinality()
11
```

```
>>> from sage.all import *
>>> G = SymmetricGroup(Integer(10))
>>> I = IntegerVectorsModPermutationGroup(G, max_part=Integer(1))
>>> I.cardinality()
11
```

Binary vectors of constant weight, up to PGL(2,17), which is 3-transitive, but not 4-transitive:

```
sage: G=PGL(2,17)
sage: I = IntegerVectorsModPermutationGroup(G, sum=3, max_part=1)
sage: I.cardinality()
1
sage: I = IntegerVectorsModPermutationGroup(G, sum=4, max_part=1)
sage: I.cardinality()
3
```

```
>>> from sage.all import *
>>> G=PGL(Integer(2),Integer(17))
>>> I = IntegerVectorsModPermutationGroup(G, sum=Integer(3), max_
↪part=Integer(1))
>>> I.cardinality()
1
>>> I = IntegerVectorsModPermutationGroup(G, sum=Integer(4), max_
```

(continues on next page)

(continued from previous page)

```
↪part=Integer(1))
>>> I.cardinality()
3
```

children(*x*)

Return the list of children of the element `x`.

This method is required to build the tree structure of `self` which inherits from the class `RecursivelyEnumeratedSet_forest`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.children(I([2,1,0,0], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.children(I([Integer(2),Integer(1),Integer(0),Integer(0)], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]
```

is_canonical(*v*, *check=True*)

Return `True` if the integer list `v` is maximal in its orbit under the action of the permutation group given to define `self`. Such integer vectors are said to be canonical. A vector v is canonical if and only if

$$v = \max_{\text{lex order}} \{g \cdot v | g \in G\}$$

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       max_part=3)
sage: I.is_canonical([3,0,0,0])
True
sage: I.is_canonical([1,0,2,0])
False
sage: I.is_canonical([2,0,1,0])
True
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       max_part=Integer(3))
>>> I.is_canonical([Integer(3),Integer(0),Integer(0),Integer(0)])
True
>>> I.is_canonical([Integer(1),Integer(0),Integer(2),Integer(0)])
False
>>> I.is_canonical([Integer(2),Integer(0),Integer(1),Integer(0)])
True
```

lift(*elt*)

Lift the element `elt` inside the ambient space from which `self` is a quotient.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       max_part=1)
sage: v = S.lift([1,0,1,0]); v
[1, 0, 1, 0]
sage: v in IntegerVectors(2,4,max_part=1)
True
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       sum=6)
sage: v = S.lift(S.list()[5]); v
[4, 1, 1, 0]
sage: v in IntegerVectors(n=6)
True
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       max_part=Integer(1))
>>> v = S.lift([Integer(1),Integer(0),Integer(1),Integer(0)]); v
[1, 0, 1, 0]
>>> v in IntegerVectors(Integer(2),Integer(4),max_part=Integer(1))
True
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       sum=Integer(6))
>>> v = S.lift(S.list()[Integer(5)]); v
[4, 1, 1, 0]
>>> v in IntegerVectors(n=Integer(6))
True
```

orbit(*v*)

Return the orbit of the vector `v` under the action of the permutation group defining `self`. The result is a set.

INPUT:

- `v` – an element of `self` or any list of length the degree of the permutation group

EXAMPLES:

We convert the result in a list in increasing lexicographic order, to get a reproducible doctest:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),␣
↪4)
sage: I.orbit([1,1,1,1])
{[1, 1, 1, 1]}
sage: sorted(I.orbit([3,0,0,1]))
[[0, 0, 1, 3], [0, 1, 3, 0], [1, 3, 0, 0], [3, 0, 0, 1]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]), Integer(4))
>>> I.orbit([Integer(1),Integer(1),Integer(1),Integer(1)])
{[1, 1, 1, 1]}
>>> sorted(I.orbit([Integer(3),Integer(0),Integer(0),Integer(1)]))
[[0, 0, 1, 3], [0, 1, 3, 0], [1, 3, 0, 0], [3, 0, 0, 1]]
```

permutation_group()

Return the permutation group given to define `self`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3)]]), 5)
sage: I.permutation_group()
Permutation Group with generators [(1,2,3)]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3))]]), Integer(5))
>>> I.permutation_group()
Permutation Group with generators [(1,2,3)]
```

retract(*elt*)

Return the canonical representative of the orbit of the integer `elt` under the action of the permutation group defining `self`.

If the element `elt` is already maximal in its orbits for the lexicographic order, `elt` is thus the good representative for its orbit.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]),
....:                                       sum=2, max_part=1)
sage: S.retract([1,1,0,0])
[1, 1, 0, 0]
sage: S.retract([1,0,1,0])
[1, 0, 1, 0]
sage: S.retract([1,0,0,1])
[1, 1, 0, 0]
sage: S.retract([0,1,1,0])
[1, 1, 0, 0]
sage: S.retract([0,1,0,1])
[1, 0, 1, 0]
sage: S.retract([0,0,1,1])
[1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]),
...                                       sum=Integer(2), max_part=Integer(1))
>>> S.retract([Integer(1),Integer(1),Integer(0),Integer(0)])
[1, 1, 0, 0]
>>> S.retract([Integer(1),Integer(0),Integer(1),Integer(0)])
[1, 0, 1, 0]
>>> S.retract([Integer(1),Integer(0),Integer(0),Integer(1)])
[1, 1, 0, 0]
>>> S.retract([Integer(0),Integer(1),Integer(1),Integer(0)])
[1, 1, 0, 0]
>>> S.retract([Integer(0),Integer(1),Integer(0),Integer(1)])
[1, 0, 1, 0]
>>> S.retract([Integer(0),Integer(0),Integer(1),Integer(1)])
[1, 1, 0, 0]
```

roots()

Return the root of generation of `self`.

This method is required to build the tree structure of `self` which inherits from the class `RecursivelyEnumeratedSet_forest`.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: I.roots()
[[0, 0, 0, 0]]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(Integer(1),
↪Integer(2),Integer(3),Integer(4))]]))
>>> I.roots()
[[0, 0, 0, 0]]
```

Iterators over the partitions of an integer

The iterators generate partitions in either increasing or decreasing lexicographic orders and a partition P is represented either in ascending ($P_i \leq P_{i+1}$) or descending ($P_i \geq P_{i+1}$) orders:

```
sage: from sage.combinat.partitions import ZS1_iterator
sage: for p in ZS1_iterator(4):
....:     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
sage: from sage.combinat.partitions import AccelDesc_iterator
sage: for p in AccelDesc_iterator(4):
....:     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
sage: from sage.combinat.partitions import ZS2_iterator
sage: for p in ZS2_iterator(4):
....:     print(p)
[1, 1, 1, 1]
[2, 1, 1]
[2, 2]
[3, 1]
[4]
sage: from sage.combinat.partitions import AccelAsc_iterator
sage: for p in AccelAsc_iterator(4):
....:     print(p)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
```

(continues on next page)

(continued from previous page)

```
[2, 2]
[4]
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator
>>> for p in ZS1_iterator(Integer(4)):
...     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
>>> from sage.combinat.partitions import AccelDesc_iterator
>>> for p in AccelDesc_iterator(Integer(4)):
...     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
>>> from sage.combinat.partitions import ZS2_iterator
>>> for p in ZS2_iterator(Integer(4)):
...     print(p)
[1, 1, 1, 1]
[2, 1, 1]
[2, 2]
[3, 1]
[4]
>>> from sage.combinat.partitions import AccelAsc_iterator
>>> for p in AccelAsc_iterator(Integer(4)):
...     print(p)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
[2, 2]
[4]
```

For each of these iterators, this module also provides a `next` method that takes a partition as input and return the next partition in the corresponding ordering:

```
sage: from sage.combinat.partitions import ZS1_next
sage: ZS1_next([2, 2])
[2, 1, 1]
sage: from sage.combinat.partitions import AccelDesc_next
sage: AccelDesc_next([2, 2])
[2, 1, 1]
sage: from sage.combinat.partitions import ZS2_next
sage: ZS2_next([2, 2])
[3, 1]
sage: from sage.combinat.partitions import AccelAsc_next
sage: AccelAsc_next([2, 2])
[4]
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_next
>>> ZS1_next([Integer(2), Integer(2)])
[2, 1, 1]
>>> from sage.combinat.partitions import AccelDesc_next
>>> AccelDesc_next([Integer(2), Integer(2)])
[2, 1, 1]
>>> from sage.combinat.partitions import ZS2_next
>>> ZS2_next([Integer(2), Integer(2)])
[3, 1]
>>> from sage.combinat.partitions import AccelAsc_next
>>> AccelAsc_next([Integer(2), Integer(2)])
[4]
```

It is also possible to iterate over the partitions of bounded length:

```
sage: from sage.combinat.partitions import ZS1_iterator_nk
sage: for p in ZS1_iterator_nk(6, 3):
....:     print(p)
[6]
[5, 1]
[4, 2]
[4, 1, 1]
[3, 3]
[3, 2, 1]
[2, 2, 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator_nk
>>> for p in ZS1_iterator_nk(Integer(6), Integer(3)):
...     print(p)
[6]
[5, 1]
[4, 2]
[4, 1, 1]
[3, 3]
[3, 2, 1]
[2, 2, 2]
```

AUTHOR:

- William Stein (2007-07-28): initial version
- Jonathan Bober (2007-07-28): wrote the program `partitions_c.cc` that does all the actual heavy lifting.
- David Coudert (2024-06-01): reshape method *`ZS1_iterator()`* to ease the implementation of *`ZS1_next()`* and add iterators and next methods based on `ZS2`, `AccelAsc` and `AccelDesc` from [ZS1998] and [KS2012].

`sage.combinat.partitions.`**`AccelAsc_iterator`**`(n)`

Return an iterator over the partitions of `n`.

The partitions are generated in the increasing lexicographic order and each partition is represented as a list in ascending order (i.e., $p_i \leq p_{i+1}$).

This is an implementation of the `AccelAsc` algorithm found in [KS2012].

See also

sage.combinat.partitions.ZS1_iterator()

EXAMPLES:

```
sage: from sage.combinat.partitions import AccelAsc_iterator
sage: for p in AccelAsc_iterator(4):
....:     print(p)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
[2, 2]
[4]
sage: next(AccelAsc_iterator(4))
[1, 1, 1, 1]
sage: type(_)
<class 'list'>
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import AccelAsc_iterator
>>> for p in AccelAsc_iterator(Integer(4)):
...     print(p)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
[2, 2]
[4]
>>> next(AccelAsc_iterator(Integer(4)))
[1, 1, 1, 1]
>>> type(_)
<class 'list'>
```

sage.combinat.partitions.**AccelAsc_next**(*P*)

Return the partition after `P` in the ordering of the `AccelAsc` algorithm.

INPUT:

- `P` – list encoding a partition of an integer n in ascending order (i.e., $P_i \leq P_{i+1}$)

EXAMPLES:

```
sage: from sage.combinat.partitions import AccelAsc_next
sage: P = [1, 1, 1, 1]
sage: while P:
....:     print(P)
....:     P = AccelAsc_next(P)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
[2, 2]
[4]
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import AccelAsc_next
>>> P = [Integer(1), Integer(1), Integer(1), Integer(1)]
>>> while P:
...     print(P)
...     P = AccelAsc_next(P)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
[2, 2]
[4]
```

sage.combinat.partitions.**AccelDesc_iterator**(*n*)

Return an iterator over the partitions of `n`.

The partitions are generated in the increasing lexicographic order and each partition is represented as a list in descending order (i.e., $p_i \geq p_{i+1}$).

This is an implementation of the AccelDesc algorithm found in [KS2012].

See also

sage.combinat.partitions.ZS1_iterator()

EXAMPLES:

```
sage: from sage.combinat.partitions import AccelDesc_iterator
sage: for p in AccelDesc_iterator(4):
....:     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
sage: next(AccelDesc_iterator(4))
[4]
sage: type(_)
<class 'list'>
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import AccelDesc_iterator
>>> for p in AccelDesc_iterator(Integer(4)):
...     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
>>> next(AccelDesc_iterator(Integer(4)))
[4]
>>> type(_)
<class 'list'>
```

Check that *ZS1_iterator()* and *AccelDesc_iterator()* generate partitions in the same order:

```
sage: from sage.combinat.partitions import ZS1_iterator
sage: from sage.misc.prandom import randint
sage: n = randint(1, 50)
sage: all(p == q for p, q in zip(ZS1_iterator(n), AccelDesc_iterator(n)))  # long␣
↪time
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator
>>> from sage.misc.prandom import randint
>>> n = randint(Integer(1), Integer(50))
>>> all(p == q for p, q in zip(ZS1_iterator(n), AccelDesc_iterator(n)))  # long␣
↪time
True
```

sage.combinat.partitions.**AccelDesc_next**(*P*)

Return the partition after `P` in the ordering of the AccelDesc algorithm.

INPUT:

- `P` – list encoding a partition of an integer n in descending order (i.e., $P_i \geq P_{i+1}$)

EXAMPLES:

```
sage: from sage.combinat.partitions import AccelDesc_iterator, AccelDesc_next
sage: P = [4]
sage: while P:
....:     print(P)
....:     P = AccelDesc_next(P)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
sage: A = [list(p) for p in Partitions(7)]
sage: all(AccelDesc_next(p) == q for p, q in zip(A, A[1:]))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import AccelDesc_iterator, AccelDesc_next
>>> P = [Integer(4)]
>>> while P:
...     print(P)
...     P = AccelDesc_next(P)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
>>> A = [list(p) for p in Partitions(Integer(7))]
>>> all(AccelDesc_next(p) == q for p, q in zip(A, A[Integer(1):]))
True
```

sage.combinat.partitions.**ZS1_iterator**(n)

Return an iterator over the partitions of `n`.

The partitions are generated in the decreasing lexicographic order and each partition is represented as a list `p` in descending order (i.e., $P_i \geq P_{i+1}$). The method yields lists and not objects of type *Partition*.

This is an implementation of the ZS1 algorithm found in [ZS1998].

See also

- *sage.combinat.partitions.ZS2_iterator()*
- *sage.combinat.partitions.AccelDesc_iterator()*

EXAMPLES:

```
sage: from sage.combinat.partitions import ZS1_iterator
sage: for p in ZS1_iterator(4):
....:     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
sage: next(ZS1_iterator(4))
[4]
sage: type(_)
<class 'list'>
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator
>>> for p in ZS1_iterator(Integer(4)):
...     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
>>> next(ZS1_iterator(Integer(4)))
[4]
>>> type(_)
<class 'list'>
```

sage.combinat.partitions.**ZS1_iterator_nk**(n, k)

An iterator for the partitions of n of length at most k (in the decreasing lexicographic order) which returns lists and not objects of type *Partition*.

The algorithm is a mild variation on *ZS1_iterator()*; I would not vow for its speed.

EXAMPLES:

```
sage: from sage.combinat.partitions import ZS1_iterator_nk
sage: it = ZS1_iterator_nk(4, 3)
sage: next(it)
```

(continues on next page)

(continued from previous page)

```
[4]
sage: type(_)
<class 'list'>
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator_nk
>>> it = ZS1_iterator_nk(Integer(4), Integer(3))
>>> next(it)
[4]
>>> type(_)
<class 'list'>
```

sage.combinat.partitions.**ZS1_next**(P)

Return the partition after `P` in the ordering of the ZS1 algorithm.

INPUT:

- `P` – list encoding a partition of an integer n in descending order (i.e., $P_i \geq P_{i+1}$)

EXAMPLES:

```
sage: from sage.combinat.partitions import ZS1_iterator, ZS1_next
sage: P = [4]
sage: while P:
....:     print(P)
....:     P = ZS1_next(P)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
sage: A = [list(p) for p in Partitions(7)]
sage: all(ZS1_next(p) == q for p, q in zip(A, A[1:]))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator, ZS1_next
>>> P = [Integer(4)]
>>> while P:
...     print(P)
...     P = ZS1_next(P)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
>>> A = [list(p) for p in Partitions(Integer(7))]
>>> all(ZS1_next(p) == q for p, q in zip(A, A[Integer(1):]))
True
```

sage.combinat.partitions.**ZS2_iterator**(n)

Return an iterator over the partitions of `n`.

The partitions are generated in the increasing lexicographic order and each partition is represented as a list in descending order (i.e., $p_i \geq p_{i+1}$).

This is an implementation of the ZS2 algorithm found in [ZS1998].

See also

sage.combinat.partitions.ZS1_iterator()

EXAMPLES:

```
sage: from sage.combinat.partitions import ZS2_iterator
sage: for p in ZS2_iterator(4):
....:     print(p)
[1, 1, 1, 1]
[2, 1, 1]
[2, 2]
[3, 1]
[4]
sage: next(ZS2_iterator(4))
[1, 1, 1, 1]
sage: type(_)
<class 'list'>
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS2_iterator
>>> for p in ZS2_iterator(Integer(4)):
...     print(p)
[1, 1, 1, 1]
[2, 1, 1]
[2, 2]
[3, 1]
[4]
>>> next(ZS2_iterator(Integer(4)))
[1, 1, 1, 1]
>>> type(_)
<class 'list'>
```

sage.combinat.partitions.**ZS2_next**(P)

Return the partition after `P` in the ordering of the ZS2 algorithm.

INPUT:

- `P` – list encoding a partition of an integer n in descending order (i.e., $P_i \geq P_{i+1}$)

EXAMPLES:

```
sage: from sage.combinat.partitions import ZS2_iterator, ZS2_next
sage: P = [1, 1, 1, 1]
sage: while P:
....:     print(P)
....:     P = ZS2_next(P)
[1, 1, 1, 1]
[2, 1, 1]
```

(continues on next page)

(continued from previous page)

```
[2, 2]
[3, 1]
[4]
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS2_iterator, ZS2_next
>>> P = [Integer(1), Integer(1), Integer(1), Integer(1)]
>>> while P:
...     print(P)
...     P = ZS2_next(P)
[1, 1, 1, 1]
[2, 1, 1]
[2, 2]
[3, 1]
[4]
```

Kazhdan-Lusztig polynomials

AUTHORS:

- Daniel Bump (2008): initial version
- Alan J.X. Guo (2014-03-18): `R_tilde()` method

class sage.combinat.kazhdan_lusztig.**KazhdanLusztigPolynomial**(*W*, *q*, *trace=False*)

Bases: `UniqueRepresentation`, `SageObject`

A Kazhdan-Lusztig polynomial.

INPUT:

- `W` – a Weyl Group
- `q` – an indeterminate

OPTIONAL:

- `trace` – if `True`, then this displays the trace: the intermediate results. This is instructive and fun.

The parent of `q` may be a `PolynomialRing()` or a `LaurentPolynomialRing()`.

EXAMPLES:

```
sage: W = WeylGroup("B3",prefix='s')
sage: [s1,s2,s3] = W.simple_reflections()
sage: R.<q> = LaurentPolynomialRing(QQ)
sage: KL = KazhdanLusztigPolynomial(W,q)
sage: KL.P(s2,s3*s2*s3*s1*s2)
1 + q
```

```
>>> from sage.all import *
>>> W = WeylGroup("B3",prefix='s')
>>> [s1,s2,s3] = W.simple_reflections()
>>> R = LaurentPolynomialRing(QQ, names=('q',)); (q,) = R._first_ngens(1)
>>> KL = KazhdanLusztigPolynomial(W,q)
>>> KL.P(s2,s3*s2*s3*s1*s2)
1 + q
```

A faster implementation (using the optional package Coxeter 3) is given by:

```
sage: W = CoxeterGroup(['B', 3], implementation='coxeter3') # optional - coxeter3
sage: W.kazhdan_lusztig_polynomial([2], [3,2,3,1,2])        # optional - coxeter3
q + 1
```

```
>>> from sage.all import *
>>> W = CoxeterGroup(['B', Integer(3)], implementation='coxeter3') # optional -␣
↪coxeter3
>>> W.kazhdan_lusztig_polynomial([Integer(2)], [Integer(3),Integer(2),Integer(3),
↪Integer(1),Integer(2)])        # optional - coxeter3
q + 1
```

P (x, y)

Return the Kazhdan-Lusztig P polynomial.

If the rank is large, this runs slowly at first but speeds up as you do repeated calculations due to the caching.

INPUT:

- `x`, `y` – elements of the underlying Coxeter group

See also

`CoxeterGroup.kazhdan_lusztig_polynomial` for a faster implementation using Fokko Ducloux's Coxeter3 C++ library.

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: W = WeylGroup("A3", prefix='s')
sage: [s1,s2,s3] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: KL.P(s2,s2*s1*s3*s2)
q + 1
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> W = WeylGroup("A3", prefix='s')
>>> [s1,s2,s3] = W.simple_reflections()
>>> KL = KazhdanLusztigPolynomial(W, q)
>>> KL.P(s2,s2*s1*s3*s2)
q + 1
```

R (x, y)

Return the Kazhdan-Lusztig R polynomial.

INPUT:

- `x`, `y` – elements of the underlying Coxeter group

EXAMPLES:

```
sage: R.<q>=QQ[]
sage: W = WeylGroup("A2", prefix='s')
```

(continues on next page)

(continued from previous page)

```
sage: [s1,s2]=W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2 - 2*q + 1, q - 1, q - 1, 0]
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> W = WeylGroup("A2", prefix='s')
>>> [s1,s2]=W.simple_reflections()
>>> KL = KazhdanLusztigPolynomial(W, q)
>>> [KL.R(x,s2*s1) for x in [Integer(1),s1,s2,s1*s2]]
[q^2 - 2*q + 1, q - 1, q - 1, 0]
```

R_tilde(*x*, *y*)

Return the Kazhdan-Lusztig $\tilde{R}$ polynomial.

Information about the $\tilde{R}$ polynomials can be found in [Dy1993] and [BB2005].

INPUT:

- `x`, `y` – elements of the underlying Coxeter group

EXAMPLES:

```
sage: R.<q> = QQ[]
sage: W = WeylGroup("A2", prefix='s')
sage: [s1,s2] = W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R_tilde(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2, q, q, 0]
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> W = WeylGroup("A2", prefix='s')
>>> [s1,s2] = W.simple_reflections()
>>> KL = KazhdanLusztigPolynomial(W, q)
>>> [KL.R_tilde(x,s2*s1) for x in [Integer(1),s1,s2,s1*s2]]
[q^2, q, q, 0]
```

Key and Atom Polynomials

Key polynomials (also known as type A Demazure characters) are defined by applying the divided difference operator π_σ, where σ is a permutation, to a monomial corresponding to an integer partition $\mu \vdash n$.

See also

For Demazure characters in other types, see

- *sage.combinat.root_system.weyl_characters.WeylCharacterRing.demazure_character()*
- sage.categories.classical_crystals.ClassicalCrystals.ParentMethods.demazure_character()

Atom polynomials (also known as Demazure atoms) are defined analogously by using a deformed divided difference operator $\bar{\pi}_i = \pi_i - 1$.

AUTHORS:

- Trevor K. Karn (2022-08-17): initial version
- Travis Scrimshaw (2025-10-10): expanded to atoms

class sage.combinat.key_polynomial.**AtomPolynomial**

Bases: *OperatorPolynomial*

An atom polynomial.

Atom polynomials are polynomials that form a basis for a polynomial ring and are indexed by weak compositions.

Elements should be created by first creating the basis *AtomPolynomialBasis* and passing a list representing the indexing composition.

EXAMPLES:

```
sage: a = AtomPolynomials(QQ)
sage: f = a([4,3,2,1]) + a([1,2,3,4]); f
a[1, 2, 3, 4] + a[4, 3, 2, 1]
sage: f in a
True
```

```
>>> from sage.all import *
>>> a = AtomPolynomials(QQ)
>>> f = a([Integer(4),Integer(3),Integer(2),Integer(1)]) + a([Integer(1),
↪Integer(2),Integer(3),Integer(4)]); f
a[1, 2, 3, 4] + a[4, 3, 2, 1]
>>> f in a
True
```

isobaric_divided_difference(*w*)

alias of *pi()*.

pi(*w*)

Return the action of the isobaric divided difference operator π_w on `self`.

EXAMPLES:

```
sage: a = AtomPolynomials(QQ)
sage: a[2,3,1].pi(2)
a[2, 1, 3] + a[2, 3, 1]
sage: a[2,3,1].pi([2,3])
a[2, 1, 0, 3] + a[2, 1, 3] + a[2, 3, 0, 1] + a[2, 3, 1]
sage: a[2,3,1].pi([2,2]) == a[2,3,1].pi(2)
True
```

```
>>> from sage.all import *
>>> a = AtomPolynomials(QQ)
>>> a[Integer(2),Integer(3),Integer(1)].pi(Integer(2))
a[2, 1, 3] + a[2, 3, 1]
>>> a[Integer(2),Integer(3),Integer(1)].pi([Integer(2),Integer(3)])
a[2, 1, 0, 3] + a[2, 1, 3] + a[2, 3, 0, 1] + a[2, 3, 1]
```

(continues on next page)

(continued from previous page)

```
>>> a[Integer(2),Integer(3),Integer(1)].pi([Integer(2),Integer(2)]) ==␣
↪a[Integer(2),Integer(3),Integer(1)].pi(Integer(2))
True
```

pibar(*w*)

Apply the operator $\bar{\pi}_w$ to `self`.

`w` may be either a `Permutation` or a list of indices of simple transpositions (1-based).

The convention is to apply from left to right so if `w = [w1, w2, ..., wm]` then we apply $\bar{\pi}_{w_2 \cdots w_m} \circ \bar{\pi}_{w_1}$.

EXAMPLES:

```
sage: a = AtomPolynomials(QQ)
sage: a([3,2,1]).pibar(2)
a[3, 1, 2]
sage: a([3,2,1]).pibar([2,1])
a[1, 3, 2]
sage: a([3,2,1]).pibar(Permutation([3,2,1]))
a[1, 2, 3]
sage: f = a([3,2,1]) + a([3,2,1,1])
sage: f.pibar(2)
a[3, 1, 2] + a[3, 1, 2, 1]
sage: a.one().pibar(1)
0

sage: a([3,2,1,0]).pibar(2).pibar(2)
-a[3, 1, 2]
sage: (-a([3,2,1,0]) + 4*a([3,1,2,0])).pibar(2)
-5*a[3, 1, 2]

sage: a = AtomPolynomials(QQ, 4)
sage: a([3,2,1,0]).pibar(2)
a[3, 1, 2, 0]
sage: a([3,2,1,0]).pibar([2,1])
a[1, 3, 2, 0]
sage: a([3,2,1,0]).pibar(Permutation([3,2,1,4]))
a[1, 2, 3, 0]
sage: f = a([3,2,1,0]) + a([3,2,1,1])
sage: f.pibar(2)
a[3, 1, 2, 0] + a[3, 1, 2, 1]
sage: a.one().pibar(1)
0
```

```
>>> from sage.all import *
>>> a = AtomPolynomials(QQ)
>>> a([Integer(3),Integer(2),Integer(1)]).pibar(Integer(2))
a[3, 1, 2]
>>> a([Integer(3),Integer(2),Integer(1)]).pibar([Integer(2),Integer(1)])
a[1, 3, 2]
>>> a([Integer(3),Integer(2),Integer(1)]).pibar(Permutation([Integer(3),
↪Integer(2),Integer(1)]))
a[1, 2, 3]
```

(continues on next page)

(continued from previous page)

```
>>> f = a([Integer(3),Integer(2),Integer(1)]) + a([Integer(3),Integer(2),
↪Integer(1),Integer(1)])
>>> f.pibar(Integer(2))
a[3, 1, 2] + a[3, 1, 2, 1]
>>> a.one().pibar(Integer(1))
0

>>> a([Integer(3),Integer(2),Integer(1),Integer(0)]).pibar(Integer(2)).
↪pibar(Integer(2))
-a[3, 1, 2]
>>> (-a([Integer(3),Integer(2),Integer(1),Integer(0)]) +␣
↪Integer(4)*a([Integer(3),Integer(1),Integer(2),Integer(0)])).
↪pibar(Integer(2))
-5*a[3, 1, 2]

>>> a = AtomPolynomials(QQ, Integer(4))
>>> a([Integer(3),Integer(2),Integer(1),Integer(0)]).pibar(Integer(2))
a[3, 1, 2, 0]
>>> a([Integer(3),Integer(2),Integer(1),Integer(0)]).pibar([Integer(2),
↪Integer(1)])
a[1, 3, 2, 0]
>>> a([Integer(3),Integer(2),Integer(1),Integer(0)]).
↪pibar(Permutation([Integer(3),Integer(2),Integer(1),Integer(4)]))
a[1, 2, 3, 0]
>>> f = a([Integer(3),Integer(2),Integer(1),Integer(0)]) + a([Integer(3),
↪Integer(2),Integer(1),Integer(1)])
>>> f.pibar(Integer(2))
a[3, 1, 2, 0] + a[3, 1, 2, 1]
>>> a.one().pibar(Integer(1))
0
```

class sage.combinat.key_polynomial.**AtomPolynomialBasis**(*R=None*, *k=None*, *poly_ring=None*)

Bases: *OperatorPolynomialBasis*

The atom polynomial basis for a polynomial ring.

For a full definition, see SymmetricFunctions.com. Atom polynomials are indexed by weak compositions α with no trailing zeros. A basis element is given by

$$a_\alpha = \bar{\pi}_\sigma x^\mu,$$

where σ is the permutation of shortest length which sorts the α into a partition μ.

EXAMPLES:

Atom polynomials are a basis, indexed by (weak) compositions, for polynomial rings:

```
sage: a = AtomPolynomials(QQ)
sage: a([3,0,1,2])
a[3, 0, 1, 2]
sage: a([3,0,1,2])/2
1/2*a[3, 0, 1, 2]
sage: R = a.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field
```

(continues on next page)

(continued from previous page)

```
sage: A = AtomPolynomials(GF(5)); A
Atom polynomial basis over Finite Field of size 5
sage: 2*A([3,0,1,2])
2*a[3, 0, 1, 2]
sage: 5*(A([3,0,1,2]) + A([3,1,1]))
0
```

```
>>> from sage.all import *
>>> a = AtomPolynomials(QQ)
>>> a([Integer(3),Integer(0),Integer(1),Integer(2)])
a[3, 0, 1, 2]
>>> a([Integer(3),Integer(0),Integer(1),Integer(2)])/Integer(2)
1/2*a[3, 0, 1, 2]
>>> R = a.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field

>>> A = AtomPolynomials(GF(Integer(5))); A
Atom polynomial basis over Finite Field of size 5
>>> Integer(2)*A([Integer(3),Integer(0),Integer(1),Integer(2)])
2*a[3, 0, 1, 2]
>>> Integer(5)*(A([Integer(3),Integer(0),Integer(1),Integer(2)]) + A([Integer(3),
↪Integer(1),Integer(1)]))
0
```

We can expand them in the standard monomial basis:

```
sage: a([2,1,3,2]).expand()
z_3^2*z_2^3*z_1*z_0^2 + z_3^2*z_2^2*z_1^2*z_0^2

sage: a[0,2,2].expand()
z_2^2*z_1^2 + z_2^2*z_1*z_0 + z_2*z_1^2*z_0
```

```
>>> from sage.all import *
>>> a([Integer(2),Integer(1),Integer(3),Integer(2)]).expand()
z_3^2*z_2^3*z_1*z_0^2 + z_3^2*z_2^2*z_1^2*z_0^2

>>> a[Integer(0),Integer(2),Integer(2)].expand()
z_2^2*z_1^2 + z_2^2*z_1*z_0 + z_2*z_1^2*z_0
```

If we have a polynomial, we can express it in the atom basis:

```
sage: z = R.gen()
sage: a.from_polynomial(z[2]^2*z[1]*z[0])
a[1, 1, 2]
sage: a.from_polynomial(z[2]^3*z[1]^2*z[0])
a[1, 2, 3]

sage: f = (z[3]^2*z[2]*z[0]^3 + z[3]^2*z[1]*z[0]^3 + z[3]*z[2]^2*z[0]^3
....:      + 2*z[3]*z[2]*z[1]*z[0]^3 + z[3]*z[1]^2*z[0]^3
....:      + z[2]^2*z[1]*z[0]^3 + z[2]*z[1]^2*z[0]^3)
sage: a.from_polynomial(f)
```

(continues on next page)

(continued from previous page)

```
a[3, 0, 1, 2] + a[3, 0, 2, 1] + a[3, 1, 0, 2] + a[3, 1, 2]
 + a[3, 2, 0, 1] + a[3, 2, 1]
```

```
>>> from sage.all import *
>>> z = R.gen()
>>> a.from_polynomial(z[Integer(2)]**Integer(2)*z[Integer(1)]*z[Integer(0)])
a[1, 1, 2]
>>> a.from_
↪polynomial(z[Integer(2)]**Integer(3)*z[Integer(1)]**Integer(2)*z[Integer(0)])
a[1, 2, 3]

>>> f = (z[Integer(3)]**Integer(2)*z[Integer(2)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(3)]**Integer(2)*z[Integer(1)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(3)]*z[Integer(2)]**Integer(2)*z[Integer(0)]**Integer(3)
...       +␣
↪Integer(2)*z[Integer(3)]*z[Integer(2)]*z[Integer(1)]*z[Integer(0)]**Integer(3)␣
↪+ z[Integer(3)]*z[Integer(1)]**Integer(2)*z[Integer(0)]**Integer(3)
...       + z[Integer(2)]**Integer(2)*z[Integer(1)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(2)]*z[Integer(1)]**Integer(2)*z[Integer(0)]**Integer(3))
>>> a.from_polynomial(f)
a[3, 0, 1, 2] + a[3, 0, 2, 1] + a[3, 1, 0, 2] + a[3, 1, 2]
 + a[3, 2, 0, 1] + a[3, 2, 1]
```

Since the ring of atom polynomials may be regarded as a different choice of basis for a polynomial ring, it forms an algebra, so we have multiplication:

```
sage: a[10,5,2] * a[1,1,1]
a[11, 6, 3]
```

```
>>> from sage.all import *
>>> a[Integer(10),Integer(5),Integer(2)] * a[Integer(1),Integer(1),Integer(1)]
a[11, 6, 3]
```

We can also multiply by polynomials in the monomial basis:

```
sage: a([10,9,1]) * z[0]
a[11, 9, 1]
sage: z[0] * a([10,9,1])
a[11, 9, 1]
sage: a([10,9,1]) * (z[0] + z[3])
a[10, 9, 1, 1] + a[11, 9, 1]
```

```
>>> from sage.all import *
>>> a([Integer(10),Integer(9),Integer(1)]) * z[Integer(0)]
a[11, 9, 1]
>>> z[Integer(0)] * a([Integer(10),Integer(9),Integer(1)])
a[11, 9, 1]
>>> a([Integer(10),Integer(9),Integer(1)]) * (z[Integer(0)] + z[Integer(3)])
a[10, 9, 1, 1] + a[11, 9, 1]
```

Element

alias of *AtomPolynomial*

from_key_polynomial(*x*)

Expand a key polynomial in `self`.

EXAMPLES:

```
sage: a = AtomPolynomials(ZZ)
sage: k = KeyPolynomials(ZZ)
sage: f = k[1,2,3]
sage: a.from_key_polynomial(f)
a[1, 2, 3] + a[1, 3, 2] + a[2, 1, 3] + a[2, 3, 1] + a[3, 1, 2] + a[3, 2, 1]
sage: a.from_key_polynomial(2)
2*a[]
sage: a(f)
a[1, 2, 3] + a[1, 3, 2] + a[2, 1, 3] + a[2, 3, 1] + a[3, 1, 2] + a[3, 2, 1]

sage: a = AtomPolynomials(GF(7), 4)
sage: a.from_key_polynomial(f)
a[1, 2, 3, 0] + a[1, 3, 2, 0] + a[2, 1, 3, 0]
 + a[2, 3, 1, 0] + a[3, 1, 2, 0] + a[3, 2, 1, 0]
```

```
>>> from sage.all import *
>>> a = AtomPolynomials(ZZ)
>>> k = KeyPolynomials(ZZ)
>>> f = k[Integer(1),Integer(2),Integer(3)]
>>> a.from_key_polynomial(f)
a[1, 2, 3] + a[1, 3, 2] + a[2, 1, 3] + a[2, 3, 1] + a[3, 1, 2] + a[3, 2, 1]
>>> a.from_key_polynomial(Integer(2))
2*a[]
>>> a(f)
a[1, 2, 3] + a[1, 3, 2] + a[2, 1, 3] + a[2, 3, 1] + a[3, 1, 2] + a[3, 2, 1]

>>> a = AtomPolynomials(GF(Integer(7)), Integer(4))
>>> a.from_key_polynomial(f)
a[1, 2, 3, 0] + a[1, 3, 2, 0] + a[2, 1, 3, 0]
 + a[2, 3, 1, 0] + a[3, 1, 2, 0] + a[3, 2, 1, 0]
```

class sage.combinat.key_polynomial.**KeyPolynomial**

Bases: *OperatorPolynomial*

A key polynomial.

Key polynomials are polynomials that form a basis for a polynomial ring and are indexed by weak compositions.

Elements should be created by first creating the basis *KeyPolynomialBasis* and passing a list representing the indexing composition.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1]) + k([1,2,3,4]); f
k[1, 2, 3, 4] + k[4, 3, 2, 1]
sage: f in k
True
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> f = k([Integer(4),Integer(3),Integer(2),Integer(1)]) + k([Integer(1),
↪Integer(2),Integer(3),Integer(4)]); f
k[1, 2, 3, 4] + k[4, 3, 2, 1]
>>> f in k
True
```

isobaric_divided_difference(*w*)

alias of *pi()*.

pi(*w*)

Apply the operator π_w to `self`.

`w` may be either a `Permutation` or a list of indices of simple transpositions (1-based).

The convention is to apply from left to right so if `w = [w1, w2, ..., wm]` then we apply $\pi_{w_2 \cdots w_m} \circ \pi_{w_1}$

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).pi(2)
k[3, 1, 2]
sage: k([3,2,1]).pi([2,1])
k[1, 3, 2]
sage: k([3,2,1]).pi(Permutation([3,2,1]))
k[1, 2, 3]
sage: f = k([3,2,1]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[]

sage: k([3,2,1,0]).pi(2).pi(2)
k[3, 1, 2]
sage: (-k([3,2,1,0]) + 4*k([3,1,2,0])).pi(2)
3*k[3, 1, 2]

sage: k = KeyPolynomials(QQ, 4)
sage: k([3,2,1,0]).pi(2)
k[3, 1, 2, 0]
sage: k([3,2,1,0]).pi([2,1])
k[1, 3, 2, 0]
sage: k([3,2,1,0]).pi(Permutation([3,2,1,4]))
k[1, 2, 3, 0]
sage: f = k([3,2,1,0]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2, 0] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(2),Integer(1)]).pi(Integer(2))
```

(continues on next page)

(continued from previous page)

```
k[3, 1, 2]
>>> k([Integer(3),Integer(2),Integer(1)]).pi([Integer(2),Integer(1)])
k[1, 3, 2]
>>> k([Integer(3),Integer(2),Integer(1)]).pi(Permutation([Integer(3),
↪Integer(2),Integer(1)]))
k[1, 2, 3]
>>> f = k([Integer(3),Integer(2),Integer(1)]) + k([Integer(3),Integer(2),
↪Integer(1),Integer(1)])
>>> f.pi(Integer(2))
k[3, 1, 2] + k[3, 1, 2, 1]
>>> k.one().pi(Integer(1))
k[]

>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi(Integer(2)).
↪pi(Integer(2))
k[3, 1, 2]
>>> (-k([Integer(3),Integer(2),Integer(1),Integer(0)]) +␣
↪Integer(4)*k([Integer(3),Integer(1),Integer(2),Integer(0)])).pi(Integer(2))
3*k[3, 1, 2]

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi(Integer(2))
k[3, 1, 2, 0]
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).pi([Integer(2),
↪Integer(1)])
k[1, 3, 2, 0]
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).
↪pi(Permutation([Integer(3),Integer(2),Integer(1),Integer(4)]))
k[1, 2, 3, 0]
>>> f = k([Integer(3),Integer(2),Integer(1),Integer(0)]) + k([Integer(3),
↪Integer(2),Integer(1),Integer(1)])
>>> f.pi(Integer(2))
k[3, 1, 2, 0] + k[3, 1, 2, 1]
>>> k.one().pi(Integer(1))
k[0, 0, 0, 0]
```

pibar(*w*)

Apply the operator $\bar{\pi}_w$ to `self`.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k[2,3,1].pibar(2)
k[2, 1, 3] - k[2, 3, 1]
sage: k[2,3,1].pibar([2,3])
k[2, 1, 0, 3] - k[2, 1, 3] - k[2, 3, 0, 1] + k[2, 3, 1]
sage: k[2,3,1].pibar([2,2]) == -k[2,3,1].pibar(2)
True
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k[Integer(2),Integer(3),Integer(1)].pibar(Integer(2))
```

(continues on next page)

(continued from previous page)

```
k[2, 1, 3] - k[2, 3, 1]
>>> k[Integer(2),Integer(3),Integer(1)].pibar([Integer(2),Integer(3)])
k[2, 1, 0, 3] - k[2, 1, 3] - k[2, 3, 0, 1] + k[2, 3, 1]
>>> k[Integer(2),Integer(3),Integer(1)].pibar([Integer(2),Integer(2)]) == -
↪k[Integer(2),Integer(3),Integer(1)].pibar(Integer(2))
True
```

class sage.combinat.key_polynomial.**KeyPolynomialBasis**(*R=None*, *k=None*, *poly_ring=None*)

Bases: *OperatorPolynomialBasis*

The key polynomial basis for a polynomial ring.

For a full definition, see SymmetricFunctions.com. Key polynomials are indexed by weak compositions with no trailing zeros, and σ is the permutation of shortest length which sorts the indexing composition into a partition.

EXAMPLES:

Key polynomials are a basis, indexed by (weak) compositions, for polynomial rings:

```
sage: k = KeyPolynomials(QQ)
sage: k([3,0,1,2])
k[3, 0, 1, 2]
sage: k([3,0,1,2])/2
1/2*k[3, 0, 1, 2]
sage: R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field

sage: K = KeyPolynomials(GF(5)); K
Key polynomial basis over Finite Field of size 5
sage: 2*K([3,0,1,2])
2*k[3, 0, 1, 2]
sage: 5*(K([3,0,1,2]) + K([3,1,1]))
0
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(0),Integer(1),Integer(2)])
k[3, 0, 1, 2]
>>> k([Integer(3),Integer(0),Integer(1),Integer(2)])/Integer(2)
1/2*k[3, 0, 1, 2]
>>> R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field

>>> K = KeyPolynomials(GF(Integer(5))); K
Key polynomial basis over Finite Field of size 5
>>> Integer(2)*K([Integer(3),Integer(0),Integer(1),Integer(2)])
2*k[3, 0, 1, 2]
>>> Integer(5)*(K([Integer(3),Integer(0),Integer(1),Integer(2)]) + K([Integer(3),
↪Integer(1),Integer(1)]))
0
```

We can expand them in the standard monomial basis:

```
sage: k([3,0,1,2]).expand()
z_3^2*z_2*z_0^3 + z_3^2*z_1*z_0^3 + z_3*z_2^2*z_0^3
 + 2*z_3*z_2*z_1*z_0^3 + z_3*z_1^2*z_0^3 + z_2^2*z_1*z_0^3
 + z_2*z_1^2*z_0^3

sage: k([0,0,2]).expand()
z_2^2 + z_2*z_1 + z_2*z_0 + z_1^2 + z_1*z_0 + z_0^2
```

```
>>> from sage.all import *
>>> k([Integer(3),Integer(0),Integer(1),Integer(2)]).expand()
z_3^2*z_2*z_0^3 + z_3^2*z_1*z_0^3 + z_3*z_2^2*z_0^3
 + 2*z_3*z_2*z_1*z_0^3 + z_3*z_1^2*z_0^3 + z_2^2*z_1*z_0^3
 + z_2*z_1^2*z_0^3

>>> k([Integer(0),Integer(0),Integer(2)]).expand()
z_2^2 + z_2*z_1 + z_2*z_0 + z_1^2 + z_1*z_0 + z_0^2
```

If we have a polynomial, we can express it in the key basis:

```
sage: z = R.gen()
sage: k.from_polynomial(z[2]^2*z[1]*z[0])
k[1, 1, 2] - k[1, 2, 1]

sage: f = z[3]^2*z[2]*z[0]^3 + z[3]^2*z[1]*z[0]^3 + z[3]*z[2]^2*z[0]^3 + \
....: 2*z[3]*z[2]*z[1]*z[0]^3 + z[3]*z[1]^2*z[0]^3 + z[2]^2*z[1]*z[0]^3 + \
....: z[2]*z[1]^2*z[0]^3
sage: k.from_polynomial(f)
k[3, 0, 1, 2]
```

```
>>> from sage.all import *
>>> z = R.gen()
>>> k.from_polynomial(z[Integer(2)]**Integer(2)*z[Integer(1)]*z[Integer(0)])
k[1, 1, 2] - k[1, 2, 1]

>>> f = z[Integer(3)]**Integer(2)*z[Integer(2)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(3)]**Integer(2)*z[Integer(1)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(3)]*z[Integer(2)]**Integer(2)*z[Integer(0)]**Integer(3) +␣
↪Integer(2)*z[Integer(3)]*z[Integer(2)]*z[Integer(1)]*z[Integer(0)]**Integer(3)␣
↪+ z[Integer(3)]*z[Integer(1)]**Integer(2)*z[Integer(0)]**Integer(3) +␣
↪z[Integer(2)]**Integer(2)*z[Integer(1)]*z[Integer(0)]**Integer(3) +␣
↪z[Integer(2)]*z[Integer(1)]**Integer(2)*z[Integer(0)]**Integer(3)
>>> k.from_polynomial(f)
k[3, 0, 1, 2]
```

Since the ring of key polynomials may be regarded as a different choice of basis for a polynomial ring, it forms an algebra, so we have multiplication:

```
sage: k([10,5,2])*k([1,1,1])
k[11, 6, 3]
```

```
>>> from sage.all import *
>>> k([Integer(10),Integer(5),Integer(2)])*k([Integer(1),Integer(1),Integer(1)])
k[11, 6, 3]
```

We can also multiply by polynomials in the monomial basis:

```
sage: k([10,9,1])*z[0]
k[11, 9, 1]
sage: z[0] * k([10,9,1])
k[11, 9, 1]
sage: k([10,9,1])*(z[0] + z[3])
k[10, 9, 1, 1] + k[11, 9, 1]
```

```
>>> from sage.all import *
>>> k([Integer(10),Integer(9),Integer(1)])*z[Integer(0)]
k[11, 9, 1]
>>> z[Integer(0)] * k([Integer(10),Integer(9),Integer(1)])
k[11, 9, 1]
>>> k([Integer(10),Integer(9),Integer(1)])*(z[Integer(0)] + z[Integer(3)])
k[10, 9, 1, 1] + k[11, 9, 1]
```

When the sorting permutation is the longest element, the key polynomial agrees with the Schur polynomial:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: k([1,2,3]).expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
sage: s[3,2,1].expand(3)
x0^3*x1^2*x2 + x0^2*x1^3*x2 + x0^3*x1*x2^2 + 2*x0^2*x1^2*x2^2
 + x0*x1^3*x2^2 + x0^2*x1*x2^3 + x0*x1^2*x2^3
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).schur()
>>> k([Integer(1),Integer(2),Integer(3)]).expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
>>> s[Integer(3),Integer(2),Integer(1)].expand(Integer(3))
x0^3*x1^2*x2 + x0^2*x1^3*x2 + x0^3*x1*x2^2 + 2*x0^2*x1^2*x2^2
 + x0*x1^3*x2^2 + x0^2*x1*x2^3 + x0*x1^2*x2^3
```

The polynomial expansions can be computed using crystals and expressed in terms of the key basis:

```
sage: T = crystals.Tableaux(['A',3],shape=[2,1])
sage: f = T.demazure_character([3,2,1])
sage: k.from_polynomial(f)
k[1, 0, 0, 2]
```

```
>>> from sage.all import *
>>> T = crystals.Tableaux(['A',Integer(3)],shape=[Integer(2),Integer(1)])
>>> f = T.demazure_character([Integer(3),Integer(2),Integer(1)])
>>> k.from_polynomial(f)
k[1, 0, 0, 2]
```

The default behavior is to work in a polynomial ring with infinitely many variables. One can work in a specicfied number of variables:

```
sage: k = KeyPolynomials(QQ, 4)
sage: k([3,0,1,2]).expand()
z_0^3*z_1^2*z_2 + z_0^3*z_1*z_2^2 + z_0^3*z_1^2*z_3
 + 2*z_0^3*z_1*z_2*z_3 + z_0^3*z_2^2*z_3 + z_0^3*z_1*z_3^2 + z_0^3*z_2*z_3^2

sage: k([0,0,2,0]).expand()
z_0^2 + z_0*z_1 + z_1^2 + z_0*z_2  + z_1*z_2 + z_2^2

sage: k([0,0,2,0]).expand().parent()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ, Integer(4))
>>> k([Integer(3),Integer(0),Integer(1),Integer(2)]).expand()
z_0^3*z_1^2*z_2 + z_0^3*z_1*z_2^2 + z_0^3*z_1^2*z_3
 + 2*z_0^3*z_1*z_2*z_3 + z_0^3*z_2^2*z_3 + z_0^3*z_1*z_3^2 + z_0^3*z_2*z_3^2

>>> k([Integer(0),Integer(0),Integer(2),Integer(0)]).expand()
z_0^2 + z_0*z_1 + z_1^2 + z_0*z_2  + z_1*z_2 + z_2^2

>>> k([Integer(0),Integer(0),Integer(2),Integer(0)]).expand().parent()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

If working in a specified number of variables, the length of the indexing composition must be the same as the number of variables:

```
sage: k([0,0,2])
Traceback (most recent call last):
 ...
TypeError: do not know how to make x (= [0, 0, 2]) an element of self
 (=Key polynomial basis over Rational Field)
```

```
>>> from sage.all import *
>>> k([Integer(0),Integer(0),Integer(2)])
Traceback (most recent call last):
 ...
TypeError: do not know how to make x (= [0, 0, 2]) an element of self
 (=Key polynomial basis over Rational Field)
```

One can also work in a specified polynomial ring:

```
sage: k = KeyPolynomials(QQ['x0', 'x1', 'x2', 'x3'])
sage: k([0,2,0,0])
k[0, 2, 0, 0]
sage: k([4,0,0,0]).expand()
x0^4
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ['x0', 'x1', 'x2', 'x3'])
>>> k([Integer(0),Integer(2),Integer(0),Integer(0)])
k[0, 2, 0, 0]
>>> k([Integer(4),Integer(0),Integer(0),Integer(0)]).expand()
x0^4
```

If one wishes to use a polynomial ring as coefficients for the key polynomials, pass the keyword argument `poly_coeffs=True`:

```
sage: k = KeyPolynomials(QQ['q'], poly_coeffs=True)
sage: R = k.base_ring(); R
Univariate Polynomial Ring in q over Rational Field
sage: R.inject_variables()
Defining q
sage: (q^2 + q + 1)*k([0,2,2,0,3,2])
(q^2+q+1)*k[0, 2, 2, 0, 3, 2]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ['q'], poly_coeffs=True)
>>> R = k.base_ring(); R
Univariate Polynomial Ring in q over Rational Field
>>> R.inject_variables()
Defining q
>>> (q**Integer(2) + q + Integer(1))*k([Integer(0),Integer(2),Integer(2),
↪Integer(0),Integer(3),Integer(2)])
(q^2+q+1)*k[0, 2, 2, 0, 3, 2]
```

Element

alias of *KeyPolynomial*

from_schubert_polynomial(*x*)

Expand a Schubert polynomial in `self`.

EXAMPLES:

```
sage: k = KeyPolynomials(ZZ)
sage: X = SchubertPolynomialRing(ZZ)
sage: f = X([2,1,5,4,3])
sage: k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]
sage: k.from_schubert_polynomial(2)
2*k[]
sage: k(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]

sage: k = KeyPolynomials(GF(7), 4)
sage: k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2, 0] + k[3, 0, 0, 1]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(ZZ)
>>> X = SchubertPolynomialRing(ZZ)
>>> f = X([Integer(2),Integer(1),Integer(5),Integer(4),Integer(3)])
>>> k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]
>>> k.from_schubert_polynomial(Integer(2))
2*k[]
>>> k(f)
k[1, 0, 2, 1] + k[2, 0, 2] + k[3, 0, 0, 1]
```

(continues on next page)

(continued from previous page)

```
>>> k = KeyPolynomials(GF(Integer(7)), Integer(4))
>>> k.from_schubert_polynomial(f)
k[1, 0, 2, 1] + k[2, 0, 2, 0] + k[3, 0, 0, 1]
```

class sage.combinat.key_polynomial.**OperatorPolynomial**

Bases: IndexedFreeModuleElement

Abstract base class for a polynomial defined recursively by divided difference type operators.

Parents should implement the divided difference operator as a staticmethod _operator.

divided_difference(*w*)

Apply the divided difference operator ∂_w to self.

The convention is to apply from left to right so if w = [w1, w2, ..., wm] then we apply $\partial_{w_2 \cdots w_m} \circ \partial_{w_1}$

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).divided_difference(2)
k[3, 1, 1]
sage: k([3,2,1]).divided_difference([2,3])
k[3, 1]

sage: k = KeyPolynomials(QQ, 4)
sage: k([3,2,1,0]).divided_difference(2)
k[3, 1, 1, 0]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(2),Integer(1)]).divided_difference(Integer(2))
k[3, 1, 1]
>>> k([Integer(3),Integer(2),Integer(1)]).divided_difference([Integer(2),
↪Integer(3)])
k[3, 1]

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).divided_
↪difference(Integer(2))
k[3, 1, 1, 0]
```

expand()

Return self written in the monomial basis (i.e., as an element in the corresponding polynomial ring).

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1])
sage: f.expand()
z_3*z_2^2*z_1^3*z_0^4

sage: f = k([1,2,3])
sage: f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
```

(continues on next page)

(continued from previous page)

```
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> f = k([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> f.expand()
z_3*z_2^2*z_1^3*z_0^4

>>> f = k([Integer(1),Integer(2),Integer(3)])
>>> f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0
 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
 + z_2*z_1^2*z_0^3
```

isobaric_divided_difference(*w*)

Apply the isobaric divided difference operator π_w to `self`.

The convention is to apply from left to right so if `w = [w1, w2, ..., wm]` then we apply $\pi_{w_2 \cdots w_m} \circ \pi_{w_1}$

EXAMPLES:

```
sage: a = AtomPolynomials(QQ)
sage: a([3,2,1]).isobaric_divided_difference(2)
a[3, 1, 2] + a[3, 2, 1]
sage: a([3,2,1]).isobaric_divided_difference([2, 3])
a[3, 1, 0, 2] + a[3, 1, 2] + a[3, 2, 0, 1] + a[3, 2, 1]

sage: a = AtomPolynomials(QQ, 4)
sage: a([3,2,1,0]).divided_difference(2)
a[3, 1, 1, 0]
```

```
>>> from sage.all import *
>>> a = AtomPolynomials(QQ)
>>> a([Integer(3),Integer(2),Integer(1)]).isobaric_divided_
↪difference(Integer(2))
a[3, 1, 2] + a[3, 2, 1]
>>> a([Integer(3),Integer(2),Integer(1)]).isobaric_divided_
↪difference([Integer(2), Integer(3)])
a[3, 1, 0, 2] + a[3, 1, 2] + a[3, 2, 0, 1] + a[3, 2, 1]

>>> a = AtomPolynomials(QQ, Integer(4))
>>> a([Integer(3),Integer(2),Integer(1),Integer(0)]).divided_
↪difference(Integer(2))
a[3, 1, 1, 0]
```

to_polynomial()

alias of *expand()*.

class sage.combinat.key_polynomial.**OperatorPolynomialBasis**(*R=None*, *k=None*, *poly_ring=None*)

Bases: *CombinatorialFreeModule*

A basis for a polynomial ring defined recursively by divided difference type operators such that the result is a triangular change of basis with the natural monomial basis.

degree_on_basis(*alpha*)

Return the degree of the basis element indexed by `alpha`.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k.degree_on_basis([2,1,0,2])
5

sage: k = KeyPolynomials(QQ, 5)
sage: k.degree_on_basis([2,1,0,2,0])
5
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.degree_on_basis([Integer(2),Integer(1),Integer(0),Integer(2)])
5

>>> k = KeyPolynomials(QQ, Integer(5))
>>> k.degree_on_basis([Integer(2),Integer(1),Integer(0),Integer(2),
↪Integer(0)])
5
```

from_polynomial(*f*)

Expand a polynomial in terms of `self`.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: z = k.poly_gens(); z
z_*
sage: p = z[0]^4*z[1]^2*z[2]*z[3] + z[0]^4*z[1]*z[2]^2*z[3]
sage: k.from_polynomial(p)
k[4, 1, 2, 1]

sage: all(k(c) == k.from_polynomial(k(c).expand()) for c in␣
↪IntegerVectors(n=5, k=4))
True

sage: T = crystals.Tableaux(['A', 4], shape=[4,2,1,1])
sage: k.from_polynomial(T.demazure_character([2]))
k[4, 1, 2, 1]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> z = k.poly_gens(); z
z_*
>>> p = z[Integer(0)]**Integer(4)*z[Integer(1)]**Integer(2)*z[Integer(2)]*z[In
↪teger(3)] + z[Integer(0)]**Integer(4)*z[Integer(1)]*z[Integer(2)]**Integer(2
↪)*z[Integer(3)]
>>> k.from_polynomial(p)
k[4, 1, 2, 1]

>>> all(k(c) == k.from_polynomial(k(c).expand()) for c in␣
```

(continues on next page)

(continued from previous page)

```
↪IntegerVectors(n=Integer(5), k=Integer(4)))
True

>>> T = crystals.Tableaux(['A', Integer(4)], shape=[Integer(4),Integer(2),
↪Integer(1),Integer(1)])
>>> k.from_polynomial(T.demazure_character([Integer(2)]))
k[4, 1, 2, 1]
```

one_basis()

Return the basis element indexing the identity.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k.one_basis()
[]

sage: k = KeyPolynomials(QQ, 4)
sage: k.one_basis()
[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.one_basis()
[]

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.one_basis()
[0, 0, 0, 0]
```

poly_gens()

Return the polynomial generators for the polynomial ring associated to `self`.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k.poly_gens()
z_*

sage: k = KeyPolynomials(QQ, 4)
sage: k.poly_gens()
(z_0, z_1, z_2, z_3)
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.poly_gens()
z_*

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.poly_gens()
(z_0, z_1, z_2, z_3)
```

polynomial_ring()

Return the polynomial ring associated to `self`.

EXAMPLES:

```
sage: k = KeyPolynomials(QQ)
sage: k.polynomial_ring()
Infinite polynomial ring in z over Rational Field

sage: k = KeyPolynomials(QQ, 4)
sage: k.polynomial_ring()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.polynomial_ring()
Infinite polynomial ring in z over Rational Field

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.polynomial_ring()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

`sage.combinat.key_polynomial.`**`divided_difference`**`(`f, i`)`

Apply the `i`-th divided difference operator to the polynomial `f`.

EXAMPLES:

```
sage: from sage.combinat.key_polynomial import divided_difference
sage: k = KeyPolynomials(QQ)
sage: z = k.poly_gens()
sage: f = z[1]*z[2]^3 + z[1]*z[2]*z[3]
sage: divided_difference(f, 3)
z_3^2*z_1 + z_3*z_2*z_1 + z_2^2*z_1

sage: k = KeyPolynomials(QQ, 4)
sage: z = k.poly_gens()
sage: f = z[1]*z[2]^3 + z[1]*z[2]*z[3]
sage: divided_difference(f, 3)
z_1*z_2^2 + z_1*z_2*z_3 + z_1*z_3^2

sage: k = KeyPolynomials(QQ)
sage: R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field
sage: z = R.gen()
sage: divided_difference(z[1]*z[2]^3, 2)
-z_2^2*z_1 - z_2*z_1^2
sage: divided_difference(z[1]*z[2]*z[3], 3)
0
sage: divided_difference(z[1]*z[2]*z[3], 4)
z_2*z_1
sage: divided_difference(z[1]*z[2]*z[4], 4)
-z_2*z_1

sage: k = KeyPolynomials(QQ, 5)
```

(continues on next page)

(continued from previous page)

```
sage: z = k.polynomial_ring().gens()
sage: divided_difference(z[1]*z[2]^3, 2)
-z_1^2*z_2 - z_1*z_2^2
sage: divided_difference(z[1]*z[2]*z[3], 3)
0
sage: divided_difference(z[1]*z[2]*z[3], 4)
z_1*z_2
sage: divided_difference(z[1]*z[2]*z[4], 4)
-z_1*z_2
```

```
>>> from sage.all import *
>>> from sage.combinat.key_polynomial import divided_difference
>>> k = KeyPolynomials(QQ)
>>> z = k.poly_gens()
>>> f = z[Integer(1)]*z[Integer(2)]**Integer(3) +␣
↪z[Integer(1)]*z[Integer(2)]*z[Integer(3)]
>>> divided_difference(f, Integer(3))
z_3^2*z_1 + z_3*z_2*z_1 + z_2^2*z_1

>>> k = KeyPolynomials(QQ, Integer(4))
>>> z = k.poly_gens()
>>> f = z[Integer(1)]*z[Integer(2)]**Integer(3) +␣
↪z[Integer(1)]*z[Integer(2)]*z[Integer(3)]
>>> divided_difference(f, Integer(3))
z_1*z_2^2 + z_1*z_2*z_3 + z_1*z_3^2

>>> k = KeyPolynomials(QQ)
>>> R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field
>>> z = R.gen()
>>> divided_difference(z[Integer(1)]*z[Integer(2)]**Integer(3), Integer(2))
-z_2^2*z_1 - z_2*z_1^2
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(3)], Integer(3))
0
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(3)], Integer(4))
z_2*z_1
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(4)], Integer(4))
-z_2*z_1

>>> k = KeyPolynomials(QQ, Integer(5))
>>> z = k.polynomial_ring().gens()
>>> divided_difference(z[Integer(1)]*z[Integer(2)]**Integer(3), Integer(2))
-z_1^2*z_2 - z_1*z_2^2
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(3)], Integer(3))
0
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(3)], Integer(4))
z_1*z_2
>>> divided_difference(z[Integer(1)]*z[Integer(2)]*z[Integer(4)], Integer(4))
-z_1*z_2
```

sage.combinat.key_polynomial.**isobaric_divided_difference**(f, w)

Apply the isobaric divided difference operator π_w to the polynomial f.

w may be either a single index or a list of indices of simple transpositions.

Warning

The simple transpositions should be applied from left to right.

EXAMPLES:

```
sage: from sage.combinat.key_polynomial import isobaric_divided_difference as idd
sage: R.<z> = InfinitePolynomialRing(GF(3))
sage: idd(z[1]^4*z[2]^2*z[4], 4)
0

sage: idd(z[1]^4*z[2]^2*z[3]*z[4], 3)
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

sage: idd(z[1]^4*z[2]^2*z[3]*z[4], [3, 4])
z_4^2*z_3*z_2*z_1^4 + z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

sage: idd(z[1]^4*z[2]^2*z[3]*z[4], [4, 3])
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

sage: idd(z[1]^2*z[2], [3, 2])
z_3*z_2^2 + z_3*z_2*z_1 + z_3*z_1^2 + z_2^2*z_1 + z_2*z_1^2
```

```
>>> from sage.all import *
>>> from sage.combinat.key_polynomial import isobaric_divided_difference as idd
>>> R = InfinitePolynomialRing(GF(Integer(3)), names=('z',)); (z,) = R._first_
↪ngens(1)
>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(4)],␣
↪Integer(4))
0

>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], Integer(3))
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], [Integer(3), Integer(4)])
z_4^2*z_3*z_2*z_1^4 + z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], [Integer(4), Integer(3)])
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

>>> idd(z[Integer(1)]**Integer(2)*z[Integer(2)], [Integer(3), Integer(2)])
z_3*z_2^2 + z_3*z_2*z_1 + z_3*z_1^2 + z_2^2*z_1 + z_2*z_1^2
```

sage.combinat.key_polynomial.**isobaric_divided_difference_bar**(f, w)

Apply the isobaric divided difference operator $\bar{\pi}_w$ to the polynomial f.

This map is defined by $\bar{\pi}_i := \pi_i - 1$.

w may be either a single index or a list of indices of simple transpositions.

Warning

The simple transpositions should be applied from left to right.

EXAMPLES:

```
sage: from sage.combinat.key_polynomial import isobaric_divided_difference_bar as␣
↪iddb
sage: R.<z> = InfinitePolynomialRing(GF(3))
sage: iddb(z[1]^4*z[2]^2*z[4], 4)
-z_4*z_2^2*z_1^4

sage: iddb(z[1]^4*z[2]^2*z[3]*z[4], 3)
z_4*z_3^2*z_2*z_1^4

sage: iddb(z[1]^4*z[2]^2*z[3]*z[4], [3, 4])
z_4^2*z_3*z_2*z_1^4

sage: iddb(z[1]^4*z[2]^2*z[3]*z[4], [4, 3])
0

sage: iddb(z[1]^2*z[2], [3, 2])
z_3*z_2^2 + z_3*z_2*z_1
```

```
>>> from sage.all import *
>>> from sage.combinat.key_polynomial import isobaric_divided_difference_bar as␣
↪iddb
>>> R = InfinitePolynomialRing(GF(Integer(3)), names=('z',)); (z,) = R._first_
↪ngens(1)
>>> iddb(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(4)],␣
↪Integer(4))
-z_4*z_2^2*z_1^4

>>> iddb(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], Integer(3))
z_4*z_3^2*z_2*z_1^4

>>> iddb(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], [Integer(3), Integer(4)])
z_4^2*z_3*z_2*z_1^4

>>> iddb(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]*z[Inte-
ger(4)], [Integer(4), Integer(3)])
0

>>> iddb(z[Integer(1)]**Integer(2)*z[Integer(2)], [Integer(3), Integer(2)])
z_3*z_2^2 + z_3*z_2*z_1
```

sage.combinat.key_polynomial.**sorting_word**(*alpha*)

Get a reduced word for the permutation which sorts `alpha` into a partition.

The result is a list `l = [i0, i1, i2, ...]` where each `ij` is a positive integer such that it applies the simple transposition $(i_j, i_j + 1)$. The transpositions are applied starting with `i0`, then `i1` is applied, followed by `i2`, and

so on. See *sage.combinat.permutation.Permutation.reduced_words()* for the convention used.

EXAMPLES:

```
sage: IV = IntegerVectors()
sage: from sage.combinat.key_polynomial import sorting_word
sage: list(sorting_word(IV([2,3,2]))[0])
[1]
sage: sorting_word(IV([2,3,2]))[1]
[3, 2, 2]
sage: list(sorting_word(IV([5,6,7]))[0])
[1, 2, 1]
sage: list(sorting_word(IV([0,3,2]))[0])
[2, 1]
sage: list(sorting_word(IV([0,3,0,2]))[0])
[2, 3, 1]
sage: list(sorting_word(IV([3,2,1]))[0])
[]
sage: list(sorting_word(IV([2,3,3]))[0])
[2, 1]
```

```
>>> from sage.all import *
>>> IV = IntegerVectors()
>>> from sage.combinat.key_polynomial import sorting_word
>>> list(sorting_word(IV([Integer(2),Integer(3),Integer(2)]))[Integer(0)])
[1]
>>> sorting_word(IV([Integer(2),Integer(3),Integer(2)]))[Integer(1)]
[3, 2, 2]
>>> list(sorting_word(IV([Integer(5),Integer(6),Integer(7)]))[Integer(0)])
[1, 2, 1]
>>> list(sorting_word(IV([Integer(0),Integer(3),Integer(2)]))[Integer(0)])
[2, 1]
>>> list(sorting_word(IV([Integer(0),Integer(3),Integer(0),
↪Integer(2)]))[Integer(0)])
[2, 3, 1]
>>> list(sorting_word(IV([Integer(3),Integer(2),Integer(1)]))[Integer(0)])
[]
>>> list(sorting_word(IV([Integer(2),Integer(3),Integer(3)]))[Integer(0)])
[2, 1]
```

Kleshchev partitions

A partition (tuple) μ is Kleshchev if it can be recursively obtained by adding a sequence of good nodes to the empty *PartitionTuple* of the same *level()* and *multicharge*. In this way, the set of Kleshchev multipartitions becomes a realization of a Kashiwara crystal *sage.combinat.crystals.crystals* for a irreducible integral highest weight representation of $U_q(\widehat{\mathfrak{sl}}_e)$.

The Kleshchev multipartitions first appeared in the work of Ariki and Mathas [AM2000] where it was shown that they index the irreducible representations of the cyclotomic Hecke algebras of type A [AK1994]. Soon afterwards Ariki [Ariki2001] showed that the set of Kleshchev multipartitions naturally label the irreducible representations of these algebras. As a far reaching generalization of these ideas the Ariki-Brundan-Kleshchev categorification theorem [Ariki1996] [BK2009] says that these algebras categorify the irreducible integral highest weight representations of the quantum group $U_q(\widehat{\mathfrak{sl}}_e)$ of the affine special linear group. Under this categorification, q corresponds to the grading shift on the cyclotomic

Hecke algebras, where the grading from the Brundan-Kleshchev graded isomorphism theorem to the *KLR algebras* of type A [BK2009].

The group algebras of the symmetric group in characteristic p are an important special case of the cyclotomic Hecke algebras of type A. In this case, depending on your prefer convention, the set of Kleshchev partitions is the set of *`p`-regular* or *`p`-restricted* `Partitions`. In this case, Kleshchev [Kle1995] proved that the *modular branching rules* were given by adding and removing *good nodes*; see `good_cells()`. Lascoux, Leclerc and Thibon [LLT1996] noticed that Kleshchev's branching rules coincided with Kashiwara's crystal operators for the fundamental representation of $L(\Lambda_0)$ of $U_q(\widehat{\mathfrak{sl}}_p)$ and their celebrated *LLT conjecture* said that decomposition matrices of the `sage.algebras.iwahori_hecke_algebra.IwahoriHeckeAlgebra` of the symmetric group should be computable using the canonical basis of $L(\Lambda_0)$. This was proved and generalised to all cyclotomic Hecke algebras of type A by Ariki [Ariki1996] and then further generalized to the graded setting by Brundan and Kleshchev [BK2009].

The main class for accessing Kleshchev partition (tuples) is `KleshchevPartitions`. Unfortunately, just as with the symmetric group, different authors use different conventions when defining Kleshchev partitions, which depends on whether you read components from left to right, or right to left, and whether you read the nodes in the partition in each component from top to bottom or bottom to top. The `KleshchevPartitions` class supports these four different conventions:

```
sage: KleshchevPartitions(2, [0,0], size=2, convention='left regular')[:]
[([1], [1]), ([2], [])]
sage: KleshchevPartitions(2, [0,0], size=2, convention='left restricted')[:]
[([1], [1]), ([], [1, 1])]
sage: KleshchevPartitions(2, [0,0], size=2, convention='right regular')[:]
[([1], [1]), ([], [2])]
sage: KleshchevPartitions(2, [0,0], size=2, convention='right restricted')[:]
[([1], [1]), ([1, 1], [])]
```

```
>>> from sage.all import *
>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='left regular')[:]
[([1], [1]), ([2], [])]
>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='left restricted')[:]
[([1], [1]), ([], [1, 1])]
>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='right regular')[:]
[([1], [1]), ([], [2])]
>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='right restricted')[:]
[([1], [1]), ([1, 1], [])]
```

By default, the `left restricted` convention is used. As a shorthand, `LG`, `LS`, `RG` and `RS`, respectively, can be used to specify the `convention` With the `left` convention the partition tuples should be ordered with the most dominant partitions in the partition tuple on the left and with the `right` convention the most dominant partition is on the right.

The `KleshchevPartitions` class can automatically convert between these four different conventions:

```
sage: KPlg = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
sage: KPls = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
sage: [KPlg(mu) for mu in KPls] # indirect doc test
[([1], [1]), ([2], [])]
```

```
>>> from sage.all import *
>>> KPlg = KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
```

(continues on next page)

(continued from previous page)

```
↪convention='left regular')
>>> KPls = KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='left restricted')
>>> [KPlg(mu) for mu in KPls] # indirect doc test
[([1], [1]), ([2], [])]
```

AUTHORS:

- Andrew Mathas and Travis Scrimshaw (2018-05-1): Initial version

class sage.combinat.partition_kleshchev.**KleshchevCrystalMixin**

Bases: object

Mixin class for the crystal structure of a Kleshchev partition.

Epsilon()

Return ε of self.

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.Epsilon()
3*Lambda[1]
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="left regular")
>>> x = C([[Integer(5),Integer(4),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(1)]])
>>> x.Epsilon()
3*Lambda[1]
```

Phi()

Return ϕ of self.

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.Phi()
3*Lambda[0] + 2*Lambda[1]
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="left regular")
>>> x = C([[Integer(5),Integer(4),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(1)]])
>>> x.Phi()
3*Lambda[0] + 2*Lambda[1]
```

epsilon(i)

Return the Kashiwara crystal operator ε_i applied to self.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: [x.epsilon(i) for i in C.index_set()]
[0, 3, 0]
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="left regular")
>>> x = C([[Integer(5),Integer(4),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(1)]])
>>> [x.epsilon(i) for i in C.index_set()]
[0, 3, 0]
```

phi(*i*)

Return the Kashiwara crystal operator φ_i applied to `self`.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: [x.phi(i) for i in C.index_set()]
[3, 2, 0]
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="left regular")
>>> x = C([[Integer(5),Integer(4),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(1)]])
>>> [x.phi(i) for i in C.index_set()]
[3, 2, 0]
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1], [3,2,1,1]])
sage: x.weight()
3*Lambda[0] - Lambda[1] - 5*delta
sage: x.Phi() - x.Epsilon()
3*Lambda[0] - Lambda[1]

sage: C = crystals.KleshchevPartitions(3, [0,2], convention="right regular")
sage: y = C([[5,1,1], [4,2,2,1,1]])
sage: y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
```

(continues on next page)

(continued from previous page)

```
sage: y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]

sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: y = C([[5,1,1], [4,2,2,1,1]])
sage: y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
sage: y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="left regular")
>>> x = C([[Integer(5),Integer(4),Integer(1)], [Integer(3),Integer(2),
↪Integer(1),Integer(1)]])
>>> x.weight()
3*Lambda[0] - Lambda[1] - 5*delta
>>> x.Phi() - x.Epsilon()
3*Lambda[0] - Lambda[1]

>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="right regular")
>>> y = C([[Integer(5),Integer(1),Integer(1)], [Integer(4),Integer(2),
↪Integer(2),Integer(1),Integer(1)]])
>>> y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
>>> y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]

>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="left regular")
>>> y = C([[Integer(5),Integer(1),Integer(1)], [Integer(4),Integer(2),
↪Integer(2),Integer(1),Integer(1)]])
>>> y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
>>> y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]
```

class sage.combinat.partition_kleshchev.**KleshchevPartition**(*parent*, *mu*)

Bases: *Partition*

Abstract base class for Kleshchev partitions. See *KleshchevPartitions*.

cogood_cells(*i=None*)

Return a list of the cells of `self` that are cogood.

The cogood i-cell is the 'last' conormal i-cell. As with the conormal cells we can choose to read either up or down the partition as specified by *convention()*.

INPUT:

- `i` – (optional) a residue

OUTPUT:

If no residue `i` is specified then a dictionary of cogood cells is returned, which gives the cogood cells for `0 <= i < e`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).cogood_cells()
{0: (1, 4), 1: (4, 2)}
sage: KP([5,4,4,3,2]).cogood_cells(0)
(1, 4)
sage: KP([5,4,4,3,2]).cogood_cells(1)
(4, 2)
sage: KP = KleshchevPartitions(4, convention='restricted')
sage: KP([5,4,4,3,2]).cogood_cells()
{1: (0, 5), 2: (4, 2), 3: (1, 4)}
sage: KP([5,4,4,3,2]).cogood_cells(0)
sage: KP([5,4,4,3,2]).cogood_cells(2)
(4, 2)
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).cogood_
↪cells()
{0: (1, 4), 1: (4, 2)}
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).cogood_
↪cells(Integer(0))
(1, 4)
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).cogood_
↪cells(Integer(1))
(4, 2)
>>> KP = KleshchevPartitions(Integer(4), convention='restricted')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).cogood_
↪cells()
{1: (0, 5), 2: (4, 2), 3: (1, 4)}
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).cogood_
↪cells(Integer(0))
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).cogood_
↪cells(Integer(2))
(4, 2)
```

conormal_cells(*i=None*)

Return a dictionary of the cells of `self` which are conormal.

Following [Kle1995], the *conormal* cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of e-residue i and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The addable i-cells that remain at the end of the this process are the conormal i-cells.

When computing conormal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting `convention = 'RS'`.

INPUT:

- `i` – (optional) a residue

OUTPUT:

If no residue `i` is specified then a dictionary of conormal cells is returned, which gives the conormal cells for `0 <= i < e`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).conormal_cells()
{0: [(1, 4)], 1: [(5, 0), (4, 2)]}
sage: KP([5,4,4,3,2]).conormal_cells(0)
[(1, 4)]
sage: KP([5,4,4,3,2]).conormal_cells(1)
[(5, 0), (4, 2)]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).conormal_cells()
{0: [(1, 4), (3, 3)], 2: [(0, 5)]}
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).conormal_
↪cells()
{0: [(1, 4)], 1: [(5, 0), (4, 2)]}
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).conormal_
↪cells(Integer(0))
[(1, 4)]
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).conormal_
↪cells(Integer(1))
[(5, 0), (4, 2)]
>>> KP = KleshchevPartitions(Integer(3), convention='restricted')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).conormal_
↪cells()
{0: [(1, 4), (3, 3)], 2: [(0, 5)]}
```

good_cell_sequence()

Return a sequence of good nodes from the empty partition to `self`, or `None` if no such sequence exists.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).good_cell_sequence()
[(0, 0), (1, 0), (0, 1), (2, 0), (1, 1), (0, 2),
 (3, 0), (2, 1), (1, 2), (3, 1), (0, 3), (1, 3),
 (2, 2), (3, 2), (4, 0), (4, 1), (0, 4), (2, 3)]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).good_cell_sequence()
[(0, 0), (0, 1), (1, 0), (0, 2), (1, 1), (2, 0),
 (0, 3), (2, 1), (1, 2), (1, 3), (3, 0), (3, 1),
 (2, 2), (4, 0), (2, 3), (3, 2), (0, 4), (4, 1)]
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cell_
↪sequence()
```

(continues on next page)

(continued from previous page)

```
[(0, 0), (1, 0), (0, 1), (2, 0), (1, 1), (0, 2),
 (3, 0), (2, 1), (1, 2), (3, 1), (0, 3), (1, 3),
 (2, 2), (3, 2), (4, 0), (4, 1), (0, 4), (2, 3)]
>>> KP = KleshchevPartitions(Integer(3), convention='restricted')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cell_
↪sequence()
[(0, 0), (0, 1), (1, 0), (0, 2), (1, 1), (2, 0),
 (0, 3), (2, 1), (1, 2), (1, 3), (3, 0), (3, 1),
 (2, 2), (4, 0), (2, 3), (3, 2), (0, 4), (4, 1)]
```

good_cells(*i=None*)

Return a list of the cells of `self` that are good.

The good i-cell is the 'first' normal i-cell. As with the normal cells we can choose to read either up or down the partition as specified by *convention()*.

INPUT:

- `i` – (optional) a residue

OUTPUT:

If no residue `i` is specified then a dictionary of good cells is returned, which gives the good cells for `0 <= i < e`.

EXAMPLES:

```
sage: KP3 = KleshchevPartitions(3, convention='regular')
sage: KP3([5,4,4,3,2]).good_cells()
{1: (2, 3)}
sage: KP3([5,4,4,3,2]).good_cells(1)
(2, 3)
sage: KP4 = KleshchevPartitions(4, convention='restricted')
sage: KP4([5,4,4,3,2]).good_cells()
{1: (2, 3)}
sage: KP4([5,4,4,3,2]).good_cells(0)
sage: KP4([5,4,4,3,2]).good_cells(1)
(2, 3)
```

```
>>> from sage.all import *
>>> KP3 = KleshchevPartitions(Integer(3), convention='regular')
>>> KP3([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cells()
{1: (2, 3)}
>>> KP3([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_
↪cells(Integer(1))
(2, 3)
>>> KP4 = KleshchevPartitions(Integer(4), convention='restricted')
>>> KP4([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cells()
{1: (2, 3)}
>>> KP4([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_
↪cells(Integer(0))
>>> KP4([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_
↪cells(Integer(1))
(2, 3)
```

good_residue_sequence()

Return a sequence of good nodes from the empty partition to `self`, or `None` if no such sequence exists.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).good_residue_sequence()
[0, 2, 1, 1, 0, 2, 0, 2, 1, 1, 0, 2, 0, 2, 2, 0, 1, 1]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).good_residue_sequence()
[0, 1, 2, 2, 0, 1, 0, 2, 1, 2, 0, 1, 0, 2, 1, 2, 1, 0]
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_residue_
↪sequence()
[0, 2, 1, 1, 0, 2, 0, 2, 1, 1, 0, 2, 0, 2, 2, 0, 1, 1]
>>> KP = KleshchevPartitions(Integer(3), convention='restricted')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_residue_
↪sequence()
[0, 1, 2, 2, 0, 1, 0, 2, 1, 2, 0, 1, 0, 2, 1, 2, 1, 0]
```

is_regular()

Return `True` if `self` is a e-regular partition tuple.

A partition tuple is e-regular if we can get to the empty partition tuple by successively removing a sequence of good cells in the down direction. Equivalently, all partitions are 0-regular and if $e > 0$ then a partition is e-regular if no e nonzero parts of `self` are equal.

EXAMPLES:

```
sage: KP = KleshchevPartitions(2)
sage: KP([2,1,1]).is_regular()
False
sage: KP = KleshchevPartitions(3)
sage: KP([2,1,1]).is_regular()
True
sage: KP([]).is_regular()
True
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(2))
>>> KP([Integer(2),Integer(1),Integer(1)]).is_regular()
False
>>> KP = KleshchevPartitions(Integer(3))
>>> KP([Integer(2),Integer(1),Integer(1)]).is_regular()
True
>>> KP([]).is_regular()
True
```

is_restricted()

Return `True` if `self` is an e-restricted partition tuple.

A partition tuple is e-restricted if we can get to the empty partition tuple by successively removing a sequence of good cells in the up direction. Equivalently, all partitions are 0-restricted and if $e > 0$ then a partition is

e-restricted if the difference of successive parts of `self` are always strictly less than e.

EXAMPLES:

```
sage: KP = KleshchevPartitions(2, convention='regular')
sage: KP([3,1]).is_restricted()
False
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([3,1]).is_restricted()
True
sage: KP([]).is_restricted()
True
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(2), convention='regular')
>>> KP([Integer(3),Integer(1)]).is_restricted()
False
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(3),Integer(1)]).is_restricted()
True
>>> KP([]).is_restricted()
True
```

mullineux_conjugate()

Return the partition tuple that is the Mullineux conjugate of `self`.

It follows from results in [BK2009], [Mat2015] that if ν is the Mullineux conjugate of the Kleshchev partition tuple μ then the simple module $D^\nu = (D^\mu)^{\mathrm{sgn}}$ is obtained from D^μ by twisting by the sgn-automorphism with is the Iwahori-Hecke algebra analogue of tensoring with the one dimensional sign representation.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).mullineux_conjugate()
[9, 7, 1, 1]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).mullineux_conjugate()
[3, 2, 2, 2, 2, 2, 2, 1, 1, 1]
sage: KP = KleshchevPartitions(3, [2], convention='regular')
sage: mc = KP([5,4,4,3,2]).mullineux_conjugate(); mc
[9, 7, 1, 1]
sage: mc.parent().multicharge()
(1,)
sage: KP = KleshchevPartitions(3, [2], convention='restricted')
sage: mc = KP([5,4,4,3,2]).mullineux_conjugate(); mc
[3, 2, 2, 2, 2, 2, 2, 1, 1, 1]
sage: mc.parent().multicharge()
(1,)
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).mullineux_
↪conjugate()
[9, 7, 1, 1]
```

(continues on next page)

(continued from previous page)

```
>>> KP = KleshchevPartitions(Integer(3), convention='restricted')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).mullineux_
↪conjugate()
[3, 2, 2, 2, 2, 2, 2, 1, 1, 1]
>>> KP = KleshchevPartitions(Integer(3), [Integer(2)], convention='regular')
>>> mc = KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).
↪mullineux_conjugate(); mc
[9, 7, 1, 1]
>>> mc.parent().multicharge()
(1,)
>>> KP = KleshchevPartitions(Integer(3), [Integer(2)], convention='restricted
↪')
>>> mc = KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).
↪mullineux_conjugate(); mc
[3, 2, 2, 2, 2, 2, 2, 1, 1, 1]
>>> mc.parent().multicharge()
(1,)
```

normal_cells(*i=None*)

Return a dictionary of the cells of the partition that are normal.

Following [Kle1995], the *normal* cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of e-residue i and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The removable i-cells that remain at the end of the this process are the normal i-cells.

When computing normal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting `convention = 'RS'`.

INPUT:

- `i` – (optional) a residue

OUTPUT:

If no residue `i` is specified then a dictionary of normal cells is returned, which gives the normal cells for `0 <= i < e`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).normal_cells()
{1: [(2, 3), (0, 4)]}
sage: KP([5,4,4,3,2]).normal_cells(1)
[(2, 3), (0, 4)]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).normal_cells()
{0: [(4, 1)], 2: [(3, 2)]}
sage: KP([5,4,4,3,2]).normal_cells(2)
[(3, 2)]
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
```

(continues on next page)

(continued from previous page)

```
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).normal_
↪cells()
{1: [(2, 3), (0, 4)]}
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).normal_
↪cells(Integer(1))
[(2, 3), (0, 4)]
>>> KP = KleshchevPartitions(Integer(3), convention='restricted')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).normal_
↪cells()
{0: [(4, 1)], 2: [(3, 2)]}
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).normal_
↪cells(Integer(2))
[(3, 2)]
```

class sage.combinat.partition_kleshchev.**KleshchevPartitionCrystal**(*parent*, *mu*)

Bases: *KleshchevPartition*, *KleshchevCrystalMixin*

Kleshchev partition with the crystal structure.

e(*i*)

Return the action of e_i on `self`.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, convention="left regular")
sage: x = C([5,4,1])
sage: x.e(0)
sage: x.e(1)
[5, 4]
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), convention="left regular")
>>> x = C([Integer(5),Integer(4),Integer(1)])
>>> x.e(Integer(0))
>>> x.e(Integer(1))
[5, 4]
```

f(*i*)

Return the action of f_i on `self`.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, convention="left regular")
sage: x = C([5,4,1])
sage: x.f(0)
[5, 5, 1]
sage: x.f(1)
```

(continues on next page)

(continued from previous page)

```
sage: x.f(2)
[5, 4, 2]
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), convention="left regular")
>>> x = C([Integer(5),Integer(4),Integer(1)])
>>> x.f(Integer(0))
[5, 5, 1]
>>> x.f(Integer(1))
>>> x.f(Integer(2))
[5, 4, 2]
```

class sage.combinat.partition_kleshchev.**KleshchevPartitionTuple**(*parent*, *mu*)

Bases: *PartitionTuple*

Abstract base class for Kleshchev partition tuples. See *KleshchevPartitions*.

cogood_cells(*i=None*)

Return a list of the cells of the partition that are cogood.

The cogood i-cell is the 'last' conormal i-cell. As with the conormal cells we can choose to read either up or down the partition as specified by *convention()*.

INPUT:

- `i` – (optional) a residue

OUTPUT:

If no residue `i` is specified then a dictionary of cogood cells is returned, which gives the cogood cells for `0 <= i < e`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.cogood_cells()
{0: (1, 2, 1), 1: (1, 3, 0)}
sage: pt.cogood_cells(0)
(1, 2, 1)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
sage: pt = KP([[5, 2, 2], [6, 1, 1]])
sage: pt.cogood_cells()
{1: (0, 0, 5), 2: (1, 3, 0)}
sage: pt.cogood_cells(0) is None
True
sage: pt.cogood_cells(1) is None
False
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)])
>>> pt = KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]])
>>> pt.cogood_cells()
{0: (1, 2, 1), 1: (1, 3, 0)}
>>> pt.cogood_cells(Integer(0))
```

(continues on next page)

(continued from previous page)

```
(1, 2, 1)
>>> KP = KleshchevPartitions(Integer(4), [Integer(0),Integer(1)], convention=
↪"left regular")
>>> pt = KP([[Integer(5), Integer(2), Integer(2)], [Integer(6), Integer(1),␣
↪Integer(1)]])
>>> pt.cogood_cells()
{1: (0, 0, 5), 2: (1, 3, 0)}
>>> pt.cogood_cells(Integer(0)) is None
True
>>> pt.cogood_cells(Integer(1)) is None
False
```

conormal_cells(*i=None*)

Return a dictionary of the cells of the partition that are conormal.

Following [Kle1995], the *conormal* cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of e-residue i and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The addable i-cells that remain at the end of the this process are the conormal i-cells.

When computing conormal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting `convention = 'RS'`.

INPUT:

- `i` – (optional) a residue

OUTPUT:

If no residue `i` is specified then a dictionary of conormal cells is returned, which gives the conormal cells for `0 <= i < e`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1], convention="left regular")
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells()
{0: [(1, 2, 1), (1, 1, 3), (1, 0, 5)],
1: [(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]}
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(1)
[(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(2)
[]
sage: KP = KleshchevPartitions(3, [0,1], convention="right restricted")
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(0)
[(1, 0, 5), (1, 1, 3), (1, 2, 1)]
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)], convention=
↪"left regular")
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪conormal_cells()
{0: [(1, 2, 1), (1, 1, 3), (1, 0, 5)],
1: [(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]}
```

(continues on next page)

(continued from previous page)

```
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪conormal_cells(Integer(1))
[(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪conormal_cells(Integer(2))
[]
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)], convention=
↪"right restricted")
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪conormal_cells(Integer(0))
[(1, 0, 5), (1, 1, 3), (1, 2, 1)]
```

good_cell_sequence()

Return a sequence of good nodes from the empty partition to `self`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3,[0,1])
sage: KP([[4, 2], [5, 3, 1]]).good_cell_sequence()
[(0, 0, 0), (1, 0, 0), (1, 0, 1), (0, 0, 1), (0, 1, 0),
 (1, 1, 0), (1, 1, 1), (1, 0, 2), (1, 2, 0), (0, 0, 2),
 (0, 1, 1), (1, 0, 3), (0, 0, 3), (1, 1, 2), (1, 0, 4)]
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3),[Integer(0),Integer(1)])
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).good_
↪cell_sequence()
[(0, 0, 0), (1, 0, 0), (1, 0, 1), (0, 0, 1), (0, 1, 0),
 (1, 1, 0), (1, 1, 1), (1, 0, 2), (1, 2, 0), (0, 0, 2),
 (0, 1, 1), (1, 0, 3), (0, 0, 3), (1, 1, 2), (1, 0, 4)]
```

good_cells(*i=None*)

Return a list of the cells of the partition tuple which are good.

The good i-cell is the 'first' normal i-cell. As with the normal cells we can choose to read either up or down the partition as specified by *convention()*.

INPUT:

- `i` – (optional) a residue

OUTPUT:

If no residue `i` is specified then a dictionary of good cells is returned, which gives the good cells for `0 <= i < e`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.good_cells()
{2: (1, 0, 4)}
sage: pt.good_cells(2)
(1, 0, 4)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
```

(continues on next page)

(continued from previous page)

```
sage: pt = KP([[5, 2, 2], [6, 2, 1]])
sage: pt.good_cells()
{0: (0, 0, 4), 2: (1, 0, 5), 3: (0, 2, 1)}
sage: pt.good_cells(1) is None
True
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)])
>>> pt = KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]])
>>> pt.good_cells()
{2: (1, 0, 4)}
>>> pt.good_cells(Integer(2))
(1, 0, 4)
>>> KP = KleshchevPartitions(Integer(4), [Integer(0),Integer(1)], convention=
↪"left regular")
>>> pt = KP([[Integer(5), Integer(2), Integer(2)], [Integer(6), Integer(2),␣
↪Integer(1)]])
>>> pt.good_cells()
{0: (0, 0, 4), 2: (1, 0, 5), 3: (0, 2, 1)}
>>> pt.good_cells(Integer(1)) is None
True
```

good_residue_sequence()

Return a sequence of good nodes from the empty partition to `self`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: KP([[4, 2], [5, 3, 1]]).good_residue_sequence()
[0, 1, 2, 1, 2, 0, 1, 0, 2, 2, 0, 1, 0, 2, 2]
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)])
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).good_
↪residue_sequence()
[0, 1, 2, 1, 2, 0, 1, 0, 2, 2, 0, 1, 0, 2, 2]
```

is_regular()

Return `True` if `self` is a e-regular partition tuple.

A partition tuple is e-regular if we can get to the empty partition tuple by successively removing a sequence of good cells in the down direction.

EXAMPLES:

```
sage: KP = KleshchevPartitions(2, [0,2], convention="right restricted")
sage: KP([[3,2,1], [2,1,1]]).is_regular()
False
sage: KP = KleshchevPartitions(4, [0,2], convention="right restricted")
sage: KP([[3,2,1], [2,1,1]]).is_regular()
True
sage: KP([[], []]).is_regular()
True
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(2), [Integer(0),Integer(2)], convention=
↪"right restricted")
>>> KP([[Integer(3),Integer(2),Integer(1)], [Integer(2),Integer(1),
↪Integer(1)]]).is_regular()
False
>>> KP = KleshchevPartitions(Integer(4), [Integer(0),Integer(2)], convention=
↪"right restricted")
>>> KP([[Integer(3),Integer(2),Integer(1)], [Integer(2),Integer(1),
↪Integer(1)]]).is_regular()
True
>>> KP([[], []]).is_regular()
True
```

is_restricted()

Return `True` if `self` is an e-restricted partition tuple.

A partition tuple is e-restricted if we can get to the empty partition tuple by successively removing a sequence of good cells in the up direction.

EXAMPLES:

```
sage: KP = KleshchevPartitions(2, [0,2], convention="left regular")
sage: KP([[3,2,1], [3,1]]).is_restricted()
False
sage: KP = KleshchevPartitions(3, [0,2], convention="left regular")
sage: KP([[3,2,1], [3,1]]).is_restricted()
True
sage: KP([[], []]).is_restricted()
True
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(2), [Integer(0),Integer(2)], convention=
↪"left regular")
>>> KP([[Integer(3),Integer(2),Integer(1)], [Integer(3),Integer(1)]]).is_
↪restricted()
False
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(2)], convention=
↪"left regular")
>>> KP([[Integer(3),Integer(2),Integer(1)], [Integer(3),Integer(1)]]).is_
↪restricted()
True
>>> KP([[], []]).is_restricted()
True
```

mullineux_conjugate()

Return the partition that is the Mullineux conjugate of `self`.

It follows from results in [Kle1996] [Bru1998] that if ν is the Mullineux conjugate of the Kleshchev partition tuple μ then the simple module $D^\nu = (D^\mu)^{\mathrm{sgn}}$ is obtained from D^μ by twisting by the sgn-automorphism with is the Hecke algebra analogue of tensoring with the one dimensional sign representation.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: mc = KP([[4, 2], [5, 3, 1]]).mullineux_conjugate(); mc
([2, 2, 1, 1], [3, 2, 2, 1, 1])
sage: mc.parent()
Kleshchev partitions with e=3 and multicharge=(0,2)
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)])
>>> mc = KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪mullineux_conjugate(); mc
([2, 2, 1, 1], [3, 2, 2, 1, 1])
>>> mc.parent()
Kleshchev partitions with e=3 and multicharge=(0,2)
```

normal_cells(*i=None*)

Return a dictionary of the removable cells of the partition that are normal.

Following [Kle1995], the *normal* cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of e-residue i and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The removable i-cells that remain at the end of the this process are the normal i-cells.

When computing normal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting `convention = 'RS'`.

INPUT:

- `i` – (optional) a residue

OUTPUT:

If no residue `i` is specified then a dictionary of normal cells is returned, which gives the normal cells for `0 <= i < e`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1], convention="left restricted")
sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{2: [(1, 0, 4), (1, 1, 2), (1, 2, 0)]}
sage: KP([[4, 2], [5, 3, 1]]).normal_cells(1)
[]
sage: KP = KleshchevPartitions(3, [0,1], convention="left regular")
sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{0: [(0, 1, 1), (0, 0, 3)], 2: [(1, 2, 0), (1, 1, 2), (1, 0, 4)]}
sage: KP = KleshchevPartitions(3, [0,1], convention="right regular")
sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{2: [(1, 2, 0), (1, 1, 2), (1, 0, 4)]}
sage: KP = KleshchevPartitions(3, [0,1], convention="right restricted")
sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{0: [(0, 0, 3), (0, 1, 1)], 2: [(1, 0, 4), (1, 1, 2), (1, 2, 0)]}
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)], convention=
```

(continues on next page)

(continued from previous page)

```
↪"left restricted")
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪normal_cells()
{2: [(1, 0, 4), (1, 1, 2), (1, 2, 0)]}
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪normal_cells(Integer(1))
[]
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)], convention=
↪"left regular")
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪normal_cells()
{0: [(0, 1, 1), (0, 0, 3)], 2: [(1, 2, 0), (1, 1, 2), (1, 0, 4)]}
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)], convention=
↪"right regular")
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪normal_cells()
{2: [(1, 2, 0), (1, 1, 2), (1, 0, 4)]}
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)], convention=
↪"right restricted")
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).
↪normal_cells()
{0: [(0, 0, 3), (0, 1, 1)], 2: [(1, 0, 4), (1, 1, 2), (1, 2, 0)]}
```

class sage.combinat.partition_kleshchev.**KleshchevPartitionTupleCrystal**(*parent*, *mu*)

Bases: *KleshchevPartitionTuple*, *KleshchevCrystalMixin*

Kleshchev partition tuple with the crystal structure.

e(*i*)

Return the action of e_i on `self`.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.e(0)
sage: x.e(1)
([5, 4, 1], [2, 2, 1, 1])
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="left regular")
>>> x = C([[Integer(5),Integer(4),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(1)]])
>>> x.e(Integer(0))
>>> x.e(Integer(1))
([5, 4, 1], [2, 2, 1, 1])
```

f(*i*)

Return the action of f_i on `self`.

INPUT:

- `i` – an element of the index set

EXAMPLES:

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.f(0)
([5, 5, 1], [3, 2, 1, 1])
sage: x.f(1)
([5, 4, 1], [3, 2, 2, 1])
sage: x.f(2)
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="left regular")
>>> x = C([[Integer(5),Integer(4),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(1)]])
>>> x.f(Integer(0))
([5, 5, 1], [3, 2, 1, 1])
>>> x.f(Integer(1))
([5, 4, 1], [3, 2, 2, 1])
>>> x.f(Integer(2))
```

class sage.combinat.partition_kleshchev.**KleshchevPartitions**

Bases: *PartitionTuples*

Kleshchev partitions.

A partition (tuple) μ is Kleshchev if it can be recursively obtained by adding a sequence of good nodes to the empty *PartitionTuple* of the same *level()* and multicharge.

There are four different conventions that are used in the literature for Kleshchev partitions, depending on whether we read partitions from top to bottom (regular) or bottom to top (restricted) and whether we read partition tuples from left to right or right to left. All of these conventions are supported:

```
sage: KleshchevPartitions(2, [0,0], size=2, convention='left regular')[:]
[([1], [1]), ([2], [])]
sage: KleshchevPartitions(2, [0,0], size=2, convention='left restricted')[:]
[([1], [1]), ([], [1, 1])]
sage: KleshchevPartitions(2, [0,0], size=2, convention='right regular')[:]
[([1], [1]), ([], [2])]
sage: KleshchevPartitions(2, [0,0], size=2, convention='right restricted')[:]
[([1], [1]), ([1, 1], [])]
```

```
>>> from sage.all import *
>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='left regular')[:]
[([1], [1]), ([2], [])]
>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='left restricted')[:]
[([1], [1]), ([], [1, 1])]
>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='right regular')[:]
```

(continues on next page)

(continued from previous page)

```
[([1], [1]), ([], [2])]
>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),␣
↪convention='right restricted')[:]
[([1], [1]), ([1, 1], [])]
```

By default, the `left restricted` convention is used. As a shorthand, `LG`, `LS`, `RG` and `RS`, respectively, can be used to specify the `convention`. With the `left` convention the partition tuples should be ordered with the most dominant partitions in the partition tuple on the left and with the `right` convention the most dominant partition is on the right.

The *KleshchevPartitions* class will automatically convert between these four different conventions:

```
sage: KPlg = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
sage: KPls = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
sage: [KPlg(mu) for mu in KPls]
[([1], [1]), ([2], [])]
```

```
>>> from sage.all import *
>>> KPlg = KleshchevPartitions(Integer(2), [Integer(0),Integer(0)],␣
↪size=Integer(2), convention='left regular')
>>> KPls = KleshchevPartitions(Integer(2), [Integer(0),Integer(0)],␣
↪size=Integer(2), convention='left restricted')
>>> [KPlg(mu) for mu in KPls]
[([1], [1]), ([2], [])]
```

EXAMPLES:

```
sage: sorted(KleshchevPartitions(5,[3,2,1],1, convention='RS'))
[([], [], [1]), ([], [1], []), ([1], [], [])]
sage: sorted(KleshchevPartitions(5, [3,2,1], 1, convention='LS'))
[([], [], [1]), ([], [1], []), ([1], [], [])]
sage: sorted(KleshchevPartitions(5, [3,2,1], 3))
[([], [], [1, 1, 1]),

- [Kle2009]

convention()

Return the convention of `self`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(4)
sage: KP.convention()
'restricted'
sage: KP = KleshchevPartitions(6, [4], 3, convention="right regular")
sage: KP.convention()
'regular'
sage: KP = KleshchevPartitions(5, [3,0,1], 1)
sage: KP.convention()
'left restricted'
sage: KP = KleshchevPartitions(5, [3,0,1], 1, convention='right regular')
sage: KP.convention()
'right regular'
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(4))
>>> KP.convention()
'restricted'
>>> KP = KleshchevPartitions(Integer(6), [Integer(4)], Integer(3), convention=
↪"right regular")
>>> KP.convention()
'regular'
>>> KP = KleshchevPartitions(Integer(5), [Integer(3),Integer(0),Integer(1)],␣
↪Integer(1))
>>> KP.convention()
'left restricted'
>>> KP = KleshchevPartitions(Integer(5), [Integer(3),Integer(0),Integer(1)],␣
↪Integer(1), convention='right regular')
>>> KP.convention()
'right regular'
```

multicharge()

Return the multicharge of `self`.

EXAMPLES:

```
sage: KP = KleshchevPartitions(6, [2])
sage: KP.multicharge()
(2,)
sage: KP = KleshchevPartitions(5, [3,0,1], 1, convention='LS')
sage: KP.multicharge()
(3, 0, 1)
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(6), [Integer(2)])
>>> KP.multicharge()
(2,)
>>> KP = KleshchevPartitions(Integer(5), [Integer(3),Integer(0),Integer(1)],␣
↪Integer(1), convention='LS')
>>> KP.multicharge()
(3, 0, 1)
```

class sage.combinat.partition_kleshchev.**KleshchevPartitions_all**(*e*, *multicharge*, *convention*)

Bases: *KleshchevPartitions*

Class of all Kleshchev partitions.

Crystal structure

We consider type $A_{e-1}^{(1)}$ crystals, and let $r = (r_i | r_i \in \mathbf{Z}/e\mathbf{Z})$ be a finite sequence of length k, which is the *level*, and $\lambda = \sum_i \Lambda_{r_i}$. We will model the highest weight $U_q(\mathfrak{g})$-crystal $B(\lambda)$ by a particular subset of partition tuples of level k.

Consider a partition tuple μ with multicharge r. We define $e_i(\mu)$ as the partition tuple obtained after the deletion of the i-*good cell* to μ and 0 if there is no i-good cell. We define $f_i(\mu)$ as the partition tuple obtained by the addition of the i-*cogood cell* to μ and 0 if there is no i-good cell.

The crystal $B(\lambda)$ is the crystal generated by the empty partition tuple. We can compute the weight of an element μ by taking $\lambda - \sum_{i=0}^{n} c_i \alpha_i$ where c_i is the number of cells of n-residue i in μ. Partition tuples in the crystal are known as *Kleshchev partitions*.

Note

We can describe normal (not restricted) Kleshchev partition tuples in $B(\lambda)$ as partition tuples μ such that $\mu^{(t)}_{r_t - r_{t+1} + x} < \mu^{(t+1)}_x$ for all $x \geq 1$ and $1 \leq t \leq k-1$.

INPUT:

- `e` – for type $A_{e-1}^{(1)}$ or 0
- `multicharge` – the multicharge sequence r
- `convention` – (default: `'LS'`) the reading convention

EXAMPLES:

We first do an example of a level 1 crystal:

```
sage: C = crystals.KleshchevPartitions(3, [0], convention="left restricted")
sage: C
Kleshchev partitions with e=3
```

(continues on next page)

(continued from previous page)

```
sage: mg = C.highest_weight_vector()
sage: mg
[]
sage: mg.f(0)
[1]
sage: mg.f(1)
sage: mg.f(2)
sage: mg.f_string([0,2,1,0])
[1, 1, 1, 1]
sage: mg.f_string([0,1,2,0])
[2, 2]
sage: GC = C.subcrystal(max_depth=5).digraph()
sage: B = crystals.LSPaths(['A',2,1], [1,0,0])
sage: GB = B.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
True
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0)], convention="left␣
↪restricted")
>>> C
Kleshchev partitions with e=3
>>> mg = C.highest_weight_vector()
>>> mg
[]
>>> mg.f(Integer(0))
[1]
>>> mg.f(Integer(1))
>>> mg.f(Integer(2))
>>> mg.f_string([Integer(0),Integer(2),Integer(1),Integer(0)])
[1, 1, 1, 1]
>>> mg.f_string([Integer(0),Integer(1),Integer(2),Integer(0)])
[2, 2]
>>> GC = C.subcrystal(max_depth=Integer(5)).digraph()
>>> B = crystals.LSPaths(['A',Integer(2),Integer(1)], [Integer(1),Integer(0),
↪Integer(0)])
>>> GB = B.subcrystal(max_depth=Integer(5)).digraph()
>>> GC.is_isomorphic(GB, edge_labels=True)
True
```

Now a higher level crystal:

```
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="right restricted")
sage: mg = C.highest_weight_vector()
sage: mg
([], [])
sage: mg.f(0)
([1], [])
sage: mg.f(2)
([], [1])
sage: mg.f_string([0,1,2,0])
([2, 2], [])
```

(continues on next page)

(continued from previous page)

```
sage: mg.f_string([0,2,1,0])
([1, 1, 1, 1], [])
sage: mg.f_string([2,0,1,0])
([2], [2])
sage: GC = C.subcrystal(max_depth=5).digraph()
sage: B = crystals.LSPaths(['A',2,1], [1,0,1])
sage: GB = B.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
True
```

```
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],␣
↪convention="right restricted")
>>> mg = C.highest_weight_vector()
>>> mg
([], [])
>>> mg.f(Integer(0))
([1], [])
>>> mg.f(Integer(2))
([], [1])
>>> mg.f_string([Integer(0),Integer(1),Integer(2),Integer(0)])
([2, 2], [])
>>> mg.f_string([Integer(0),Integer(2),Integer(1),Integer(0)])
([1, 1, 1, 1], [])
>>> mg.f_string([Integer(2),Integer(0),Integer(1),Integer(0)])
([2], [2])
>>> GC = C.subcrystal(max_depth=Integer(5)).digraph()
>>> B = crystals.LSPaths(['A',Integer(2),Integer(1)], [Integer(1),Integer(0),
↪Integer(1)])
>>> GB = B.subcrystal(max_depth=Integer(5)).digraph()
>>> GC.is_isomorphic(GB, edge_labels=True)
True
```

The ordering of the residues gives a different representation of the higher level crystals (but it is still isomorphic):

```
sage: C2 = crystals.KleshchevPartitions(3, [2,0], convention="right restricted")
sage: mg2 = C2.highest_weight_vector()
sage: mg2.f_string([0,1,2,0])
([2], [2])
sage: mg2.f_string([0,2,1,0])
([1, 1, 1], [1])
sage: mg2.f_string([2,0,1,0])
([2, 1], [1])
sage: GC2 = C2.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GC2, edge_labels=True)
True
```

```
>>> from sage.all import *
>>> C2 = crystals.KleshchevPartitions(Integer(3), [Integer(2),Integer(0)],␣
↪convention="right restricted")
>>> mg2 = C2.highest_weight_vector()
>>> mg2.f_string([Integer(0),Integer(1),Integer(2),Integer(0)])
```

(continues on next page)

(continued from previous page)

```
([2], [2])
>>> mg2.f_string([Integer(0),Integer(2),Integer(1),Integer(0)])
([1, 1, 1], [1])
>>> mg2.f_string([Integer(2),Integer(0),Integer(1),Integer(0)])
([2, 1], [1])
>>> GC2 = C2.subcrystal(max_depth=Integer(5)).digraph()
>>> GC.is_isomorphic(GC2, edge_labels=True)
True
```

class sage.combinat.partition_kleshchev.**KleshchevPartitions_size**(*e*, *multicharge=(0,)*, *size=0*, *convention='RS'*)

Bases: *KleshchevPartitions*

Kleshchev partitions of a fixed size.

Element

alias of *KleshchevPartitionTuple*

Knutson-Tao puzzles

This module implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the list of the fillings of the puzzle with the specified pieces.

Acknowledgements

This code was written during Sage Days 45 at ICERM with Franco Saliola, Anne Schilling, and Avinash Dalal in discussions with Allen Knutson. The code was tested afterwards by Liz Beazley and Ed Richmond.

Todo

Functionality to add:

- plotter will not plot edge labels higher than 2; e.g. in BK puzzles, the labels are 1,…, n and so in 3-step examples, none of the edge labels with 3 appear
- we should also have a 3-step puzzle pieces constructor, taken from p22 of arXiv math/0610538
- implement the bijection from puzzles to tableaux; see for example R. Vakil, A geometric Littlewood-Richardson rule, arXiv math/0302294 or K. Purbhoo, Puzzles, Tableaux and Mosaics, arXiv 0705.1184.

sage.combinat.knutson_tao_puzzles.**BK_pieces**(*max_letter*)

The puzzle pieces used in computing the Belkale-Kumar coefficients for any partial flag variety in type A.

There are two types of puzzle pieces:

- a triangle, with each edge labeled with the same letter;
- a rhombus, with edges labeled i, j, i, j in clockwise order with $i > j$.

Each of these is rotated by 60 degrees, but not reflected.

We model the rhombus pieces as two triangles: a delta piece north-west label i, north-east label j and south label $i(j)$; and a nabla piece with south-east label i, south-west label j and north label $i(j)$.

INPUT:

- `max_letter` – positive integer specifying the number of steps in the partial flag variety, equivalently, the number of elements in the alphabet for the edge labels. The smallest label is 1.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import BK_pieces
sage: BK_pieces(3)
Nablas : [1\1/1, 1\2(1)/2, 1\3(1)/3, 2(1)\2/1, 2\1/2(1), 2\2/2, 2\3(2)/3, 3(1)\3/
↪1, 3(2)\3/2, 3\1/3(1), 3\2/3(2), 3\3/3]
Deltas : [1/1\1, 1/2\2(1), 1/3\3(1), 2(1)/1\2, 2/2(1)\1, 2/2\2, 2/3\3(2), 3(1)/1\
↪3, 3(2)/2\3, 3/3(1)\1, 3/3(2)\2, 3/3\3]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import BK_pieces
>>> BK_pieces(Integer(3))
Nablas : [1\1/1, 1\2(1)/2, 1\3(1)/3, 2(1)\2/1, 2\1/2(1), 2\2/2, 2\3(2)/3, 3(1)\3/
↪1, 3(2)\3/2, 3\1/3(1), 3\2/3(2), 3\3/3]
Deltas : [1/1\1, 1/2\2(1), 1/3\3(1), 2(1)/1\2, 2/2(1)\1, 2/2\2, 2/3\3(2), 3(1)/1\
↪3, 3(2)/2\3, 3/3(1)\1, 3/3(2)\2, 3/3\3]
```

class sage.combinat.knutson_tao_puzzles.**DeltaPiece**(*south*, *north_west*, *north_east*)

Bases: *PuzzlePiece*

Delta Piece takes as input three labels, inputted as strings. They label the South, Northwest and Northeast edges, respectively.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: DeltaPiece('a','b','c')
b/a\c
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> DeltaPiece('a','b','c')
b/a\c
```

clockwise_rotation()

Rotate the Delta piece by 120 degree clockwise.

OUTPUT: Delta piece

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','2','3')
sage: delta.clockwise_rotation()
1/3\2
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('1','2','3')
>>> delta.clockwise_rotation()
1/3\2
```

edges()

Return the tuple of edge names.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','2','3')
sage: delta.edges()
('south', 'north_west', 'north_east')
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('1','2','3')
>>> delta.edges()
('south', 'north_west', 'north_east')
```

half_turn_rotation()

Rotate the Delta piece by 180 degree.

OUTPUT: Nabla piece

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','2','3')
sage: delta.half_turn_rotation()
3\1/2
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('1','2','3')
>>> delta.half_turn_rotation()
3\1/2
```

sage.combinat.knutson_tao_puzzles.**HT_grassmannian_pieces**()

Define the puzzle pieces used in computing the torus-equivariant cohomology of the Grassmannian.

REFERENCES:

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import HT_grassmannian_pieces
sage: HT_grassmannian_pieces()
```

(continues on next page)

(continued from previous page)

Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1, K/K\K]
```

class sage.combinat.knutson_tao_puzzles.**KnutsonTaoPuzzleSolver**(*puzzle_pieces*)

Bases: UniqueRepresentation

Return puzzle solver function used to create all puzzles with given boundary conditions.

This class implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the list of the fillings of the puzzle with the specified pieces.

INPUT:

- `puzzle_pieces` – takes either a collection of puzzle pieces or a string indicating a pre-programmed collection of puzzle pieces:
  - `H` – cohomology of the Grassmannian
  - `HT` – equivariant cohomology of the Grassmannian
  - `K` – K-theory
  - `H2step` – cohomology of the *2-step* Grassmannian
  - `HT2step` – equivariant cohomology of the *2-step* Grassmannian
  - `BK` – Belkale-Kumar puzzle pieces
- `max_letter` – `None` or a positive integer(default: `None`); this is only required for Belkale-Kumar puzzles

EXAMPLES:

Each puzzle piece is an edge-labelled triangle oriented in such a way that it has a south edge (called a *delta* piece) or a north edge (called a *nabla* piece). For example, the puzzle pieces corresponding to the cohomology of the Grassmannian are the following:

```
sage: from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
sage: H_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
>>> H_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

In the string representation, the nabla pieces are depicted as `c\a/b`, where a is the label of the north edge, b is the label of the south-east edge, c is the label of the south-west edge. A similar string representation exists for the delta pieces.

To create a puzzle solver, one specifies a collection of puzzle pieces:

```
sage: KnutsonTaoPuzzleSolver(H_grassmannian_pieces())
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> KnutsonTaoPuzzleSolver(H_grassmannian_pieces())
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The following shorthand to create the above puzzle solver is also supported:

```
sage: KnutsonTaoPuzzleSolver('H')
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> KnutsonTaoPuzzleSolver('H')
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The solver will compute all fillings of the puzzle with the given puzzle pieces. The user specifies the labels of north-east and north-west sides of the puzzle boundary and the output is a list of the fillings of the puzzle with the specified pieces. For example, there is one solution to the puzzle whose north-west and north-east edges are both labeled '0':

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps('0', '0')
[{(1, 1): 0/0\0}]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> ps('0', '0')
[{(1, 1): 0/0\0}]
```

There are two solutions to the puzzle whose north-west and north-east edges are both labeled '0101':

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: len(solns)
2
sage: solns.sort(key=str)
sage: solns
[{(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,
  (1, 4): 1/\0  0\/1,
  (2, 2): 1/1\1,
  (2, 3): 0/\10  1\/1,
  (2, 4): 1/\1  10\/0,
  (3, 3): 1/1\1,
  (3, 4): 0/\0  1\/10,
  (4, 4): 10/0\1}, {(1, 1): 0/1\10,
  (1, 2): 1/\1  10\/0,
  (1, 3): 0/\0  1\/10,
  (1, 4): 1/\0  0\/1,
  (2, 2): 0/0\0,
  (2, 3): 10/\1  0\/0,
  (2, 4): 1/\1  1\/1,
  (3, 3): 0/0\0,
  (3, 4): 1/\0  0\/1,
  (4, 4): 1/1\1}]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> solns = ps('0101', '0101')
>>> len(solns)
2
>>> solns.sort(key=str)
>>> solns
[{(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,
  (1, 4): 1/\0  0\/1,
  (2, 2): 1/1\1,
  (2, 3): 0/\10  1\/1,
  (2, 4): 1/\1  10\/0,
  (3, 3): 1/1\1,
  (3, 4): 0/\0  1\/10,
  (4, 4): 10/0\1}, {(1, 1): 0/1\10,
  (1, 2): 1/\1  10\/0,
  (1, 3): 0/\0  1\/10,
  (1, 4): 1/\0  0\/1,
  (2, 2): 0/0\0,
  (2, 3): 10/\1  0\/0,
  (2, 4): 1/\1  1\/1,
  (3, 3): 0/0\0,
  (3, 4): 1/\0  0\/1,
  (4, 4): 1/1\1}]
```

The pieces in a puzzle filling are indexed by pairs of nonnegative integers (i, j) with $1 \leq i \leq j \leq n$, where n is the length of the word labelling the triangle edge. The pieces indexed by (i, i) are the triangles along the south edge of the puzzle.

```
sage: f = solns[0]
sage: [f[i, i] for i in range(1,5)]
[0/0\0, 1/1\1, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> f = solns[Integer(0)]
>>> [f[i, i] for i in range(Integer(1),Integer(5))]
[0/0\0, 1/1\1, 1/1\1, 10/0\1]
```

The pieces indexed by (i, j) for $j > i$ are a pair consisting of a delta piece and nabla piece glued together along the south edge and north edge, respectively (these pairs are called *rhombi*).

```
sage: f = solns[0]
sage: f[1, 2]
1/\0  0\/1
```

```
>>> from sage.all import *
>>> f = solns[Integer(0)]
>>> f[Integer(1), Integer(2)]
1/\0  0\/1
```

There are various methods and options to display puzzle solutions. A single puzzle can be displayed using the plot

method of the puzzle:

```
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.plot()  #not tested
sage: puzzle.plot(style='fill')  #not tested
sage: puzzle.plot(style='edges')  #not tested
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> puzzle = ps('0101','1001')[Integer(0)]
>>> puzzle.plot()  #not tested
>>> puzzle.plot(style='fill')  #not tested
>>> puzzle.plot(style='edges')  #not tested
```

To plot several puzzle solutions, use the plot method of the puzzle solver:

```
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: solns = ps('0101', '0101')
sage: ps.plot(solns)        # not tested
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('K')
>>> solns = ps('0101', '0101')
>>> ps.plot(solns)        # not tested
```

The code can also generate a PDF of a puzzle (using LaTeX and *tikz*):

```
sage: latex.extra_preamble(r'''\usepackage{tikz}''')
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: view(solns[0], viewer='pdf')  # not tested
```

```
>>> from sage.all import *
>>> latex.extra_preamble(r'''\usepackage{tikz}''')
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> solns = ps('0101', '0101')
>>> view(solns[Integer(0)], viewer='pdf')  # not tested
```

Below are examples of using each of the currently supported puzzles.

Cohomology of the Grassmannian:

```
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: solns = ps('0101', '0101')
sage: sorted(solns, key=str)
[{(1, 1): 0/0\0,
  (1, 2): 1/\0  0\/1,
  (1, 3): 0/\0  0\/0,
  (1, 4): 1/\0  0\/1,
  (2, 2): 1/1\1,
  (2, 3): 0/\10  1\/1,
  (2, 4): 1/\1  10\/0,
  (3, 3): 1/1\1,
```

  (4, 4): 2/2\2,
  (4, 5): 1/\1  2\/2(1),
  (5, 5): 2(1)/1\2}]
```

plot(*puzzles*)

Return plot of puzzles.

INPUT:

- `puzzles` – list of puzzles

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: solns = ps('0101', '0101')
sage: ps.plot(solns)        # not tested
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver('K')
```

(continues on next page)

(continued from previous page)

```
>>> solns = ps('0101', '0101')
>>> ps.plot(solns)        # not tested
```

puzzle_pieces()

The puzzle pieces used for filling in the puzzles.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps.puzzle_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> ps.puzzle_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

solutions(*lamda*, *mu*, *algorithm='strips'*)

structure_constants(*lamda*, *mu*, *nu=None*)

Compute cohomology structure coefficients from puzzles.

INPUT:

- `pieces` – puzzle pieces to be used
- `lambda`, `mu` – edge labels of puzzle for northwest and north east side
- `nu` – (default: `None`) if `nu` is not specified a dictionary is returned with the structure coefficients corresponding to all south labels; if `nu` is given, only the coefficients with the specified label is returned

OUTPUT: dictionary

EXAMPLES:

Note: In order to standardize the output of the following examples, we output a sorted list of items from the dictionary instead of the dictionary itself.

Grassmannian cohomology:

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1)]
sage: ps.structure_constants('001001', '001010', '010100')
1
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('H')
>>> cp = ps.structure_constants('0101', '0101')
>>> sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1)]
```

(continues on next page)

(continued from previous page)

```
>>> ps.structure_constants('001001', '001010', '010100')
1
```

Equivariant cohomology:

```
sage: ps = KnutsonTaoPuzzleSolver('HT')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '0', '1'), y2 - y3),
 (('0', '1', '1', '0'), 1),
 (('1', '0', '0', '1'), 1)]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('HT')
>>> cp = ps.structure_constants('0101', '0101')
>>> sorted(cp.items(), key=str)
[(('0', '1', '0', '1'), y2 - y3),
 (('0', '1', '1', '0'), 1),
 (('1', '0', '0', '1'), 1)]
```

K-theory:

```
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1), (('1', '0', '1', '0'),␣
↪-1)]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('K')
>>> cp = ps.structure_constants('0101', '0101')
>>> sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1), (('1', '0', '1', '0'),␣
↪-1)]
```

Two-step:

```
sage: ps = KnutsonTaoPuzzleSolver('H2step')
sage: cp = ps.structure_constants('01122', '01122')
sage: sorted(cp.items(), key=str)
[(('0', '1', '1', '2', '2'), 1)]
sage: cp = ps.structure_constants('01201', '01021')
sage: sorted(cp.items(), key=str)
[(('0', '2', '1', '1', '0'), 1),
 (('1', '2', '0', '0', '1'), 1),
 (('2', '0', '1', '0', '1'), 1)]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('H2step')
>>> cp = ps.structure_constants('01122', '01122')
>>> sorted(cp.items(), key=str)
[(('0', '1', '1', '2', '2'), 1)]
```

(continues on next page)

(continued from previous page)

```
>>> cp = ps.structure_constants('01201', '01021')
>>> sorted(cp.items(), key=str)
[(('0', '2', '1', '1', '0'), 1),
 (('1', '2', '0', '0', '1'), 1),
 (('2', '0', '1', '0', '1'), 1)]
```

Two-step equivariant:

```
sage: ps = KnutsonTaoPuzzleSolver('HT2step')
sage: cp = ps.structure_constants('10212', '12012')
sage: sorted(cp.items(), key=str)
[(('1', '2', '0', '1', '2'), y1*y2 - y2*y3 - y1*y4 + y3*y4),
 (('1', '2', '0', '2', '1'), y1 - y3),
 (('1', '2', '1', '0', '2'), y2 - y4),
 (('1', '2', '1', '2', '0'), 1),
 (('1', '2', '2', '0', '1'), 1),
 (('2', '1', '0', '1', '2'), y1 - y3),
 (('2', '1', '1', '0', '2'), 1)]
```

```
>>> from sage.all import *
>>> ps = KnutsonTaoPuzzleSolver('HT2step')
>>> cp = ps.structure_constants('10212', '12012')
>>> sorted(cp.items(), key=str)
[(('1', '2', '0', '1', '2'), y1*y2 - y2*y3 - y1*y4 + y3*y4),
 (('1', '2', '0', '2', '1'), y1 - y3),
 (('1', '2', '1', '0', '2'), y2 - y4),
 (('1', '2', '1', '2', '0'), 1),
 (('1', '2', '2', '0', '1'), 1),
 (('2', '1', '0', '1', '2'), y1 - y3),
 (('2', '1', '1', '0', '2'), 1)]
```

class sage.combinat.knutson_tao_puzzles.**NablaPiece**(*north*, *south_east*, *south_west*)

Bases: *PuzzlePiece*

Nabla Piece takes as input three labels, inputted as strings. They label the North, Southeast and Southwest edges, respectively.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: NablaPiece('a','b','c')
c\a/b
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> NablaPiece('a','b','c')
c\a/b
```

clockwise_rotation()

Rotate the Nabla piece by 120 degree clockwise.

OUTPUT: Nabla piece

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.clockwise_rotation()
2\3/1
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nabla = NablaPiece('1','2','3')
>>> nabla.clockwise_rotation()
2\3/1
```

edges()

Return the tuple of edge names.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.edges()
('north', 'south_east', 'south_west')
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nabla = NablaPiece('1','2','3')
>>> nabla.edges()
('north', 'south_east', 'south_west')
```

half_turn_rotation()

Rotate the Nabla piece by 180 degree.

OUTPUT: Delta piece

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1','2','3')
sage: nabla.half_turn_rotation()
2/1\3
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nabla = NablaPiece('1','2','3')
>>> nabla.half_turn_rotation()
2/1\3
```

class sage.combinat.knutson_tao_puzzles.**PuzzleFilling**(*north_west_labels*, *north_east_labels*)

Bases: object

Create partial puzzles and provides methods to build puzzles from them.

add_piece(*piece*)

Add `piece` to partial puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
sage: piece = DeltaPiece('0','1','0')
sage: P = PuzzleFilling('0101','0101'); P
{}
sage: P.add_piece(piece); P
{(1, 4): 1/0\0}
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
>>> piece = DeltaPiece('0','1','0')
>>> P = PuzzleFilling('0101','0101'); P
{}
>>> P.add_piece(piece); P
{(1, 4): 1/0\0}
```

add_pieces(*pieces*)

Add `piece` to partial puzzle.

INPUT:

- `pieces` – tuple of pieces

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
sage: P = PuzzleFilling('0101','0101'); P
{}
sage: piece = DeltaPiece('0','1','0')
sage: pieces = [piece,piece]
sage: P.add_pieces(pieces)
sage: P
{(1, 4): 1/0\0, (2, 4): 1/0\0}
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
>>> P = PuzzleFilling('0101','0101'); P
{}
>>> piece = DeltaPiece('0','1','0')
>>> pieces = [piece,piece]
>>> P.add_pieces(pieces)
>>> P
{(1, 4): 1/0\0, (2, 4): 1/0\0}
```

contribution()

Return equivariant contributions from `self` in polynomial ring.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("HT")
sage: puzzles = ps('0101','1001')
sage: sorted([p.contribution() for p in puzzles], key=str)
[1, y1 - y3]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("HT")
>>> puzzles = ps('0101','1001')
>>> sorted([p.contribution() for p in puzzles], key=str)
[1, y1 - y3]
```

copy()

Return copy of `self`.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
sage: piece = DeltaPiece('0','1','0')
sage: P = PuzzleFilling('0101','0101'); P
{}
sage: PP = P.copy()
sage: P.add_piece(piece); P
{(1, 4): 1/0\0}
sage: PP
{}
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
>>> piece = DeltaPiece('0','1','0')
>>> P = PuzzleFilling('0101','0101'); P
{}
>>> PP = P.copy()
>>> P.add_piece(piece); P
{(1, 4): 1/0\0}
>>> PP
{}
```

is_completed()

Whether partial puzzle is complete (completely filled) or not.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.is_completed()
False

sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.is_completed()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P.is_completed()
```

(continues on next page)

(continued from previous page)

```
False

>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> puzzle = ps('0101','1001')[Integer(0)]
>>> puzzle.is_completed()
True
```

is_in_south_edge()

Check whether kink coordinates of partial puzzle is in south corner.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.is_in_south_edge()
False
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P.is_in_south_edge()
False
```

kink_coordinates()

Provide the coordinates of the kinks.

The kink coordinates are the coordinates up to which the puzzle has already been built. The kink starts in the north corner and then moves down the diagonals as the puzzles is built.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P
{}
sage: P.kink_coordinates()
(1, 4)
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P
{}
>>> P.kink_coordinates()
(1, 4)
```

north_east_label_of_kink()

Return north east label of kink.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.north_east_label_of_kink()
'0'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P.north_east_label_of_kink()
'0'
```

north_west_label_of_kink()

Return north-west label of kink.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.north_west_label_of_kink()
'1'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzleFilling
>>> P = PuzzleFilling('0101','0101')
>>> P.north_west_label_of_kink()
'1'
```

plot(*labels=True*, *style='fill'*)

Plot completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.plot()  #not tested
sage: puzzle.plot(style='fill')  #not tested
sage: puzzle.plot(style='edges')  #not tested
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> puzzle = ps('0101','1001')[Integer(0)]
>>> puzzle.plot()  #not tested
>>> puzzle.plot(style='fill')  #not tested
>>> puzzle.plot(style='edges')  #not tested
```

south_labels()

Return south labels for completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: ps('0101','1001')[0].south_labels()
('1', '0', '1', '0')
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> ps('0101','1001')[Integer(0)].south_labels()
('1', '0', '1', '0')
```

class sage.combinat.knutson_tao_puzzles.**PuzzlePiece**

Bases: object

Abstract class for puzzle pieces.

This abstract class contains information on how to test equality of puzzle pieces, and sets color and plotting options.

border()

Return the border of self.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('a','b','c')
sage: sorted(delta.border())
['a', 'b', 'c']
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('a','b','c')
>>> sorted(delta.border())
['a', 'b', 'c']
```

color()

Return the color of self.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('a','b','c')
sage: delta.color()
'white'
sage: delta = DeltaPiece('0','0','0')
sage: delta.color()
'red'
sage: delta = DeltaPiece('1','1','1')
sage: delta.color()
'blue'
sage: delta = DeltaPiece('2','2','2')
sage: delta.color()
'green'
sage: delta = DeltaPiece('2','K','2')
```

(continues on next page)

(continued from previous page)

```
sage: delta.color()
'orange'
sage: delta = DeltaPiece('2','T1/2','2')
sage: delta.color()
'yellow'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('a','b','c')
>>> delta.color()
'white'
>>> delta = DeltaPiece('0','0','0')
>>> delta.color()
'red'
>>> delta = DeltaPiece('1','1','1')
>>> delta.color()
'blue'
>>> delta = DeltaPiece('2','2','2')
>>> delta.color()
'green'
>>> delta = DeltaPiece('2','K','2')
>>> delta.color()
'orange'
>>> delta = DeltaPiece('2','T1/2','2')
>>> delta.color()
'yellow'
```

edge_color(*edge*)

Color of the specified edge of `self` (to be used when plotting the piece).

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','0','10')
sage: delta.edge_color('south')
'blue'
sage: delta.edge_color('north_west')
'red'
sage: delta.edge_color('north_east')
'white'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('1','0','10')
>>> delta.edge_color('south')
'blue'
>>> delta.edge_color('north_west')
'red'
>>> delta.edge_color('north_east')
'white'
```

edge_label(*edge*)

Return the edge label of `edge`.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('2','K','2')
sage: delta.edge_label('south')
'2'
sage: delta.edge_label('north_east')
'2'
sage: delta.edge_label('north_west')
'K'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('2','K','2')
>>> delta.edge_label('south')
'2'
>>> delta.edge_label('north_east')
'2'
>>> delta.edge_label('north_west')
'K'
```

class sage.combinat.knutson_tao_puzzles.**PuzzlePieces**(*forbidden_border_labels=None*)

Bases: object

Construct a valid set of puzzle pieces.

This class constructs the set of valid puzzle pieces. It can take a list of forbidden border labels as input. These labels are forbidden from appearing on the south edge of a puzzle filling. The user can add valid nabla or delta pieces and specify which rotations of these pieces are legal. For example, `rotations=0` does not add any additional pieces (only the piece itself), `rotations=60` adds six pieces (the pieces and its rotations by 60, 120, 180, 240, 300), etc..

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, NablaPiece
sage: forbidden_border_labels = ['10']
sage: pieces = PuzzlePieces(forbidden_border_labels)
sage: pieces.add_piece(NablaPiece('0','0','0'), rotations=60)
sage: pieces.add_piece(NablaPiece('1','1','1'), rotations=60)
sage: pieces.add_piece(NablaPiece('1','0','10'), rotations=60)
sage: pieces
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, NablaPiece
>>> forbidden_border_labels = ['10']
>>> pieces = PuzzlePieces(forbidden_border_labels)
>>> pieces.add_piece(NablaPiece('0','0','0'), rotations=Integer(60))
>>> pieces.add_piece(NablaPiece('1','1','1'), rotations=Integer(60))
>>> pieces.add_piece(NablaPiece('1','0','10'), rotations=Integer(60))
>>> pieces
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The user can obtain the list of valid rhombi pieces as follows:

```
sage: sorted([p for p in pieces.rhombus_pieces()], key=str)
[0/\0  0\/0, 0/\0  1\/10, 0/\10  10\/0, 0/\10  1\/1, 1/\0  0\/1,
1/\1  10\/0, 1/\1  1\/1, 10/\1  0\/0, 10/\1  1\/10]
```

```
>>> from sage.all import *
>>> sorted([p for p in pieces.rhombus_pieces()], key=str)
[0/\0  0\/0, 0/\0  1\/10, 0/\10  10\/0, 0/\10  1\/1, 1/\0  0\/1,
1/\1  10\/0, 1/\1  1\/1, 10/\1  0\/0, 10/\1  1\/10]
```

add_T_piece(*label1*, *label2*)

Add a nabla and delta piece with `label1` and `label2`.

This method adds a nabla piece with edges `label2`T``label1``|``label2`` / `label1`. and a delta piece with edges `label1`/ T``label1``|``label2`` `label2`. It also adds T``label1``|``label2`` to the forbidden list.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_T_piece('1','3')
sage: pieces
Nablas : [3\T1|3/1]
Deltas : [1/T1|3\3]
sage: pieces._forbidden_border_labels
['T1|3']
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces
>>> pieces = PuzzlePieces()
>>> pieces.add_T_piece('1','3')
>>> pieces
Nablas : [3\T1|3/1]
Deltas : [1/T1|3\3]
>>> pieces._forbidden_border_labels
['T1|3']
```

add_forbidden_label(*label*)

Add forbidden border labels.

INPUT:

- `label` – string specifying a new forbidden label

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_forbidden_label('1')
sage: pieces._forbidden_border_labels
['1']
sage: pieces.add_forbidden_label('2')
sage: pieces._forbidden_border_labels
['1', '2']
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces
>>> pieces = PuzzlePieces()
>>> pieces.add_forbidden_label('1')
>>> pieces._forbidden_border_labels
['1']
>>> pieces.add_forbidden_label('2')
>>> pieces._forbidden_border_labels
['1', '2']
```

add_piece(*piece*, *rotations=120*)

Add `piece` to the list of pieces.

INPUT:

- `piece` – a nabla piece or a delta piece
- `rotations` – (default: 120) 0, 60, 120, 180

The user can add valid nabla or delta pieces and specify which rotations of these pieces are legal. For example, `rotations=0` does not add any additional pieces (only the piece itself), `rotations=60` adds six pieces (namely three delta and three nabla pieces), while `rotations=120` adds only delta or nabla (depending on which piece `self` is). `rotations=180` adds the piece and its 180 degree rotation, i.e. one delta and one nabla piece.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: delta = DeltaPiece('a','b','c')
sage: pieces = PuzzlePieces()
sage: pieces
Nablas : []
Deltas : []
sage: pieces.add_piece(delta)
sage: pieces
Nablas : []
Deltas : [a/c\b, b/a\c, c/b\a]

sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta,rotations=0)
sage: pieces
Nablas : []
Deltas : [b/a\c]

sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta,rotations=60)
sage: pieces
Nablas : [a\b/c, b\c/a, c\a/b]
Deltas : [a/c\b, b/a\c, c/b\a]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> delta = DeltaPiece('a','b','c')
>>> pieces = PuzzlePieces()
>>> pieces
```

(continues on next page)

(continued from previous page)

```
Nablas : []
Deltas : []
>>> pieces.add_piece(delta)
>>> pieces
Nablas : []
Deltas : [a/c\b, b/a\c, c/b\a]

>>> pieces = PuzzlePieces()
>>> pieces.add_piece(delta,rotations=Integer(0))
>>> pieces
Nablas : []
Deltas : [b/a\c]

>>> pieces = PuzzlePieces()
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> pieces
Nablas : [a\b/c, b\c/a, c\a/b]
Deltas : [a/c\b, b/a\c, c/b\a]
```

boundary_deltas()

Return deltas with south edges not in the forbidden list.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces(['a'])
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta,rotations=60)
sage: sorted([p for p in pieces.boundary_deltas()], key=str)
[a/c\b, c/b\a]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces(['a'])
>>> delta = DeltaPiece('a','b','c')
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> sorted([p for p in pieces.boundary_deltas()], key=str)
[a/c\b, c/b\a]
```

delta_pieces()

Return the delta pieces as a set.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta,rotations=60)
sage: sorted([p for p in pieces.delta_pieces()], key=str)
[a/c\b, b/a\c, c/b\a]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
```

(continues on next page)

(continued from previous page)

```
>>> pieces = PuzzlePieces()
>>> delta = DeltaPiece('a','b','c')
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> sorted([p for p in pieces.delta_pieces()], key=str)
[a/c\b, b/a\c, c/b\a]
```

nabla_pieces()

Return the nabla pieces as a set.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta,rotations=60)
sage: sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces()
>>> delta = DeltaPiece('a','b','c')
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

rhombus_pieces()

Return a set of all allowable rhombus pieces.

Allowable rhombus pieces are those where the south edge of the delta piece equals the north edge of the nabla piece.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a','b','c')
sage: pieces.add_piece(delta,rotations=60)
sage: sorted([p for p in pieces.rhombus_pieces()], key=str)
[a/\b  b\/a, b/\c  c\/b, c/\a  a\/c]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces()
>>> delta = DeltaPiece('a','b','c')
>>> pieces.add_piece(delta,rotations=Integer(60))
>>> sorted([p for p in pieces.rhombus_pieces()], key=str)
[a/\b  b\/a, b/\c  c\/b, c/\a  a\/c]
```

class sage.combinat.knutson_tao_puzzles.**RhombusPiece**(*north_piece*, *south_piece*)

Bases: *PuzzlePiece*

Class of rhombi pieces.

To construct a rhombus piece we input a delta and a nabla piece. The delta and nabla pieces are joined along the south and north edge, respectively.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: RhombusPiece(delta,nabla)
2/\3  6\/5
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
>>> delta = DeltaPiece('1','2','3')
>>> nabla = NablaPiece('4','5','6')
>>> RhombusPiece(delta,nabla)
2/\3  6\/5
```

edges()

Return the tuple of edge names.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: RhombusPiece(delta,nabla).edges()
('north_west', 'north_east', 'south_east', 'south_west')
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
>>> delta = DeltaPiece('1','2','3')
>>> nabla = NablaPiece('4','5','6')
>>> RhombusPiece(delta,nabla).edges()
('north_west', 'north_east', 'south_east', 'south_west')
```

north_piece()

Return the north piece.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: r = RhombusPiece(delta,nabla)
sage: r.north_piece()
2/1\3
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
>>> delta = DeltaPiece('1','2','3')
>>> nabla = NablaPiece('4','5','6')
>>> r = RhombusPiece(delta,nabla)
>>> r.north_piece()
2/1\3
```

south_piece()

Return the south piece.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
sage: delta = DeltaPiece('1','2','3')
sage: nabla = NablaPiece('4','5','6')
sage: r = RhombusPiece(delta,nabla)
sage: r.south_piece()
6\4/5
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,␣
↪RhombusPiece
>>> delta = DeltaPiece('1','2','3')
>>> nabla = NablaPiece('4','5','6')
>>> r = RhombusPiece(delta,nabla)
>>> r.south_piece()
6\4/5
```

Littlewood-Richardson tableaux

A semistandard tableau is Littlewood-Richardson with respect to the sequence of partitions $(\mu^{(1)}, \ldots, \mu^{(k)})$ if, when restricted to each alphabet $\{|\mu^{(1)}| + \cdots + |\mu^{(i-1)}| + 1, \ldots, |\mu^{(1)}| + \cdots + |\mu^{(i)}| - 1\}$, is Yamanouchi.

AUTHORS:

- Maria Gillespie, Jake Levinson, Anne Schilling (2016): initial version

class sage.combinat.lr_tableau.**LittlewoodRichardsonTableau**(*parent*, *t*)

Bases: *SemistandardTableau*

A semistandard tableau is Littlewood-Richardson with respect to the sequence of partitions $(\mu^{(1)}, \ldots, \mu^{(k)})$ if, when restricted to each alphabet $\{|\mu^{(1)}| + \cdots + |\mu^{(i-1)}| + 1, \ldots, |\mu^{(1)}| + \cdots + |\mu^{(i)}| - 1\}$, is Yamanouchi.

INPUT:

- `t` – Littlewood-Richardson tableau; the input is supposed to be a list of lists specifying the rows of the tableau

EXAMPLES:

```
sage: from sage.combinat.lr_tableau import LittlewoodRichardsonTableau
sage: LittlewoodRichardsonTableau([[1,1,3],[2,3],[4]], [[2,1],[2,1]])
[[1, 1, 3], [2, 3], [4]]
```

```
>>> from sage.all import *
>>> from sage.combinat.lr_tableau import LittlewoodRichardsonTableau
>>> LittlewoodRichardsonTableau([[Integer(1),Integer(1),Integer(3)],[Integer(2),
↪Integer(3)],[Integer(4)]], [[Integer(2),Integer(1)],[Integer(2),Integer(1)]])
[[1, 1, 3], [2, 3], [4]]
```

check()

Check that `self` is a valid Littlewood-Richardson tableau.

EXAMPLES:

```
sage: from sage.combinat.lr_tableau import LittlewoodRichardsonTableau
sage: t = LittlewoodRichardsonTableau([[1,1,3],[2,3],[4]], [[2,1],[2,1]])
sage: t.check()
```

```
>>> from sage.all import *
>>> from sage.combinat.lr_tableau import LittlewoodRichardsonTableau
>>> t = LittlewoodRichardsonTableau([[Integer(1),Integer(1),Integer(3)],
↪[Integer(2),Integer(3)],[Integer(4)]], [[Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]])
>>> t.check()
```

class sage.combinat.lr_tableau.**LittlewoodRichardsonTableaux**(*shape*, *weight*)

Bases: *SemistandardTableaux*

Littlewood-Richardson tableaux.

A semistandard tableau t is *Littlewood-Richardson* with respect to the sequence of partitions $(\mu^{(1)}, \ldots, \mu^{(k)})$ (called the weight) if t is Yamanouchi when restricted to each alphabet $\{|\mu^{(1)}| + \cdots + |\mu^{(i-1)}| + 1, \ldots, |\mu^{(1)}| + \cdots + |\mu^{(i)}| - 1\}$.

INPUT:

- `shape` – the shape of the Littlewood-Richardson tableaux
- `weight` – the weight is a sequence of partitions

EXAMPLES:

```
sage: LittlewoodRichardsonTableaux([3,2,1],[[2,1],[2,1]])
Littlewood-Richardson Tableaux of shape [3, 2, 1] and weight ([2, 1], [2, 1])
```

```
>>> from sage.all import *
>>> LittlewoodRichardsonTableaux([Integer(3),Integer(2),Integer(1)],[[Integer(2),
↪Integer(1)],[Integer(2),Integer(1)]])
Littlewood-Richardson Tableaux of shape [3, 2, 1] and weight ([2, 1], [2, 1])
```

Element

alias of *LittlewoodRichardsonTableau*

sage.combinat.lr_tableau.**is_littlewood_richardson**(*t*, *heights*)

Return whether semistandard tableau `t` is Littleword-Richardson with respect to `heights`.

A tableau is Littlewood-Richardson with respect to `heights` given by $(h_1, h_2, \ldots)$ if each subtableau with respect to the alphabets $\{1, 2, \ldots, h_1\}$, $\{h_1 + 1, \ldots, h_1 + h_2\}$, etc. is Yamanouchi.

EXAMPLES:

```
sage: from sage.combinat.lr_tableau import is_littlewood_richardson
sage: t = Tableau([[1,1,2,3,4],[2,3,3],[3]])
sage: is_littlewood_richardson(t,[2,2])
False
sage: t = Tableau([[1,1,3],[2,3],[4,4]])
sage: is_littlewood_richardson(t,[2,2])
True
sage: t = Tableau([[7],[8]])
sage: is_littlewood_richardson(t,[2,3,3])
False
sage: is_littlewood_richardson([[2],[3]],[3,3])
False
```

```
>>> from sage.all import *
>>> from sage.combinat.lr_tableau import is_littlewood_richardson
>>> t = Tableau([[Integer(1),Integer(1),Integer(2),Integer(3),Integer(4)],
↪[Integer(2),Integer(3),Integer(3)],[Integer(3)]])
>>> is_littlewood_richardson(t,[Integer(2),Integer(2)])
False
>>> t = Tableau([[Integer(1),Integer(1),Integer(3)],[Integer(2),Integer(3)],
↪[Integer(4),Integer(4)]])
>>> is_littlewood_richardson(t,[Integer(2),Integer(2)])
True
>>> t = Tableau([[Integer(7)],[Integer(8)]])
>>> is_littlewood_richardson(t,[Integer(2),Integer(3),Integer(3)])
False
>>> is_littlewood_richardson([[Integer(2)],[Integer(3)]],[Integer(3),Integer(3)])
False
```

Miscellaneous

class sage.combinat.misc.**DoublyLinkedList**(*l*)

Bases: object

A doubly linked list class that provides constant time hiding and unhiding of entries.

Note that this list's indexing is 1-based.

EXAMPLES:

```
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3]); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(1); dll
Doubly linked list of [1, 2, 3]: [2, 3]
sage: dll.unhide(1); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(2); dll
Doubly linked list of [1, 2, 3]: [1, 3]
sage: dll.unhide(2); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
```

```
>>> from sage.all import *
>>> dll = sage.combinat.misc.DoublyLinkedList([Integer(1),Integer(2),Integer(3)]);
```

(continues on next page)

(continued from previous page)

```
↪ dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
>>> dll.hide(Integer(1)); dll
Doubly linked list of [1, 2, 3]: [2, 3]
>>> dll.unhide(Integer(1)); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
>>> dll.hide(Integer(2)); dll
Doubly linked list of [1, 2, 3]: [1, 3]
>>> dll.unhide(Integer(2)); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
```

head()

hide(*i*)

next(*j*)

prev(*j*)

unhide(*i*)

class sage.combinat.misc.**IterableFunctionCall**(*f*, **args*, ***kwargs*)

Bases: object

This class wraps functions with a yield statement (generators) by an object that can be iterated over. For example,

EXAMPLES:

```
sage: def f(): yield 'a'; yield 'b'
```

```
>>> from sage.all import *
>>> def f(): yield 'a'; yield 'b'
```

This does not work:

```
sage: for z in f: print(z)
Traceback (most recent call last):
...
TypeError: 'function' object is not iterable
```

```
>>> from sage.all import *
>>> for z in f: print(z)
Traceback (most recent call last):
...
TypeError: 'function' object is not iterable
```

Use IterableFunctionCall if you want something like the above to work:

```
sage: from sage.combinat.misc import IterableFunctionCall
sage: g = IterableFunctionCall(f)
sage: for z in g: print(z)
a
b
```

```
>>> from sage.all import *
>>> from sage.combinat.misc import IterableFunctionCall
>>> g = IterableFunctionCall(f)
>>> for z in g: print(z)
a
b
```

If your function takes arguments, just put them after the function name. You needn't enclose them in a tuple or anything, just put them there:

```
sage: def f(n, m): yield 'a' * n; yield 'b' * m; yield 'foo'
sage: g = IterableFunctionCall(f, 2, 3)
sage: for z in g: print(z)
aa
bbb
foo
```

```
>>> from sage.all import *
>>> def f(n, m): yield 'a' * n; yield 'b' * m; yield 'foo'
>>> g = IterableFunctionCall(f, Integer(2), Integer(3))
>>> for z in g: print(z)
aa
bbb
foo
```

sage.combinat.misc.**check_integer_list_constraints**(*l*, ***kwargs*)

EXAMPLES:

```
sage: from sage.combinat.misc import check_integer_list_constraints
sage: cilc = check_integer_list_constraints
sage: l = [[2,1,3],[1,2],[3,3],[4,1,1]]
sage: cilc(l, min_part=2)
[[3, 3]]
sage: cilc(l, max_part=2)
[[1, 2]]
sage: cilc(l, length=2)
[[1, 2], [3, 3]]
sage: cilc(l, max_length=2)
[[1, 2], [3, 3]]
sage: cilc(l, min_length=3)
[[2, 1, 3], [4, 1, 1]]
sage: cilc(l, max_slope=0)
[[3, 3], [4, 1, 1]]
sage: cilc(l, min_slope=1)
[[1, 2]]
sage: cilc(l, outer=[2,2])
[[1, 2]]
sage: cilc(l, inner=[2,2])
[[3, 3]]
```

```
>>> from sage.all import *
>>> from sage.combinat.misc import check_integer_list_constraints
```

(continues on next page)

(continued from previous page)

```
>>> cilc = check_integer_list_constraints
>>> l = [[Integer(2),Integer(1),Integer(3)],[Integer(1),Integer(2)],[Integer(3),
↪Integer(3)],[Integer(4),Integer(1),Integer(1)]]
>>> cilc(l, min_part=Integer(2))
[[3, 3]]
>>> cilc(l, max_part=Integer(2))
[[1, 2]]
>>> cilc(l, length=Integer(2))
[[1, 2], [3, 3]]
>>> cilc(l, max_length=Integer(2))
[[1, 2], [3, 3]]
>>> cilc(l, min_length=Integer(3))
[[2, 1, 3], [4, 1, 1]]
>>> cilc(l, max_slope=Integer(0))
[[3, 3], [4, 1, 1]]
>>> cilc(l, min_slope=Integer(1))
[[1, 2]]
>>> cilc(l, outer=[Integer(2),Integer(2)])
[[1, 2]]
>>> cilc(l, inner=[Integer(2),Integer(2)])
[[3, 3]]
```

```
sage: cilc([1,2,3], length=3, singleton=True)
[1, 2, 3]
sage: cilc([1,2,3], length=2, singleton=True) is None
True
```

```
>>> from sage.all import *
>>> cilc([Integer(1),Integer(2),Integer(3)], length=Integer(3), singleton=True)
[1, 2, 3]
>>> cilc([Integer(1),Integer(2),Integer(3)], length=Integer(2), singleton=True)␣
↪is None
True
```

sage.combinat.misc.**umbral_operation**(*poly*)

Return the umbral operation $\downarrow$ applied to poly.

The umbral operation replaces each instance of $x_i^{a_i}$ with $x_i * (x_i - 1) * \cdots * (x_i - a_i + 1)$.

EXAMPLES:

```
sage: P = PolynomialRing(QQ, 2, 'x')
sage: x = P.gens()
sage: from sage.combinat.misc import umbral_operation
sage: umbral_operation(x[0]^3) == x[0]*(x[0]-1)*(x[0]-2)
True
sage: umbral_operation(x[0]*x[1])
x0*x1
sage: umbral_operation(x[0]+x[1])
x0 + x1
sage: umbral_operation(x[0]^2*x[1]^2) == x[0]*(x[0]-1)*x[1]*(x[1]-1)
True
```

```
>>> from sage.all import *
>>> P = PolynomialRing(QQ, Integer(2), 'x')
>>> x = P.gens()
>>> from sage.combinat.misc import umbral_operation
>>> umbral_operation(x[Integer(0)]**Integer(3)) == x[Integer(0)]*(x[Integer(0)]-
↪Integer(1))*(x[Integer(0)]-Integer(2))
True
>>> umbral_operation(x[Integer(0)]*x[Integer(1)])
x0*x1
>>> umbral_operation(x[Integer(0)]+x[Integer(1)])
x0 + x1
>>> umbral_operation(x[Integer(0)]**Integer(2)*x[Integer(1)]**Integer(2)) ==␣
↪x[Integer(0)]*(x[Integer(0)]-Integer(1))*x[Integer(1)]*(x[Integer(1)]-
↪Integer(1))
True
```

Necklaces

The algorithm used in this file comes from

- Sawada, Joe. *A fast algorithm to generate necklaces with fixed content*, Theoretical Computer Science archive Volume 301, Issue 1-3 (May 2003) doi:10.1016/S0304-3975(03)00049-5

`sage.combinat.necklace.`**`Necklaces`**(*content*)

Return the set of necklaces with evaluation `content`.

A necklace is a list of integers that such that the list is the smallest lexicographic representative of all the cyclic shifts of the list.

See also

LyndonWords

INPUT:

- `content` – list or tuple of nonnegative integers

EXAMPLES:

```
sage: Necklaces([2,1,1])
Necklaces with evaluation [2, 1, 1]
sage: Necklaces([2,1,1]).cardinality()
3
sage: Necklaces([2,1,1]).first()
[1, 1, 2, 3]
sage: Necklaces([2,1,1]).last()
[1, 2, 1, 3]
sage: Necklaces([2,1,1]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
sage: Necklaces([0,2,1,1]).list()
[[2, 2, 3, 4], [2, 2, 4, 3], [2, 3, 2, 4]]
sage: Necklaces([2,0,1,1]).list()
[[1, 1, 3, 4], [1, 1, 4, 3], [1, 3, 1, 4]]
```

```
>>> from sage.all import *
>>> Necklaces([Integer(2),Integer(1),Integer(1)])
Necklaces with evaluation [2, 1, 1]
>>> Necklaces([Integer(2),Integer(1),Integer(1)]).cardinality()
3
>>> Necklaces([Integer(2),Integer(1),Integer(1)]).first()
[1, 1, 2, 3]
>>> Necklaces([Integer(2),Integer(1),Integer(1)]).last()
[1, 2, 1, 3]
>>> Necklaces([Integer(2),Integer(1),Integer(1)]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
>>> Necklaces([Integer(0),Integer(2),Integer(1),Integer(1)]).list()
[[2, 2, 3, 4], [2, 2, 4, 3], [2, 3, 2, 4]]
>>> Necklaces([Integer(2),Integer(0),Integer(1),Integer(1)]).list()
[[1, 1, 3, 4], [1, 1, 4, 3], [1, 3, 1, 4]]
```

class sage.combinat.necklace.**Necklaces_evaluation**(*content*)

Bases: UniqueRepresentation, Parent

Necklaces with a fixed evaluation (content).

INPUT:

- content – list or tuple of nonnegative integers

cardinality()

Return the number of integer necklaces with the evaluation content.

The formula for the number of necklaces of content α a composition of n is:

$$\sum_{d|gcd(\alpha)} \phi(d) \binom{n/d}{\alpha_1/d, \ldots, \alpha_\ell/d},$$

where $\phi(d)$ is the Euler ϕ function.

EXAMPLES:

```
sage: Necklaces([]).cardinality()
0
sage: Necklaces([2,2]).cardinality()
2
sage: Necklaces([2,3,2]).cardinality()
30
sage: Necklaces([0,3,2]).cardinality()
2
```

```
>>> from sage.all import *
>>> Necklaces([]).cardinality()
0
>>> Necklaces([Integer(2),Integer(2)]).cardinality()
2
>>> Necklaces([Integer(2),Integer(3),Integer(2)]).cardinality()
30
>>> Necklaces([Integer(0),Integer(3),Integer(2)]).cardinality()
2
```

Check to make sure that the count matches up with the number of necklace words generated.

```
sage: comps = [[],[2,2],[3,2,7],[4,2],[0,4,2],[2,0,4]] + Compositions(4).
↪list()
sage: ns = [Necklaces(comp) for comp in comps]
sage: all(n.cardinality() == len(n.list()) for n in ns)                    #␣
↪needs sage.libs.pari
True
```

```
>>> from sage.all import *
>>> comps = [[],[Integer(2),Integer(2)],[Integer(3),Integer(2),Integer(7)],
↪[Integer(4),Integer(2)],[Integer(0),Integer(4),Integer(2)],[Integer(2),
↪Integer(0),Integer(4)]] + Compositions(Integer(4)).list()
>>> ns = [Necklaces(comp) for comp in comps]
>>> all(n.cardinality() == len(n.list()) for n in ns)                      #␣
↪needs sage.libs.pari
True
```

content()

Return the content (or evaluation) of the necklaces.

EXAMPLES:

```
sage: N = Necklaces([2,2,2])
sage: N.content()
[2, 2, 2]
```

```
>>> from sage.all import *
>>> N = Necklaces([Integer(2),Integer(2),Integer(2)])
>>> N.content()
[2, 2, 2]
```

Non-decreasing parking functions

A *non-decreasing parking function* of size n is a non-decreasing function f from $\{1, \ldots, n\}$ to itself such that for all i, one has $f(i) \leq i$.

The number of non-decreasing parking functions of size n is the n-th *Catalan number*.

The set of non-decreasing parking functions of size n is in bijection with the set of *Dyck words* of size n.

AUTHORS:

- Florent Hivert (2009-04)
- Christian Stump (2012-11) added pretty printing

class sage.combinat.non_decreasing_parking_function.**NonDecreasingParkingFunction**(*lst*)

Bases: Element

A *non decreasing parking function* of size n is a non-decreasing function f from $\{1, \ldots, n\}$ to itself such that for all i, one has $f(i) \leq i$.

EXAMPLES:

```
sage: NonDecreasingParkingFunction([])
[]
```

(continues on next page)

(continued from previous page)

```
sage: NonDecreasingParkingFunction([1])
[1]
sage: NonDecreasingParkingFunction([2])
Traceback (most recent call last):
...
ValueError: [2] is not a non-decreasing parking function
sage: NonDecreasingParkingFunction([1,2])

[1, 1, 2]
>>> NonDecreasingParkingFunction([Integer(1),Integer(1),Integer(4)])
Traceback (most recent call last):
...
ValueError: [1, 1, 4] is not a non-decreasing parking function
```

classmethod from_dyck_word(*dw*)

Bijection from *Dyck words*. It is the inverse of the bijection *to_dyck_word()*. You can find there the mathematical definition.

EXAMPLES:

```
sage: NonDecreasingParkingFunction.from_dyck_word([])
[]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0])
[1]
sage: NonDecreasingParkingFunction.from_dyck_word([1,1,0,0])
[1, 1]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0,1,0])
[1, 2]
sage: NonDecreasingParkingFunction.from_dyck_word([1,0,1,1,0,1,0,0,1,0])
[1, 2, 2, 3, 5]
```

```
>>> from sage.all import *
>>> NonDecreasingParkingFunction.from_dyck_word([])
```

(continues on next page)

(continued from previous page)

```
[]
>>> NonDecreasingParkingFunction.from_dyck_word([Integer(1),Integer(0)])
[1]
>>> NonDecreasingParkingFunction.from_dyck_word([Integer(1),Integer(1),
↪Integer(0),Integer(0)])
[1, 1]
>>> NonDecreasingParkingFunction.from_dyck_word([Integer(1),Integer(0),
↪Integer(1),Integer(0)])
[1, 2]
>>> NonDecreasingParkingFunction.from_dyck_word([Integer(1),Integer(0),
↪Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),Integer(0),
↪Integer(1),Integer(0)])
[1, 2, 2, 3, 5]
```

grade()

Return the length of `self`.

EXAMPLES:

```
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: len(ndpf.random_element())
5
```

```
>>> from sage.all import *
>>> ndpf = NonDecreasingParkingFunctions(Integer(5))
>>> len(ndpf.random_element())
5
```

to_dyck_word()

Implement the bijection to *Dyck words*, which is defined as follows. Take a non decreasing parking function, say [1,1,2,4,5,5], and draw its graph:

```
        ___
       |  . 5
      _|  . 5
   ___|  . . 4
 _|  . . . . 2
|  . . . . . 1
|  . . . . . 1
```

The corresponding Dyck word [1,1,0,1,0,0,1,0,1,1,0,0] is then read off from the sequence of horizontal and vertical steps. The converse bijection is *from_dyck_word()*.

EXAMPLES:

```
sage: NonDecreasingParkingFunction([1,1,2,4,5,5]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0, 1, 1, 0, 0]
sage: NonDecreasingParkingFunction([]).to_dyck_word()
[]
sage: NonDecreasingParkingFunction([1,1,1]).to_dyck_word()
[1, 1, 1, 0, 0, 0]
sage: NonDecreasingParkingFunction([1,2,3]).to_dyck_word()
[1, 0, 1, 0, 1, 0]
```

(continues on next page)

(continued from previous page)

```
sage: NonDecreasingParkingFunction([1,1,3,3,4,6,6]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> NonDecreasingParkingFunction([Integer(1),Integer(1),Integer(2),Integer(4),
↪Integer(5),Integer(5)]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0, 1, 1, 0, 0]
>>> NonDecreasingParkingFunction([]).to_dyck_word()
[]
>>> NonDecreasingParkingFunction([Integer(1),Integer(1),Integer(1)]).to_dyck_
↪word()
[1, 1, 1, 0, 0, 0]
>>> NonDecreasingParkingFunction([Integer(1),Integer(2),Integer(3)]).to_dyck_
↪word()
[1, 0, 1, 0, 1, 0]
>>> NonDecreasingParkingFunction([Integer(1),Integer(1),Integer(3),Integer(3),
↪Integer(4),Integer(6),Integer(6)]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```

sage.combinat.non_decreasing_parking_function.**NonDecreasingParkingFunctions**(*n=None*)

Return the set of Non-Decreasing Parking Functions.

A *non-decreasing parking function* of size n is a non-decreasing function f from $\{1, \ldots, n\}$ to itself such that for all i, one has $f(i) \leq i$.

EXAMPLES:

Here are all the-non decreasing parking functions of size 5:

```
sage: NonDecreasingParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
```

```
>>> from sage.all import *
>>> NonDecreasingParkingFunctions(Integer(3)).list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
```

If no size is specified, then NonDecreasingParkingFunctions returns the set of all non-decreasing parking functions.

```
sage: PF = NonDecreasingParkingFunctions(); PF
Non-decreasing parking functions
sage: [] in PF
True
sage: [1] in PF
True
sage: [2] in PF
False
sage: [1,1,3] in PF
True
sage: [1,1,4] in PF
False
```

```
>>> from sage.all import *
>>> PF = NonDecreasingParkingFunctions(); PF
```

(continues on next page)

(continued from previous page)

```
Non-decreasing parking functions
>>> [] in PF
True
>>> [Integer(1)] in PF
True
>>> [Integer(2)] in PF
False
>>> [Integer(1),Integer(1),Integer(3)] in PF
True
>>> [Integer(1),Integer(1),Integer(4)] in PF
False
```

If the size n is specified, then NonDecreasingParkingFunctions returns the set of all non-decreasing parking functions of size n.

```
sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.list()
[[]]
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.list()
[[1]]
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]

sage: PF3 = NonDecreasingParkingFunctions(3); PF3
Non-decreasing parking functions of size 3
sage: [] in PF3
False
sage: [1] in PF3
False
sage: [1,1,3] in PF3
True
sage: [1,1,4] in PF3
False
```

```
>>> from sage.all import *
>>> PF = NonDecreasingParkingFunctions(Integer(0))
>>> PF.list()
[[]]
>>> PF = NonDecreasingParkingFunctions(Integer(1))
>>> PF.list()
[[1]]
>>> PF = NonDecreasingParkingFunctions(Integer(3))
>>> PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]

>>> PF3 = NonDecreasingParkingFunctions(Integer(3)); PF3
Non-decreasing parking functions of size 3
>>> [] in PF3
False
>>> [Integer(1)] in PF3
```

(continues on next page)

(continued from previous page)

```
False
>>> [Integer(1),Integer(1),Integer(3)] in PF3
True
>>> [Integer(1),Integer(1),Integer(4)] in PF3
False
```

class sage.combinat.non_decreasing_parking_function.**NonDecreasingParkingFunctions_all**

Bases: UniqueRepresentation, Parent

graded_component(*n*)

Return the graded component.

EXAMPLES:

```
sage: P = NonDecreasingParkingFunctions()
sage: P.graded_component(4) == NonDecreasingParkingFunctions(4)
True
```

```
>>> from sage.all import *
>>> P = NonDecreasingParkingFunctions()
>>> P.graded_component(Integer(4)) ==␣
↪NonDecreasingParkingFunctions(Integer(4))
True
```

class sage.combinat.non_decreasing_parking_function.**NonDecreasingParkingFunctions_n**(*n*)

Bases: UniqueRepresentation, Parent

The combinatorial class of non-decreasing parking functions of size n.

A *non-decreasing parking function* of size n is a non-decreasing function f from $\{1, \ldots, n\}$ to itself such that for all i, one has $f(i) \leq i$.

The number of non-decreasing parking functions of size n is the n-th Catalan number.

EXAMPLES:

```
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
sage: PF = NonDecreasingParkingFunctions(4)
sage: PF.list()
[[1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 1, 3], [1, 1, 1, 4], [1, 1, 2, 2], [1, 1, 2,␣

```

Warning

The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

AUTHORS:

- Florent Hivert

Element

alias of *NonDecreasingParkingFunction*

cardinality()

Return the number of non-decreasing parking functions of size n.

This number is the n-th *Catalan number*.

EXAMPLES:

```
sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.cardinality()
1
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.cardinality()
1
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.cardinality()
5
sage: PF = NonDecreasingParkingFunctions(5)
sage: PF.cardinality()
42
```

```
>>> from sage.all import *
>>> PF = NonDecreasingParkingFunctions(Integer(0))
>>> PF.cardinality()
1
>>> PF = NonDecreasingParkingFunctions(Integer(1))
>>> PF.cardinality()
1
>>> PF = NonDecreasingParkingFunctions(Integer(3))
>>> PF.cardinality()
5
>>> PF = NonDecreasingParkingFunctions(Integer(5))
>>> PF.cardinality()
42
```

one()

Return the unit of this monoid.

This is the non-decreasing parking function [1, 2, …, n].

EXAMPLES:

```
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: x = ndpf.random_element(); x  # random
sage: e = ndpf.one()
sage: x == e*x == x*e
True
```

```
>>> from sage.all import *
>>> ndpf = NonDecreasingParkingFunctions(Integer(5))
>>> x = ndpf.random_element(); x  # random
>>> e = ndpf.one()
>>> x == e*x == x*e
True
```

random_element()

Return a random parking function of the given size.

EXAMPLES:

```
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: x = ndpf.random_element(); x  # random
[1, 2, 2, 4, 5]
sage: x in ndpf
True
```

```
>>> from sage.all import *
>>> ndpf = NonDecreasingParkingFunctions(Integer(5))
>>> x = ndpf.random_element(); x  # random
[1, 2, 2, 4, 5]
>>> x in ndpf
True
```

sage.combinat.non_decreasing_parking_function.**is_a**(*x*, *n=None*)

Check whether a list is a non-decreasing parking function.

If a size n is specified, checks if a list is a non-decreasing parking function of size n.

Nonnegative integer vectors

AUTHORS:

- Mike Hansen (2007): original module
- Nathann Cohen, David Joyner (2009-2010): Gale-Ryser stuff
- Nathann Cohen, David Joyner (2011): Gale-Ryser bugfix
- Travis Scrimshaw (2012-05-12): updated docstrings to tell the user of that the class's name is a misnomer (that they only contains nonnegative entries).
- Federico Poloni (2013): specialized `rank()`
- Travis Scrimshaw (2013-02-04): refactored to use `ClonableIntArray`

class sage.combinat.integer_vector.**IntegerVector**

Bases: ClonableArray

An integer vector.

check()

Check to make sure this is a valid integer vector by making sure all entries are nonnegative.

EXAMPLES:

```
sage: IV = IntegerVectors()
sage: elt = IV([1,2,1])
sage: elt.check()
```

```
>>> from sage.all import *
>>> IV = IntegerVectors()
>>> elt = IV([Integer(1),Integer(2),Integer(1)])
>>> elt.check()
```

Check Issue #34510:

```
sage: IV3 = IntegerVectors(n=3)
sage: IV3([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
sage: IVk3 = IntegerVectors(k=3)
sage: IVk3([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
sage: IV33 = IntegerVectors(n=3, k=3)
sage: IV33([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
```

```
>>> from sage.all import *
>>> IV3 = IntegerVectors(n=Integer(3))
>>> IV3([Integer(2),Integer(2)])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
>>> IVk3 = IntegerVectors(k=Integer(3))
>>> IVk3([Integer(2),Integer(2)])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
>>> IV33 = IntegerVectors(n=Integer(3), k=Integer(3))
>>> IV33([Integer(2),Integer(2)])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
```

specht_module(*base_ring=None*)

Return the Specht module corresponding to `self`.

EXAMPLES:

```
sage: SM = IntegerVectors()([2,0,1,0,2]).specht_module(QQ); SM                #␣
↪needs sage.combinat sage.modules
Specht module of [(0, 0), (0, 1), (2, 0), (4, 0), (4, 1)] over Rational Field
sage: s = SymmetricFunctions(QQ).s()                                          #␣
↪needs sage.combinat sage.modules
sage: s(SM.frobenius_image())                                                 #␣
↪needs sage.combinat sage.modules
s[2, 2, 1]
```

```
>>> from sage.all import *
>>> SM = IntegerVectors()([Integer(2),Integer(0),Integer(1),Integer(0),
↪Integer(2)]).specht_module(QQ); SM              # needs sage.combinat sage.
↪modules
Specht module of [(0, 0), (0, 1), (2, 0), (4, 0), (4, 1)] over Rational Field
>>> s = SymmetricFunctions(QQ).s()                                            #␣
↪needs sage.combinat sage.modules
>>> s(SM.frobenius_image())                                                   #␣
↪needs sage.combinat sage.modules
s[2, 2, 1]
```

specht_module_dimension(*base_ring=None*)

Return the dimension of the Specht module corresponding to `self`.

INPUT:

- `BR` – (default: **Q**) the base ring

EXAMPLES:

```
sage: IntegerVectors()([2,0,1,0,2]).specht_module_dimension()                 #␣
↪needs sage.combinat sage.modules
5
sage: IntegerVectors()([2,0,1,0,2]).specht_module_dimension(GF(2))            #␣
↪needs sage.combinat sage.modules sage.rings.finite_rings
5
```

```
>>> from sage.all import *
>>> IntegerVectors()([Integer(2),Integer(0),Integer(1),Integer(0),
↪Integer(2)]).specht_module_dimension()               # needs sage.combinat␣
↪sage.modules
5
>>> IntegerVectors()([Integer(2),Integer(0),Integer(1),Integer(0),
↪Integer(2)]).specht_module_dimension(GF(Integer(2)))          # needs sage.
↪combinat sage.modules sage.rings.finite_rings
5
```

trim()

Remove trailing zeros from the integer vector.

EXAMPLES:

```
sage: IV = IntegerVectors()
sage: IV([5,3,5,1,0,0]).trim()
[5, 3, 5, 1]
sage: IV([5,0,5,1,0]).trim()
[5, 0, 5, 1]
sage: IV([4,3,3]).trim()
[4, 3, 3]
sage: IV([0,0,0]).trim()
[]

sage: IV = IntegerVectors(k=4)
sage: v = IV([4,3,2,0]).trim(); v
[4, 3, 2]
sage: v.parent()
Integer vectors
```

```
>>> from sage.all import *
>>> IV = IntegerVectors()
>>> IV([Integer(5),Integer(3),Integer(5),Integer(1),Integer(0),Integer(0)]).
↪trim()
[5, 3, 5, 1]
>>> IV([Integer(5),Integer(0),Integer(5),Integer(1),Integer(0)]).trim()
[5, 0, 5, 1]
>>> IV([Integer(4),Integer(3),Integer(3)]).trim()
[4, 3, 3]
>>> IV([Integer(0),Integer(0),Integer(0)]).trim()
[]

>>> IV = IntegerVectors(k=Integer(4))
>>> v = IV([Integer(4),Integer(3),Integer(2),Integer(0)]).trim(); v
[4, 3, 2]
>>> v.parent()
Integer vectors
```

class sage.combinat.integer_vector.**IntegerVectors**(*category=None*)

Bases: Parent

The class of (nonnegative) integer vectors.

INPUT:

- n – if set to an integer, returns the combinatorial class of integer vectors whose sum is n; if set to None (default), no such constraint is defined
- k – the length of the vectors; set to None (default) if you do not want such a constraint

Note

The entries are nonnegative integers.

EXAMPLES:

If n is not specified, it returns the class of all integer vectors:

```
sage: IntegerVectors()
Integer vectors
sage: [] in IntegerVectors()
True
sage: [1,2,1] in IntegerVectors()
True
sage: [1, 0, 0] in IntegerVectors()
True
```

```
>>> from sage.all import *
>>> IntegerVectors()
Integer vectors
>>> [] in IntegerVectors()
True
>>> [Integer(1),Integer(2),Integer(1)] in IntegerVectors()
True
>>> [Integer(1), Integer(0), Integer(0)] in IntegerVectors()
True
```

Entries are nonnegative:

```
sage: [-1, 2] in IntegerVectors()
False
```

```
>>> from sage.all import *
>>> [-Integer(1), Integer(2)] in IntegerVectors()
False
```

If `n` is specified, then it returns the class of all integer vectors which sum to `n`:

```
sage: IV3 = IntegerVectors(3); IV3
Integer vectors that sum to 3
```

```
>>> from sage.all import *
>>> IV3 = IntegerVectors(Integer(3)); IV3
Integer vectors that sum to 3
```

Note that trailing zeros are ignored so that `[3, 0]` does not show up in the following list (since `[3]` does):

```
sage: IntegerVectors(3, max_length=2).list()
[[3], [2, 1], [1, 2], [0, 3]]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(3), max_length=Integer(2)).list()
[[3], [2, 1], [1, 2], [0, 3]]
```

If `n` and `k` are both specified, then it returns the class of integer vectors that sum to `n` and are of length `k`:

```
sage: IV53 = IntegerVectors(5,3); IV53
Integer vectors of length 3 that sum to 5
sage: IV53.cardinality()
21
```

(continues on next page)

(continued from previous page)

```
sage: IV53.first()
[5, 0, 0]
sage: IV53.last()
[0, 0, 5]
sage: IV53.random_element().parent() is IV53
True
```

```
>>> from sage.all import *
>>> IV53 = IntegerVectors(Integer(5),Integer(3)); IV53
Integer vectors of length 3 that sum to 5
>>> IV53.cardinality()
21
>>> IV53.first()
[5, 0, 0]
>>> IV53.last()
[0, 0, 5]
>>> IV53.random_element().parent() is IV53
True
```

Further examples:

```

 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 1],
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 1],
 [0, 0, 0, 1, 1]]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(0), Integer(3), outer=[Integer(0),Integer(0),
↪Integer(0)]).list()
[[0, 0, 0]]
>>> IntegerVectors(Integer(1), Integer(3), outer=[Integer(0),Integer(0),
↪Integer(0)]).list()
[]
>>> IntegerVectors(Integer(2), Integer(3), outer=[Integer(0),Integer(2),
↪Integer(0)]).list()
[[0, 2, 0]]
>>> IntegerVectors(Integer(2), Integer(3), outer=[Integer(1),Integer(2),
↪Integer(1)]).list()
[[1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1]]
>>> IntegerVectors(Integer(2), Integer(3), outer=[Integer(1),Integer(1),
↪Integer(1)]).list()
[[1, 1, 0], [1, 0, 1], [0, 1, 1]]
>>> IntegerVectors(Integer(2), Integer(5), outer=[Integer(1),Integer(1),
↪Integer(1),Integer(1),Integer(1)]).list()
[[1, 1, 0, 0, 0],
 [1, 0, 1, 0, 0],
 [1, 0, 0, 1, 0],
 [1, 0, 0, 0, 1],
 [0, 1, 1, 0, 0],
 [0, 1, 0, 1, 0],
 [0, 1, 0, 0, 1],
```

(continues on next page)

(continued from previous page)

```
 [0, 0, 1, 1, 0],
 [0, 0, 1, 0, 1],
 [0, 0, 0, 1, 1]]
```

```
sage: iv = [ IntegerVectors(n,k) for n in range(-2, 7) for k in range(7) ]
sage: all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
sage: essai = [[1,1,1], [2,5,6], [6,5,2]]
sage: iv = [ IntegerVectors(x[0], x[1], max_part = x[2]-1) for x in essai ]
sage: all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
```

```
>>> from sage.all import *
>>> iv = [ IntegerVectors(n,k) for n in range(-Integer(2), Integer(7)) for k in␣
↪range(Integer(7)) ]
>>> all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
>>> essai = [[Integer(1),Integer(1),Integer(1)], [Integer(2),Integer(5),
↪Integer(6)], [Integer(6),Integer(5),Integer(2)]]
>>> iv = [ IntegerVectors(x[Integer(0)], x[Integer(1)], max_part = x[Integer(2)]-
↪Integer(1)) for x in essai ]
>>> all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
```

An example showing the same output by using IntegerListsLex:

```
sage: IntegerVectors(4, max_length=2).list()
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
sage: list(IntegerListsLex(4, max_length=2))
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(4), max_length=Integer(2)).list()
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
>>> list(IntegerListsLex(Integer(4), max_length=Integer(2)))
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
```

sage.combinat.integer_lists.invlex.IntegerListsLex

Element

alias of *IntegerVector*

is_finite()

Return whether `self` is finite.

EXAMPLES:

```
sage: IntegerVectors().is_finite()
False
```

(continues on next page)

(continued from previous page)

```
sage: IntegerVectors(3).is_finite()
False
sage: IntegerVectors(length=5).is_finite()
False
sage: IntegerVectors(3, 5).is_finite()
True
```

```
>>> from sage.all import *
>>> IntegerVectors().is_finite()
False
>>> IntegerVectors(Integer(3)).is_finite()
False
>>> IntegerVectors(length=Integer(5)).is_finite()
False
>>> IntegerVectors(Integer(3), Integer(5)).is_finite()
True
```

class sage.combinat.integer_vector.**IntegerVectorsConstraints**(*n=None*, *k=None*, ***constraints*)

Bases: *IntegerVectors*

Class of integer vectors subject to various constraints.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: IntegerVectors(3, 3, min_part=1).cardinality()
1
sage: IntegerVectors(5, 3, min_part=1).cardinality()
6
sage: IntegerVectors(13, 4, max_part=4).cardinality()
20
sage: IntegerVectors(k=4, max_part=3).cardinality()
256
sage: IntegerVectors(k=3, min_part=2, max_part=4).cardinality()
27
sage: IntegerVectors(13, 4, min_part=2, max_part=4).cardinality()
16

sage: P = IntegerVectors(length=0, max_part=0)
sage: P.cardinality()
1
sage: list(P)
[[]]
sage: Q = IntegerVectors(max_length=0)
sage: Q.cardinality()
1
sage: list(Q)
[[]]
sage: P = IntegerVectors(1, length=1, max_length=0, max_part=1)
sage: [1] in P
True
```

(continues on next page)

(continued from previous page)

```
sage: P.cardinality()
1
sage: list(P)
[[1]]
sage: Q = IntegerVectors(max_length=0, min_length=1)
sage: [] in Q
False
sage: Q.cardinality()
0
sage: list(Q)
[]
sage: R = IntegerVectors(0, length=0, min_length=1)
sage: [] in R
True
sage: R.cardinality()
1
sage: list(R)
[[]]
```

```

>>> IntegerVectors(Integer(3), Integer(3), min_part=Integer(1)).cardinality()
1
>>> IntegerVectors(Integer(5), Integer(3), min_part=Integer(1)).cardinality()
6
>>> IntegerVectors(Integer(13), Integer(4), max_part=Integer(4)).cardinality()
20
>>> IntegerVectors(k=Integer(4), max_part=Integer(3)).cardinality()
256
>>> IntegerVectors(k=Integer(3), min_part=Integer(2), max_part=Integer(4)).
↪cardinality()
27
>>> IntegerVectors(Integer(13), Integer(4), min_part=Integer(2), max_
↪part=Integer(4)).cardinality()
16

>>> P = IntegerVectors(length=Integer(0), max_part=Integer(0))
>>> P.cardinality()
1
>>> list(P)
[[]]
>>> Q = IntegerVectors(max_length=Integer(0))
>>> Q.cardinality()
1
>>> list(Q)
[[]]
>>> P = IntegerVectors(Integer(1), length=Integer(1), max_length=Integer(0),␣
↪max_part=Integer(1))
>>> [Integer(1)] in P
True
>>> P.cardinality()
1
>>> list(P)
```

(continues on next page)

(continued from previous page)

```
[[1]]
>>> Q = IntegerVectors(max_length=Integer(0), min_length=Integer(1))
>>> [] in Q
False
>>> Q.cardinality()
0
>>> list(Q)
[]
>>> R = IntegerVectors(Integer(0), length=Integer(0), min_length=Integer(1))
>>> [] in R
True
>>> R.cardinality()
1
>>> list(R)
[[]]
```

class sage.combinat.integer_vector.**IntegerVectors_all**

Bases: UniqueRepresentation, *IntegerVectors*

Class of all integer vectors.

class sage.combinat.integer_vector.**IntegerVectors_k**(k)

Bases: UniqueRepresentation, *IntegerVectors*

Integer vectors of length k.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: IntegerVectors(k=0).cardinality()
1
sage: IntegerVectors(k=10).cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> IntegerVectors(k=Integer(0)).cardinality()
1
>>> IntegerVectors(k=Integer(10)).cardinality()
+Infinity
```

rank(x)

Return the rank of a given element.

INPUT:

- `x` – list with `len(x) == k`

EXAMPLES:

```
sage: IntegerVectors(k=5).rank([0,0,0,0,0])
0
sage: IntegerVectors(k=5).rank([1,1,0,0,0])
7
```

```
>>> from sage.all import *
>>> IntegerVectors(k=Integer(5)).rank([Integer(0),Integer(0),Integer(0),
↪Integer(0),Integer(0)])
0
>>> IntegerVectors(k=Integer(5)).rank([Integer(1),Integer(1),Integer(0),
↪Integer(0),Integer(0)])
7
```

unrank(*x*)

Return the element at given rank x.

INPUT:

- x – integer such that `x < self.cardinality()`

EXAMPLES:

```
sage: IntegerVectors(k=5).unrank(10)
[1, 0, 0, 0, 1]
sage: IntegerVectors(k=5).unrank(15)
[0, 0, 2, 0, 0]
sage: IntegerVectors(k=0).unrank(0)
[]
```

```
>>> from sage.all import *
>>> IntegerVectors(k=Integer(5)).unrank(Integer(10))
[1, 0, 0, 0, 1]
>>> IntegerVectors(k=Integer(5)).unrank(Integer(15))
[0, 0, 2, 0, 0]
>>> IntegerVectors(k=Integer(0)).unrank(Integer(0))
[]
```

class sage.combinat.integer_vector.**IntegerVectors_n**(*n*)

Bases: UniqueRepresentation, *IntegerVectors*

Integer vectors that sum to n.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: IntegerVectors(n=0).cardinality()
1
sage: IntegerVectors(n=10).cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> IntegerVectors(n=Integer(0)).cardinality()
1
>>> IntegerVectors(n=Integer(10)).cardinality()
+Infinity
```

rank(*x*)

Return the rank of a given element.

INPUT:

- x – list with sum(x) == n

EXAMPLES:

```
sage: IntegerVectors(n=5).rank([5,0])
1
sage: IntegerVectors(n=5).rank([3,2])
3
```

```
>>> from sage.all import *
>>> IntegerVectors(n=Integer(5)).rank([Integer(5),Integer(0)])
1
>>> IntegerVectors(n=Integer(5)).rank([Integer(3),Integer(2)])
3
```

unrank(*x*)

Return the element at given rank x.

INPUT:

- x – integer

EXAMPLES:

```
sage: IntegerVectors(n=5).unrank(2)
[4, 1]
sage: IntegerVectors(n=10).unrank(10)
[1, 9]
```

```
>>> from sage.all import *
>>> IntegerVectors(n=Integer(5)).unrank(Integer(2))
[4, 1]
>>> IntegerVectors(n=Integer(10)).unrank(Integer(10))
[1, 9]
```

class sage.combinat.integer_vector.**IntegerVectors_nk**(*n*, *k*)

Bases: UniqueRepresentation, *IntegerVectors*

Integer vectors of length k that sum to n.

AUTHORS:

- Martin Albrecht
- Mike Hansen

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: IntegerVectors(3,5).cardinality()
35
sage: IntegerVectors(99, 3).cardinality()
5050
sage: IntegerVectors(10^9 - 1, 3).cardinality()
500000000500000000
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(3),Integer(5)).cardinality()
35
>>> IntegerVectors(Integer(99), Integer(3)).cardinality()
5050
>>> IntegerVectors(Integer(10)**Integer(9) - Integer(1), Integer(3)).
↪cardinality()
500000000500000000
```

is_finite()

Return whether `self` is finite.

EXAMPLES:

```
sage: IntegerVectors(3,5).is_finite()
True
sage: IntegerVectors(99, 3).is_finite()
True
sage: IntegerVectors(2*10^9, 10^9).is_finite()
True
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(3),Integer(5)).is_finite()
True
>>> IntegerVectors(Integer(99), Integer(3)).is_finite()
True
>>> IntegerVectors(Integer(2)*Integer(10)**Integer(9),␣
↪Integer(10)**Integer(9)).is_finite()
True
```

rank(*x*)

Return the rank of a given element.

INPUT:

- `x` – list with `sum(x) == n` and `len(x) == k`

unrank(*x*)

Return the element at given rank x.

INPUT:

- `x` – integer such that `x < self.cardinality()`

EXAMPLES:

```
sage: IntegerVectors(4,5).unrank(30)
[1, 0, 1, 0, 2]
sage: IntegerVectors(2,3).unrank(5)
[0, 0, 2]
```

```
>>> from sage.all import *
>>> IntegerVectors(Integer(4),Integer(5)).unrank(Integer(30))
[1, 0, 1, 0, 2]
>>> IntegerVectors(Integer(2),Integer(3)).unrank(Integer(5))
[0, 0, 2]
```

class sage.combinat.integer_vector.**IntegerVectors_nnondescents**(*n*, *comp*)

Bases: UniqueRepresentation, *IntegerVectors*

Integer vectors graded by two parameters.

The grading parameters on the integer vector v are:

- `n` – the sum of the parts of v
- `c` – the non descents composition of v

In other words: the length of v equals $c_1+\cdots+c_k$, and v is decreasing in the consecutive blocs of length $c_1, \ldots, c_k$,

INPUT:

- `n` – the positive integer n
- `comp` – the composition c

Those are the integer vectors of sum n that are lexicographically maximal (for the natural left-to-right reading) in their orbit by the Young subgroup $S_{c_1} \times \cdots \times S_{c_k}$. In particular, they form a set of orbit representative of integer vectors with respect to this Young subgroup.

sage.combinat.integer_vector.**gale_ryser_theorem**(*p1*, *p2*, *algorithm*, *solver*, *integrality_tolerance='gale'*)

Return the binary matrix given by the Gale-Ryser theorem.

The Gale Ryser theorem asserts that if p_1, p_2 are two partitions of n of respective lengths k_1, k_2, then there is a binary $k_1 \times k_2$ matrix M such that p_1 is the vector of row sums and p_2 is the vector of column sums of M, if and only if the conjugate of p_2 dominates p_1.

INPUT:

- `p1`, `p2` – list of integers representing the vectors of row/column sums
- `algorithm` – two possible string values:
  - `'ryser'` implements the construction due to Ryser [Ryser63].
  - `'gale'` (default) implements the construction due to Gale [Gale57].
- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

OUTPUT: a binary matrix if it exists, `None` otherwise

Gale's Algorithm:

(Gale [Gale57]): A matrix satisfying the constraints of its sums can be defined as the solution of the following Linear Program, which Sage knows how to solve.

$$\forall i \sum_{j=1}^{k_2} b_{i,j} = p_{1,j}$$

$$\forall i \sum_{j=1}^{k_1} b_{j,i} = p_{2,j}$$

$b_{i,j}$ is a binary variable

Ryser's Algorithm:

(Ryser [Ryser63]): The construction of an $m \times n$ matrix $A = A_{r,s}$, due to Ryser, is described as follows. The construction works if and only if have $s \preceq r^*$.

- Construct the $m \times n$ matrix B from r by defining the i-th row of B to be the vector whose first r_i entries are 1, and the remainder are 0s, $1 \leq i \leq m$. This maximal matrix B with row sum r and ones left justified has column sum r^*.
- Shift the last 1 in certain rows of B to column n in order to achieve the sum s_n. Call this B again.
  - The 1's in column n are to appear in those rows in which A has the largest row sums, giving preference to the bottom-most positions in case of ties.
  - Note: When this step automatically "fixes" other columns, one must skip ahead to the first column index with a wrong sum in the step below.
- Proceed inductively to construct columns $n-1$, ..., 2, 1. Note: when performing the induction on step k, we consider the row sums of the first k columns.
- Set $A = B$. Return A.

EXAMPLES:

Computing the matrix for $p_1 = p_2 = 2 + 2 + 1$:

```
sage: # needs sage.combinat sage.modules
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: p1 = [2,2,1]
sage: p2 = [2,2,1]
sage: print(gale_ryser_theorem(p1, p2))         # not tested
[1 1 0]
[1 0 1]
[0 1 0]
sage: A = gale_ryser_theorem(p1, p2)
sage: rs = [sum(x) for x in A.rows()]
sage: cs = [sum(x) for x in A.columns()]
sage: p1 == rs; p2 == cs
True
True
```

```
>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> from sage.combinat.integer_vector import gale_ryser_theorem
>>> p1 = [Integer(2),Integer(2),Integer(1)]
>>> p2 = [Integer(2),Integer(2),Integer(1)]
>>> print(gale_ryser_theorem(p1, p2))         # not tested
[1 1 0]
[1 0 1]
[0 1 0]
>>> A = gale_ryser_theorem(p1, p2)
>>> rs = [sum(x) for x in A.rows()]
>>> cs = [sum(x) for x in A.columns()]
>>> p1 == rs; p2 == cs
True
True
```

Or for a non-square matrix with $p_1 = 3 + 3 + 2 + 1$ and $p_2 = 3 + 2 + 2 + 1 + 1$, using Ryser's algorithm:

```
sage: # needs sage.combinat sage.modules
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: p1 = [3,3,1,1]
```

(continues on next page)

(continued from previous page)

```
sage: p2 = [3,3,1,1]
sage: gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 0]
[1 1 0 1]
[1 0 0 0]
[0 1 0 0]
sage: p1 = [4,2,2]
sage: p2 = [3,3,1,1]
sage: gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 1]
[1 1 0 0]
[1 1 0 0]
sage: p1 = [4,2,2,0]
sage: p2 = [3,3,1,1,0,0]
sage: gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 1 0 0]
[1 1 0 0 0 0]
[1 1 0 0 0 0]
[0 0 0 0 0 0]
sage: p1 = [3,3,2,1]
sage: p2 = [3,2,2,1,1]
sage: print(gale_ryser_theorem(p1, p2, algorithm='gale'))       # not tested
[1 1 1 0 0]
[1 1 0 0 1]
[1 0 1 0 0]
[0 0 0 1 0]
```

```
>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> from sage.combinat.integer_vector import gale_ryser_theorem
>>> p1 = [Integer(3),Integer(3),Integer(1),Integer(1)]
>>> p2 = [Integer(3),Integer(3),Integer(1),Integer(1)]
>>> gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 0]
[1 1 0 1]
[1 0 0 0]
[0 1 0 0]
>>> p1 = [Integer(4),Integer(2),Integer(2)]
>>> p2 = [Integer(3),Integer(3),Integer(1),Integer(1)]
>>> gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 1]
[1 1 0 0]
[1 1 0 0]
>>> p1 = [Integer(4),Integer(2),Integer(2),Integer(0)]
>>> p2 = [Integer(3),Integer(3),Integer(1),Integer(1),Integer(0),Integer(0)]
>>> gale_ryser_theorem(p1, p2, algorithm='ryser')
[1 1 1 1 0 0]
[1 1 0 0 0 0]
[1 1 0 0 0 0]
[0 0 0 0 0 0]
>>> p1 = [Integer(3),Integer(3),Integer(2),Integer(1)]
>>> p2 = [Integer(3),Integer(2),Integer(2),Integer(1),Integer(1)]
```

(continues on next page)

(continued from previous page)

```
>>> print(gale_ryser_theorem(p1, p2, algorithm='gale'))       # not tested
[1 1 1 0 0]
[1 1 0 0 1]
[1 0 1 0 0]
[0 0 0 1 0]
```

With 0 in the sequences, and with unordered inputs:

```
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: gale_ryser_theorem([3,3,0,1,1,0], [3,1,3,1,0], algorithm='ryser')          #␣

↪needs sage.combinat sage.modules
[1 1 1 0]
[1 0 0 0]
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
```

REFERENCES:

sage.combinat.integer_vector.**integer_vectors_nk_fast_iter**(n, k)

A fast iterator for integer vectors of `n` of length `k` which yields Python lists filled with Sage Integers.

EXAMPLES:

```
sage: from sage.combinat.integer_vector import integer_vectors_nk_fast_iter
sage: list(integer_vectors_nk_fast_iter(3, 2))
[[3, 0], [2, 1], [1, 2], [0, 3]]
sage: list(integer_vectors_nk_fast_iter(2, 2))
[[2, 0], [1, 1], [0, 2]]
sage: list(integer_vectors_nk_fast_iter(1, 2))
[[1, 0], [0, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_vector import integer_vectors_nk_fast_iter
>>> list(integer_vectors_nk_fast_iter(Integer(3), Integer(2)))
[[3, 0], [2, 1], [1, 2], [0, 3]]
>>> list(integer_vectors_nk_fast_iter(Integer(2), Integer(2)))
[[2, 0], [1, 1], [0, 2]]
>>> list(integer_vectors_nk_fast_iter(Integer(1), Integer(2)))
[[1, 0], [0, 1]]
```

We check some corner cases:

```
sage: list(integer_vectors_nk_fast_iter(5, 1))
[[5]]
sage: list(integer_vectors_nk_fast_iter(1, 1))
[[1]]
sage: list(integer_vectors_nk_fast_iter(2, 0))
[]
sage: list(integer_vectors_nk_fast_iter(0, 2))
[[0, 0]]
sage: list(integer_vectors_nk_fast_iter(0, 0))
[[]]
```

```
>>> from sage.all import *
>>> list(integer_vectors_nk_fast_iter(Integer(5), Integer(1)))
[[5]]
>>> list(integer_vectors_nk_fast_iter(Integer(1), Integer(1)))
[[1]]
>>> list(integer_vectors_nk_fast_iter(Integer(2), Integer(0)))
[]
>>> list(integer_vectors_nk_fast_iter(Integer(0), Integer(2)))
[[0, 0]]
>>> list(integer_vectors_nk_fast_iter(Integer(0), Integer(0)))
[[]]
```

sage.combinat.integer_vector.**is_gale_ryser**(r, s)

Test whether the given sequences satisfy the condition of the Gale-Ryser theorem.

Given a binary matrix B of dimension $n \times m$, the vector of row sums is defined as the vector whose i^{th} component is equal to the sum of the i^{th} row in A. The vector of column sums is defined similarly.

If, given a binary matrix, these two vectors are easy to compute, the Gale-Ryser theorem lets us decide whether, given two nonnegative vectors r, s, there exists a binary matrix whose row/column sums vectors are r and s.

This functions answers accordingly.

INPUT:

- r, s – lists of nonnegative integers

ALGORITHM:

Without loss of generality, we can assume that:

- The two given sequences do not contain any 0 (which would correspond to an empty column/row)
- The two given sequences are ordered in decreasing order (reordering the sequence of row (resp. column) sums amounts to reordering the rows (resp. columns) themselves in the matrix, which does not alter the columns (resp. rows) sums.

We can then assume that r and s are partitions (see the corresponding class *Partition*)

If r^* denote the conjugate of r, the Gale-Ryser theorem asserts that a binary Matrix satisfying the constraints exists if and only if $s \preceq r^*$, where $\preceq$ denotes the domination order on partitions.

EXAMPLES:

```
sage: from sage.combinat.integer_vector import is_gale_ryser
sage: is_gale_ryser([4,2,2], [3,3,1,1])                                    #␣
↪needs sage.combinat
True
sage: is_gale_ryser([4,2,1,1], [3,3,1,1])                                  #␣
↪needs sage.combinat
True
sage: is_gale_ryser([3,2,1,1], [3,3,1,1])                                  #␣
↪needs sage.combinat
False
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_vector import is_gale_ryser
>>> is_gale_ryser([Integer(4),Integer(2),Integer(2)], [Integer(3),Integer(3),
↪Integer(1),Integer(1)])                                    # needs sage.
↪combinat
True
>>> is_gale_ryser([Integer(4),Integer(2),Integer(1),Integer(1)], [Integer(3),
↪Integer(3),Integer(1),Integer(1)])                                      #␣
↪needs sage.combinat
True
>>> is_gale_ryser([Integer(3),Integer(2),Integer(1),Integer(1)], [Integer(3),
↪Integer(3),Integer(1),Integer(1)])                                      #␣
↪needs sage.combinat
False
```

REMARK: In the literature, what we are calling a Gale-Ryser sequence sometimes goes by the (rather generic-sounding) term "realizable sequence".

sage.combinat.integer_vector.**list2func**(*l*, *default=None*)

Given a list l, return a function that takes in a value i and return l[i]. If default is not None, then the function will return the default value for out of range i's.

EXAMPLES:

```
sage: f = sage.combinat.integer_vector.list2func([1,2,3])
sage: f(0)
1
sage: f(1)
```

(continues on next page)

(continued from previous page)

```
2
sage: f(2)
3
sage: f(3)
Traceback (most recent call last):
...
IndexError: list index out of range
```

```
>>> from sage.all import *
>>> f = sage.combinat.integer_vector.list2func([Integer(1),Integer(2),Integer(3)])
>>> f(Integer(0))
1
>>> f(Integer(1))
2
>>> f(Integer(2))
3
>>> f(Integer(3))
Traceback (most recent call last):
...
IndexError: list index out of range
```

```
sage: f = sage.combinat.integer_vector.list2func([1,2,3], 0)
sage: f(2)
3
sage: f(3)
0
```

```
>>> from sage.all import *
>>> f = sage.combinat.integer_vector.list2func([Integer(1),Integer(2),Integer(3)],
↪ Integer(0))
>>> f(Integer(2))
3
>>> f(Integer(3))
0
```

Ordered multiset partitions into sets and the minimaj crystal

This module provides element and parent classes for ordered multiset partitions. It also implements the minimaj crystal of Benkart et al. [BCHOPSY2017]. (See *MinimajCrystal*.)

REFERENCES:

- [BCHOPSY2017]
- [HRW2015]
- [HRS2016]
- [LM2018]

EXAMPLES:

An ordered multiset partition into sets of the multiset $\{\{1, 3, 3, 5\}\}$:

```
sage: OrderedMultisetPartitionIntoSets([[5, 3], [1, 3]])
[{3,5}, {1,3}]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(5), Integer(3)], [Integer(1),␣
↪Integer(3)]])
[{3,5}, {1,3}]
```

Ordered multiset partitions into sets of the multiset $\{\{1, 3, 3\}\}$:

```
sage: OrderedMultisetPartitionsIntoSets([1,1,3]).list()
[[{1}, {1}, {3}], [{1}, {1,3}], [{1}, {3}, {1}], [{1,3}, {1}], [{3}, {1}, {1}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(3)]).list()
[[{1}, {1}, {3}], [{1}, {1,3}], [{1}, {3}, {1}], [{1,3}, {1}], [{3}, {1}, {1}]]
```

Ordered multiset partitions into sets of the integer 4:

```
sage: OrderedMultisetPartitionsIntoSets(4).list()
[[{4}], [{1,3}], [{3}, {1}], [{1,2}, {1}], [{2}, {2}], [{2}, {1}, {1}],
 [{1}, {3}], [{1}, {1,2}], [{1}, {2}, {1}], [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(4)).list()
[[{4}], [{1,3}], [{3}, {1}], [{1,2}, {1}], [{2}, {2}], [{2}, {1}, {1}],
 [{1}, {3}], [{1}, {1,2}], [{1}, {2}, {1}], [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
```

Ordered multiset partitions into sets on the alphabet $\{1, 4\}$ of order 3:

```
sage: OrderedMultisetPartitionsIntoSets([1,4], 3).list()
[[{1,4}, {1}], [{1,4}, {4}], [{1}, {1,4}], [{4}, {1,4}], [{1}, {1}, {1}],
 [{1}, {1}, {4}], [{1}, {4}, {1}], [{1}, {4}, {4}], [{4}, {1}, {1}],
 [{4}, {1}, {4}], [{4}, {4}, {1}], [{4}, {4}, {4}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(4)], Integer(3)).list()
[[{1,4}, {1}], [{1,4}, {4}], [{1}, {1,4}], [{4}, {1,4}], [{1}, {1}, {1}],
 [{1}, {1}, {4}], [{1}, {4}, {1}], [{1}, {4}, {4}], [{4}, {1}, {1}],
 [{4}, {1}, {4}], [{4}, {4}, {1}], [{4}, {4}, {4}]]
```

Crystal of ordered multiset partitions into sets on the alphabet $\{1, 2, 3\}$ with 4 letters divided into 2 blocks:

```
sage: crystals.Minimaj(3, 4, 2).list()                                    #␣
↪needs sage.modules
[((2, 3, 1), (1,)), ((2, 3), (1, 2)), ((2, 3), (1, 3)), ((2, 1), (1, 2)),
 ((3, 1), (1, 2)), ((3, 1, 2), (2,)), ((3, 1), (1, 3)), ((3, 1), (2, 3)),
 ((3, 2), (2, 3)), ((2, 1), (1, 3)), ((2,), (1, 2, 3)), ((3,), (1, 2, 3)),
 ((1,), (1, 2, 3)), ((1, 2), (2, 3)), ((1, 2, 3), (3,))]
```

```
>>> from sage.all import *
>>> crystals.Minimaj(Integer(3), Integer(4), Integer(2)).list()              ␣
```

(continues on next page)

(continued from previous page)

```
↪                          # needs sage.modules
[((2, 3, 1), (1,)), ((2, 3), (1, 2)), ((2, 3), (1, 3)), ((2, 1), (1, 2)),
 ((3, 1), (1, 2)), ((3, 1, 2), (2,)), ((3, 1), (1, 3)), ((3, 1), (2, 3)),
 ((3, 2), (2, 3)), ((2, 1), (1, 3)), ((2,), (1, 2, 3)), ((3,), (1, 2, 3)),
 ((1,), (1, 2, 3)), ((1, 2), (2, 3)), ((1, 2, 3), (3,))]
```

AUTHORS:

- Aaron Lauve (2018): initial implementation. First draft of minimaj crystal code provided by Anne Schilling.

class sage.combinat.multiset_partition_into_sets_ordered.**MinimajCrystal**(*n*, *ell*, *k*)

Bases: UniqueRepresentation, Parent

Crystal of ordered multiset partitions into sets with ell letters from alphabet $\{1, 2, \ldots, n\}$ divided into k blocks.

Elements are represented in the minimaj ordering of blocks as in Benkart et al. [BCHOPSY2017].

Note

Elements are not stored internally as ordered multiset partitions into sets, but as certain (pairs of) words stemming from the minimaj bijection ϕ of [BCHOPSY2017]. See *sage.combinat.multiset_partition_into_sets_ordered.MinimajCrystal.Element* for further details.

AUTHORS:

- Anne Schilling (2018): initial draft
- Aaron Lauve (2018): changed to use Letters crystal for elements

EXAMPLES:

```
sage: list(crystals.Minimaj(2,3,2))                                             #␣
↪needs sage.modules
[((2, 1), (1,)), ((2,), (1, 2)), ((1,), (1, 2)), ((1, 2), (2,))]

sage: b = crystals.Minimaj(3, 5, 2).an_element(); b                             #␣
↪needs sage.modules
((2, 3, 1), (1, 2))
sage: b.f(2)                                                                    #␣
↪needs sage.modules
((2, 3, 1), (1, 3))
sage: b.e(2)                                                                    #␣
↪needs sage.modules
```

```
>>> from sage.all import *
>>> list(crystals.Minimaj(Integer(2),Integer(3),Integer(2)))                    ␣
↪                          # needs sage.modules
[((2, 1), (1,)), ((2,), (1, 2)), ((1,), (1, 2)), ((1, 2), (2,))]

>>> b = crystals.Minimaj(Integer(3), Integer(5), Integer(2)).an_element(); b    ␣
↪                          # needs sage.modules
((2, 3, 1), (1, 2))
>>> b.f(Integer(2))                                                            ␣
↪      # needs sage.modules
```

(continues on next page)

(continued from previous page)

```
((2, 3, 1), (1, 3))
>>> b.e(Integer(2))
↪     # needs sage.modules
```

class Element

Bases: `ElementWrapper`

An element of a Minimaj crystal.

Note

Minimaj elements b are stored internally as pairs `(w, breaks)`, where:

- `w` – a word of length `self.parent().ell` over the letters 1 up to `self.parent().n`;
- `breaks` is a list of de-concatenation points to turn `w` into a list of row words of (skew-)tableaux that represent b under the minimaj bijection ϕ of [BCHOPSY2017].

The pair `(w, breaks)` may be recovered via `b.value`.

e(i)

Return e_i on `self`.

EXAMPLES:

```
sage: B = crystals.Minimaj(4,3,2)
↪needs sage.modules
sage: b = B([[2,3], [3]]); b
↪needs sage.modules
((2, 3), (3,))
sage: [b.e(i) for i in range(1,4)]
↪needs sage.modules
[((1, 3), (3,)), ((2,), (2, 3)), None]
```

```
>>> from sage.all import *
>>> B = crystals.Minimaj(Integer(4),Integer(3),Integer(2))
↪                    # needs sage.modules
>>> b = B([[Integer(2),Integer(3)], [Integer(3)]]); b
↪                    # needs sage.modules
((2, 3), (3,))
>>> [b.e(i) for i in range(Integer(1),Integer(4))]
↪              # needs sage.modules
[((1, 3), (3,)), ((2,), (2, 3)), None]
```

f(i)

Return f_i on `self`.

EXAMPLES:

```
sage: B = crystals.Minimaj(4,3,2)
↪needs sage.modules
sage: b = B([[2,3], [3]]); b
↪needs sage.modules
```

(continues on next page)

(continued from previous page)

```
((2, 3), (3,))
sage: [b.f(i) for i in range(1,4)]                                          #␣
↪needs sage.modules
[None, None, ((2, 3), (4,))]
```

```
>>> from sage.all import *
>>> B = crystals.Minimaj(Integer(4),Integer(3),Integer(2))                  ␣
↪                        # needs sage.modules
>>> b = B([[Integer(2),Integer(3)], [Integer(3)]]); b                       ␣
↪                        # needs sage.modules
((2, 3), (3,))
>>> [b.f(i) for i in range(Integer(1),Integer(4))]                          ␣
↪              # needs sage.modules
[None, None, ((2, 3), (4,))]
```

to_tableaux_words()

Return the image of the ordered multiset partition into sets `self` under the minimaj bijection ϕ of [BCHOPSY2017].

EXAMPLES:

```
sage: # needs sage.modules
sage: B = crystals.Minimaj(4,5,3)
sage: b = B.an_element(); b
((2, 3, 1), (1,), (1,))
sage: b.to_tableaux_words()
[[1], [3], [2, 1, 1]]
sage: b = B([[1,3,4], [3], [3]]); b
((4, 1, 3), (3,), (3,))
sage: b.to_tableaux_words()
[[3, 1], [], [4, 3, 3]]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> B = crystals.Minimaj(Integer(4),Integer(5),Integer(3))
>>> b = B.an_element(); b
((2, 3, 1), (1,), (1,))
>>> b.to_tableaux_words()
[[1], [3], [2, 1, 1]]
>>> b = B([[Integer(1),Integer(3),Integer(4)], [Integer(3)],␣
↪[Integer(3)]]); b
((4, 1, 3), (3,), (3,))
>>> b.to_tableaux_words()
[[3, 1], [], [4, 3, 3]]
```

from_tableau(*t*)

Return the bijection ϕ^{-1} of [BCHOPSY2017] applied to `t`.

INPUT:

- `t` – a sequence of column tableaux and a ribbon tableau

EXAMPLES:

```
sage: # needs sage.modules
sage: B = crystals.Minimaj(3,6,3)
sage: b = B.an_element(); b
((3, 1, 2), (2, 1), (1,))
sage: t = b.to_tableaux_words(); t
[[1], [2, 1], [], [3, 2, 1]]
sage: B.from_tableau(t)
((3, 1, 2), (2, 1), (1,))
sage: B.from_tableau(t) == b
True
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> B = crystals.Minimaj(Integer(3),Integer(6),Integer(3))
>>> b = B.an_element(); b
((3, 1, 2), (2, 1), (1,))
>>> t = b.to_tableaux_words(); t
[[1], [2, 1], [], [3, 2, 1]]
>>> B.from_tableau(t)
((3, 1, 2), (2, 1), (1,))
>>> B.from_tableau(t) == b
True
```

val(*q='q'*)

Return the Val polynomial corresponding to `self`.

EXAMPLES:

Verifying Example 4.5 from [BCHOPSY2017]:

```
sage: B = crystals.Minimaj(3, 4, 2)  # for `Val_{4,1}^{(3)}`                #␣
↪needs sage.modules
sage: B.val()                                                               #␣
↪needs sage.modules
(q^2+q+1)*s[2, 1, 1] + q*s[2, 2]
```

```
>>> from sage.all import *
>>> B = crystals.Minimaj(Integer(3), Integer(4), Integer(2))  # for `Val_{4,1}
↪^{(3)}`                # needs sage.modules
>>> B.val()                                                                 #␣
↪needs sage.modules
(q^2+q+1)*s[2, 1, 1] + q*s[2, 2]
```

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionIntoSets**(*parent*, *data*)

Bases: `ClonableArray`

Ordered Multiset Partition into sets.

An *ordered multiset partition into sets* c of a multiset X is a list $[c_1, \ldots, c_r]$ of nonempty subsets of X (note: not sub-multisets), called the *blocks* of c, whose multi-union is X.

EXAMPLES:

The simplest way to create an ordered multiset partition into sets is by specifying its blocks as a list or tuple:

```
sage: OrderedMultisetPartitionIntoSets([[3],[2,1]])
[{3}, {1,2}]
sage: OrderedMultisetPartitionIntoSets(((3,), (1,2)))
[{3}, {1,2}]
sage: OrderedMultisetPartitionIntoSets([set([i]) for i in range(2,5)])
[{2}, {3}, {4}]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(3)],[Integer(2),Integer(1)]])
[{3}, {1,2}]
>>> OrderedMultisetPartitionIntoSets(((Integer(3),), (Integer(1),Integer(2))))
[{3}, {1,2}]
>>> OrderedMultisetPartitionIntoSets([set([i]) for i in range(Integer(2),
↪Integer(5))])
[{2}, {3}, {4}]
```

REFERENCES:

- [HRW2015]
- [HRS2016]
- [LM2018]

check()

Check that we are a valid ordered multiset partition into sets.

EXAMPLES:

```
sage: c = OrderedMultisetPartitionsIntoSets(4)([[1], [1,2]])
sage: c.check()

sage: OMPs = OrderedMultisetPartitionsIntoSets()
sage: c = OMPs([[1], [1], ['a']])
sage: c.check()
```

```
>>> from sage.all import *
>>> c = OrderedMultisetPartitionsIntoSets(Integer(4))([[Integer(1)],␣
↪[Integer(1),Integer(2)]])
>>> c.check()

>>> OMPs = OrderedMultisetPartitionsIntoSets()
>>> c = OMPs([[Integer(1)], [Integer(1)], ['a']])
>>> c.check()
```

deconcatenate(*k=2*)

Return the list of k-deconcatenations of `self`.

A k-tuple $(C_1, \ldots, C_k)$ of ordered multiset partitions into sets represents a k-deconcatenation of an ordered multiset partition into sets C if $C_1 + \cdots + C_k = C$.

> **Note**
>
> This is not to be confused with `self.split_blocks()`, which splits each block of `self` before making k-tuples of ordered multiset partitions into sets.

EXAMPLES:

```
sage: OrderedMultisetPartitionIntoSets([[7,1],[3,4,5]]).deconcatenate()
[([{1,7}, {3,4,5}], []), ([{1,7}], [{3,4,5}]), ([], [{1,7}, {3,4,5}])]
sage: OrderedMultisetPartitionIntoSets([['b','c'],['a']]).deconcatenate()
[([{'b','c'}, {'a'}], []), ([{'b','c'}], [{'a'}]), ([], [{'b','c'}, {'a'}])]
sage: OrderedMultisetPartitionIntoSets([['a','b','c']]).deconcatenate(3)
[([{'a','b','c'}], [], []),
 ([], [{'a','b','c'}], []),
 ([], [], [{'a','b','c'}])]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(7),Integer(1)],[Integer(3),
↪Integer(4),Integer(5)]]).deconcatenate()
[([{1,7}, {3,4,5}], []), ([{1,7}], [{3,4,5}]), ([], [{1,7}, {3,4,5}])]
>>> OrderedMultisetPartitionIntoSets([['b','c'],['a']]).deconcatenate()
[([{'b','c'}, {'a'}], []), ([{'b','c'}], [{'a'}]), ([], [{'b','c'}, {'a'}])]
>>> OrderedMultisetPartitionIntoSets([['a','b','c']]).
↪deconcatenate(Integer(3))
[([{'a','b','c'}], [], []),
 ([], [{'a','b','c'}], []),
 ([], [], [{'a','b','c'}])]
```

fatten(*grouping*)

Return the ordered multiset partition into sets fatter than `self`, obtained by grouping together consecutive parts according to `grouping` (whenever this does not violate the strictness condition).

INPUT:

- `grouping` – a composition (or list) whose sum is the length of `self`

EXAMPLES:

Let us start with the composition:

```
sage: C = OrderedMultisetPartitionIntoSets([[4,1,5], [2], [7,1]]); C
[{1,4,5}, {2}, {1,7}]
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(4),Integer(1),Integer(5)],␣
↪[Integer(2)], [Integer(7),Integer(1)]]); C
[{1,4,5}, {2}, {1,7}]
```

With `grouping` equal to $(1, 1, 1)$, C is left unchanged:

```
sage: C.fatten([1,1,1])
[{1,4,5}, {2}, {1,7}]
```

```
>>> from sage.all import *
>>> C.fatten([Integer(1),Integer(1),Integer(1)])
[{1,4,5}, {2}, {1,7}]
```

With `grouping` equal to $(2, 1)$ or $(1, 2)$, a union of consecutive parts is achieved:

```
sage: C.fatten([2,1])
[{1,2,4,5}, {1,7}]
sage: C.fatten([1,2])
[{1,4,5}, {1,2,7}]
```

```
>>> from sage.all import *
>>> C.fatten([Integer(2),Integer(1)])
[{1,2,4,5}, {1,7}]
>>> C.fatten([Integer(1),Integer(2)])
[{1,4,5}, {1,2,7}]
```

However, the `grouping` (3) will throw an error, as 1 cannot appear twice in any block of `C`:

```
sage: C.fatten(Composition([3]))
Traceback (most recent call last):
...
ValueError: [{1,4,5,2,1,7}] is not a valid ordered multiset partition into␣
↪sets
```

```
>>> from sage.all import *
>>> C.fatten(Composition([Integer(3)]))
Traceback (most recent call last):
...
ValueError: [{1,4,5,2,1,7}] is not a valid ordered multiset partition into␣
↪sets
```

fatter()

Return the set of ordered multiset partitions into sets which are fatter than `self`.

An ordered multiset partition into sets A is fatter than another B if, reading left-to-right, every block of A is the union of some consecutive blocks of B.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([{1,4,5}, {2}, {1,7}]).fatter()
sage: len(C)
3
sage: sorted(C)
[[{1,4,5}, {2}, {1,7}], [{1,4,5}, {1,2,7}], [{1,2,4,5}, {1,7}]]
sage: sorted(OrderedMultisetPartitionIntoSets([['a','b'],['c'],['a']]).
↪fatter())
[[{'a','b'}, {'c'}, {'a'}], [{'a','b'}, {'a','c'}], [{'a','b','c'}, {'a'}]]
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([{Integer(1),Integer(4),Integer(5)},
↪{Integer(2)}, {Integer(1),Integer(7)}]).fatter()
>>> len(C)
```

(continues on next page)

(continued from previous page)

```
3
>>> sorted(C)
[[{1,4,5}, {2}, {1,7}], [{1,4,5}, {1,2,7}], [{1,2,4,5}, {1,7}]]
>>> sorted(OrderedMultisetPartitionIntoSets([['a','b'],['c'],['a']]).fatter())
[[{'a','b'}, {'c'}, {'a'}], [{'a','b'}, {'a','c'}], [{'a','b','c'}, {'a'}]]
```

Some extreme cases:

```
sage: list(OrderedMultisetPartitionIntoSets([['a','b','c']]).fatter())
[[{'a','b','c'}]]
sage: list(OrderedMultisetPartitionIntoSets([]).fatter())
[[]]
sage: A = OrderedMultisetPartitionIntoSets([[1], [2], [3], [4]])
sage: B = OrderedMultisetPartitionIntoSets([[1,2,3,4]])
sage: A.fatter().issubset(B.finer())
True
```

```
>>> from sage.all import *
>>> list(OrderedMultisetPartitionIntoSets([['a','b','c']]).fatter())
[[{'a','b','c'}]]
>>> list(OrderedMultisetPartitionIntoSets([]).fatter())
[[]]
>>> A = OrderedMultisetPartitionIntoSets([[Integer(1)], [Integer(2)],␣
↪[Integer(3)], [Integer(4)]])
>>> B = OrderedMultisetPartitionIntoSets([[Integer(1),Integer(2),Integer(3),
↪Integer(4)]])
>>> A.fatter().issubset(B.finer())
True
```

finer(*strong=False*)

Return the set of ordered multiset partitions into sets that are finer than `self`.

An ordered multiset partition into sets A is finer than another B if, reading left-to-right, every block of B is the union of some consecutive blocks of A.

If optional argument `strong` is set to `True`, then return only those A whose blocks are deconcatenations of blocks of B. (Here, we view blocks of B as sorted lists instead of sets.)

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3,2]]).finer()
sage: len(C)
3
sage: sorted(C, key=str)
[[{2,3}], [{2}, {3}], [{3}, {2}]]
sage: OrderedMultisetPartitionIntoSets([]).finer()
{[]}
sage: O = OrderedMultisetPartitionsIntoSets([1, 1, 'a', 'b'])
sage: o = O([{1}, {'a', 'b'}, {1}])
sage: sorted(o.finer(), key=str)
[[{1}, {'a','b'}, {1}], [{1}, {'a'}, {'b'}, {1}], [{1}, {'b'}, {'a'}, {1}]]
sage: o.finer() & o.fatter() == set([o])
True
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3),Integer(2)]]).finer()
>>> len(C)
3
>>> sorted(C, key=str)
[[{2,3}], [{2}, {3}], [{3}, {2}]]
>>> OrderedMultisetPartitionIntoSets([]).finer()
{[]}
>>> O = OrderedMultisetPartitionsIntoSets([Integer(1), Integer(1), 'a', 'b'])
>>> o = O([{Integer(1)}, {'a', 'b'}, {Integer(1)}])
>>> sorted(o.finer(), key=str)
[[{1}, {'a','b'}, {1}], [{1}, {'a'}, {'b'}, {1}], [{1}, {'b'}, {'a'}, {1}]]
>>> o.finer() & o.fatter() == set([o])
True
```

is_finer(*co*)

Return `True` if the ordered multiset partition into sets `self` is finer than the composition `co`; otherwise, return `False`.

EXAMPLES:

```
sage: OrderedMultisetPartitionIntoSets([[4],[1],[2]]).is_finer([[1,4],[2]])
True
sage: OrderedMultisetPartitionIntoSets([[1],[4],[2]]).is_finer([[1,4],[2]])
True
sage: OrderedMultisetPartitionIntoSets([[1,4],[1],[1]]).is_finer([[1,4],[2]])
False
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(4)],[Integer(1)],
↪[Integer(2)]]).is_finer([[Integer(1),Integer(4)],[Integer(2)]])
True
>>> OrderedMultisetPartitionIntoSets([[Integer(1)],[Integer(4)],
↪[Integer(2)]]).is_finer([[Integer(1),Integer(4)],[Integer(2)]])
True
>>> OrderedMultisetPartitionIntoSets([[Integer(1),Integer(4)],[Integer(1)],
↪[Integer(1)]]).is_finer([[Integer(1),Integer(4)],[Integer(2)]])
False
```

length()

Return the number of blocks of `self`.

EXAMPLES:

```
sage: OrderedMultisetPartitionIntoSets([[7,1],[3]]).length()
2
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(7),Integer(1)],[Integer(3)]]).
↪length()
2
```

letters()

Return the set of distinct elements occurring within the blocks of `self`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[{1,3,4}, {2}, {1,2,3,7}]
sage: C.letters()
frozenset({1, 2, 3, 4, 7})
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4),␣
↪Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3),␣
↪Integer(7)]]); C
[{1,3,4}, {2}, {1,2,3,7}]
>>> C.letters()
frozenset({1, 2, 3, 4, 7})
```

major_index()

Return the major index of `self`.

The major index is a statistic on ordered multiset partitions into sets, which we define here via an example.

1. Sort each block in the list `self` in descending order to create a word w, keeping track of the original separation into blocks:

```
in:  [{3,4,5}, {2,3,4}, {1}, {4,5}]
out: [ 5,4,3 /  4,3,2 /  1 /  5,4 ]
```

2. Create a sequence $v = (v_0, v_1, v_2, \ldots)$ of length `self.order()+1`, built recursively by:
   1. $v_0 = 0$
   2. $v_j = v_{j-1} + \delta(j)$, where $\delta(j) = 1$ if j is the index of an end of a block, and zero otherwise.

```
in:    [ 5,4,3 /  4,3,2 /  1 /  5,4]
out: (0, 0,0,1,   1,1,2,   3,   3,4)
```

3. Compute $\sum_j v_j$, restricted to descent positions in w, i.e., sum over those j with $w_j > w_{j+1}$:

```
in:  w:   [5, 4, 3, 4, 3, 2, 1, 5, 4]
     v: (0 0, 0, 1, 1, 1, 2, 3, 3, 4)
maj :=     0 +0    +1 +1 +2    +3     = 7
```

REFERENCES:

- [HRW2015]

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([{1,5,7}, {2,4}, {5,6}, {4,6,8},
↪{1,3}, {1,2,3}])
sage: C.major_index()
27
sage: C = OrderedMultisetPartitionIntoSets([{3,4,5}, {2,3,4}, {1}, {4,5}])
sage: C.major_index()
7
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([{Integer(1),Integer(5),Integer(7)},
↪{Integer(2),Integer(4)}, {Integer(5),Integer(6)}, {Integer(4),Integer(6),
↪Integer(8)}, {Integer(1),Integer(3)}, {Integer(1),Integer(2),Integer(3)}])
>>> C.major_index()
27
>>> C = OrderedMultisetPartitionIntoSets([{Integer(3),Integer(4),Integer(5)},
↪{Integer(2),Integer(3),Integer(4)}, {Integer(1)}, {Integer(4),Integer(5)}])
>>> C.major_index()
7
```

max_letter()

Return the maximum letter appearing in `self.letters()` of `self`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]])
sage: C.max_letter()
7
sage: D = OrderedMultisetPartitionIntoSets([['a','b','c'],['a','b'],['a'],['b
↪','c','f'],['c','d']])
sage: D.max_letter()
'f'
sage: C = OrderedMultisetPartitionIntoSets([])
sage: C.max_letter()
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4),␣
↪Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3),␣
↪Integer(7)]])
>>> C.max_letter()
7
>>> D = OrderedMultisetPartitionIntoSets([['a','b','c'],['a','b'],['a'],['b',
↪'c','f'],['c','d']])
>>> D.max_letter()
'f'
>>> C = OrderedMultisetPartitionIntoSets([])
>>> C.max_letter()
```

minimaj()

Return the minimaj statistic on ordered multiset partitions into sets.

We define $minimaj$ via an example:

1. Sort the block in `self` as prescribed by `self.minimaj_word()`, keeping track of the original separation into blocks:

```
in:   [{1,5,7}, {2,4}, {5,6}, {4,6,8}, {1,3}, {1,2,3}]
out:  ( 5,7,1 /  2,4 /  5,6 /  4,6,8 /  3,1 /  1,2,3 )
```

2. Record the indices where descents in this word occur:

```
word:       (5, 7, 1 / 2, 4 / 5, 6 / 4, 6, 8 / 3, 1 / 1, 2, 3)
indices:     1  2  3   4  5   6  7   8  9 10  11 12  13 14 15
```

(continues on next page)

(continued from previous page)

```
descents:  {   2,              7,       10, 11            }
```

3. Compute the sum of the descents:

```
minimaj = 2 + 7 + 10 + 11 = 30
```

minimaj_blocks()

Return the minimaj ordering on blocks of `self`.

We define the ordering via the example below.

Sort the blocks $[B_1, ..., B_k]$ of `self` from right to left via:

1. Sort the last block B_k in increasing order, call it the word W_k
2. If blocks $B_{i+1}, \ldots, B_k$ have been converted to words $W_{i+1}, \ldots, W_k$, use the letters in B_i to make the unique word W_i that has a factorization $W_i = (u, v)$ satisfying:
   - letters of u and v appear in increasing order, with v possibly empty;
   - letters in vu appear in increasing order;
   - `v[-1]` is the largest letter $a \in B_i$ satisfying `a <= W_{i+1}[0]`.

EXAMPLES:

```
sage: OrderedMultisetPartitionIntoSets([[1,5,7], [2,4], [5,6], [4,6,8], [1,3],
↪ [1,2,3]])
[{1,5,7}, {2,4}, {5,6}, {4,6,8}, {1,3}, {1,2,3}]
sage: _.minimaj_blocks()
((5, 7, 1), (2, 4), (5, 6), (4, 6, 8), (3, 1), (1, 2, 3))
sage: OrderedMultisetPartitionIntoSets([]).minimaj_blocks()
()
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(1),Integer(5),Integer(7)],␣
↪[Integer(2),Integer(4)], [Integer(5),Integer(6)], [Integer(4),Integer(6),
↪Integer(8)], [Integer(1),Integer(3)], [Integer(1),Integer(2),Integer(3)]])
[{1,5,7}, {2,4}, {5,6}, {4,6,8}, {1,3}, {1,2,3}]
>>> _.minimaj_blocks()
((5, 7, 1), (2, 4), (5, 6), (4, 6, 8), (3, 1), (1, 2, 3))
>>> OrderedMultisetPartitionIntoSets([]).minimaj_blocks()
()
```

minimaj_word()

Return an ordering of `self._multiset` derived from the minimaj ordering on blocks of `self`.

See also

OrderedMultisetPartitionIntoSets.minimaj_blocks().

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[2,1], [1,2,3], [1,2], [3], [1]]);
↪ C
[{1,2}, {1,2,3}, {1,2}, {3}, {1}]
sage: C.minimaj_blocks()
((1, 2), (2, 3, 1), (1, 2), (3,), (1,))
```

(continues on next page)

(continued from previous page)

```
sage: C.minimaj_word()
(1, 2, 2, 3, 1, 1, 2, 3, 1)
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(2),Integer(1)],␣
↪[Integer(1),Integer(2),Integer(3)], [Integer(1),Integer(2)], [Integer(3)],␣
↪[Integer(1)]]); C
[{1,2}, {1,2,3}, {1,2}, {3}, {1}]
>>> C.minimaj_blocks()
((1, 2), (2, 3, 1), (1, 2), (3,), (1,))
>>> C.minimaj_word()
(1, 2, 2, 3, 1, 1, 2, 3, 1)
```

multiset(*as_dict=False*)

Return the multiset corresponding to `self`.

INPUT:

- `as_dict` – boolean (default: `False`); whether to return the multiset as a tuple of a dict of multiplicities

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[{1,3,4}, {2}, {1,2,3,7}]
sage: C.multiset()
(1, 1, 2, 2, 3, 3, 4, 7)
sage: C.multiset(as_dict=True)
{1: 2, 2: 2, 3: 2, 4: 1, 7: 1}
sage: OrderedMultisetPartitionIntoSets([]).multiset() == ()
True
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4),␣
↪Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3),␣
↪Integer(7)]]); C
[{1,3,4}, {2}, {1,2,3,7}]
>>> C.multiset()
(1, 1, 2, 2, 3, 3, 4, 7)
>>> C.multiset(as_dict=True)
{1: 2, 2: 2, 3: 2, 4: 1, 7: 1}
>>> OrderedMultisetPartitionIntoSets([]).multiset() == ()
True
```

order()

Return the total number of elements in all blocks of `self`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[{1,3,4}, {2}, {1,2,3,7}]
sage: C.order()
8
sage: C.order() == sum(C.weight().values())
```

(continues on next page)

(continued from previous page)

```
True
sage: C.order() == sum(k for k in C.shape_from_cardinality())
True
sage: OrderedMultisetPartitionIntoSets([[7,1],[3]]).order()
3
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4),␣
↪Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3),␣
↪Integer(7)]]); C
[{1,3,4}, {2}, {1,2,3,7}]
>>> C.order()
8
>>> C.order() == sum(C.weight().values())
True
>>> C.order() == sum(k for k in C.shape_from_cardinality())
True
>>> OrderedMultisetPartitionIntoSets([[Integer(7),Integer(1)],[Integer(3)]]).
↪order()
3
```

reversal()

Return the reverse ordered multiset partition into sets of `self`.

Given an ordered multiset partition into sets $(B_1, B_2, \ldots, B_k)$, its reversal is defined to be the ordered multiset partition into sets $(B_k, \ldots, B_2, B_1)$.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[1], [1, 3], [2, 3, 4]]); C
[{1}, {1,3}, {2,3,4}]
sage: C.reversal()
[{2,3,4}, {1,3}, {1}]
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(1)], [Integer(1),␣
↪Integer(3)], [Integer(2), Integer(3), Integer(4)]]); C
[{1}, {1,3}, {2,3,4}]
>>> C.reversal()
[{2,3,4}, {1,3}, {1}]
```

shape_from_cardinality()

Return a composition that records the cardinality of each block of `self`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[{1,3,4}, {2}, {1,2,3,7}]
sage: C.shape_from_cardinality()
[3, 1, 4]
sage: OrderedMultisetPartitionIntoSets([]).shape_from_cardinality() ==␣
↪Composition([])
True
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4),␣
↪Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3),␣
↪Integer(7)]]); C
[{1,3,4}, {2}, {1,2,3,7}]
>>> C.shape_from_cardinality()
[3, 1, 4]
>>> OrderedMultisetPartitionIntoSets([]).shape_from_cardinality() ==␣
↪Composition([])
True
```

shape_from_size()

Return a composition that records the sum of entries of each block of `self`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[{1,3,4}, {2}, {1,2,3,7}]
sage: C.shape_from_size()
[8, 2, 13]
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4),␣
↪Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3),␣
↪Integer(7)]]); C
[{1,3,4}, {2}, {1,2,3,7}]
>>> C.shape_from_size()
[8, 2, 13]
```

shuffle_product(*other*, *overlap=False*)

Return the shuffles (with multiplicity) of blocks of `self` with blocks of `other`.

In case optional argument `overlap` is `True`, instead return the allowable overlapping shuffles. An overlapping shuffle C is allowable if, whenever one of its blocks c comes from the union $c = a \cup b$ of a block of `self` and a block of `other`, then this union is disjoint.

See also

Composition.shuffle_product()

EXAMPLES:

```
sage: A = OrderedMultisetPartitionIntoSets([[2,1,3], [1,2]]); A
[{1,2,3}, {1,2}]
sage: B = OrderedMultisetPartitionIntoSets([[3,4]]); B
[{3,4}]
sage: C = OrderedMultisetPartitionIntoSets([[4,5]]); C
[{4,5}]
sage: list(A.shuffle_product(B))
[[{1,2,3}, {1,2}, {3,4}], [{3,4}, {1,2,3}, {1,2}], [{1,2,3}, {3,4}, {1,2}]]
sage: list(A.shuffle_product(B, overlap=True))
[[{1,2,3}, {1,2}, {3,4}], [{1,2,3}, {3,4}, {1,2}],
```

(continues on next page)

(continued from previous page)

```
 [{3,4}, {1,2,3}, {1,2}], [{1,2,3}, {1,2,3,4}]]
sage: list(A.shuffle_product(C, overlap=True))
[[{1,2,3}, {1,2}, {4,5}], [{1,2,3}, {4,5}, {1,2}], [{4,5}, {1,2,3}, {1,2}],
 [{1,2,3,4,5}, {1,2}], [{1,2,3}, {1,2,4,5}]]
```

```
>>> from sage.all import *
>>> A = OrderedMultisetPartitionIntoSets([[Integer(2),Integer(1),Integer(3)],␣
↪[Integer(1),Integer(2)]]); A
[{1,2,3}, {1,2}]
>>> B = OrderedMultisetPartitionIntoSets([[Integer(3),Integer(4)]]); B
[{3,4}]
>>> C = OrderedMultisetPartitionIntoSets([[Integer(4),Integer(5)]]); C
[{4,5}]
>>> list(A.shuffle_product(B))
[[{1,2,3}, {1,2}, {3,4}], [{3,4}, {1,2,3}, {1,2}], [{1,2,3}, {3,4}, {1,2}]]
>>> list(A.shuffle_product(B, overlap=True))
[[{1,2,3}, {1,2}, {3,4}], [{1,2,3}, {3,4}, {1,2}],
 [{3,4}, {1,2,3}, {1,2}], [{1,2,3}, {1,2,3,4}]]
>>> list(A.shuffle_product(C, overlap=True))
[[{1,2,3}, {1,2}, {4,5}], [{1,2,3}, {4,5}, {1,2}], [{4,5}, {1,2,3}, {1,2}],
 [{1,2,3,4,5}, {1,2}], [{1,2,3}, {1,2,4,5}]]
```

size()

Return the size of `self` (that is, the sum of all integers in all blocks) if `self` is a list of subsets of positive integers.

Else, return `None`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[{1,3,4}, {2}, {1,2,3,7}]
sage: C.size()
23
sage: C.size() == sum(k for k in C.shape_from_size())
True
sage: OrderedMultisetPartitionIntoSets([[7,1],[3]]).size()
11
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4),␣
↪Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3),␣
↪Integer(7)]]); C
[{1,3,4}, {2}, {1,2,3,7}]
>>> C.size()
23
>>> C.size() == sum(k for k in C.shape_from_size())
True
>>> OrderedMultisetPartitionIntoSets([[Integer(7),Integer(1)],[Integer(3)]]).
↪size()
11
```

split_blocks(*k=2*)

Return a dictionary representing the k-splittings of `self`.

A k-tuple $(A^1, \ldots, A^k)$ of ordered multiset partitions into sets represents a k-splitting of an ordered multiset partition into sets $A = [b_1, \ldots, b_r]$ if one can express each block b_i as an (ordered) disjoint union of sets $b_i = b_i^1 \sqcup \cdots \sqcup b_i^k$ (some possibly empty) so that each A^j is the ordered multiset partition into sets corresponding to the list $[b_1^j, b_2^j, \ldots, b_r^j]$, excising empty sets appearing therein.

This operation represents the coproduct in Hopf algebra of ordered multiset partitions into sets in its natural basis [LM2018].

EXAMPLES:

```
sage: sorted(OrderedMultisetPartitionIntoSets([[1,2],[3,4]]).split_blocks(),␣
↪key=str)
[([], [{1,2}, {3,4}]),
 ([{1,2}, {3,4}], []),
 ([{1,2}, {3}], [{4}]),
 ([{1,2}, {4}], [{3}]),
 ([{1,2}], [{3,4}]),
 ([{1}, {3,4}], [{2}]),
 ([{1}, {3}], [{2}, {4}]),
 ([{1}, {4}], [{2}, {3}]),
 ([{1}], [{2}, {3,4}]),
 ([{2}, {3,4}], [{1}]),
 ([{2}, {3}], [{1}, {4}]),
 ([{2}, {4}], [{1}, {3}]),
 ([{2}], [{1}, {3,4}]),
 ([{3,4}], [{1,2}]),
 ([{3}], [{1,2}, {4}]),
 ([{4}], [{1,2}, {3}])]
sage: sorted(OrderedMultisetPartitionIntoSets([[1,2]]).split_blocks(3),␣
↪key=str)
[([], [], [{1,2}]), ([], [{1,2}], []), ([], [{1}], [{2}]),
 ([], [{2}], [{1}]), ([{1,2}], [], []), ([{1}], [], [{2}]),
 ([{1}], [{2}], []), ([{2}], [], [{1}]), ([{2}], [{1}], [])]
sage: OrderedMultisetPartitionIntoSets([[4],[4]]).split_blocks()
{([], [{4}, {4}]): 1, ([{4}], [{4}]): 2, ([{4}, {4}], []): 1}
```

```
>>> from sage.all import *
>>> sorted(OrderedMultisetPartitionIntoSets([[Integer(1),Integer(2)],
↪[Integer(3),Integer(4)]]).split_blocks(), key=str)
[([], [{1,2}, {3,4}]),
 ([{1,2}, {3,4}], []),
 ([{1,2}, {3}], [{4}]),
 ([{1,2}, {4}], [{3}]),
 ([{1,2}], [{3,4}]),
 ([{1}, {3,4}], [{2}]),
 ([{1}, {3}], [{2}, {4}]),
 ([{1}, {4}], [{2}, {3}]),
 ([{1}], [{2}, {3,4}]),
 ([{2}, {3,4}], [{1}]),
 ([{2}, {3}], [{1}, {4}]),
 ([{2}, {4}], [{1}, {3}]),
 ([{2}], [{1}, {3,4}]),
```

(continues on next page)

(continued from previous page)

```
 ([{3,4}], [{1,2}]),
 ([{3}], [{1,2}, {4}]),
 ([{4}], [{1,2}, {3}])]
>>> sorted(OrderedMultisetPartitionIntoSets([[Integer(1),Integer(2)]]).split_
↪blocks(Integer(3)), key=str)
[([], [], [{1,2}]), ([], [{1,2}], []), ([], [{1}], [{2}]),
 ([], [{2}], [{1}]), ([{1,2}], [], []), ([{1}], [], [{2}]),
 ([{1}], [{2}], []), ([{2}], [], [{1}]), ([{2}], [{1}], [])]
>>> OrderedMultisetPartitionIntoSets([[Integer(4)],[Integer(4)]]).split_
↪blocks()
{([], [{4}, {4}]): 1, ([{4}], [{4}]): 2, ([{4}, {4}], []): 1}
```

to_tableaux_words()

Return a sequence of lists corresponding to row words of (skew-)tableaux.

OUTPUT:

The minimaj bijection ϕ of [BCHOPSY2017] applied to `self`.

Todo

Implement option for mapping to sequence of (skew-)tableaux?

EXAMPLES:

```
sage: co = ((1,2,4),(4,5),(3,),(4,6,1),(2,3,1),(1,),(2,5))
sage: OrderedMultisetPartitionIntoSets(co).to_tableaux_words()
[[5, 1], [3, 1], [6], [5, 4, 2], [1, 4, 3, 4, 2, 1, 2]]
```

```
>>> from sage.all import *
>>> co = ((Integer(1),Integer(2),Integer(4)),(Integer(4),Integer(5)),
↪(Integer(3),),(Integer(4),Integer(6),Integer(1)),(Integer(2),Integer(3),
↪Integer(1)),(Integer(1),),(Integer(2),Integer(5)))
>>> OrderedMultisetPartitionIntoSets(co).to_tableaux_words()
[[5, 1], [3, 1], [6], [5, 4, 2], [1, 4, 3, 4, 2, 1, 2]]
```

weight(*as_weak_comp=False*)

Return a dictionary, with keys being the letters in `self.letters()` and values being their (positive) frequency.

Alternatively, if `as_weak_comp` is `True`, count the number of instances n_i for each distinct positive integer i across all blocks of `self`. Return as a list $[n_1, n_2, n_3, ..., n_k]$, where k is the max letter appearing in `self.letters()`.

EXAMPLES:

```
sage: c = OrderedMultisetPartitionIntoSets([[6,1],[1,3],[1,3,6]])
sage: c.weight()
{1: 3, 3: 2, 6: 2}
sage: c.weight(as_weak_comp=True)
[3, 0, 2, 0, 0, 2]
```

```
>>> from sage.all import *
>>> c = OrderedMultisetPartitionIntoSets([[Integer(6),Integer(1)],[Integer(1),
↪Integer(3)],[Integer(1),Integer(3),Integer(6)]])
>>> c.weight()
{1: 3, 3: 2, 6: 2}
>>> c.weight(as_weak_comp=True)
[3, 0, 2, 0, 0, 2]
```

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionsIntoSets**(*is_finite=None*, ***constraints*)

Bases: UniqueRepresentation, Parent

Ordered Multiset Partitions into Sets.

An *ordered multiset partition into sets* c of a multiset X is a list of nonempty subsets (not multisets), called the *blocks* of c, whose multi-union is X.

The number of blocks of c is called its *length*. The *order* of c is the cardinality of the multiset X. If, additionally, X is a multiset of positive integers, then the *size* of c is the sum of all elements of X.

The user may wish to focus on ordered multiset partitions into sets of a given size, or over a given alphabet. Hence, this class allows a variety of arguments as input.

INPUT:

Expects one or two arguments, with different behaviors resulting:

- One Argument:
  - X – a dictionary or list or tuple (representing a multiset for c), or an integer (representing the size of c)
- Two Arguments:
  - A – list (representing allowable letters within blocks of c), or a positive integer (representing the maximal allowable letter)
  - n – a nonnegative integer (the total number of letters within c)

Optional keyword arguments are as follows: (See corresponding methods in see *OrderedMultisetPartitionIntoSets* for more details.)

- `weight=X` (list or dictionary X) specifies the multiset for c
- `size=n` (integer n) specifies the size of c
- `alphabet=A` (iterable A) specifies allowable elements for the blocks of c
- `length=k` (integer k) specifies the number of blocks in the partition
- `min_length=k` (integer k) specifies minimum number of blocks in the partition
- `max_length=k` (integer k) specifies maximum number of blocks in the partition
- `order=n` (integer n) specifies the cardinality of the multiset that c partitions
- `min_order=n` (integer n) specifies minimum number of elements in the partition
- `max_order=n` (integer n) specifies maximum number of elements in the partition

EXAMPLES:

Passing one argument to *OrderedMultisetPartitionsIntoSets*:

There are 5 ordered multiset partitions into sets of the multiset $\{\{1, 1, 4\}\}$:

```
sage: OrderedMultisetPartitionsIntoSets([1,1,4]).cardinality()
5
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(4)]).
↪cardinality()
5
```

Here is the list of them:

```
sage: OrderedMultisetPartitionsIntoSets([1,1,4]).list()
[[{1}, {1}, {4}], [{1}, {1,4}], [{1}, {4}, {1}], [{1,4}, {1}], [{4}, {1}, {1}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(4)]).list()
[[{1}, {1}, {4}], [{1}, {1,4}], [{1}, {4}, {1}], [{1,4}, {1}], [{4}, {1}, {1}]]
```

By chance, there are also 5 ordered multiset partitions into sets of the integer 3:

```
sage: OrderedMultisetPartitionsIntoSets(3).cardinality()
5
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(3)).cardinality()
5
```

Here is the list of them:

```
sage: OrderedMultisetPartitionsIntoSets(3).list()
[[{3}], [{1,2}], [{2}, {1}], [{1}, {2}], [{1}, {1}, {1}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(3)).list()
[[{3}], [{1,2}], [{2}, {1}], [{1}, {2}], [{1}, {1}, {1}]]
```

Passing two arguments to *OrderedMultisetPartitionsIntoSets*:

There are also 5 ordered multiset partitions into sets of order 2 over the alphabet $\{1, 4\}$:

```
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2)
Ordered Multiset Partitions into Sets of order 2 over alphabet {1, 4}
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2).cardinality()
5
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1), Integer(4)], Integer(2))
Ordered Multiset Partitions into Sets of order 2 over alphabet {1, 4}
>>> OrderedMultisetPartitionsIntoSets([Integer(1), Integer(4)], Integer(2)).
↪cardinality()
5
```

Here is the list of them:

```
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2).list()
[[{1,4}], [{1}, {1}], [{1}, {4}], [{4}, {1}], [{4}, {4}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1), Integer(4)], Integer(2)).list()
[[{1,4}], [{1}, {1}], [{1}, {4}], [{4}, {1}], [{4}, {4}]]
```

If no arguments are passed to *OrderedMultisetPartitionsIntoSets*, then the code returns all ordered multiset partitions into sets:

```
sage: OrderedMultisetPartitionsIntoSets()
Ordered Multiset Partitions into Sets
sage: [] in OrderedMultisetPartitionsIntoSets()
True
sage: [[2,3], [1]] in OrderedMultisetPartitionsIntoSets()
True
sage: [['a','b'], ['a']] in OrderedMultisetPartitionsIntoSets()
True
sage: [[-2,3], [3]] in OrderedMultisetPartitionsIntoSets()
True
sage: [[2], [3,3]] in OrderedMultisetPartitionsIntoSets()
False
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets()
Ordered Multiset Partitions into Sets
>>> [] in OrderedMultisetPartitionsIntoSets()
True
>>> [[Integer(2),Integer(3)], [Integer(1)]] in OrderedMultisetPartitionsIntoSets()
True
>>> [['a','b'], ['a']] in OrderedMultisetPartitionsIntoSets()
True
>>> [[-Integer(2),Integer(3)], [Integer(3)]] in␣
↪OrderedMultisetPartitionsIntoSets()
True
>>> [[Integer(2)], [Integer(3),Integer(3)]] in OrderedMultisetPartitionsIntoSets()
False
```

The following examples show how to test whether or not an object is an ordered multiset partition into sets:

```
sage: [[3,2],[2]] in OrderedMultisetPartitionsIntoSets()
True
sage: [[3,2],[2]] in OrderedMultisetPartitionsIntoSets(7)
True
sage: [[3,2],[2]] in OrderedMultisetPartitionsIntoSets([2,2,3])
True
sage: [[3,2],[2]] in OrderedMultisetPartitionsIntoSets(5)
False
```

```
>>> from sage.all import *
>>> [[Integer(3),Integer(2)],[Integer(2)]] in OrderedMultisetPartitionsIntoSets()
True
```

(continues on next page)

(continued from previous page)

```
>>> [[Integer(3),Integer(2)],[Integer(2)]] in␣
↪OrderedMultisetPartitionsIntoSets(Integer(7))
True
>>> [[Integer(3),Integer(2)],[Integer(2)]] in␣
↪OrderedMultisetPartitionsIntoSets([Integer(2),Integer(2),Integer(3)])
True
>>> [[Integer(3),Integer(2)],[Integer(2)]] in␣
↪OrderedMultisetPartitionsIntoSets(Integer(5))
False
```

Optional keyword arguments

Passing keyword arguments that are incompatible with required requirements results in an error; otherwise, the collection of ordered multiset partitions into sets is restricted accordingly:

The `weight` *keyword:*

This is used to specify which multiset X is to be considered, if this multiset was not passed as one of the required arguments for *OrderedMultisetPartitionsIntoSets*. In principle, it is a dictionary, but weak compositions are also allowed. For example, the ordered multiset partitions into sets of integer 4 are listed by weight below:

```
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,0,0,1])
Ordered Multiset Partitions into Sets of integer 4 with constraint: weight={4: 1}
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,0,0,1]).list()
[[{4}]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[1,0,1]).list()
[[{1}, {3}], [{1,3}], [{3}, {1}]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,2]).list()
[[{2}, {2}]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,1,1]).list()
[]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[2,1]).list()
[[{1}, {1}, {2}], [{1}, {1,2}], [{1}, {2}, {1}], [{1,2}, {1}], [{2}, {1}, {1}]]
sage: O1 = OrderedMultisetPartitionsIntoSets(weight=[2,0,1])
sage: O2 = OrderedMultisetPartitionsIntoSets(weight={1:2, 3:1})
sage: O1 == O2
True
sage: OrderedMultisetPartitionsIntoSets(4, weight=[4]).list()
[[{1}, {1}, {1}, {1}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(0),Integer(0),
↪Integer(0),Integer(1)])
Ordered Multiset Partitions into Sets of integer 4 with constraint: weight={4: 1}
>>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(0),Integer(0),
↪Integer(0),Integer(1)]).list()
[[{4}]]
>>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(1),Integer(0),
↪Integer(1)]).list()
[[{1}, {3}], [{1,3}], [{3}, {1}]]
>>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(0),Integer(2)]).
↪list()
[[{2}, {2}]]
```

(continues on next page)

(continued from previous page)

```
>>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(0),Integer(1),
↪Integer(1)]).list()
[]
>>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(2),Integer(1)]).
↪list()
[[{1}, {1}, {2}], [{1}, {1,2}], [{1}, {2}, {1}], [{1,2}, {1}], [{2}, {1}, {1}]]
>>> O1 = OrderedMultisetPartitionsIntoSets(weight=[Integer(2),Integer(0),
↪Integer(1)])
>>> O2 = OrderedMultisetPartitionsIntoSets(weight={Integer(1):Integer(2),␣
↪Integer(3):Integer(1)})
>>> O1 == O2
True
>>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(4)]).list()
[[{1}, {1}, {1}, {1}]]
```

The `size` *keyword:*

This is used to constrain the sum of entries across all blocks of the ordered multiset partition into sets. (This size is not pre-determined when alphabet A and order d are passed as required arguments.) For example, the ordered multiset partitions into sets of order 3 over the alphabet $[1, 2, 4]$ that have size equal to 5 are as follows:

```
sage: OMPs = OrderedMultisetPartitionsIntoSets
sage: OMPs([1,2,4], 3, size=5).list()
[[{1,2}, {2}], [{2}, {1,2}], [{2}, {2}, {1}],
 [{2}, {1}, {2}], [{1}, {2}, {2}]]
```

```
>>> from sage.all import *
>>> OMPs = OrderedMultisetPartitionsIntoSets
>>> OMPs([Integer(1),Integer(2),Integer(4)], Integer(3), size=Integer(5)).list()
[[{1,2}, {2}], [{2}, {1,2}], [{2}, {2}, {1}],
 [{2}, {1}, {2}], [{1}, {2}, {2}]]
```

The `alphabet` *option:*

This is used to constrain which integers appear across all blocks of the ordered multiset partition into sets. For example, the ordered multiset partitions into sets of integer 4 are listed for different choices of alphabet below. Note that `alphabet` is allowed to be an integer or an iterable:

```
sage: OMPs = OrderedMultisetPartitionsIntoSets
sage: OMPs(4, alphabet=3).list()
[[{1,3}], [{3}, {1}],
 [{1,2}, {1}], [{2}, {2}],
 [{2}, {1}, {1}], [{1}, {3}],
 [{1}, {1,2}], [{1}, {2}, {1}],
 [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
sage: OMPs(4, alphabet=3) == OMPs(4, alphabet=[1,2,3])
True
sage: OMPs(4, alphabet=[3]).list()
[]
sage: OMPs(4, alphabet=[1,3]).list()
[[{1,3}], [{3}, {1}], [{1}, {3}], [{1}, {1}, {1}, {1}]]
sage: OMPs(4, alphabet=[2]).list()
[[{2}, {2}]]
```

(continues on next page)

(continued from previous page)

```
sage: OMPs(4, alphabet=[1,2]).list()
[[{1,2}, {1}], [{2}, {2}], [{2}, {1}, {1}], [{1}, {1,2}],
 [{1}, {2}, {1}], [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
sage: OMPs(4, alphabet=4).list() == OMPs(4).list()
True
```

```
>>> from sage.all import *
>>> OMPs = OrderedMultisetPartitionsIntoSets
>>> OMPs(Integer(4), alphabet=Integer(3)).list()
[[{1,3}], [{3}, {1}],
 [{1,2}, {1}], [{2}, {2}],
 [{2}, {1}, {1}], [{1}, {3}],
 [{1}, {1,2}], [{1}, {2}, {1}],
 [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
>>> OMPs(Integer(4), alphabet=Integer(3)) == OMPs(Integer(4),␣
↪alphabet=[Integer(1),Integer(2),Integer(3)])
True
>>> OMPs(Integer(4), alphabet=[Integer(3)]).list()
[]
>>> OMPs(Integer(4), alphabet=[Integer(1),Integer(3)]).list()
[[{1,3}], [{3}, {1}], [{1}, {3}], [{1}, {1}, {1}, {1}]]
>>> OMPs(Integer(4), alphabet=[Integer(2)]).list()
[[{2}, {2}]]
>>> OMPs(Integer(4), alphabet=[Integer(1),Integer(2)]).list()
[[{1,2}, {1}], [{2}, {2}], [{2}, {1}, {1}], [{1}, {1,2}],
 [{1}, {2}, {1}], [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
>>> OMPs(Integer(4), alphabet=Integer(4)).list() == OMPs(Integer(4)).list()
True
```

The `length`, `min_length`, *and* `max_length` *options:*

These are used to constrain the number of blocks within the ordered multiset partitions into sets. For example, the ordered multiset partitions into sets of integer 4 of length exactly 2, at least 2, and at most 2 are given by:

```
sage: OrderedMultisetPartitionsIntoSets(4, length=2).list()
[[{3}, {1}], [{1,2}, {1}], [{2}, {2}], [{1}, {3}], [{1}, {1,2}]]
sage: OrderedMultisetPartitionsIntoSets(4, min_length=3).list()
[[{2}, {1}, {1}], [{1}, {2}, {1}], [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
sage: OrderedMultisetPartitionsIntoSets(4, max_length=2).list()
[[{4}], [{1,3}], [{3}, {1}], [{1,2}, {1}], [{2}, {2}], [{1}, {3}],
 [{1}, {1,2}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(4), length=Integer(2)).list()
[[{3}, {1}], [{1,2}, {1}], [{2}, {2}], [{1}, {3}], [{1}, {1,2}]]
>>> OrderedMultisetPartitionsIntoSets(Integer(4), min_length=Integer(3)).list()
[[{2}, {1}, {1}], [{1}, {2}, {1}], [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
>>> OrderedMultisetPartitionsIntoSets(Integer(4), max_length=Integer(2)).list()
[[{4}], [{1,3}], [{3}, {1}], [{1,2}, {1}], [{2}, {2}], [{1}, {3}],
 [{1}, {1,2}]]
```

The `order`, `min_order`, *and* `max_order` *options:*

These are used to constrain the number of elements across all blocks of the ordered multiset partitions into sets. For example, the ordered multiset partitions into sets of integer 4 are listed by order below:

```
sage: OrderedMultisetPartitionsIntoSets(4, order=1).list()
[[{4}]]
sage: OrderedMultisetPartitionsIntoSets(4, order=2).list()
[[{1,3}], [{3}, {1}], [{2}, {2}], [{1}, {3}]]
sage: OrderedMultisetPartitionsIntoSets(4, order=3).list()
[[{1,2}, {1}], [{2}, {1}, {1}], [{1}, {1,2}], [{1}, {2}, {1}], [{1}, {1}, {2}]]
sage: OrderedMultisetPartitionsIntoSets(4, order=4).list()
[[{1}, {1}, {1}, {1}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(4), order=Integer(1)).list()
[[{4}]]
>>> OrderedMultisetPartitionsIntoSets(Integer(4), order=Integer(2)).list()
[[{1,3}], [{3}, {1}], [{2}, {2}], [{1}, {3}]]
>>> OrderedMultisetPartitionsIntoSets(Integer(4), order=Integer(3)).list()
[[{1,2}, {1}], [{2}, {1}, {1}], [{1}, {1,2}], [{1}, {2}, {1}], [{1}, {1}, {2}]]
>>> OrderedMultisetPartitionsIntoSets(Integer(4), order=Integer(4)).list()
[[{1}, {1}, {1}, {1}]]
```

Also, here is a use of `max_order`, giving the ordered multiset partitions into sets of integer 4 with order 1 or 2:

```
sage: OrderedMultisetPartitionsIntoSets(4, max_order=2).list()
[[{4}], [{1,3}], [{3}, {1}], [{2}, {2}], [{1}, {3}]]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(4), max_order=Integer(2)).list()
[[{4}], [{1,3}], [{3}, {1}], [{2}, {2}], [{1}, {3}]]
```

Element

alias of *OrderedMultisetPartitionIntoSets*

subset(*size*)

Return a subset of all ordered multiset partitions into sets.

INPUT:

- `size` – integer representing a slice of all ordered multiset partitions into sets

The slice alluded to above is taken with respect to length, or to order, or to size, depending on the constraints of `self`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionsIntoSets(weight={2:2, 3:1, 5:1})
sage: C.subset(3)
Ordered Multiset Partitions into Sets of multiset {{2, 2, 3, 5}} with␣
↪constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets(weight={2:2, 3:1, 5:1}, min_
↪length=2)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of multiset {{2, 2, 3, 5}} with␣
↪constraint: length=3
```

(continues on next page)

(continued from previous page)

```
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5])
sage: C.subset(3)
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5}
sage: C = OrderedMultisetPartitionsIntoSets(order=5)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of integer 3 with constraint: order=5
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5], order=5,␣
↪length=3)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5} with␣
↪constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets()
sage: C.subset(3)
Ordered Multiset Partitions into Sets of integer 3
sage: C.subset(3) == OrderedMultisetPartitionsIntoSets(3)
True
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionsIntoSets(weight={Integer(2):Integer(2),␣
↪Integer(3):Integer(1), Integer(5):Integer(1)})
>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of multiset {{2, 2, 3, 5}} with␣
↪constraint: length=3
>>> C = OrderedMultisetPartitionsIntoSets(weight={Integer(2):Integer(2),␣
↪Integer(3):Integer(1), Integer(5):Integer(1)}, min_length=Integer(2))
>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of multiset {{2, 2, 3, 5}} with␣
↪constraint: length=3
>>> C = OrderedMultisetPartitionsIntoSets(alphabet=[Integer(2),Integer(3),
↪Integer(5)])
>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5}
>>> C = OrderedMultisetPartitionsIntoSets(order=Integer(5))
>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of integer 3 with constraint: order=5
>>> C = OrderedMultisetPartitionsIntoSets(alphabet=[Integer(2),Integer(3),
↪Integer(5)], order=Integer(5), length=Integer(3))
>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5} with␣
↪constraint: length=3
>>> C = OrderedMultisetPartitionsIntoSets()
>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of integer 3
>>> C.subset(Integer(3)) == OrderedMultisetPartitionsIntoSets(Integer(3))
True
```

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionsIntoSets_X**(X)

Bases: *OrderedMultisetPartitionsIntoSets*

Class of ordered multiset partitions into sets of a fixed multiset X.

cardinality()

Return the number of ordered partitions of multiset X.

random_element()

Return a random element of `self`.

This method does not return elements of `self` with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random permutation `p` of the multiset;
- create blocks of an OMP `fat` by breaking `p` after non-ascents;
- take a random element of `fat.finer()`.

EXAMPLES:

```
sage: OrderedMultisetPartitionsIntoSets([1,1,3]).random_element()  # random
[{1}, {1,3}]
sage: OrderedMultisetPartitionsIntoSets([1,1,3]).random_element()  # random
[{3}, {1}, {1}]

sage: OMP = OrderedMultisetPartitionsIntoSets([1,1,3,3])
sage: d = {}
sage: for _ in range(1000):
....:     x = OMP.random_element()
....:     d[x] = d.get(x, 0) + 1
sage: d.values()  # random
[102, 25, 76, 24, 66, 88, 327, 27, 83, 83, 239, 72, 88]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(3)]).
↪random_element()  # random
[{1}, {1,3}]
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(3)]).
↪random_element()  # random
[{3}, {1}, {1}]

>>> OMP = OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(3),
↪Integer(3)])
>>> d = {}
>>> for _ in range(Integer(1000)):
...     x = OMP.random_element()
...     d[x] = d.get(x, Integer(0)) + Integer(1)
>>> d.values()  # random
[102, 25, 76, 24, 66, 88, 327, 27, 83, 83, 239, 72, 88]
```

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionsIntoSets_X_constrai**

Bases: *OrderedMultisetPartitionsIntoSets*

Class of ordered multiset partitions into sets of a fixed multiset X satisfying constraints.

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionsIntoSets_all_constr**

Bases: *OrderedMultisetPartitionsIntoSets*

All ordered multiset partitions into sets (with or without constraints).

EXAMPLES:

```
sage: C = OrderedMultisetPartitionsIntoSets(); C
Ordered Multiset Partitions into Sets
sage: [[1],[1,'a']] in C
True

sage: OrderedMultisetPartitionsIntoSets(weight=[2,0,1], length=2)
Ordered Multiset Partitions into Sets of multiset {{1, 1, 3}} with constraint:␣
↪length=2
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionsIntoSets(); C
Ordered Multiset Partitions into Sets
>>> [[Integer(1)],[Integer(1),'a']] in C
True

>>> OrderedMultisetPartitionsIntoSets(weight=[Integer(2),Integer(0),Integer(1)],␣
↪length=Integer(2))
Ordered Multiset Partitions into Sets of multiset {{1, 1, 3}} with constraint:␣
↪length=2
```

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionsIntoSets_alph_d**(A, d)

Bases: *OrderedMultisetPartitionsIntoSets*

Class of ordered multiset partitions into sets of specified order d over a fixed alphabet A.

cardinality()

Return the number of ordered partitions of order `self._order` on alphabet `self._alphabet`.

random_element()

Return a random element of `self`.

This method does not return elements of `self` with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random composition C;
- choose random subsets of `self._alphabet` of size c for each c in C.

EXAMPLES:

```
sage: OrderedMultisetPartitionsIntoSets([1,4], 3).random_element()  # random
[{4}, {1,4}]
sage: OrderedMultisetPartitionsIntoSets([1,3], 4).random_element()  # random
[{1,3}, {1}, {3}]

sage: OMP = OrderedMultisetPartitionsIntoSets([2,3,4], 2)
sage: d = {}
sage: for _ in range(1200):
....:     x = OMP.random_element()
....:     d[x] = d.get(x, 0) + 1
sage: d.values()  # random
[192, 68, 73, 61, 69, 60, 77, 204, 210, 66, 53, 67]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(4)], Integer(3)).
↪random_element()  # random
[{4}, {1,4}]
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(3)], Integer(4)).
↪random_element()  # random
[{1,3}, {1}, {3}]

>>> OMP = OrderedMultisetPartitionsIntoSets([Integer(2),Integer(3),
↪Integer(4)], Integer(2))
>>> d = {}
>>> for _ in range(Integer(1200)):
...     x = OMP.random_element()
...     d[x] = d.get(x, Integer(0)) + Integer(1)
>>> d.values()  # random
[192, 68, 73, 61, 69, 60, 77, 204, 210, 66, 53, 67]
```

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionsIntoSets_alph_d_co**

Bases: *OrderedMultisetPartitionsIntoSets*

Class of ordered multiset partitions into sets of specified order d over a fixed alphabet A satisfying constraints.

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionsIntoSets_n**(*n*)

Bases: *OrderedMultisetPartitionsIntoSets*

Ordered multiset partitions into sets of a fixed integer n.

cardinality()

Return the number of elements in `self`.

random_element()

Return a random element of `self`.

This method does not return elements of `self` with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random composition C;
- choose a random partition of c into distinct parts for each c in C.

EXAMPLES:

```
sage: OrderedMultisetPartitionsIntoSets(5).random_element()  # random
[{1,2}, {1}, {1}]
sage: OrderedMultisetPartitionsIntoSets(5).random_element()  # random
[{2}, {1,2}]

sage: OMP = OrderedMultisetPartitionsIntoSets(5)
sage: d = {}
sage: for _ in range(1100):
....:     x = OMP.random_element()
....:     d[x] = d.get(x, 0) + 1
sage: d.values()  # random
[72, 73, 162, 78, 135, 75, 109, 65, 135, 134, 62]
```

```
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(5)).random_element()  # random
[{1,2}, {1}, {1}]
>>> OrderedMultisetPartitionsIntoSets(Integer(5)).random_element()  # random
[{2}, {1,2}]

>>> OMP = OrderedMultisetPartitionsIntoSets(Integer(5))
>>> d = {}
>>> for _ in range(Integer(1100)):
...     x = OMP.random_element()
...     d[x] = d.get(x, Integer(0)) + Integer(1)
>>> d.values()  # random
[72, 73, 162, 78, 135, 75, 109, 65, 135, 134, 62]
```

class sage.combinat.multiset_partition_into_sets_ordered.**OrderedMultisetPartitionsIntoSets_n_constrai**

Bases: *OrderedMultisetPartitionsIntoSets*

Class of ordered multiset partitions into sets of a fixed integer n satisfying constraints.

Ordered rooted trees

AUTHORS:

- Florent Hivert (2010-2011): initial revision
- Frédéric Chapoton (2010): contributed some methods

class sage.combinat.ordered_tree.**LabelledOrderedTree**(*parent*, *children*, *label=None*, *check=True*)

Bases: *AbstractLabelledClonableTree*, *OrderedTree*

Labelled ordered trees.

A labelled ordered tree is an ordered tree with a label attached at each node.

INPUT:

- `children` – list or tuple or more generally any iterable of trees or object convertible to trees
- `label` – any Sage object (default: `None`)

EXAMPLES:

```
sage: x = LabelledOrderedTree([], label = 3); x
3[]
sage: LabelledOrderedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledOrderedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledOrderedTree([[],[[], []]], label = 3)
3[None[], None[None[], None[]]]
```

```
>>> from sage.all import *
>>> x = LabelledOrderedTree([], label = Integer(3)); x
3[]
>>> LabelledOrderedTree([x, x, x], label = Integer(2))
```

(continues on next page)

(continued from previous page)

```
2[3[], 3[], 3[]]
>>> LabelledOrderedTree((x, x, x), label = Integer(2))
2[3[], 3[], 3[]]
>>> LabelledOrderedTree([[],[[], []]], label = Integer(3))
3[None[], None[None[], None[]]]
```

left_right_symmetry()

Return the symmetric tree of `self`.

The symmetric tree $s(T)$ of a labelled ordered tree T is defined as follows: If T is a labelled ordered tree with children $C_1, C_2, \ldots, C_k$ (listed from left to right), then the symmetric tree $s(T)$ of T is a labelled ordered tree with children $s(C_k), s(C_{k-1}), \ldots, s(C_1)$ (from left to right), and with the same root label as T.

Note

If you have a subclass of *LabelledOrderedTree()* which also inherits from another subclass of *OrderedTree()* which does not come with a labelling, then (depending on the method resolution order) it might happen that this method gets overridden by an implementation from that other subclass, and thus forgets about the labels. In this case you need to manually override this method on your subclass.

EXAMPLES:

```
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.left_right_symmetry()
4[3[], 2[]]
sage: T223 = LabelledOrderedTree([L2, T23], label=17)
sage: T223.left_right_symmetry()
17[4[3[], 2[]], 2[]]
sage: T223.left_right_symmetry().left_right_symmetry() == T223
True
```

```
>>> from sage.all import *
>>> L2 = LabelledOrderedTree([], label=Integer(2))
>>> L3 = LabelledOrderedTree([], label=Integer(3))
>>> T23 = LabelledOrderedTree([L2, L3], label=Integer(4))
>>> T23.left_right_symmetry()
4[3[], 2[]]
>>> T223 = LabelledOrderedTree([L2, T23], label=Integer(17))
>>> T223.left_right_symmetry()
17[4[3[], 2[]], 2[]]
>>> T223.left_right_symmetry().left_right_symmetry() == T223
True
```

sort_key()

Return a tuple of nonnegative integers encoding the labelled tree `self`.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.

This tuple characterizes the labelled tree uniquely, and can be used to sort the labelled ordered trees provided that the labels belong to a type which is totally ordered.

Warning

This method overrides *OrderedTree.sort_key()* and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of *LabelledOrderedTree*; under some circumstances they could inherit it from another superclass instead of from *OrderedTree*, which would cause the method to forget the labelling. See the docstring of *OrderedTree.sort_key()*.

EXAMPLES:

```
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.sort_key()
((2, 4), (0, 2), (0, 3))
sage: T32 = LabelledOrderedTree([L3, L2], label=5)
sage: T32.sort_key()
((2, 5), (0, 3), (0, 2))
sage: T23322 = LabelledOrderedTree([T23, T32, L2], label=14)
sage: T23322.sort_key()
((3, 14), (2, 4), (0, 2), (0, 3), (2, 5), (0, 3), (0, 2), (0, 2))
```

```
>>> from sage.all import *
>>> L2 = LabelledOrderedTree([], label=Integer(2))
>>> L3 = LabelledOrderedTree([], label=Integer(3))
>>> T23 = LabelledOrderedTree([L2, L3], label=Integer(4))
>>> T23.sort_key()
((2, 4), (0, 2), (0, 3))
>>> T32 = LabelledOrderedTree([L3, L2], label=Integer(5))
>>> T32.sort_key()
((2, 5), (0, 3), (0, 2))
>>> T23322 = LabelledOrderedTree([T23, T32, L2], label=Integer(14))
>>> T23322.sort_key()
((3, 14), (2, 4), (0, 2), (0, 3), (2, 5), (0, 3), (0, 2), (0, 2))
```

class sage.combinat.ordered_tree.**LabelledOrderedTrees**(*category=None*)

Bases: UniqueRepresentation, Parent

This is a parent stub to serve as a factory class for trees with various label constraints.

EXAMPLES:

```
sage: LOT = LabelledOrderedTrees(); LOT
Labelled ordered trees
sage: x = LOT([], label = 3); x
3[]
sage: x.parent() is LOT
True
sage: y = LOT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
```

(continues on next page)

(continued from previous page)

```
sage: y.parent() is LOT
True
```

```
>>> from sage.all import *
>>> LOT = LabelledOrderedTrees(); LOT
Labelled ordered trees
>>> x = LOT([], label = Integer(3)); x
3[]
>>> x.parent() is LOT
True
>>> y = LOT([x, x, x], label = Integer(2)); y
2[3[], 3[], 3[]]
>>> y.parent() is LOT
True
```

Element

alias of *LabelledOrderedTree*

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: LabelledOrderedTrees().cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> LabelledOrderedTrees().cardinality()
+Infinity
```

labelled_trees()

Return the set of labelled trees associated to `self`.

This is precisely `self`, because `self` already is the set of labelled ordered trees.

EXAMPLES:

```
sage: LabelledOrderedTrees().labelled_trees()
Labelled ordered trees
sage: LOT = LabelledOrderedTrees()
sage: x = LOT([], label = 3)
sage: y = LOT([x, x, x], label = 2)
sage: y.canonical_labelling()
1[2[], 3[], 4[]]
```

```
>>> from sage.all import *
>>> LabelledOrderedTrees().labelled_trees()
Labelled ordered trees
>>> LOT = LabelledOrderedTrees()
>>> x = LOT([], label = Integer(3))
>>> y = LOT([x, x, x], label = Integer(2))
>>> y.canonical_labelling()
1[2[], 3[], 4[]]
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

This is the set of ordered trees, since `self` is the set of labelled ordered trees.

EXAMPLES:

```
sage: LabelledOrderedTrees().unlabelled_trees()
Ordered trees
```

```
>>> from sage.all import *
>>> LabelledOrderedTrees().unlabelled_trees()
Ordered trees
```

class sage.combinat.ordered_tree.**OrderedTree**(*parent=None*, *children=None*, *check=True*)

Bases: *AbstractClonableTree*, ClonableList

The class of (ordered rooted) trees.

An ordered tree is constructed from a node, called the root, on which one has grafted a possibly empty list of trees. There is a total order on the children of a node which is given by the order of the elements in the list. Note that there is no empty ordered tree (so the smallest ordered tree consists of just one node).

INPUT:

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree. Alternatively a string is also accepted. The syntax is the same as for printing: children are grouped by square brackets.

EXAMPLES:

```
sage: x = OrderedTree([])
sage: x1 = OrderedTree([x,x])
sage: x2 = OrderedTree([[],[]])
sage: x1 == x2
True
sage: tt1 = OrderedTree([x,x1,x2])
sage: tt2 = OrderedTree([[], [[], []], x2])
sage: tt1 == tt2
True

sage: OrderedTree([]) == OrderedTree()
True
```

```
>>> from sage.all import *
>>> x = OrderedTree([])
>>> x1 = OrderedTree([x,x])
>>> x2 = OrderedTree([[],[]])
>>> x1 == x2
True
>>> tt1 = OrderedTree([x,x1,x2])
>>> tt2 = OrderedTree([[], [[], []], x2])
>>> tt1 == tt2
True

>>> OrderedTree([]) == OrderedTree()
True
```

is_empty()

Return if `self` is the empty tree.

For ordered trees, this always returns `False`.

> **Note**
>
> this is different from `bool(t)` which returns whether `t` has some child or not.

EXAMPLES:

```
sage: t = OrderedTrees(4)([[],[[]]])
sage: t.is_empty()
False
sage: bool(t)
True
```

```
>>> from sage.all import *
>>> t = OrderedTrees(Integer(4))([[],[[]]])
>>> t.is_empty()
False
>>> bool(t)
True
```

left_right_symmetry()

Return the symmetric tree of `self`.

The symmetric tree $s(T)$ of an ordered tree T is defined as follows: If T is an ordered tree with children $C_1, C_2, \ldots, C_k$ (listed from left to right), then the symmetric tree $s(T)$ of T is the ordered tree with children $s(C_k), s(C_{k-1}), \ldots, s(C_1)$ (from left to right).

EXAMPLES:

```
sage: T = OrderedTree([[],[[]]])
sage: T.left_right_symmetry()
[[[]], []]
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T.left_right_symmetry()
[[[[]], []], [[], []], []]
```

```
>>> from sage.all import *
>>> T = OrderedTree([[],[[]]])
>>> T.left_right_symmetry()
[[[]], []]
>>> T = OrderedTree([[], [[], []], [[], [[]]]])
>>> T.left_right_symmetry()
[[[[]], []], [[], []], []]
```

normalize(*inplace=False*)

Return the normalized tree of `self`.

INPUT:

- `inplace` – boolean (default: `False`); if `True`, then `self` is modified and nothing returned. Otherwise the normalized tree is returned.

The normalization of an ordered tree t is an ordered tree s which has the property that t and s are isomorphic as *unordered* rooted trees, and that if two ordered trees t and t' are isomorphic as *unordered* rooted trees, then the normalizations of t and t' are identical. In other words, normalization is a map from the set of ordered trees to itself which picks a representative from every equivalence class with respect to the relation of "being isomorphic as unordered trees", and maps every ordered tree to the representative chosen from its class.

This map proceeds recursively by first normalizing every subtree, and then sorting the subtrees according to the value of the *sort_key()* method.

Consider the quotient map π that sends a planar rooted tree to the associated unordered rooted tree. Normalization is the composite $s \circ \pi$, where s is a section of π.

EXAMPLES:

```
sage: OT = OrderedTree
sage: ta = OT([[],[[]]])
sage: tb = OT([[[]],[]])
sage: ta.normalize() == tb.normalize()
True
sage: ta == tb
False
```

```
>>> from sage.all import *
>>> OT = OrderedTree
>>> ta = OT([[],[[]]])
>>> tb = OT([[[]],[]])
>>> ta.normalize() == tb.normalize()
True
>>> ta == tb
False
```

An example with inplace normalization:

```
sage: OT = OrderedTree
sage: ta = OT([[],[[]]])
sage: tb = OT([[[]],[]])
sage: ta.normalize(inplace=True); ta
[[], [[]]]
sage: tb.normalize(inplace=True); tb
[[], [[]]]
```

```
>>> from sage.all import *
>>> OT = OrderedTree
>>> ta = OT([[],[[]]])
>>> tb = OT([[[]],[]])
>>> ta.normalize(inplace=True); ta
[[], [[]]]
>>> tb.normalize(inplace=True); tb
[[], [[]]]
```

plot()

Plot the tree `self`.

Warning

For a labelled tree, this will fail unless all labels are distinct. For unlabelled trees, some arbitrary labels are chosen. Use `_latex_`, `view`, `_ascii_art_()` or `pretty_print` for more faithful representations of the data of the tree.

EXAMPLES:

```
sage: p = OrderedTree([[[]],[],[]])
sage: ascii_art(p)
  _o__
 / / /
o o o
|
o
sage: p.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 10 graphics primitives
```

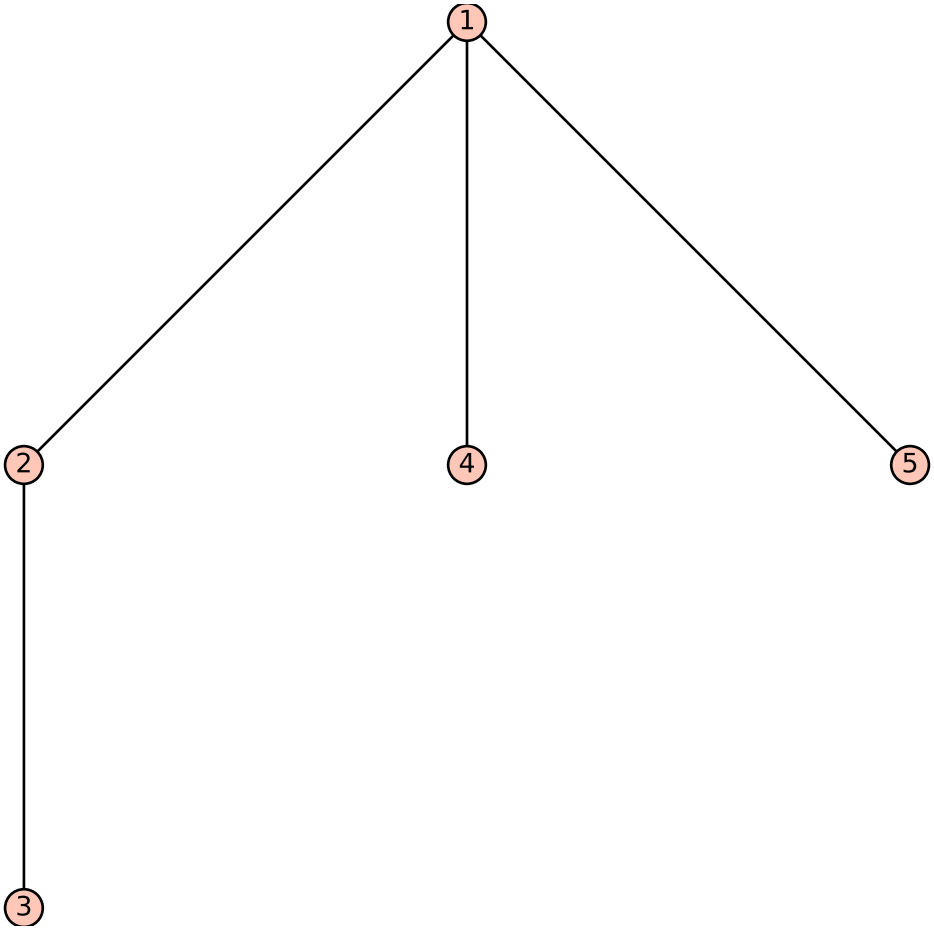
```
>>> from sage.all import *
>>> p = OrderedTree([[[]],[],[]])
>>> ascii_art(p)
  _o__
 / / /
o o o
|
o
>>> p.plot()                                                                #␣
↪needs sage.plot
Graphics object consisting of 10 graphics primitives
```

Now a labelled example:

```
sage: g = OrderedTree([[],[[]],[]]).canonical_labelling()
sage: ascii_art(g)
  _1__
 / / /
2 3 5
  |
  4
sage: g.plot()                                                              #␣
↪needs sage.plot
Graphics object consisting of 10 graphics primitives
```

```
>>> from sage.all import *
>>> g = OrderedTree([[],[[]],[]]).canonical_labelling()
>>> ascii_art(g)
  _1__
 / / /
2 3 5
  |
  4
```

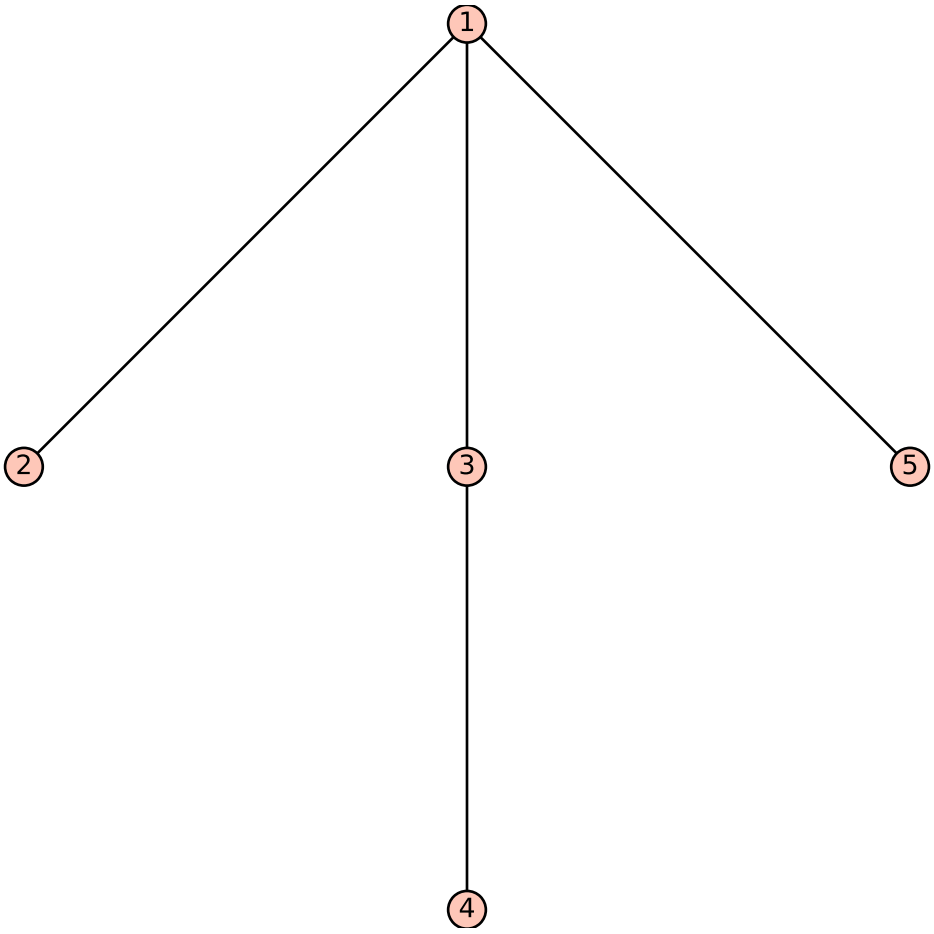
(continues on next page)



1
2
4
5
3

(continued from previous page)

```
>>> g.plot()                                                                #␣
↪needs sage.plot
Graphics object consisting of 10 graphics primitives
```



sort_key()

Return a tuple of nonnegative integers encoding the ordered tree `self`.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.

This tuple characterizes the tree uniquely, and can be used to sort the ordered trees.

Note

By default, this method does not encode any extra structure that `self` might have – e.g., if you were to define a class `EdgeColoredOrderedTree` which implements edge-colored trees and which inherits from *OrderedTree*, then the *sort_key()* method it would inherit would forget about the colors of the edges (and thus would not characterize edge-colored trees uniquely). If you want to preserve extra data, you need to override this method or use a new method. For instance, on the *LabelledOrderedTree* subclass, this method is overridden by a slightly different method, which encodes not only the numbers of children of the nodes of `self`, but also their labels. Be careful with using overridden methods, however: If you have (say) a class `BalancedTree` which inherits from *OrderedTree* and which encodes

balanced trees, and if you have another class `BalancedLabelledOrderedTree` which inherits both from `BalancedOrderedTree` and from *LabelledOrderedTree*, then (depending on the MRO) the default *sort_key()* method on `BalancedLabelledOrderedTree` (unless manually overridden) will be taken either from `BalancedTree` or from *LabelledOrderedTree*, and in the former case will ignore the labelling!

EXAMPLES:

```
sage: RT = OrderedTree
sage: RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[]]).sort_key()
(2, 1, 0, 0)
```

```
>>> from sage.all import *
>>> RT = OrderedTree
>>> RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
>>> RT([[[]],[]]).sort_key()
(2, 1, 0, 0)
```

to_binary_tree_left_branch()

Return a binary tree of size $n-1$ (where n is the size of t, and where t is `self`) obtained from t by the following recursive rule:

- if x is the left brother of y in t, then x becomes the left child of y;
- if x is the last child of y in t, then x becomes the right child of y,

and removing the root of t.

EXAMPLES:

```
sage: T = OrderedTree([[],[]])
sage: T.to_binary_tree_left_branch()
[[., .], .]
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T.to_binary_tree_left_branch()
[[[., .], [[., .], .]], [[., .], [., .]]]
```

```
>>> from sage.all import *
>>> T = OrderedTree([[],[]])
>>> T.to_binary_tree_left_branch()
[[., .], .]
>>> T = OrderedTree([[], [[], []], [[], [[]]]])
>>> T.to_binary_tree_left_branch()
[[[., .], [[., .], .]], [[., .], [., .]]]
```

to_binary_tree_right_branch()

Return a binary tree of size $n-1$ (where n is the size of t, and where t is `self`) obtained from t by the following recursive rule:

- if x is the right brother of y in t, then`x` becomes the right child of y;
- if x is the first child of y in t, then x becomes the left child of y,

and removing the root of t.

EXAMPLES:

```
sage: T = OrderedTree([[],[]])
sage: T.to_binary_tree_right_branch()
[., [., .]]
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T.to_binary_tree_right_branch()
[., [[., [., .]], [[., [[., .], .]], .]]]
```

```
>>> from sage.all import *
>>> T = OrderedTree([[],[]])
>>> T.to_binary_tree_right_branch()
[., [., .]]
>>> T = OrderedTree([[], [[], []], [[], [[]]]])
>>> T.to_binary_tree_right_branch()
[., [[., [., .]], [[., [[., .], .]], .]]]
```

to_dyck_word()

Return the Dyck path corresponding to `self` where the maximal height of the Dyck path is the depth of `self`.

EXAMPLES:

```
sage: T = OrderedTree([[],[]])
sage: T.to_dyck_word()                                                  #␣
↪needs sage.combinat
[1, 0, 1, 0]
sage: T = OrderedTree([[],[[]]])
sage: T.to_dyck_word()                                                  #␣
↪needs sage.combinat
[1, 0, 1, 1, 0, 0]
sage: T = OrderedTree([[], [[], []], [[], [[]]]])
sage: T.to_dyck_word()                                                  #␣
↪needs sage.combinat
[1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0]
```

```
>>> from sage.all import *
>>> T = OrderedTree([[],[]])
>>> T.to_dyck_word()                                                    #␣
↪needs sage.combinat
[1, 0, 1, 0]
>>> T = OrderedTree([[],[[]]])
>>> T.to_dyck_word()                                                    #␣
↪needs sage.combinat
[1, 0, 1, 1, 0, 0]
>>> T = OrderedTree([[], [[], []], [[], [[]]]])
>>> T.to_dyck_word()                                                    #␣
↪needs sage.combinat
[1, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0]
```

to_parallelogram_polyomino(*bijection=None*)

Return a polyomino parallelogram.

INPUT:

- `bijection` – (default: `'Boussicault-Socci'`) is the name of the bijection to use. Possible values are `'Boussicault-Socci'`, `'via dyck and Delest-Viennot'`.

EXAMPLES:

```
sage: # needs sage.combinat sage.modules
sage: T = OrderedTree([[[], [[]]], [], [[[],[]]], [], []])
sage: T.to_parallelogram_polyomino(bijection='Boussicault-Socci')
[[0, 0, 0, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1],
 [1, 1, 1, 1, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0]]
sage: T = OrderedTree( [] )
sage: T.to_parallelogram_polyomino()
[[1], [1]]
sage: T = OrderedTree( [[]] )
sage: T.to_parallelogram_polyomino()
[[0, 1], [1, 0]]
sage: T = OrderedTree( [[],[]] )
sage: T.to_parallelogram_polyomino()
[[0, 1, 1], [1, 1, 0]]
sage: T = OrderedTree( [[[]]] )
sage: T.to_parallelogram_polyomino()
[[0, 0, 1], [1, 0, 0]]
```

```
>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> T = OrderedTree([[[], [[]]], [], [[[],[]]], [], []])
>>> T.to_parallelogram_polyomino(bijection='Boussicault-Socci')
[[0, 0, 0, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1],
 [1, 1, 1, 1, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0]]
>>> T = OrderedTree( [] )
>>> T.to_parallelogram_polyomino()
[[1], [1]]
>>> T = OrderedTree( [[]] )
>>> T.to_parallelogram_polyomino()
[[0, 1], [1, 0]]
>>> T = OrderedTree( [[],[]] )
>>> T.to_parallelogram_polyomino()
[[0, 1, 1], [1, 1, 0]]
>>> T = OrderedTree( [[[]]] )
>>> T.to_parallelogram_polyomino()
[[0, 0, 1], [1, 0, 0]]
```

to_poset(*root_to_leaf=False*)

Return the poset obtained by interpreting the tree as a Hasse diagram. The default orientation is from leaves to root but you can pass `root_to_leaf=True` to obtain the inverse orientation.

INPUT:

- `root_to_leaf` – boolean (default: `False`); `True` if the poset orientation should be from root to leaves

EXAMPLES:

```
sage: t = OrderedTree([])
sage: t.to_poset()
```

(continues on next page)

(continued from previous page)

```
Finite poset containing 1 elements
sage: p = OrderedTree([[[]],[],[]]).to_poset()
sage: p.height(), p.width()                                                 #␣
↪needs networkx
(3, 3)
```

```
>>> from sage.all import *
>>> t = OrderedTree([])
>>> t.to_poset()
Finite poset containing 1 elements
>>> p = OrderedTree([[[]],[],[]]).to_poset()
>>> p.height(), p.width()                                                 #␣
↪needs networkx
(3, 3)
```

If the tree is labelled, we use its labelling to label the poset. Otherwise, we use the poset canonical labelling:

```
sage: t = OrderedTree([[[]],[],[]]).canonical_labelling().to_poset()
sage: t.height(), t.width()                                                 #␣
↪needs networkx
(3, 3)
```

```
>>> from sage.all import *
>>> t = OrderedTree([[[]],[],[]]).canonical_labelling().to_poset()
>>> t.height(), t.width()                                                 #␣
↪needs networkx
(3, 3)
```

to_undirected_graph()

Return the undirected graph obtained from the tree nodes and edges.

The graph is endowed with an embedding, so that it will be displayed correctly.

EXAMPLES:

```
sage: t = OrderedTree([])
sage: t.to_undirected_graph()
Graph on 1 vertex
sage: t = OrderedTree([[[]],[],[]])
sage: t.to_undirected_graph()
Graph on 5 vertices
```

```
>>> from sage.all import *
>>> t = OrderedTree([])
>>> t.to_undirected_graph()
Graph on 1 vertex
>>> t = OrderedTree([[[]],[],[]])
>>> t.to_undirected_graph()
Graph on 5 vertices
```

If the tree is labelled, we use its labelling to label the graph. This will fail if the labels are not all distinct. Otherwise, we use the graph canonical labelling which means that two different trees can have the same graph.

EXAMPLES:

```
sage: t = OrderedTree([[[]],[],[]])
sage: t.canonical_labelling().to_undirected_graph()
Graph on 5 vertices
```

```
>>> from sage.all import *
>>> t = OrderedTree([[[]],[],[]])
>>> t.canonical_labelling().to_undirected_graph()
Graph on 5 vertices
```

class sage.combinat.ordered_tree.**OrderedTrees**

Bases: UniqueRepresentation, Parent

Factory for ordered trees.

INPUT:

- size – integer (optional)

OUTPUT:

- the set of all ordered trees (of the given size if specified)

EXAMPLES:

```
sage: OrderedTrees()
Ordered trees

sage: OrderedTrees(2)
Ordered trees of size 2
```

```
>>> from sage.all import *
>>> OrderedTrees()
Ordered trees

>>> OrderedTrees(Integer(2))
Ordered trees of size 2
```

Note

this is a factory class whose constructor returns instances of subclasses.

Note

the fact that OrderedTrees is a class instead of a simple callable is an implementation detail. It could be changed in the future and one should not rely on it.

leaf()

Return a leaf tree with self as parent.

EXAMPLES:

```
sage: OrderedTrees().leaf()
[]
```

```
sage: from sage.all import *
sage: OrderedTrees().leaf()
[]
```

class sage.combinat.ordered_tree.**OrderedTrees_all**

Bases: DisjointUnionEnumeratedSets, *OrderedTrees*

The set of all ordered trees.

EXAMPLES:

```
sage: OT = OrderedTrees(); OT
Ordered trees
sage: OT.cardinality()
+Infinity
```

```
sage: from sage.all import *
sage: OT = OrderedTrees(); OT
Ordered trees
sage: OT.cardinality()
+Infinity
```

Element

alias of *OrderedTree*

labelled_trees()

Return the set of labelled trees associated to `self`.

EXAMPLES:

```
sage: OrderedTrees().labelled_trees()
Labelled ordered trees
```

```
sage: from sage.all import *
sage: OrderedTrees().labelled_trees()
Labelled ordered trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

EXAMPLES:

```
sage: OrderedTrees().unlabelled_trees()
Ordered trees
```

```
sage: from sage.all import *
sage: OrderedTrees().unlabelled_trees()
Ordered trees
```

class sage.combinat.ordered_tree.**OrderedTrees_size**(*size*)

Bases: *OrderedTrees*

The enumerated sets of binary trees of a given size.

EXAMPLES:

```
sage: S = OrderedTrees(3); S
Ordered trees of size 3
sage: S.cardinality()
2
sage: S.list()
[[[], []], [[[]]]]
```

```
>>> from sage.all import *
>>> S = OrderedTrees(Integer(3)); S
Ordered trees of size 3
>>> S.cardinality()
2
>>> S.list()
[[[], []], [[[]]]]
```

cardinality()

The cardinality of `self`.

This is a Catalan number.

element_class()

The class of the element of `self`.

EXAMPLES:

```
sage: from sage.combinat.ordered_tree import OrderedTrees_size, OrderedTrees_
↪all
sage: S = OrderedTrees_size(3)
sage: S.element_class is OrderedTrees().element_class
True
sage: S.first().__class__ == OrderedTrees_all().first().__class__
True
```

```
>>> from sage.all import *
>>> from sage.combinat.ordered_tree import OrderedTrees_size, OrderedTrees_all
>>> S = OrderedTrees_size(Integer(3))
>>> S.element_class is OrderedTrees().element_class
True
>>> S.first().__class__ == OrderedTrees_all().first().__class__
True
```

random_element()

Return a random `OrderedTree` with uniform probability.

This method generates a random `DyckWord` and then uses a bijection between Dyck words and ordered trees.

EXAMPLES:

```
sage: OrderedTrees(5).random_element()  # random                              #␣
↪needs sage.combinat
[[[], []], []]
sage: OrderedTrees(0).random_element()
Traceback (most recent call last):
...
```

(continues on next page)

(continued from previous page)

```
EmptySetError: there are no ordered trees of size 0
sage: OrderedTrees(1).random_element()                                  #␣
↪needs sage.combinat
[]
```

```
>>> from sage.all import *
>>> OrderedTrees(Integer(5)).random_element()  # random                 ␣
↪     # needs sage.combinat
[[[], []], []]
>>> OrderedTrees(Integer(0)).random_element()
Traceback (most recent call last):
...
EmptySetError: there are no ordered trees of size 0
>>> OrderedTrees(Integer(1)).random_element()                            ␣
↪     # needs sage.combinat
[]
```

Ordered set partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration)
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through *Ordered-SetPartition*.

class sage.combinat.set_partition_ordered.**OrderedSetPartition**(*parent*, *s*, *check=True*)

Bases: `ClonableArray`

An ordered partition of a set.

An ordered set partition p of a set s is a list of pairwise disjoint nonempty subsets of s such that the union of these subsets is s. These subsets are called the parts of the partition.

We represent an ordered set partition as a list of sets. By extension, an ordered set partition of a nonnegative integer n is the set partition of the integers from 1 to n. The number of ordered set partitions of n is called the n-th ordered Bell number.

There is a natural integer composition associated with an ordered set partition, that is the sequence of sizes of all its parts in order.

The number T_n of ordered set partitions of $\{1, 2, \ldots, n\}$ is the so-called n-th *Fubini number* (also known as the n-th ordered Bell number; see Wikipedia article Ordered Bell number). Its exponential generating function is

$$\sum_n \frac{T_n}{n!} x^n = \frac{1}{2 - e^x}.$$

(See sequence OEIS sequence A000670 in OEIS.)

INPUT:

- `parts` – an object or iterable that defines an ordered set partition (e.g., a list of pairwise disjoint sets) or a packed word (e.g., a list of letters on some alphabet). If there is ambiguity and if the input should be treated as a packed word, the keyword `from_word` should be used.

EXAMPLES:

There are 13 ordered set partitions of $\{1, 2, 3\}$:

```
sage: OrderedSetPartitions(3).cardinality()
13
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(3)).cardinality()
13
```

Here is the list of them:

```
sage: OrderedSetPartitions(3).list()
[[{1}, {2}, {3}],
 [{1}, {3}, {2}],
 [{2}, {1}, {3}],
 [{3}, {1}, {2}],
 [{2}, {3}, {1}],
 [{3}, {2}, {1}],
 [{1}, {2, 3}],
 [{2}, {1, 3}],
 [{3}, {1, 2}],
 [{1, 2}, {3}],
 [{1, 3}, {2}],
 [{2, 3}, {1}],
 [{1, 2, 3}]]
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(3)).list()
[[{1}, {2}, {3}],
 [{1}, {3}, {2}],
 [{2}, {1}, {3}],
 [{3}, {1}, {2}],
 [{2}, {3}, {1}],
 [{3}, {2}, {1}],
 [{1}, {2, 3}],
 [{2}, {1, 3}],
 [{3}, {1, 2}],
 [{1, 2}, {3}],
 [{1, 3}, {2}],
 [{2, 3}, {1}],
 [{1, 2, 3}]]
```

There are 12 ordered set partitions of $\{1, 2, 3, 4\}$ whose underlying composition is $[1, 2, 1]$:

```
sage: OrderedSetPartitions(4,[1,2,1]).list()
[[{1}, {2, 3}, {4}],
 [{1}, {2, 4}, {3}],
 [{1}, {3, 4}, {2}],
 [{2}, {1, 3}, {4}],
 [{2}, {1, 4}, {3}],
 [{3}, {1, 2}, {4}],
 [{4}, {1, 2}, {3}],
```

(continues on next page)

(continued from previous page)

```
 [{3}, {1, 4}, {2}],
 [{4}, {1, 3}, {2}],
 [{2}, {3, 4}, {1}],
 [{3}, {2, 4}, {1}],
 [{4}, {2, 3}, {1}]]
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(4),[Integer(1),Integer(2),Integer(1)]).list()
[[{1}, {2, 3}, {4}],
 [{1}, {2, 4}, {3}],
 [{1}, {3, 4}, {2}],
 [{2}, {1, 3}, {4}],
 [{2}, {1, 4}, {3}],
 [{3}, {1, 2}, {4}],
 [{4}, {1, 2}, {3}],
 [{3}, {1, 4}, {2}],
 [{4}, {1, 3}, {2}],
 [{2}, {3, 4}, {1}],
 [{3}, {2, 4}, {1}],
 [{4}, {2, 3}, {1}]]
```

Since Issue #14140, we can create an ordered set partition directly by *OrderedSetPartition* which creates the parent object by taking the union of the partitions passed in. However it is recommended and (marginally) faster to create the parent first and then create the ordered set partition from that.

```
sage: s = OrderedSetPartition([[1,3],[2,4]]); s
[{1, 3}, {2, 4}]
sage: s.parent()
Ordered set partitions of {1, 2, 3, 4}
```

```
>>> from sage.all import *
>>> s = OrderedSetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]); s
[{1, 3}, {2, 4}]
>>> s.parent()
Ordered set partitions of {1, 2, 3, 4}
```

We can construct the ordered set partition from a word, which we consider as packed:

```
sage: OrderedSetPartition([2,4,1,2])
[{3}, {1, 4}, {2}]
sage: OrderedSetPartition(from_word=[2,4,1,2])
[{3}, {1, 4}, {2}]
sage: OrderedSetPartition(from_word='bdab')
[{3}, {1, 4}, {2}]
```

```
>>> from sage.all import *
>>> OrderedSetPartition([Integer(2),Integer(4),Integer(1),Integer(2)])
[{3}, {1, 4}, {2}]
>>> OrderedSetPartition(from_word=[Integer(2),Integer(4),Integer(1),Integer(2)])
[{3}, {1, 4}, {2}]
>>> OrderedSetPartition(from_word='bdab')
[{3}, {1, 4}, {2}]
```

Warning

The elements of the underlying set should be hashable.

REFERENCES:

Wikipedia article Ordered_partition_of_a_set

base_set()

Return the base set of `self`.

This is the union of all parts of `self`.

EXAMPLES:

```
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set()
frozenset({1, 2, 3, 4})
sage: OrderedSetPartition([[1,2,3,4]]).base_set()
frozenset({1, 2, 3, 4})
sage: OrderedSetPartition([]).base_set()
frozenset()
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4)]]).base_set()
frozenset({1, 2, 3, 4})
>>> OrderedSetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_
↪set()
frozenset({1, 2, 3, 4})
>>> OrderedSetPartition([]).base_set()
frozenset()
```

base_set_cardinality()

Return the cardinality of the base set of `self`.

This is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of an ordered set partition.

EXAMPLES:

```
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: OrderedSetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4)]]).base_set_cardinality()
4
>>> OrderedSetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_
↪set_cardinality()
4
```

static bottom_up_osp(*X*, *comp*)

Return the ordered set partition obtained by listing the elements of the set `X` in increasing order, and placing bars between some of them according to the integer composition `comp` (namely, the bars are placed in such a way that the lengths of the resulting blocks are exactly the entries of `comp`).

INPUT:

- `X` – a finite set (or list or tuple)
- `comp` – a composition whose sum is the size of `X` (can be given as a list or tuple or composition)

EXAMPLES:

```
sage: buo = OrderedSetPartition.bottom_up_osp
sage: buo(Set([1, 4, 7, 9]), [2, 1, 1])
[{1, 4}, {7}, {9}]
sage: buo(Set([1, 4, 7, 9]), [1, 3])
[{1}, {4, 7, 9}]
sage: buo(Set([1, 4, 7, 9]), [1, 1, 1, 1])
[{1}, {4}, {7}, {9}]
sage: buo(range(8), [1, 4, 2, 1])
[{0}, {1, 2, 3, 4}, {5, 6}, {7}]
sage: buo([], [])
[]
```

```
>>> from sage.all import *
>>> buo = OrderedSetPartition.bottom_up_osp
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(2),␣
↪Integer(1), Integer(1)])
[{1, 4}, {7}, {9}]
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(1),␣
↪Integer(3)])
[{1}, {4, 7, 9}]
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(1),␣
↪Integer(1), Integer(1), Integer(1)])
[{1}, {4}, {7}, {9}]
>>> buo(range(Integer(8)), [Integer(1), Integer(4), Integer(2), Integer(1)])
[{0}, {1, 2, 3, 4}, {5, 6}, {7}]
>>> buo([], [])
[]
```

check()

Check that we are a valid ordered set partition.

EXAMPLES:

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.check()
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions(Integer(4))
>>> s = OS([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])
>>> s.check()
```

complement()

Return the complement of the ordered set partition `self`.

This assumes that `self` is an ordered set partition of an interval of $\mathbf{Z}$.

Let $(P_1, P_2, \ldots, P_k)$ be an ordered set partition of some interval I of $\mathbf{Z}$. Let ω be the unique strictly decreasing bijection $I \to I$. Then, the *complement* of $(P_1, P_2, \ldots, P_k)$ is defined to be the ordered set partition $(\omega(P_1), \omega(P_2), \ldots, \omega(P_k))$.

EXAMPLES:

```
sage: OrderedSetPartition([[1, 2], [3]]).complement()
[{2, 3}, {1}]
sage: OrderedSetPartition([[1, 3], [2]]).complement()
[{1, 3}, {2}]
sage: OrderedSetPartition([[2, 3]]).complement()
[{2, 3}]
sage: OrderedSetPartition([[1, 5], [2, 3], [4]]).complement()
[{1, 5}, {3, 4}, {2}]
sage: OrderedSetPartition([[-1], [-2], [1, 2], [0]]).complement()
[{1}, {2}, {-2, -1}, {0}]
sage: OrderedSetPartition([]).complement()
[]
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1), Integer(2)], [Integer(3)]]).complement()
[{2, 3}, {1}]
>>> OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).complement()
[{1, 3}, {2}]
>>> OrderedSetPartition([[Integer(2), Integer(3)]]).complement()
[{2, 3}]
>>> OrderedSetPartition([[Integer(1), Integer(5)], [Integer(2), Integer(3)],␣
↪[Integer(4)]]).complement()
[{1, 5}, {3, 4}, {2}]
>>> OrderedSetPartition([[-Integer(1)], [-Integer(2)], [Integer(1),␣
↪Integer(2)], [Integer(0)]]).complement()
[{1}, {2}, {-2, -1}, {0}]
>>> OrderedSetPartition([]).complement()
[]
```

fatten(*grouping*)

Return the ordered set partition fatter than `self`, obtained by grouping together consecutive parts according to the integer composition `grouping`.

See *finer()* for the definition of "fatter".

INPUT:

- `grouping` – a composition whose sum is the length of `self`

EXAMPLES:

Let us start with the ordered set partition:

```
sage: c = OrderedSetPartition([[2, 5], [1], [3, 4]])
```

```
>>> from sage.all import *
>>> c = OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1)],␣
↪[Integer(3), Integer(4)]])
```

With `grouping` equal to $(1, \ldots, 1)$, c is left unchanged:

```
sage: c.fatten(Composition([1,1,1]))
[{2, 5}, {1}, {3, 4}]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(1),Integer(1),Integer(1)]))
[{2, 5}, {1}, {3, 4}]
```

With `grouping` equal to (ℓ) where ℓ is the length of c, this yields the coarsest ordered set partition above c:

```
sage: c.fatten(Composition([3]))
[{1, 2, 3, 4, 5}]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(3)]))
[{1, 2, 3, 4, 5}]
```

Other values for `grouping` yield (all the) other ordered set partitions coarser than c:

```
sage: c.fatten(Composition([2,1]))
[{1, 2, 5}, {3, 4}]
sage: c.fatten(Composition([1,2]))
[{2, 5}, {1, 3, 4}]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(2),Integer(1)]))
[{1, 2, 5}, {3, 4}]
>>> c.fatten(Composition([Integer(1),Integer(2)]))
[{2, 5}, {1, 3, 4}]
```

fatter()

Return the set of ordered set partitions which are fatter than `self`.

See *finer()* for the definition of "fatter".

EXAMPLES:

```
sage: C = OrderedSetPartition([[2, 5], [1], [3, 4]]).fatter()
sage: C.cardinality()
4
sage: sorted(C)
[[{2, 5}, {1}, {3, 4}],
 [{2, 5}, {1, 3, 4}],
 [{1, 2, 5}, {3, 4}],
 [{1, 2, 3, 4, 5}]]

sage: OrderedSetPartition([[4, 9], [-1, 2]]).fatter().list()
[[{4, 9}, {-1, 2}], [{-1, 2, 4, 9}]]
```

```
>>> from sage.all import *
>>> C = OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1)],␣
↪[Integer(3), Integer(4)]]).fatter()
>>> C.cardinality()
4
>>> sorted(C)
[[{2, 5}, {1}, {3, 4}],
 [{2, 5}, {1, 3, 4}],
 [{1, 2, 5}, {3, 4}],
 [{1, 2, 3, 4, 5}]]

>>> OrderedSetPartition([[Integer(4), Integer(9)], [-Integer(1),␣
↪Integer(2)]]).fatter().list()
[[{4, 9}, {-1, 2}], [{-1, 2, 4, 9}]]
```

Some extreme cases:

```
sage: list(OrderedSetPartition([[5]]).fatter())
[[{5}]]
sage: list(Composition([]).fatter())
[[]]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).fatter())
[[{1}, {2}, {3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2, 3, 4}],
 [{1, 2}, {3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2, 3, 4}]]
```

```
>>> from sage.all import *
>>> list(OrderedSetPartition([[Integer(5)]]).fatter())
[[{5}]]
>>> list(Composition([]).fatter())
[[]]
>>> sorted(OrderedSetPartition([[Integer(1)], [Integer(2)], [Integer(3)],␣
↪[Integer(4)]]).fatter())
[[{1}, {2}, {3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2, 3, 4}],
 [{1, 2}, {3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2, 3, 4}]]
```

finer()

Return the set of ordered set partitions which are finer than `self`.

See *is_finer()* for the definition of "finer".

EXAMPLES:

```
sage: C = OrderedSetPartition([[1, 3], [2]]).finer()
sage: C.cardinality()
3
sage: C.list()
[[{1}, {3}, {2}], [{3}, {1}, {2}], [{1, 3}, {2}]]

sage: OrderedSetPartition([]).finer()
{[]}

sage: W = OrderedSetPartition([[4, 9], [-1, 2]])
sage: W.finer().list()
[[{9}, {4}, {2}, {-1}],
 [{9}, {4}, {-1}, {2}],
 [{9}, {4}, {-1, 2}],
 [{4}, {9}, {2}, {-1}],
 [{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {2}, {-1}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]
```

```
>>> from sage.all import *
>>> C = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).finer()
>>> C.cardinality()
3
>>> C.list()
[[{1}, {3}, {2}], [{3}, {1}, {2}], [{1, 3}, {2}]]

>>> OrderedSetPartition([]).finer()
{[]}

>>> W = OrderedSetPartition([[Integer(4), Integer(9)], [-Integer(1),␣
↪Integer(2)]])
>>> W.finer().list()
[[{9}, {4}, {2}, {-1}],
 [{9}, {4}, {-1}, {2}],
 [{9}, {4}, {-1, 2}],
 [{4}, {9}, {2}, {-1}],
 [{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {2}, {-1}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]
```

is_finer(*co2*)

Return `True` if the ordered set partition `self` is finer than the ordered set partition `co2`; otherwise, return `False`.

If A and B are two ordered set partitions of the same set, then A is said to be *finer* than B if B can be obtained from A by (repeatedly) merging consecutive parts. In this case, we say that B is *fatter* than A.

EXAMPLES:

```
sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_finer(B)
False
sage: B.is_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_finer(C)
False
sage: C.is_finer(A)
True
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_finer(OrderedSetPartition([[2,␣
↪5], [1, 4]]))
False
```

```
>>> from sage.all import *
>>> A = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]])
>>> B = OrderedSetPartition([[Integer(1)], [Integer(3)], [Integer(2)]])
>>> A.is_finer(B)
False
>>> B.is_finer(A)
True
>>> C = OrderedSetPartition([[Integer(3)], [Integer(1)], [Integer(2)]])
>>> A.is_finer(C)
False
>>> C.is_finer(A)
True
>>> OrderedSetPartition([[Integer(2)], [Integer(5)], [Integer(1)],␣
↪[Integer(4)]]).is_finer(OrderedSetPartition([[Integer(2), Integer(5)],␣
↪[Integer(1), Integer(4)]]))
True
>>> OrderedSetPartition([[Integer(5)], [Integer(2)], [Integer(1)],␣
↪[Integer(4)]]).is_finer(OrderedSetPartition([[Integer(2), Integer(5)],␣
↪[Integer(1), Integer(4)]]))
True
>>> OrderedSetPartition([[Integer(2)], [Integer(1)], [Integer(5)],␣
↪[Integer(4)]]).is_finer(OrderedSetPartition([[Integer(2), Integer(5)],␣
↪[Integer(1), Integer(4)]]))
False
>>> OrderedSetPartition([[Integer(2), Integer(5), Integer(1)], [Integer(4)]]).
↪is_finer(OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1),␣
↪Integer(4)]]))
False
```

is_strongly_finer(*co2*)

Return `True` if the ordered set partition `self` is strongly finer than the ordered set partition `co2`; otherwise, return `False`.

If A and B are two ordered set partitions of the same set, then A is said to be *strongly finer* than B if B can be obtained from A by (repeatedly) merging consecutive parts, provided that every time we merge two consecutive parts C_i and C_{i+1}, we have $\max C_i < \min C_{i+1}$. In this case, we say that B is *strongly fatter* than A.

EXAMPLES:

```
sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_strongly_finer(B)
False
sage: B.is_strongly_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_strongly_finer(C)
False
sage: C.is_strongly_finer(A)
False
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_strongly_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_strongly_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_strongly_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_strongly_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
```

```
>>> from sage.all import *
>>> A = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]])
>>> B = OrderedSetPartition([[Integer(1)], [Integer(3)], [Integer(2)]])
>>> A.is_strongly_finer(B)
False
>>> B.is_strongly_finer(A)
True
>>> C = OrderedSetPartition([[Integer(3)], [Integer(1)], [Integer(2)]])
>>> A.is_strongly_finer(C)
False
>>> C.is_strongly_finer(A)
False
>>> OrderedSetPartition([[Integer(2)], [Integer(5)], [Integer(1)],␣
↪[Integer(4)]]).is_strongly_finer(OrderedSetPartition([[Integer(2),␣
↪Integer(5)], [Integer(1), Integer(4)]]))
True
>>> OrderedSetPartition([[Integer(5)], [Integer(2)], [Integer(1)],␣
↪[Integer(4)]]).is_strongly_finer(OrderedSetPartition([[Integer(2),␣
↪Integer(5)], [Integer(1), Integer(4)]]))
```

(continues on next page)

(continued from previous page)

```
False
>>> OrderedSetPartition([[Integer(2)], [Integer(1)], [Integer(5)],␣
↪[Integer(4)]]).is_strongly_finer(OrderedSetPartition([[Integer(2),␣
↪Integer(5)], [Integer(1), Integer(4)]]))
False
>>> OrderedSetPartition([[Integer(2), Integer(5), Integer(1)], [Integer(4)]]).
↪is_strongly_finer(OrderedSetPartition([[Integer(2), Integer(5)],␣
↪[Integer(1), Integer(4)]]))
False
```

length()

Return the number of parts of `self`.

EXAMPLES:

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.length()
2
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions(Integer(4))
>>> s = OS([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])
>>> s.length()
2
```

number_of_inversions()

Return the number of inversions in `self`.

An inversion of an ordered set partition with blocks $[B_1, B_2, \ldots, B_k]$ is a pair of letters i and j with $i < j$ such that i is minimal in B_m, $j \in B_l$, and $l < m$.

REFERENCES:

- [Wilson2016]

EXAMPLES:

```
sage: OrderedSetPartition([{2,5},{4,6},{1,3}]).number_of_inversions()
5
sage: OrderedSetPartition([{1,3,8},{2,4},{5,6,7}]).number_of_inversions()
3
```

```
>>> from sage.all import *
>>> OrderedSetPartition([{Integer(2),Integer(5)},{Integer(4),Integer(6)},
↪{Integer(1),Integer(3)}]).number_of_inversions()
5
>>> OrderedSetPartition([{Integer(1),Integer(3),Integer(8)},{Integer(2),
↪Integer(4)},{Integer(5),Integer(6),Integer(7)}]).number_of_inversions()
3
```

reversed()

Return the reversal of the ordered set partition `self`.

The *reversal* of an ordered set partition $(P_1, P_2, \ldots, P_k)$ is defined to be the ordered set partition $(P_k, P_{k-1}, \ldots, P_1)$.

EXAMPLES:

```
sage: OrderedSetPartition([[1, 3], [2]]).reversed()
[{2}, {1, 3}]
sage: OrderedSetPartition([[1, 5], [2, 4]]).reversed()
[{2, 4}, {1, 5}]
sage: OrderedSetPartition([[-1], [-2], [3, 4], [0]]).reversed()
[{0}, {3, 4}, {-2}, {-1}]
sage: OrderedSetPartition([]).reversed()
[]
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).reversed()
[{2}, {1, 3}]
>>> OrderedSetPartition([[Integer(1), Integer(5)], [Integer(2), Integer(4)]]).
↪reversed()
[{2, 4}, {1, 5}]
>>> OrderedSetPartition([[-Integer(1)], [-Integer(2)], [Integer(3),␣
↪Integer(4)], [Integer(0)]]).reversed()
[{0}, {3, 4}, {-2}, {-1}]
>>> OrderedSetPartition([]).reversed()
[]
```

size()

alias of *base_set_cardinality()*.

strongly_fatter()

Return the set of ordered set partitions which are strongly fatter than `self`.

See *strongly_finer()* for the definition of "strongly fatter".

EXAMPLES:

```
sage: C = OrderedSetPartition([[2, 5], [1], [3, 4]]).strongly_fatter()
sage: C.cardinality()
2
sage: sorted(C)
[[{2, 5}, {1}, {3, 4}], [{2, 5}, {1, 3, 4}]]

sage: OrderedSetPartition([[4, 9], [-1, 2]]).strongly_fatter().list()
[[{4, 9}, {-1, 2}]]
```

```
>>> from sage.all import *
>>> C = OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1)],␣
↪[Integer(3), Integer(4)]]).strongly_fatter()
>>> C.cardinality()
2
>>> sorted(C)
[[{2, 5}, {1}, {3, 4}], [{2, 5}, {1, 3, 4}]]

>>> OrderedSetPartition([[Integer(4), Integer(9)], [-Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(2)]]).strongly_fatter().list()
[[{4, 9}, {-1, 2}]]
```

Some extreme cases:

```
sage: list(OrderedSetPartition([[5]]).strongly_fatter())
[[{5}]]
sage: list(OrderedSetPartition([]).strongly_fatter())
[[]]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).strongly_fatter())
[[{1}, {2}, {3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2, 3, 4}],
 [{1, 2}, {3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2, 3, 4}]]
sage: sorted(OrderedSetPartition([[1], [3], [2], [4]]).strongly_fatter())
[[{1}, {3}, {2}, {4}],
 [{1}, {3}, {2, 4}],
 [{1, 3}, {2}, {4}],
 [{1, 3}, {2, 4}]]
sage: sorted(OrderedSetPartition([[4], [1], [5], [3]]).strongly_fatter())
[[{4}, {1}, {5}, {3}], [{4}, {1, 5}, {3}]]
```

```
>>> from sage.all import *
>>> list(OrderedSetPartition([[Integer(5)]]).strongly_fatter())
[[{5}]]
>>> list(OrderedSetPartition([]).strongly_fatter())
[[]]
>>> sorted(OrderedSetPartition([[Integer(1)], [Integer(2)], [Integer(3)],␣
↪[Integer(4)]]).strongly_fatter())
[[{1}, {2}, {3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2, 3, 4}],
 [{1, 2}, {3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2, 3, 4}]]
>>> sorted(OrderedSetPartition([[Integer(1)], [Integer(3)], [Integer(2)],␣
↪[Integer(4)]]).strongly_fatter())
[[{1}, {3}, {2}, {4}],
 [{1}, {3}, {2, 4}],
 [{1, 3}, {2}, {4}],
 [{1, 3}, {2, 4}]]
>>> sorted(OrderedSetPartition([[Integer(4)], [Integer(1)], [Integer(5)],␣
↪[Integer(3)]]).strongly_fatter())
[[{4}, {1}, {5}, {3}], [{4}, {1, 5}, {3}]]
```

strongly_finer()

Return the set of ordered set partitions which are strongly finer than `self`.

See *is_strongly_finer()* for the definition of "strongly finer".

EXAMPLES:

```
sage: C = OrderedSetPartition([[1, 3], [2]]).strongly_finer()
sage: C.cardinality()
2
sage: C.list()
[[{1}, {3}, {2}], [{1, 3}, {2}]]

sage: OrderedSetPartition([]).strongly_finer()
{[]}

sage: W = OrderedSetPartition([[4, 9], [-1, 2]])
sage: W.strongly_finer().list()
[[{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]
```

```
>>> from sage.all import *
>>> C = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).
↪strongly_finer()
>>> C.cardinality()
2
>>> C.list()
[[{1}, {3}, {2}], [{1, 3}, {2}]]

>>> OrderedSetPartition([]).strongly_finer()
{[]}

>>> W = OrderedSetPartition([[Integer(4), Integer(9)], [-Integer(1),␣
↪Integer(2)]])
>>> W.strongly_finer().list()
[[{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]
```

static sum(*osps*)

Return the concatenation of the given ordered set partitions `osps` (provided they have no elements in common).

INPUT:

- `osps` – list (or iterable) of ordered set partitions

EXAMPLES:

```
sage: OrderedSetPartition.sum([OrderedSetPartition([[4, 1], [3]]),␣
↪OrderedSetPartition([[7], [2]]), OrderedSetPartition([[5, 6]])])
[{1, 4}, {3}, {7}, {2}, {5, 6}]
```

```
>>> from sage.all import *
>>> OrderedSetPartition.sum([OrderedSetPartition([[Integer(4), Integer(1)],␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(3)]]), OrderedSetPartition([[Integer(7)], [Integer(2)]]),␣
↪OrderedSetPartition([[Integer(5), Integer(6)]])])
[{1, 4}, {3}, {7}, {2}, {5, 6}]
```

Any iterable can be provided as input:

```
sage: OrderedSetPartition.sum([OrderedSetPartition([[2*i,2*i+1]]) for i in [4,
↪1,3]])
[{8, 9}, {2, 3}, {6, 7}]
```

```
>>> from sage.all import *
>>> OrderedSetPartition.sum([OrderedSetPartition([[Integer(2)*i,
↪Integer(2)*i+Integer(1)]]) for i in [Integer(4),Integer(1),Integer(3)]])
[{8, 9}, {2, 3}, {6, 7}]
```

Empty inputs are handled gracefully:

```
sage: OrderedSetPartition.sum([]) == OrderedSetPartition([])
True
```

```
>>> from sage.all import *
>>> OrderedSetPartition.sum([]) == OrderedSetPartition([])
True
```

to_composition()

Return the integer composition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = OrderedSetPartitions(5)
sage: x = S([[3,5,4], [1, 2]])
sage: x.to_composition()
[3, 2]
sage: y = S([[3,1], [2], [5,4]])
sage: y.to_composition()
[2, 1, 2]
```

```
>>> from sage.all import *
>>> S = OrderedSetPartitions(Integer(5))
>>> x = S([[Integer(3),Integer(5),Integer(4)], [Integer(1), Integer(2)]])
>>> x.to_composition()
[3, 2]
>>> y = S([[Integer(3),Integer(1)], [Integer(2)], [Integer(5),Integer(4)]])
>>> y.to_composition()
[2, 1, 2]
```

to_packed_word()

Return the packed word on alphabet $\{1, 2, 3, \ldots\}$ corresponding to `self`.

A *packed word* on alphabet $\{1, 2, 3, \ldots\}$ is any word whose maximum letter is the same as its total number of distinct letters. Let P be an ordered set partition of a set X. The corresponding packed word $w_1 w_2 \cdots w_n$ is constructed by having letter $w_i = j$ if the i-th smallest entry in X occurs in the j-th block of P.

See also

sage.combinat.words.finite_word.FiniteWord_class.to_ordered_set_partition()

Warning

This assumes there is a total order on the underlying set.

EXAMPLES:

```
sage: S = OrderedSetPartitions()
sage: x = S([[3,5], [2], [1,4,6]])
sage: x.to_packed_word()
word: 321313

sage: x = S([['a', 'c', 'e'], ['b', 'd']])
sage: x.to_packed_word()
word: 12121
```

```
>>> from sage.all import *
>>> S = OrderedSetPartitions()
>>> x = S([[Integer(3),Integer(5)], [Integer(2)], [Integer(1),Integer(4),
↪Integer(6)]])
>>> x.to_packed_word()
word: 321313

>>> x = S([['a', 'c', 'e'], ['b', 'd']])
>>> x.to_packed_word()
word: 12121
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions**(*s*)

Bases: UniqueRepresentation, Parent

Return the combinatorial class of ordered set partitions of `s`.

The optional argument `c`, if specified, restricts the parts of the partition to have certain sizes (the entries of `c`).

EXAMPLES:

```
sage: OS = OrderedSetPartitions([1,2,3,4]); OS
Ordered set partitions of {1, 2, 3, 4}
sage: OS.cardinality()
75
sage: OS.first()
[{1}, {2}, {3}, {4}]
sage: OS.last()
[{1, 2, 3, 4}]
sage: OS.random_element().parent() is OS
True
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)]); OS
```

(continues on next page)

(continued from previous page)

```
Ordered set partitions of {1, 2, 3, 4}
>>> OS.cardinality()
75
>>> OS.first()
[{1}, {2}, {3}, {4}]
>>> OS.last()
[{1, 2, 3, 4}]
>>> OS.random_element().parent() is OS
True
```

```
sage: OS = OrderedSetPartitions([1,2,3,4], [2,2]); OS
Ordered set partitions of {1, 2, 3, 4} into parts of size [2, 2]
sage: OS.cardinality()
6
sage: OS.first()
[{1, 2}, {3, 4}]
sage: OS.last()
[{3, 4}, {1, 2}]
sage: OS.list()
[[{1, 2}, {3, 4}],
 [{1, 3}, {2, 4}],
 [{1, 4}, {2, 3}],
 [{2, 3}, {1, 4}],
 [{2, 4}, {1, 3}],
 [{3, 4}, {1, 2}]]
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)],␣
↪[Integer(2),Integer(2)]); OS
Ordered set partitions of {1, 2, 3, 4} into parts of size [2, 2]
>>> OS.cardinality()
6
>>> OS.first()
[{1, 2}, {3, 4}]
>>> OS.last()
[{3, 4}, {1, 2}]
>>> OS.list()
[[{1, 2}, {3, 4}],
 [{1, 3}, {2, 4}],
 [{1, 4}, {2, 3}],
 [{2, 3}, {1, 4}],
 [{2, 4}, {1, 3}],
 [{3, 4}, {1, 2}]]
```

```
sage: OS = OrderedSetPartitions("cat")
sage: OS  # random
Ordered set partitions of {'a', 't', 'c'}
sage: sorted(OS.list(), key=str)
[[{'a', 'c', 't'}],
 [{'a', 'c'}, {'t'}],
 [{'a', 't'}, {'c'}],
```

(continues on next page)

(continued from previous page)

```
 [{'a'}, {'c', 't'}],
 [{'a'}, {'c'}, {'t'}],
 [{'a'}, {'t'}, {'c'}],
 [{'c', 't'}, {'a'}],
 [{'c'}, {'a', 't'}],
 [{'c'}, {'a'}, {'t'}],
 [{'c'}, {'t'}, {'a'}],
 [{'t'}, {'a', 'c'}],
 [{'t'}, {'a'}, {'c'}],
 [{'t'}, {'c'}, {'a'}]]
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions("cat")
>>> OS  # random
Ordered set partitions of {'a', 't', 'c'}
>>> sorted(OS.list(), key=str)
[[{'a', 'c', 't'}],
 [{'a', 'c'}, {'t'}],
 [{'a', 't'}, {'c'}],
 [{'a'}, {'c', 't'}],
 [{'a'}, {'c'}, {'t'}],
 [{'a'}, {'t'}, {'c'}],
 [{'c', 't'}, {'a'}],
 [{'c'}, {'a', 't'}],
 [{'c'}, {'a'}, {'t'}],
 [{'c'}, {'t'}, {'a'}],
 [{'t'}, {'a', 'c'}],
 [{'t'}, {'a'}, {'c'}],
 [{'t'}, {'c'}, {'a'}]]
```

Element

alias of *OrderedSetPartition*

from_finite_word(*w*, *check=True*)

Return the unique ordered set partition of $\{1, 2, \ldots, n\}$ corresponding to a word w of length n.

See also

sage.combinat.words.finite_word.FiniteWord_class.to_ordered_set_partition()

EXAMPLES:

```
sage: A = OrderedSetPartitions().from_finite_word('abcabcabd'); A
[{1, 4, 7}, {2, 5, 8}, {3, 6}, {9}]
sage: B = OrderedSetPartitions().from_finite_word([1,2,3,1,2,3,1,2,4])
sage: A == B
True
```

```
>>> from sage.all import *
>>> A = OrderedSetPartitions().from_finite_word('abcabcabd'); A
[{1, 4, 7}, {2, 5, 8}, {3, 6}, {9}]
```

(continues on next page)

(continued from previous page)

```
>>> B = OrderedSetPartitions().from_finite_word([Integer(1),Integer(2),
↪Integer(3),Integer(1),Integer(2),Integer(3),Integer(1),Integer(2),
↪Integer(4)])
>>> A == B
True
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_all**

Bases: *OrderedSetPartitions*

Ordered set partitions of $\{1, \ldots, n\}$ for all $n \in \mathbf{Z}_{\geq 0}$.

class Element(*parent*, *s*, *check=True*)

Bases: *OrderedSetPartition*

subset(*size=None*, ***kwargs*)

Return the subset of ordered set partitions of a given size and additional keyword arguments.

EXAMPLES:

```
sage: P = OrderedSetPartitions()
sage: P.subset(4)
Ordered set partitions of {1, 2, 3, 4}
```

```
>>> from sage.all import *
>>> P = OrderedSetPartitions()
>>> P.subset(Integer(4))
Ordered set partitions of {1, 2, 3, 4}
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_s**(*s*)

Bases: *OrderedSetPartitions*

Class of ordered partitions of a set S.

cardinality()

EXAMPLES:

```
sage: OrderedSetPartitions(0).cardinality()
1
sage: OrderedSetPartitions(1).cardinality()
1
sage: OrderedSetPartitions(2).cardinality()
3
sage: OrderedSetPartitions(3).cardinality()
13
sage: OrderedSetPartitions([1,2,3]).cardinality()
13
sage: OrderedSetPartitions(4).cardinality()
75
sage: OrderedSetPartitions(5).cardinality()
541
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(0)).cardinality()
1
```

(continues on next page)

(continued from previous page)

```
>>> OrderedSetPartitions(Integer(1)).cardinality()
1
>>> OrderedSetPartitions(Integer(2)).cardinality()
3
>>> OrderedSetPartitions(Integer(3)).cardinality()
13
>>> OrderedSetPartitions([Integer(1),Integer(2),Integer(3)]).cardinality()
13
>>> OrderedSetPartitions(Integer(4)).cardinality()
75
>>> OrderedSetPartitions(Integer(5)).cardinality()
541
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_scomp**(*s*, *comp*)

Bases: *OrderedSetPartitions*

cardinality()

Return the cardinality of `self`.

The number of ordered set partitions of a set of length k with composition shape μ is equal to

$$\frac{k!}{\prod_{\mu_i \neq 0} \mu_i!}.$$

EXAMPLES:

```
sage: OrderedSetPartitions(5,[2,3]).cardinality()
10
sage: OrderedSetPartitions(0, []).cardinality()
1
sage: OrderedSetPartitions(0, [0]).cardinality()
1
sage: OrderedSetPartitions(0, [0,0]).cardinality()
1
sage: OrderedSetPartitions(5, [2,0,3]).cardinality()
10
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(5),[Integer(2),Integer(3)]).cardinality()
10
>>> OrderedSetPartitions(Integer(0), []).cardinality()
1
>>> OrderedSetPartitions(Integer(0), [Integer(0)]).cardinality()
1
>>> OrderedSetPartitions(Integer(0), [Integer(0),Integer(0)]).cardinality()
1
>>> OrderedSetPartitions(Integer(5), [Integer(2),Integer(0),Integer(3)]).
↪cardinality()
10
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_sn**(*s*, *n*)

Bases: *OrderedSetPartitions*

cardinality()

Return the cardinality of `self`.

The number of ordered partitions of a set of size n into k parts is equal to $k!S(n,k)$ where $S(n,k)$ denotes the Stirling number of the second kind.

EXAMPLES:

```
sage: OrderedSetPartitions(4,2).cardinality()
14
sage: OrderedSetPartitions(4,1).cardinality()
1
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(4),Integer(2)).cardinality()
14
>>> OrderedSetPartitions(Integer(4),Integer(1)).cardinality()
1
```

sage.combinat.set_partition_ordered.**multiset_permutation_next_lex**(l)

Return the next multiset permutation after `l`.

EXAMPLES:

```
sage: from sage.combinat.set_partition_ordered import multiset_permutation_next_
↪lex
sage: l = [0, 0, 1, 1, 2]
sage: while multiset_permutation_next_lex(l):
....:     print(l)
[0, 0, 1, 2, 1]
[0, 0, 2, 1, 1]
[0, 1, 0, 1, 2]
[0, 1, 0, 2, 1]
[0, 1, 1, 0, 2]
[0, 1, 1, 2, 0]
...
[1, 1, 2, 0, 0]
[1, 2, 0, 0, 1]
[1, 2, 0, 1, 0]
[1, 2, 1, 0, 0]
[2, 0, 0, 1, 1]
[2, 0, 1, 0, 1]
[2, 0, 1, 1, 0]
[2, 1, 0, 0, 1]
[2, 1, 0, 1, 0]
[2, 1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition_ordered import multiset_permutation_next_lex
>>> l = [Integer(0), Integer(0), Integer(1), Integer(1), Integer(2)]
>>> while multiset_permutation_next_lex(l):
...     print(l)
[0, 0, 1, 2, 1]
[0, 0, 2, 1, 1]
```

(continues on next page)

(continued from previous page)

```
[0, 1, 0, 1, 2]
[0, 1, 0, 2, 1]
[0, 1, 1, 0, 2]
[0, 1, 1, 2, 0]
...
[1, 1, 2, 0, 0]
[1, 2, 0, 0, 1]
[1, 2, 0, 1, 0]
[1, 2, 1, 0, 0]
[2, 0, 0, 1, 1]
[2, 0, 1, 0, 1]
[2, 0, 1, 1, 0]
[2, 1, 0, 0, 1]
[2, 1, 0, 1, 0]
[2, 1, 1, 0, 0]
```

sage.combinat.set_partition_ordered.**multiset_permutation_to_ordered_set_partition**(*l*, *m*)

Convert a multiset permutation to an ordered set partition.

INPUT:

- `l` – a multiset permutation
- `m` – number of parts

EXAMPLES:

```
sage: from sage.combinat.set_partition_ordered import multiset_permutation_to_
↪ordered_set_partition
sage: l = [0, 0, 1, 1, 2]
sage: multiset_permutation_to_ordered_set_partition(l, 3)
[[0, 1], [2, 3], [4]]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition_ordered import multiset_permutation_to_
↪ordered_set_partition
>>> l = [Integer(0), Integer(0), Integer(1), Integer(1), Integer(2)]
>>> multiset_permutation_to_ordered_set_partition(l, Integer(3))
[[0, 1], [2, 3], [4]]
```

Output functions

These are the output functions for latexing and ascii/unicode art versions of partitions and tableaux.

AUTHORS:

- Mike Hansen (?): initial version
- Andrew Mathas (2013-02-14): Added support for displaying conventions and lines, and tableaux of skew partition, composition, and skew/composition/partition/tableaux tuple shape.
- Travis Scrimshaw (2020-08): Added support for ascii/unicode art

sage.combinat.output.**ascii_art_table**(*data*, *use_unicode=False*, *convention='English'*)

Return an ascii art table of `data`.

EXAMPLES:

```
sage: from sage.combinat.output import ascii_art_table

sage: data = [[None, None, 1], [2, 2], [3,4,5], [None, None, 10], [], [6]]
sage: print(ascii_art_table(data))
        +----+
        | 1  |
+---+---+----+
| 2 | 2 |
+---+---+----+
| 3 | 4 | 5  |
+---+---+----+
        | 10 |
        +----+

+---+
| 6 |
+---+
sage: print(ascii_art_table(data, use_unicode=True))
        ┌────┐
        | 1  |

sage.combinat.output.**ascii_art_table_russian**(*data*, *use_unicode=False*, *compact=False*)

Return an ascii art table of `data` for the russian convention.

EXAMPLES:

```
sage: from sage.combinat.output import ascii_art_table_russian
sage: data = [[None, None, 1], [2, 2], [3,4,5], [None, None, 10], [], [6]]
sage: print(ascii_art_table_russian(data))
   / \          / \
  /   \        /   \
```

 \ /
```

sage.combinat.output.**box_exists**(*tab*, *i*, *j*)

Return `True` if `tab[i][j]` exists and is not `None`.

In particular this allows for $tab[i][j]$ to be `''` or `0`.

INPUT:

- `tab` – list of lists
- `i` – first coordinate
- `j` – second coordinate

sage.combinat.output.**svg_from_array**(*array*, *with_lines=True*)

Return the svg code for this array.

EXAMPLES:

```
sage: array=[[1,9,1],[6,9,1],[2,8,3,3]]
sage: sage.combinat.output.svg_from_array(array)
'<?xml version="1.0" ...</svg>'
```

```
>>> from sage.all import *
>>> array=[[Integer(1),Integer(9),Integer(1)],[Integer(6),Integer(9),Integer(1)],
↪[Integer(2),Integer(8),Integer(3),Integer(3)]]
>>> sage.combinat.output.svg_from_array(array)
'<?xml version="1.0" ...</svg>'
```

sage.combinat.output.**svg_from_skew_array**(*array*, *with_lines=False*, *align='b'*)

Return the svg code for this skew array.

EXAMPLES:

```
sage: array=[[None, 2,3,4],[None,None],[5,6,7,8]]
sage: sage.combinat.output.svg_from_skew_array(array)
'<?xml version="1.0" ...</svg>'
```

```
>>> from sage.all import *
>>> array=[[None, Integer(2),Integer(3),Integer(4)],[None,None],[Integer(5),
↪Integer(6),Integer(7),Integer(8)]]
>>> sage.combinat.output.svg_from_skew_array(array)
'<?xml version="1.0" ...</svg>'
```

sage.combinat.output.**tex_from_array**(*array*, *with_lines=True*)

Return a latex string for a two dimensional array of partition, composition or skew composition shape.

INPUT:

- `array` – list of list
- `with_lines` – boolean (default: `True`); whether to draw a line to separate the entries in the array

Empty rows are allowed; however, such rows should be given as `[None]` rather than `[]`.

The array is drawn using either the English or French convention following *Tableaux.options()*.

sage.combinat.output.**tex_from_array_tuple**(*a_tuple*, *with_lines=True*)

Return a latex string for a tuple of two dimensional array of partition, composition or skew composition shape.

INPUT:

- `a_tuple` – tuple of lists of lists
- `with_lines` – boolean (default: `True`); whether to draw lines to separate the entries in the components of `a_tuple`

See also

tex_from_array() for the description of each array

EXAMPLES:

```
sage: from sage.combinat.output import tex_from_array_tuple
sage: print(tex_from_array_tuple([[[1,2,3],[4,5]],[],[[None,6,7],[None,8],[9]]]))
{\def\lr#1{\multicolumn{1}{|@{\hspace{.6ex}}c@{\hspace{.6ex}}|}{\raisebox{-.3ex}{$

sage.combinat.output.**tex_from_skew_array**(*array*, *with_lines=False*, *align='b'*)

Create latex code for a "skew composition" `array`.

That is, for a two dimensional array in which each row can begin with an arbitrary number `None`'s and the remaining entries could, in principle, be anything but probably should be strings or integers of similar width. A row consisting

completely of `None`'s is allowed.

INPUT:

- `array` – the array
- `with_lines` – (default: `False`) if `True` lines are drawn, if `False` they are not
- `align` – (default: `'b'`) determine the alignment on the latex array environments

EXAMPLES:

```
sage: array=[[None, 2,3,4],[None,None],[5,6,7,8]]
sage: print(sage.combinat.output.tex_from_skew_array(array))
\raisebox{-.6ex}{$\begin{array}[b]{*{4}c}\\
&\lr{2}&\lr{3}&\lr{4}\\
&\\
\lr{5}&\lr{6}&\lr{7}&\lr{8}\\
\end{array}$}
```

```
>>> from sage.all import *
>>> array=[[None, Integer(2),Integer(3),Integer(4)],[None,None],[Integer(5),
↪Integer(6),Integer(7),Integer(8)]]
>>> print(sage.combinat.output.tex_from_skew_array(array))
\raisebox{-.6ex}{$\begin{array}[b]{*{4}c}\\
&\lr{2}&\lr{3}&\lr{4}\\
&\\
\lr{5}&\lr{6}&\lr{7}&\lr{8}\\
\end{array}$}
```

Parallelogram polyominoes

The goal of this module is to give some tools to manipulate the parallelogram polyominoes.

class sage.combinat.parallelogram_polyomino.**LocalOptions**(*name=''*, ***options*)

Bases: `object`

This class allow to add local options to an object. LocalOptions is like a dictionary, it has keys and values that represent options and the values associated to the option. This is useful to decorate an object with some optional informations.

LocalOptions should be used as follow.

INPUT:

- `name` – the name of the LocalOptions
- `<options>=dict(...)` – dictionary specifying an option

The options are specified by keyword arguments with their values being a dictionary which describes the option. The allowed/expected keys in the dictionary are:

- `checker` – a function for checking whether a particular value for the option is valid
- `default` – the default value of the option
- `values` – dictionary of the legal values for this option (this automatically defines the corresponding `checker`); this dictionary gives the possible options, as keys, together with a brief description of them

```
sage: from sage.combinat.parallelogram_polyomino import LocalOptions
sage: o = LocalOptions(
....:     'Name Example',
....:     delim=dict(
....:         default='b',
....:         values={'b':'the option b', 'p':'the option p'}
....:     )
....: )
sage: class Ex:
....:     options=o
....:     def _repr_b(self): return "b"
....:     def _repr_p(self): return "p"
....:     def __repr__(self): return self.options._dispatch(
....:         self, '_repr_','delim'
....:     )
sage: e = Ex(); e
b
sage: e.options(delim='p'); e
p
```

```
>>> from sage.all import *
>>> from sage.combinat.parallelogram_polyomino import LocalOptions
>>> o = LocalOptions(
...     'Name Example',
...     delim=dict(
...         default='b',
...         values={'b':'the option b', 'p':'the option p'}
...     )
... )
>>> class Ex:
...     options=o
...     def _repr_b(self): return "b"
...     def _repr_p(self): return "p"
...     def __repr__(self): return self.options._dispatch(
...         self, '_repr_','delim'
...     )
>>> e = Ex(); e
b
>>> e.options(delim='p'); e
p
```

This class is temporary, in the future, this class should be integrated in sage.structure.global_options.py. We should split global_option in two classes LocalOptions and GlobalOptions.

keys()

Return the list of the options in `self`.

EXAMPLES:

```
sage: from sage.combinat.parallelogram_polyomino import (
....:     LocalOptions
....: )
sage: o = LocalOptions(
```

(continues on next page)

(continued from previous page)

```
....:     "Name Example",

class sage.combinat.parallelogram_polyomino.**ParallelogramPolyomino**(*parent*, *value*, *check=True*)

Bases: ClonableList

Parallelogram Polyominoes.

A parallelogram polyomino is a finite connected union of cells whose boundary can be decomposed in two paths, the upper and the lower paths, which are comprised of north and east unit steps and meet only at their starting and final points.

Parallelogram Polyominoes can be defined with those two paths.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp
[[0, 1], [1, 0]]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp
[[0, 1], [1, 0]]
```

area()

Return the area of the parallelogram polyomino. The area of a parallelogram polyomino is the number of cells of the parallelogram polyomino.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 1, 0, 1, 1, 1, 0, 0, 1, 1],
....:         [1, 1, 0, 1, 0, 1, 1, 0, 1, 0, 0]
....:     ]
....: )
sage: pp.area()
13

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.area()
1

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.area()
0
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0)]
...     ]
... )
>>> pp.area()
13

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(0)]])
>>> pp.area()
1

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.area()
0
```

bounce(*direction=1*)

Return the bounce of the parallelogram polyomino.

Let `p` be the bounce path of the parallelogram polyomino (*bounce_path()*). The bounce is defined by:

```
sum([(1+ floor(i/2))*p[i] for i in range(len(p))])
```

INPUT:

- `direction` – the initial direction of the bounce path (see *bounce_path()* for the definition)

EXAMPLES:

```
sage: PP = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]
....: )
sage: PP.bounce(direction=1)
6
sage: PP.bounce(direction=0)
7

sage: PP = ParallelogramPolyomino(
....:     [
....:         [0, 0, 1, 1, 1, 0, 0, 1, 1],
....:         [1, 1, 1, 0, 1, 1, 0, 0, 0]
....:     ]
....: )
sage: PP.bounce(direction=1)
12
sage: PP.bounce(direction=0)
10

sage: PP = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: PP.bounce(direction=1)
1
sage: PP.bounce(direction=0)
1

sage: PP = ParallelogramPolyomino([[1], [1]])
sage: PP.bounce(direction=1)
0
sage: PP.bounce(direction=0)
0
```

```
>>> from sage.all import *
>>> PP = ParallelogramPolyomino(
```

(continues on next page)

(continued from previous page)

```
...      [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(1)], [Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]]
... )
>>> PP.bounce(direction=Integer(1))
6
>>> PP.bounce(direction=Integer(0))
7

>>> PP = ParallelogramPolyomino(
...      [
...          [Integer(0), Integer(0), Integer(1), Integer(1), Integer(1),␣
↪Integer(0), Integer(0), Integer(1), Integer(1)],
...          [Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0)]
...      ]
... )
>>> PP.bounce(direction=Integer(1))
12
>>> PP.bounce(direction=Integer(0))
10

>>> PP = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> PP.bounce(direction=Integer(1))
1
>>> PP.bounce(direction=Integer(0))
1

>>> PP = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> PP.bounce(direction=Integer(1))
0
>>> PP.bounce(direction=Integer(0))
0
```

bounce_path(*direction=1*)

Return the bounce path of the parallelogram polyomino.

The bounce path is a path with two steps (1, 0) and (0, 1).

If 'direction' is 1 (resp. 0), the bounce path is the path starting at position (h=1, w=0) (resp. (h=0, w=1)) with initial direction, the vector (0, 1) (resp. (1, 0)), and turning each time the path crosses the perimeter of the parallelogram polyomino.

The path is coded by a list of integers. Each integer represents the size of the path between two turnings.

You can visualize the two bounce paths by using the following commands.

INPUT:

- `direction` – the initial direction of the bounce path (see above for the definition)

EXAMPLES:

```
sage: PP = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]
....: )
sage: PP.bounce_path(direction=1)
[2, 2, 1]
sage: PP.bounce_path(direction=0)
[2, 1, 1, 1]

sage: PP = ParallelogramPolyomino(
....:     [
....:         [0, 0, 1, 1, 1, 0, 0, 1, 1],
....:         [1, 1, 1, 0, 1, 1, 0, 0, 0]
....:     ]
....: )
sage: PP.bounce_path(direction=1)
[3, 1, 2, 2]
sage: PP.bounce_path(direction=0)
[2, 4, 2]

sage: PP = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]
....: )
sage: PP.set_options(
....:     drawing_components=dict(
....:         diagram = True
....:         , bounce_0 = True
....:         , bounce_1 = True
....:     )
....: )
sage: view(PP) # not tested

sage: PP = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: PP.bounce_path(direction=1)
[1]
sage: PP.bounce_path(direction=0)
[1]

sage: PP = ParallelogramPolyomino([[1], [1]])
sage: PP.bounce_path(direction=1)
[]
sage: PP.bounce_path(direction=0)
[]
```

```
>>> from sage.all import *
>>> PP = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(1)], [Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]]
... )
>>> PP.bounce_path(direction=Integer(1))
[2, 2, 1]
>>> PP.bounce_path(direction=Integer(0))
```

(continues on next page)

(continued from previous page)

```
[2, 1, 1, 1]

>>> PP = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(1), Integer(1), Integer(1),␣
↪Integer(0), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0)]
...     ]
... )
>>> PP.bounce_path(direction=Integer(1))
[3, 1, 2, 2]
>>> PP.bounce_path(direction=Integer(0))
[2, 4, 2]

>>> PP = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(1)], [Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(0)]]
... )
>>> PP.set_options(
...     drawing_components=dict(
...         diagram = True
...         , bounce_0 = True
...         , bounce_1 = True
...     )
... )
>>> view(PP) # not tested

>>> PP = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> PP.bounce_path(direction=Integer(1))
[1]
>>> PP.bounce_path(direction=Integer(0))
[1]

>>> PP = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> PP.bounce_path(direction=Integer(1))
[]
>>> PP.bounce_path(direction=Integer(0))
[]
```

box_is_node(*pos*)

Return `True` if the box contains a node in the context of the Aval-Boussicault bijection between parallelogram polyomino and binary tree.

A box is a node if there is no cell on the top of the box in the same column or on the left of the box.in the same row.

INPUT:

- `pos` – the [x,y] coordinate of the box

OUTPUT: boolean

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
....: )
sage: pp.set_options(display='drawing')
sage: pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: pp.box_is_node([2,1])
True
sage: pp.box_is_node([2,0])
False
sage: pp.box_is_node([1,1])
False
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]]
... )
>>> pp.set_options(display='drawing')
>>> pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
>>> pp.box_is_node([Integer(2),Integer(1)])
True
>>> pp.box_is_node([Integer(2),Integer(0)])
False
>>> pp.box_is_node([Integer(1),Integer(1)])
False
```

box_is_root(*box*)

Return `True` if the box contains the root of the tree : it is the top-left box of the parallelogram polyomino.

INPUT:

- `box` – the x,y coordinate of the cell

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
....: )
sage: pp.box_is_root([0, 0])
True
sage: pp.box_is_root([0, 1])
False
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]]
... )
>>> pp.box_is_root([Integer(0), Integer(0)])
True
>>> pp.box_is_root([Integer(0), Integer(1)])
False
```

cell_is_inside(*w*, *h*)

Determine whether the cell at a given position is inside the parallelogram polyomino.

INPUT:

- `w` – the x coordinate of the box position
- `h` – the y coordinate of the box position

OUTPUT:

Return 0 if there is no cell at the given position, return 1 if there is a cell.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 1, 0, 0, 1, 1, 0, 1, 1, 1],
....:         [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]
....:     ]
....: )
sage: pp.cell_is_inside(0, 0)
1
sage: pp.cell_is_inside(1, 0)
1
sage: pp.cell_is_inside(0, 1)
0
sage: pp.cell_is_inside(3, 0)
0
sage: pp.cell_is_inside(pp.width()-1,pp.height()-1)
1
sage: pp.cell_is_inside(pp.width(),pp.height()-1)
0
sage: pp.cell_is_inside(pp.width()-1,pp.height())
0
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(1), Integer(1)],
...         [Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),␣
↪Integer(0), Integer(0), Integer(1), Integer(1), Integer(0)]
...     ]
```

(continues on next page)

(continued from previous page)

```
... )
>>> pp.cell_is_inside(Integer(0), Integer(0))
1
>>> pp.cell_is_inside(Integer(1), Integer(0))
1
>>> pp.cell_is_inside(Integer(0), Integer(1))
0
>>> pp.cell_is_inside(Integer(3), Integer(0))
0
>>> pp.cell_is_inside(pp.width()-Integer(1),pp.height()-Integer(1))
1
>>> pp.cell_is_inside(pp.width(),pp.height()-Integer(1))
0
>>> pp.cell_is_inside(pp.width()-Integer(1),pp.height())
0
```

check()

This method raises an error if the internal data of the class does not represent a parallelogram polyomino.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 0, 1, 1, 0, 0, 1, 0, 0]
....:     ]
....: )
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp = ParallelogramPolyomino([[1], [1]])

sage: pp = ParallelogramPolyomino(                # indirect doctest
....:     [[1, 0], [0, 1]]
....: )
Traceback (most recent call last):

ValueError: the lower or the upper path can...t be equal to []
```

degree_convexity()

Return the degree convexity of a parallelogram polyomino.

A convex polyomino is said to be k-convex if every pair of its cells can be connected by a monotone path (path with south and east steps) with at most k changes of direction. The degree of convexity of a convex polyomino P is the smallest integer k such that P is k-convex.

If the parallelogram polyomino is empty, the function return -1.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 0, 1, 1, 0, 0, 1, 0, 0]
....:     ]
....: )
sage: pp.degree_convexity()
3

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.degree_convexity()
0

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.degree_convexity()
-1
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(0), Integer(0)]
...     ]
... )
>>> pp.degree_convexity()
3

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.degree_convexity()
0

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.degree_convexity()
-1
```

static from_dyck_word(*dyck*, *bijection=None*)

Convert a Dyck word to parallelogram polyomino.

INPUT:

- `dyck` – a Dyck word
- `bijection` – string or `None` (default: `None`); the bijection to use. See *to_dyck_word()* for more details.

OUTPUT: a parallelogram polyomino

EXAMPLES:

```
sage: dyck = DyckWord([1, 1, 0, 1, 1, 0, 1, 0, 0, 0])
sage: ParallelogramPolyomino.from_dyck_word(dyck)
[[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
sage: ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot')
[[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
sage: ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot-
↪beta')
[[0, 0, 1, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
```

```
>>> from sage.all import *
>>> dyck = DyckWord([Integer(1), Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(0), Integer(0), Integer(0)])
>>> ParallelogramPolyomino.from_dyck_word(dyck)
[[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
>>> ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot')
[[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
>>> ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot-beta
↪')
[[0, 0, 1, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
```

geometry()

Return a pair [h, w] containing the height and the width of the parallelogram polyomino.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0, 1, 1, 1, 1], [1, 1, 1, 1, 0]]
....: )
sage: pp.geometry()
[1, 4]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.geometry()
[1, 1]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.geometry()
[0, 1]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(1), Integer(1), Integer(1), Integer(1)],␣
↪[Integer(1), Integer(1), Integer(1), Integer(1), Integer(0)]]
... )
>>> pp.geometry()
[1, 4]

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.geometry()
[1, 1]

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.geometry()
[0, 1]
```

get_BS_nodes()

Return the list of cells containing node of the left and right planar tree in the Boussicault-Socci bijection.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
....: )
sage: pp.set_options(display='drawing')
sage: pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: sorted(pp.get_BS_nodes())
[[0, 1], [1, 0], [1, 2], [2, 1], [3, 1], [4, 1]]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]]
... )
>>> pp.set_options(display='drawing')
>>> pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
>>> sorted(pp.get_BS_nodes())
[[0, 1], [1, 0], [1, 2], [2, 1], [3, 1], [4, 1]]
```

You can draw the point inside the parallelogram polyomino by typing (the left nodes are in blue, and the right node are in red)

```
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp) # not tested
```

```
>>> from sage.all import *
>>> pp.set_options(drawing_components=dict(tree=True))
>>> view(pp) # not tested
```

get_array()

Return an array of 0s and 1s such that the 1s represent the boxes of the parallelogram polyomino.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 0, 0, 1, 0, 1, 0, 1],
....:         [1, 0, 0, 0, 1, 1, 0, 0, 0]
....:     ]
....: )
sage: matrix(pp.get_array())
[1 0 0]
[1 0 0]
[1 0 0]
[1 1 1]
[0 1 1]
[0 0 1]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.get_array()
[[1]]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.get_array()
[]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(0), Integer(1), Integer(0), Integer(1)],
...         [Integer(1), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0)]
...     ]
... )
>>> matrix(pp.get_array())
[1 0 0]
[1 0 0]
[1 0 0]
[1 1 1]
[0 1 1]
[0 0 1]

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.get_array()
[[1]]

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.get_array()
[]
```

get_left_BS_nodes()

Return the list of cells containing node of the left planar tree in the Boussicault-Socci bijection between parallelogram polyominoes and pair of ordered trees.

OUTPUT: list of [row,column] position of cells

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
....: )
sage: pp.set_options(display='drawing')
sage: pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: sorted(pp.get_left_BS_nodes())
[[0, 1], [2, 1], [3, 1], [4, 1]]

sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 0, 1, 1, 0, 0, 0, 0]]
....: )
sage: pp.set_options(display='drawing')
sage: pp
[1 0 0]
[1 1 1]
```

(continues on next page)

(continued from previous page)

```
[0 1 1]
[0 1 1]
[0 1 1]
sage: sorted(pp.get_left_BS_nodes())
[]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]]
... )
>>> pp.set_options(display='drawing')
>>> pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
>>> sorted(pp.get_left_BS_nodes())
[[0, 1], [2, 1], [3, 1], [4, 1]]

>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]]
... )
>>> pp.set_options(display='drawing')
>>> pp
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
>>> sorted(pp.get_left_BS_nodes())
[]
```

You can draw the point inside the parallelogram polyomino by typing (the left nodes are in blue, and the right node are in red)

```
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp) # not tested
```

```
>>> from sage.all import *
>>> pp.set_options(drawing_components=dict(tree=True))
>>> view(pp) # not tested
```

get_node_position_from_box(*box_position*, *direction*, *nb_crossed_nodes=None*)

This function starts from a cell inside a parallelogram polyomino and a direction.

If `direction` is equal to 0, the function selects the column associated with the y-coordinate of `box_position` and then returns the topmost cell of the column that is on the top of `box_position` (the cell of `box_position` is included).

If direction is equal to 1, the function selects the row associated with the x-coordinate of box_position and then returns the leftmost cell of the row that is on the left of box_position. (the cell of box_position is included).

This function updates the entry of nb_crossed_nodes. The function increases the entry of nb_crossed_nodes by the number of boxes that is a node (see box_is_node) located on the top if direction is 0 (resp. on the left if direction is 1) of box_position (cell at box_position is excluded).

INPUT:

- box_position – the position of the starting cell
- direction – the direction (0 or 1)
- nb_crossed_nodes – [0] (default) a list containing just one integer

OUTPUT: a [row,column] position of the cell

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 0, 1, 1, 0, 0, 0, 0]]
....: )
sage: matrix(pp.get_array())
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 2], 0, l)
[1, 2]
sage: l
[1]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 2], 1, l)
[3, 1]
sage: l
[1]
sage: l = [0]
sage: pp.get_node_position_from_box([1, 2], 0, l)
[1, 2]
sage: l
[0]
sage: l = [0]
sage: pp.get_node_position_from_box([1, 2], 1, l)
[1, 0]
sage: l
[2]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 1], 0, l)
[1, 1]
sage: l
[2]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 1], 1, l)
[3, 1]
```

(continues on next page)

(continued from previous page)

```
sage: l
[0]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]]
... )
>>> matrix(pp.get_array())
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
>>> l = [Integer(0)]
>>> pp.get_node_position_from_box([Integer(3), Integer(2)], Integer(0), l)
[1, 2]
>>> l
[1]
>>> l = [Integer(0)]
>>> pp.get_node_position_from_box([Integer(3), Integer(2)], Integer(1), l)
[3, 1]
>>> l
[1]
>>> l = [Integer(0)]
>>> pp.get_node_position_from_box([Integer(1), Integer(2)], Integer(0), l)
[1, 2]
>>> l
[0]
>>> l = [Integer(0)]
>>> pp.get_node_position_from_box([Integer(1), Integer(2)], Integer(1), l)
[1, 0]
>>> l
[2]
>>> l = [Integer(0)]
>>> pp.get_node_position_from_box([Integer(3), Integer(1)], Integer(0), l)
[1, 1]
>>> l
[2]
>>> l = [Integer(0)]
>>> pp.get_node_position_from_box([Integer(3), Integer(1)], Integer(1), l)
[3, 1]
>>> l
[0]
```

get_options()

Return all the options of the object.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
```

(continues on next page)

(continued from previous page)

```
sage: pp.get_options()
Current options for ParallelogramPolyominoes_size
  - display:            'list'
  - drawing_components: {'bounce_0': False,
 'bounce_1': False,
 'bounce_values': False,
 'diagram': True,
 'tree': False}
  - latex:              'drawing'
  - tikz_options:       {'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.get_options()
Current options for ParallelogramPolyominoes_size
  - display:            'list'
  - drawing_components: {'bounce_0': False,
 'bounce_1': False,
 'bounce_values': False,
 'diagram': True,
 'tree': False}
  - latex:              'drawing'
  - tikz_options:       {'color_bounce_0': 'red',
 'color_bounce_1': 'blue',

 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

get_right_BS_nodes()

Return the list of cells containing node of the right planar tree in the Boussicault-Socci bijection between parallelogram polyominoes and pair of ordered trees.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
....: )
```

(continues on next page)

(continued from previous page)

```
sage: pp.set_options(display='drawing')
sage: pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: sorted(pp.get_right_BS_nodes())
[[1, 0], [1, 2]]

sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 0, 1, 1, 0, 0, 0, 0]]
....: )
sage: pp.set_options(display='drawing')
sage: pp
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
sage: sorted(pp.get_right_BS_nodes())
[[1, 0], [1, 1], [1, 2], [2, 1], [3, 1], [4, 1]]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]]
... )
>>> pp.set_options(display='drawing')
>>> pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
>>> sorted(pp.get_right_BS_nodes())
[[1, 0], [1, 2]]

>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]]
... )
>>> pp.set_options(display='drawing')
>>> pp
[1 0 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]
>>> sorted(pp.get_right_BS_nodes())
```

(continues on next page)

(continued from previous page)

```
[[1, 0], [1, 1], [1, 2], [2, 1], [3, 1], [4, 1]]
```

You can draw the point inside the parallelogram polyomino by typing, (the left nodes are in blue, and the right node are in red)

```
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp) # not tested
```

```
>>> from sage.all import *
>>> pp.set_options(drawing_components=dict(tree=True))
>>> view(pp) # not tested
```

get_tikz_options()

Return all the tikz options permitting to draw the parallelogram polyomino.

See *LocalOptions* to have more informations about the modification of those options.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.get_tikz_options()
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.get_tikz_options()
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

height()

Return the height of the parallelogram polyomino.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 1, 0, 0, 1, 1, 0, 1, 1, 1],
....:         [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]
....:     ]
....: )
sage: pp.height()
4

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.height()
1

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.height()
0
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(1), Integer(1)],
...         [Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),␣
↪Integer(0), Integer(0), Integer(1), Integer(1), Integer(0)]
...     ]
... )
>>> pp.height()
4

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.height()
1

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.height()
0
```

heights()

Return a list of heights of the parallelogram polyomino.

Namely, the parallelogram polyomino is split column by column and the method returns the list containing the sizes of the columns.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 0, 1, 1, 0, 0, 1, 0, 0]
....:     ]
....: )
sage: pp.heights()
```

(continues on next page)

(continued from previous page)

```
[3, 3, 4, 2]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.heights()
[1]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.heights()
[0]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(0), Integer(0)]
...     ]
... )
>>> pp.heights()
[3, 3, 4, 2]

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.heights()
[1]

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.heights()
[0]
```

is_flat()

Return whether the two bounce paths join together in the rightmost cell of the bottom row of P.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 0, 1, 1, 0, 0, 1, 0, 0]
....:     ]
....: )
sage: pp.is_flat()
False

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.is_flat()
True

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.is_flat()
True
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(0), Integer(0)]
...     ]
... )
>>> pp.is_flat()
False

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.is_flat()
True

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.is_flat()
True
```

is_k_directed(k)

Return whether the Polyomino Parallelogram is k-directed.

A convex polyomino is said to be k-convex if every pair of its cells can be connected by a monotone path (path with south and east steps) with at most k changes of direction.

The degree of convexity of a convex polyomino P is the smallest integer k such that P is k-convex.

INPUT:

- `k` – nonnegative integer

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 0, 1, 1, 0, 0, 1, 0, 0]
....:     ]
....: )
sage: pp.is_k_directed(3)
True
sage: pp.is_k_directed(4)
True
sage: pp.is_k_directed(5)
True
sage: pp.is_k_directed(0)
False
sage: pp.is_k_directed(1)
False
sage: pp.is_k_directed(2)
False

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
```

(continues on next page)

(continued from previous page)

```
sage: pp.is_k_directed(0)
True
sage: pp.is_k_directed(1)
True

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.is_k_directed(0)
True
sage: pp.is_k_directed(1)
True
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(0), Integer(0)]
...     ]
... )
>>> pp.is_k_directed(Integer(3))
True
>>> pp.is_k_directed(Integer(4))
True
>>> pp.is_k_directed(Integer(5))
True
>>> pp.is_k_directed(Integer(0))
False
>>> pp.is_k_directed(Integer(1))
False
>>> pp.is_k_directed(Integer(2))
False

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.is_k_directed(Integer(0))
True
>>> pp.is_k_directed(Integer(1))
True

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.is_k_directed(Integer(0))
True
>>> pp.is_k_directed(Integer(1))
True
```

lower_heights()

Return the list of heights associated to each vertical step of the parallelogram polyomino's lower path.

OUTPUT: list of integers

EXAMPLES:

```
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).lower_heights()
[1]
sage: ParallelogramPolyomino(
....:     [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
....: ).lower_heights()
[2, 2, 3, 3, 3]
```

```
>>> from sage.all import *
>>> ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]]).lower_heights()
[1]
>>> ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]]
... ).lower_heights()
[2, 2, 3, 3, 3]
```

lower_path()

Get the lower path of the parallelogram polyomino.

EXAMPLES:

```
sage: lower_path = [0, 0, 1, 0, 1, 1]
sage: upper_path = [1, 1, 0, 1, 0, 0]
sage: pp = ParallelogramPolyomino([lower_path, upper_path])
sage: pp.lower_path()
[0, 0, 1, 0, 1, 1]
```

```
>>> from sage.all import *
>>> lower_path = [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(1)]
>>> upper_path = [Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),␣
↪Integer(0)]
>>> pp = ParallelogramPolyomino([lower_path, upper_path])
>>> pp.lower_path()
[0, 0, 1, 0, 1, 1]
```

lower_widths()

Return the list of widths associated to each horizontal step of the parallelogram polyomino's lower path.

OUTPUT: list of integers

EXAMPLES:

```
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).lower_widths()
[0]
sage: ParallelogramPolyomino(
....:     [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
....: ).lower_widths()
[0, 0, 2]
```

```
>>> from sage.all import *
>>> ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]]).lower_widths()
[0]
>>> ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]]
... ).lower_widths()
[0, 0, 2]
```

plot()

Return a plot of `self`.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino([[0,1],[1,0]])
sage: pp.plot()                                                             #␣
↪needs sage.plot
Graphics object consisting of 4 graphics primitives
sage: pp.set_options(
....:     drawing_components=dict(
....:         diagram=True,
....:         bounce_0=True,
....:         bounce_1=True,
....:         bounce_values=0,
....:     )
....: )
sage: pp.plot()                                                             #␣
↪needs sage.plot
Graphics object consisting of 7 graphics primitives
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0),Integer(1)],[Integer(1),
↪Integer(0)]])
>>> pp.plot()                                                               #␣
↪needs sage.plot
Graphics object consisting of 4 graphics primitives
>>> pp.set_options(
...     drawing_components=dict(
...         diagram=True,
...         bounce_0=True,
...         bounce_1=True,
...         bounce_values=Integer(0),
...     )
... )
>>> pp.plot()                                                               #␣
↪needs sage.plot
Graphics object consisting of 7 graphics primitives
```

reflect()

Return the parallelogram polyomino obtained by switching rows and columns.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino([[0,0,0,0,1,1,0,1,0,1], [1,0,1,0,0,1,1,0,0,
↪0]])
sage: pp.heights(), pp.upper_heights()
([4, 3, 2, 3], [0, 1, 3, 3])
sage: pp = pp.reflect()
sage: pp.widths(), pp.lower_widths()
([4, 3, 2, 3], [0, 1, 3, 3])

sage: pp = ParallelogramPolyomino([[0,0,0,1,1], [1,0,0,1,0]])
sage: ascii_art(pp)
*
*
**
sage: ascii_art(pp.reflect())
***
  *
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0),Integer(0),Integer(0),Integer(0),
↪Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),Integer(1)],␣
↪[Integer(1),Integer(0),Integer(1),Integer(0),Integer(0),Integer(1),
↪Integer(1),Integer(0),Integer(0),Integer(0)]])
>>> pp.heights(), pp.upper_heights()
([4, 3, 2, 3], [0, 1, 3, 3])
>>> pp = pp.reflect()
>>> pp.widths(), pp.lower_widths()
([4, 3, 2, 3], [0, 1, 3, 3])

>>> pp = ParallelogramPolyomino([[Integer(0),Integer(0),Integer(0),Integer(1),
↪Integer(1)], [Integer(1),Integer(0),Integer(0),Integer(1),Integer(0)]])
>>> ascii_art(pp)
*
*
**
>>> ascii_art(pp.reflect())
***
  *
```

rotate()

Return the parallelogram polyomino obtained by rotation of 180 degrees.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino([[0,0,0,1,1], [1,0,0,1,0]])
sage: ascii_art(pp)
*
*
**
sage: ascii_art(pp.rotate())
**
 *
 *
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0),Integer(0),Integer(0),Integer(1),
↪Integer(1)], [Integer(1),Integer(0),Integer(0),Integer(1),Integer(0)]])
>>> ascii_art(pp)
*
*
**
>>> ascii_art(pp.rotate())
**
 *
 *
```

set_options(**get_value*, ***set_value*)

Set new options to the object. See *LocalOptions* for more info.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 0, 0, 1, 0, 1, 0, 1],
....:         [1, 0, 0, 0, 1, 1, 0, 0, 0]
....:     ]
....: )
sage: pp
[[0, 0, 0, 0, 1, 0, 1, 0, 1], [1, 0, 0, 0, 1, 1, 0, 0, 0]]
sage: pp.set_options(display='drawing')
sage: pp
[1 0 0]
[1 0 0]
[1 0 0]
[1 1 1]
[0 1 1]
[0 0 1]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: view(PP) # not tested
sage: pp.set_options(
....:     drawing_components=dict(
....:         diagram = True,
....:         bounce_0 = True,
....:         bounce_1 = True,
....:     )
....: )
sage: view(PP) # not tested
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(0), Integer(1), Integer(0), Integer(1)],
...         [Integer(1), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(0), Integer(0)]
...     ]
```

(continues on next page)

(continued from previous page)

```
... )
>>> pp
[[0, 0, 0, 0, 1, 0, 1, 0, 1], [1, 0, 0, 0, 1, 1, 0, 0, 0]]
>>> pp.set_options(display='drawing')
>>> pp
[1 0 0]
[1 0 0]
[1 0 0]
[1 1 1]
[0 1 1]
[0 0 1]

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> view(PP) # not tested
>>> pp.set_options(
...     drawing_components=dict(
...         diagram = True,
...         bounce_0 = True,
...         bounce_1 = True,
...     )
... )
>>> view(PP) # not tested
```

size()

Return the size of the parallelogram polyomino.

The size of a parallelogram polyomino is its half-perimeter.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 0, 0, 1, 0, 1, 1], [1, 0, 0, 0, 1, 1, 0, 0]]
....: )
sage: pp.size()
8

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.size()
2

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.size()
1
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(0),␣
↪Integer(0), Integer(1), Integer(1), Integer(0), Integer(0)]]
... )
>>> pp.size()
8
```

(continues on next page)

(continued from previous page)

```
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.size()
2

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.size()
1
```

to_binary_tree(*bijection=None*)

Convert to a binary tree.

INPUT:

- `bijection` – string or `None` (default: `None`); the name of bijection to use for the conversion. The possible values are `None` or `'Aval-Boussicault'`. The `None` value is equivalent to `'Aval-Boussicault'`.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
....:     ]
....: )
sage: pp.to_binary_tree()
[[., [[., .], [[., [., .]], .]]], [[., .], .]]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.to_binary_tree()
[., .]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.to_binary_tree()
.
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(0), Integer(0), Integer(0), Integer(1), Integer(0)]
...     ]
... )
>>> pp.to_binary_tree()
[[., [[., .], [[., [., .]], .]]], [[., .], .]]

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.to_binary_tree()
```

(continues on next page)

(continued from previous page)

```
[., .]

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.to_binary_tree()
.
```

to_dyck_word(*bijection=None*)

Convert to a Dyck word.

INPUT:

- `bijection` – string or `None` (default: `None`); the name of the bijection. If it is set to `None` then the `'Delest-Viennot'` bijection is used. Expected values are `None`, `'Delest-Viennot'`, or `'Delest-Viennot-beta'`.

OUTPUT: a Dyck word

EXAMPLES:

```
sage: pp = ParallelogramPolyomino([[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]])
sage: pp.to_dyck_word()
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]
sage: pp.to_dyck_word(bijection='Delest-Viennot')
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]

sage: pp.to_dyck_word(bijection='Delest-Viennot-beta')
[1, 0, 1, 1, 1, 0, 1, 0, 0, 0]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(1),␣
↪Integer(0), Integer(0), Integer(0)]])
>>> pp.to_dyck_word()
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]
>>> pp.to_dyck_word(bijection='Delest-Viennot')
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]

>>> pp.to_dyck_word(bijection='Delest-Viennot-beta')
[1, 0, 1, 1, 1, 0, 1, 0, 0, 0]
```

to_ordered_tree(*bijection=None*)

Return an ordered tree from the parallelogram polyomino.

Different bijections can be specified.

The bijection 'via dyck and Delest-Viennot' is the composition of `_to_dyck_delest_viennot` and the classical bijection between dyck paths and ordered trees.

The bijection between Dyck Word and ordered trees is described in [DerZak1980] (See page 12 and 13 and Figure 3.1).

The bijection 'Boussicault-Socci' is described in [BRS2015].

INPUT:

- `bijection` – string or `None` (default: `None`); the name of bijection to use for the conversion. The possible value are `None`, `'Boussicault-Socci'` or `'via dyck and Delest-Viennot'`. The `None`

value is equivalent to the `'Boussicault-Socci'` value.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
....:     ]
....: )
sage: pp.to_ordered_tree()
[[[[[[]]]]], [[[[[[[[]]]]]]]], [[[[]]]]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.to_ordered_tree()
[[[]]]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.to_ordered_tree()
[]

sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
....:     ]
....: )
sage: pp.to_ordered_tree('via dyck and Delest-Viennot')
[[[[[]]]], [[[[]]]], [[[]]], [[[[]]]]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(0), Integer(0), Integer(0), Integer(1), Integer(0)]
...     ]
... )
>>> pp.to_ordered_tree()
[[[[[[]]]]], [[[[[[[[]]]]]]]], [[[[]]]]

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.to_ordered_tree()
[[[]]]

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.to_ordered_tree()
[]

>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)],
...          [Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),␣
↪Integer(0), Integer(0), Integer(0), Integer(1), Integer(0)]
...      ]
... )
>>> pp.to_ordered_tree('via dyck and Delest-Viennot')
[[[[]], [[[]], [[]], [[]]]
```

to_tikz()

Return the tikz code of the parallelogram polyomino.

This code is the code present inside a tikz latex environment.

We can modify the output with the options.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [[0,0,0,1,1,0,1,0,0,1,1,1],[1,1,1,0,0,1,1,0,0,1,0,0]]
....: )
sage: print(pp.to_tikz())

  \draw[color=black, line width=1] (0.000000, 6.000000) --
(0.000000, 3.000000);
  \draw[color=black, line width=1] (6.000000, 2.000000) --
(6.000000, 0.000000);
  \draw[color=black, line width=1] (0.000000, 6.000000) --
(3.000000, 6.000000);
  \draw[color=black, line width=1] (3.000000, 0.000000) --
(6.000000, 0.000000);
  \draw[color=black, line width=1] (1.000000, 6.000000) --
(1.000000, 3.000000);
  \draw[color=black, line width=1] (2.000000, 6.000000) --
(2.000000, 2.000000);
  \draw[color=black, line width=1] (3.000000, 6.000000) --
(3.000000, 0.000000);

  \filldraw[color=black] (0.500000, 5.500000) circle (3.5pt);
```

upper_heights()

Return the list of heights associated to each vertical step of the parallelogram polyomino's upper path.

OUTPUT: list of integers

EXAMPLES:

```
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).upper_heights()
[0]
sage: ParallelogramPolyomino(
....:     [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
....: ).upper_heights()
[0, 1, 1, 2, 2]
```

```
>>> from sage.all import *
>>> ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]]).upper_heights()
[0]
>>> ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]]
... ).upper_heights()
[0, 1, 1, 2, 2]
```

upper_path()

Get the upper path of the parallelogram polyomino.

EXAMPLES:

```
sage: lower_path = [0, 0, 1, 0, 1, 1]
sage: upper_path = [1, 1, 0, 1, 0, 0]
sage: pp = ParallelogramPolyomino([lower_path, upper_path])
sage: pp.upper_path()
[1, 1, 0, 1, 0, 0]
```

```
>>> from sage.all import *
>>> lower_path = [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),␣
↪Integer(1)]
```

(continues on next page)

(continued from previous page)

```
>>> upper_path = [Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),␣
↪Integer(0)]
>>> pp = ParallelogramPolyomino([lower_path, upper_path])
>>> pp.upper_path()
[1, 1, 0, 1, 0, 0]
```

upper_widths()

Return the list of widths associated to each horizontal step of the parallelogram polyomino's upper path.

OUTPUT: list of integers

EXAMPLES:

```
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).upper_widths()
[1]
sage: ParallelogramPolyomino(
....:     [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
....: ).upper_widths()
[1, 3, 5]
```

```
>>> from sage.all import *
>>> ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]]).upper_widths()
[1]
>>> ParallelogramPolyomino(
...     [[Integer(0), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(1), Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]]
... ).upper_widths()
[1, 3, 5]
```

width()

Return the width of the parallelogram polyomino.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 1, 0, 0, 1, 1, 0, 1, 1, 1],
....:         [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]
....:     ]
....: )
sage: pp.width()
6

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.width()
1

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.width()
1
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(1), Integer(0), Integer(0), Integer(1),␣
↪Integer(1), Integer(0), Integer(1), Integer(1), Integer(1)],
...         [Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),␣
↪Integer(0), Integer(0), Integer(1), Integer(1), Integer(0)]
...     ]
... )
>>> pp.width()
6

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.width()
1

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.width()
1
```

widths()

Return a list of the widths of the parallelogram polyomino.

Namely, the parallelogram polyomino is split row by row and the method returns the list containing the sizes of the rows.

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
....:     [
....:         [0, 0, 0, 1, 0, 1, 0, 1, 1],
....:         [1, 0, 1, 1, 0, 0, 1, 0, 0]
....:     ]
....: )
sage: pp.widths()
[1, 3, 3, 3, 2]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.widths()
[1]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.widths()
[]
```

```
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [
...         [Integer(0), Integer(0), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(0), Integer(1), Integer(1)],
...         [Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),␣
↪Integer(0), Integer(1), Integer(0), Integer(0)]
```

(continues on next page)

(continued from previous page)

```
...      ]
... )
>>> pp.widths()
[1, 3, 3, 3, 2]

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),␣
↪Integer(0)]])
>>> pp.widths()
[1]

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.widths()
[]
```

sage.combinat.parallelogram_polyomino.**ParallelogramPolyominoes**(*size=None*, *policy=None*)

Return a family of parallelogram polyominoes enumerated with the parameter constraints.

INPUT:

- **size – integer (default: None); the size of the parallelogram**
  polyominoes contained in the family. If set to None, the family returned contains all the parallelogram polyominoes.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes(size=4)
sage: PPS
Parallelogram polyominoes of size 4
sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]

sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes
sage: PPS.cardinality()
+Infinity

sage: PPS = ParallelogramPolyominoes(size=None)
sage: PPS
Parallelogram polyominoes
sage: PPS.cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(size=Integer(4))
>>> PPS
Parallelogram polyominoes of size 4
>>> sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
```

(continues on next page)

(continued from previous page)

```
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]

>>> PPS = ParallelogramPolyominoes()
>>> PPS
Parallelogram polyominoes
>>> PPS.cardinality()
+Infinity

>>> PPS = ParallelogramPolyominoes(size=None)
>>> PPS
Parallelogram polyominoes
>>> PPS.cardinality()
+Infinity
```

class sage.combinat.parallelogram_polyomino.**ParallelogramPolyominoesFactory**

Bases: SetFactory

The parallelogram polyominoes factory.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes(size=4)
sage: PPS
Parallelogram polyominoes of size 4

sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]

sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes
sage: PPS.cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(size=Integer(4))
>>> PPS
Parallelogram polyominoes of size 4

>>> sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]
```

(continues on next page)

(continued from previous page)

```
>>> PPS = ParallelogramPolyominoes()
>>> PPS
Parallelogram polyominoes
>>> PPS.cardinality()
+Infinity
```

sage.combinat.parallelogram_polyomino.**ParallelogramPolyominoesOptions = Current options for ParallelogramPolyominoes_size - display: 'list' - drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False} - latex: 'drawing' - tikz_options: {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}**

This global option contains all the data needed by the Parallelogram classes to draw, display in ASCII, compile in latex a parallelogram polyomino.

The available options are:

- tikz_options : this option configurate all the information useful to generate TIKZ code. For example, color, line size, etc …
- drawing_components : this option is used to explain to the system which component of the drawing you want to draw. For example, you can ask to draw some elements of the following list: - the diagram, - the tree inside the parallelogram polyomino, - the bounce paths inside the parallelogram polyomino, - the value of the bounce on each square of a bounce path.
- display : this option is used to configurate the ASCII display. The available options are: - list : (this is the default value) is used to represent PP as a list containing the upper and lower path. - drawing : this value is used to explain we want to display an array with the PP drawn inside (with connected 1).
- latex : Same as display. The default is “drawing”.

See *ParallelogramPolyomino.get_options()* for more details and for an user use of options.

EXAMPLES:

```
sage: from sage.combinat.parallelogram_polyomino import (
....:     ParallelogramPolyominoesOptions
....: )
sage: opt = ParallelogramPolyominoesOptions['tikz_options']
sage: opt
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

```
>>> from sage.all import *
>>> from sage.combinat.parallelogram_polyomino import (
...     ParallelogramPolyominoesOptions
```

(continues on next page)

(continued from previous page)

```
... )
>>> opt = ParallelogramPolyominoesOptions['tikz_options']
>>> opt
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

class sage.combinat.parallelogram_polyomino.**ParallelogramPolyominoes_all**(*policy*)

Bases: ParentWithSetFactory, DisjointUnionEnumeratedSets

This class enumerates all the parallelogram polyominoes.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes()
>>> PPS
Parallelogram polyominoes
```

check_element(*el*, *check*)

Check is a given element *el* is in the set of parallelogram polyominoes.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes()
sage: ParallelogramPolyomino(                    # indirect doctest
....:     [[0, 1, 1], [1, 1, 0]]
....: ) in PPS
True
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes()
>>> ParallelogramPolyomino(                    # indirect doctest
...     [[Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1),␣
↪Integer(0)]]
... ) in PPS
True
```

get_options()

Return all the options associated with the set of parallelogram polyominoes.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes()
sage: options = PPS.get_options()
sage: options
Current options for ParallelogramPolyominoes_size
  - display:            'list'
...
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes()
>>> options = PPS.get_options()
>>> options
Current options for ParallelogramPolyominoes_size
  - display:            'list'
...
```

options = Current options for ParallelogramPolyominoes_size - display: 'list' - drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False} - latex: 'drawing' - tikz_options: {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}

The options for ParallelogramPolyominoes.

set_options(**get_value*, ***set_value*)

Set new options to the object.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes()
sage: PPS.set_options(
....:     drawing_components=dict(
....:         diagram = True,
....:         bounce_0 = True,
....:         bounce_1 = True,
....:     )
....: )
sage: pp = next(iter(PPS))
sage: view(pp) # not tested
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes()
>>> PPS.set_options(
...     drawing_components=dict(
...         diagram = True,
...         bounce_0 = True,
...         bounce_1 = True,
...     )
... )
>>> pp = next(iter(PPS))
>>> view(pp) # not tested
```

class sage.combinat.parallelogram_polyomino.**ParallelogramPolyominoes_size**(*size*, *policy*)

Bases: ParentWithSetFactory, UniqueRepresentation

The parallelogram polyominoes of size n.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes(4)
sage: PPS
Parallelogram polyominoes of size 4
sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(Integer(4))
>>> PPS
Parallelogram polyominoes of size 4
>>> sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]
```

cardinality()

Return the number of parallelogram polyominoes.

The number of parallelogram polyominoes of size n is given by the Catalan number c_{n-1}.

EXAMPLES:

```
sage: ParallelogramPolyominoes(1).cardinality()
1
sage: ParallelogramPolyominoes(2).cardinality()
1
sage: ParallelogramPolyominoes(3).cardinality()
2
sage: ParallelogramPolyominoes(4).cardinality()
5

sage: all(
....:     ParallelogramPolyominoes(i).cardinality()
....:     == len(list(ParallelogramPolyominoes(i)))
....:     for i in range(1,7)
....: )
True
```

```
>>> from sage.all import *
>>> ParallelogramPolyominoes(Integer(1)).cardinality()
1
>>> ParallelogramPolyominoes(Integer(2)).cardinality()
1
>>> ParallelogramPolyominoes(Integer(3)).cardinality()
```

(continues on next page)

(continued from previous page)

```
2
>>> ParallelogramPolyominoes(Integer(4)).cardinality()
5

>>> all(
...     ParallelogramPolyominoes(i).cardinality()
...     == len(list(ParallelogramPolyominoes(i)))
...     for i in range(Integer(1),Integer(7))
... )
True
```

check_element(*el*, *check*)

Check is a given element *el* is in the set of parallelogram polyominoes of a fixed size.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes(3)
sage: ParallelogramPolyomino(                    # indirect doctest
....:     [[0, 1, 1], [1, 1, 0]]
....: ) in PPS
True
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(Integer(3))
>>> ParallelogramPolyomino(                    # indirect doctest
...     [[Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1),␣
↪Integer(0)]]
... ) in PPS
True
```

get_options()

Return all the options associated with all the elements of the set of parallelogram polyominoes with a fixed size.

EXAMPLES:

```
sage: pps = ParallelogramPolyominoes(5)
sage: pps.get_options()
Current options for ParallelogramPolyominoes_size
  - display:           'list'
...
```

```
>>> from sage.all import *
>>> pps = ParallelogramPolyominoes(Integer(5))
>>> pps.get_options()
Current options for ParallelogramPolyominoes_size
  - display:           'list'
...
```

options = Current options for ParallelogramPolyominoes_size - display: 'list' - drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False} - latex: 'drawing' - tikz_options: {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}

The options for ParallelogramPolyominoes.

set_options(**get_value*, ***set_value*)

Set new options to the object.

EXAMPLES:

```
sage: PPS = ParallelogramPolyominoes(3)
sage: PPS.set_options(
....:     drawing_components=dict(
....:         diagram = True,
....:         bounce_0 = True,
....:         bounce_1 = True,
....:     )
....: )
sage: pp = PPS[0]
sage: view(pp) # not tested
```

```
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(Integer(3))
>>> PPS.set_options(
...     drawing_components=dict(
...         diagram = True,
...         bounce_0 = True,
...         bounce_1 = True,
...     )
... )
>>> pp = PPS[Integer(0)]
>>> view(pp) # not tested
```

size()

Return the size of the parallelogram polyominoes generated by this parent.

EXAMPLES:

```
sage: ParallelogramPolyominoes(0).size()
0
sage: ParallelogramPolyominoes(1).size()
1
sage: ParallelogramPolyominoes(5).size()
5
```

```
>>> from sage.all import *
>>> ParallelogramPolyominoes(Integer(0)).size()
0
>>> ParallelogramPolyominoes(Integer(1)).size()
1
```

(continues on next page)

(continued from previous page)

```
>>> ParallelogramPolyominoes(Integer(5)).size()
5
```

sage.combinat.parallelogram_polyomino.**default_tikz_options = {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}**

This is the default TIKZ options.

This option is used to configurate element of a drawing to allow TIKZ code generation.

Parking functions

INFORMALLY (reference [Beck]):

Imagine a one-way cul-de-sac with n parking spots. We will give the first parking spot the number 1, the next one number 2, etc., down to the last one, number n. Initially they are all free, but there are n cars approaching the street, and they would all like to park there. To make life interesting, every car has a parking preference, and we record the preferences in a sequence; For example, if $n = 3$, the sequence $(2, 1, 1)$ means that the first car would like to park at spot number 2, the second car prefers parking spot number 1, and the last car would also like to part at number 1. The street is very narrow, so there is no way to back up. Now each car enters the street and approaches its preferred parking spot; if it is free, it parks there, and if not, it moves down the street to the first available spot. We call a sequence a parking function (of length n) if all cars end up finding a parking spot. For example, the sequence $(2, 1, 1)$ is a parking sequence (of length 3), whereas the sequence $(2, 3, 2)$ is not.

FORMALLY:

A parking function of size n is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size n is a pair (L, D) of two sequences L and D where L is a permutation and D is an area sequence of a Dyck path of size n such that $D[i] \geq 0$, $D[i + 1] \leq D[i] + 1$ and if $D[i + 1] = D[i] + 1$ then $L[i + 1] > L[i]$.

The number of parking functions of size n is equal to the number of rooted forests on n vertices and is equal to $(n+1)^{n-1}$.

sage.combinat.parking_functions.**PF**

alias of *ParkingFunction*

class sage.combinat.parking_functions.**ParkingFunction**(*parent*, *lst*)

Bases: ClonableArray

A Parking Function.

A *parking function* of size n is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A *parking function* of size n is a pair (L, D) of two sequences L and D where L is a permutation and D is an area sequence of a Dyck Path of size n such that $D[i] \geq 0$, $D[i + 1] \leq D[i] + 1$ and if $D[i + 1] = D[i] + 1$ then $L[i + 1] > L[i]$.

The number of parking functions of size n is equal to the number of rooted forests on n vertices and is equal to $(n + 1)^{n-1}$.

INPUT:

- `pf` – (default: `None`) a list whose increasing rearrangement satisfies $b_i \leq i$
- `labelling` – (default: `None`) a labelling of the Dyck path
- `area_sequence` – (default: `None`) an area sequence of a Dyck path
- `labelled_dyck_word` – (default: `None`) a Dyck word with 1s replaced by labelling

OUTPUT: a parking function

EXAMPLES:

```
sage: ParkingFunction([])
[]
sage: ParkingFunction([1])
[1]
sage: ParkingFunction([2])
Traceback (most recent call last):

↪sequence=[Integer(0),Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: [3, 1, 2] is not a valid labeling of area sequence [0, 1, 1]
```

area()

Return the area of the labelled Dyck path corresponding to the parking function.

OUTPUT:

- the sum of squares under and over the main diagonal the Dyck Path, corresponding to the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.area()
6
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.area()
6
```

```
sage: ParkingFunction([3,1,1,4]).area()
1
sage: ParkingFunction([4,1,1,1]).area()
3
sage: ParkingFunction([2,1,4,1]).area()
2
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).area()
1
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).area()
3
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).area()
2
```

cars_permutation()

Return the sequence of cars that take parking spots 1 through n and corresponding to the parking function.

For example, `cars_permutation(PF) = [2, 4, 5, 6, 3, 1, 7]` means that car 2 takes spots 1, car 4 takes spot 2, …, car 1 takes spot 6 and car 7 takes spot 7.

OUTPUT:

- the permutation of cars corresponding to the parking function and which is the same size as parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.cars_permutation()
[2, 4, 5, 6, 3, 1, 7]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.cars_permutation()
[2, 4, 5, 6, 3, 1, 7]
```

```
sage: ParkingFunction([3,1,1,4]).cars_permutation()
[2, 3, 1, 4]
sage: ParkingFunction([4,1,1,1]).cars_permutation()
[2, 3, 4, 1]
sage: ParkingFunction([2,1,4,1]).cars_permutation()
[2, 1, 4, 3]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).cars_
↪permutation()
[2, 3, 1, 4]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).cars_
↪permutation()
[2, 3, 4, 1]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).cars_
↪permutation()
[2, 1, 4, 3]
```

characteristic_quasisymmetric_function(*q=None*, *R=Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field*)

Return the characteristic quasisymmetric function of `self`.

The characteristic function of the Parking Function is the sum over all permutation labellings of the Dyck path $q^{dinv(PF)}F_{ides(PF)}$ where $ides(PF)$ (*ides_composition()*) is the descent composition of diagonal reading word of the parking function.

INPUT:

- `q` – (default: `q = R('q')`) a parameter for the generating function power
- `R` – (default: `R = QQ['q','t'].fraction_field()`) the base ring to do the calculations over

OUTPUT: an element of the quasisymmetric functions over the ring `R`

EXAMPLES:

```
sage: # needs sage.modules
sage: R = QQ['q','t'].fraction_field()
sage: q, t = R.gens()
```

(continues on next page)

(continued from previous page)

```
sage: cqf = sum(t**PF.area() * PF.characteristic_quasisymmetric_function()
....:           for PF in ParkingFunctions(3)); cqf
(q^3+q^2*t+q*t^2+t^3+q*t)*F[1, 1, 1] + (q^2+q*t+t^2+q+t)*F[1, 2]
 + (q^2+q*t+t^2+q+t)*F[2, 1] + F[3]
sage: s = SymmetricFunctions(R).s()
sage: s(cqf.to_symmetric_function())
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: s(cqf.to_symmetric_function()).nabla(power=-1)
s[1, 1, 1]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> R = QQ['q','t'].fraction_field()
>>> q, t = R.gens()
>>> cqf = sum(t**PF.area() * PF.characteristic_quasisymmetric_function()
...           for PF in ParkingFunctions(Integer(3))); cqf
(q^3+q^2*t+q*t^2+t^3+q*t)*F[1, 1, 1] + (q^2+q*t+t^2+q+t)*F[1, 2]
 + (q^2+q*t+t^2+q+t)*F[2, 1] + F[3]
>>> s = SymmetricFunctions(R).s()
>>> s(cqf.to_symmetric_function())
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
>>> s(cqf.to_symmetric_function()).nabla(power=-Integer(1))
s[1, 1, 1]
```

```
sage: p = ParkingFunction([3, 1, 2])
sage: p.characteristic_quasisymmetric_function()                              #␣
↪needs sage.modules
q*F[2, 1]
sage: pf = ParkingFunction([1,2,7,2,1,2,3,2,1])
sage: pf.characteristic_quasisymmetric_function()                             #␣
↪needs sage.modules
q^2*F[1, 1, 1, 2, 1, 3]
```

```
>>> from sage.all import *
>>> p = ParkingFunction([Integer(3), Integer(1), Integer(2)])
>>> p.characteristic_quasisymmetric_function()                                #␣
↪needs sage.modules
q*F[2, 1]
>>> pf = ParkingFunction([Integer(1),Integer(2),Integer(7),Integer(2),
↪Integer(1),Integer(2),Integer(3),Integer(2),Integer(1)])
>>> pf.characteristic_quasisymmetric_function()                               #␣
↪needs sage.modules
q^2*F[1, 1, 1, 2, 1, 3]
```

check()

Check that `self` is a valid parking function.

EXAMPLES:

```
sage: PF = ParkingFunction([1, 1, 2, 2, 5, 6])
sage: PF.check()
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(5), Integer(6)])
>>> PF.check()
```

diagonal_composition()

alias of *touch_composition()*.

diagonal_reading_word()

Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

OUTPUT:

- returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to `self` and the same size as `self`

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]
```

```
sage: ParkingFunction([1, 1, 1]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 1, 3, 4]).diagonal_reading_word()
[2, 4, 3, 1]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(1), Integer(1), Integer(1)]).diagonal_reading_
↪word()
[3, 2, 1]
>>> ParkingFunction([Integer(1), Integer(2), Integer(3)]).diagonal_reading_
↪word()
[3, 2, 1]
>>> ParkingFunction([Integer(1), Integer(1), Integer(3), Integer(4)]).
↪diagonal_reading_word()
[2, 4, 3, 1]
```

```
sage: ParkingFunction([1, 1, 1]).diagonal_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_word()
[3, 2, 1]
sage: ParkingFunction([1, 4, 3, 1]).diagonal_word()
[4, 2, 3, 1]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(1), Integer(1), Integer(1)]).diagonal_word()
[3, 2, 1]
>>> ParkingFunction([Integer(1), Integer(2), Integer(3)]).diagonal_word()
[3, 2, 1]
>>> ParkingFunction([Integer(1), Integer(4), Integer(3), Integer(1)]).
↪diagonal_word()
[4, 2, 3, 1]
```

diagonal_word()

alias of *diagonal_reading_word()*.

dinv()

Return the number of inversions of a labelled Dyck path corresponding to the parking function (see [Hag08] p. 74).

Same as the cardinality of *dinversion_pairs()*.

OUTPUT: the number of dinversion pairs

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinv()
6
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.dinv()
6
```

```
sage: ParkingFunction([3,1,1,4]).dinv()
3
sage: ParkingFunction([4,1,1,1]).dinv()
1
sage: ParkingFunction([2,1,4,1]).dinv()
2
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).dinv()
3
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).dinv()
1
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).dinv()
2
```

dinversion_pairs()

Return the descent inversion pairs of a labelled Dyck path corresponding to the parking function.

OUTPUT: the primary and secondary diversion pairs

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinversion_pairs()
[(0, 4), (1, 5), (2, 5), (1, 4), (2, 4), (3, 6)]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.dinversion_pairs()
[(0, 4), (1, 5), (2, 5), (1, 4), (2, 4), (3, 6)]
```

```
sage: ParkingFunction([3,1,1,4]).dinversion_pairs()
[(0, 3), (2, 3), (1, 2)]
sage: ParkingFunction([4,1,1,1]).dinversion_pairs()
[(1, 3)]
sage: ParkingFunction([2,1,4,1]).dinversion_pairs()
[(0, 3), (1, 3)]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).dinversion_
↪pairs()
[(0, 3), (2, 3), (1, 2)]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).dinversion_
↪pairs()
[(1, 3)]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).dinversion_
↪pairs()
[(0, 3), (1, 3)]
```

grade()

Return the length of the parking function.

EXAMPLES:

```
sage: PF = ParkingFunction([1, 1, 2, 2, 5, 6])
sage: PF.grade()
6
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(5), Integer(6)])
>>> PF.grade()
6
```

ides()

Return the *descents()* sequence of the inverse of the *diagonal_reading_word()* of `self`.

> **Warning**
>
> Here we use the standard convention that descent labels start at 1. This behaviour has been changed in Issue #20555.

For example, `ides(PF) = [2, 3, 4, 6]` means that descents are at the 2nd, 3rd, 4th and 6th positions in the inverse of the *diagonal_reading_word()* of the parking function (see [GXZ] p. 2).

OUTPUT:

- the descents sequence of the inverse of the *diagonal_reading_word()* of the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides()
[2, 3, 4, 6]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.ides()
[2, 3, 4, 6]
```

```
sage: ParkingFunction([3,1,1,4]).ides()
[2]
sage: ParkingFunction([4,1,1,1]).ides()
[2, 3]
sage: ParkingFunction([4,3,1,1]).ides()
[3]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).ides()
[2]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).ides()
[2, 3]
>>> ParkingFunction([Integer(4),Integer(3),Integer(1),Integer(1)]).ides()
[3]
```

ides_composition()

Return the *descents_composition()* of the inverse of the *diagonal_reading_word()* of corresponding parking function.

For example, `ides_composition(PF) = [4, 2, 1]` means that the descents of the inverse of the permutation *diagonal_reading_word()* of the parking function with word `PF` are at the 4th and 6th positions.

OUTPUT:

- the descents composition of the inverse of the *diagonal_reading_word()* of the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides_composition()
[2, 1, 1, 2, 1]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.ides_composition()
[2, 1, 1, 2, 1]
```

```
sage: ParkingFunction([3,1,1,4]).ides_composition()
[2, 2]
sage: ParkingFunction([4,1,1,1]).ides_composition()
[2, 1, 1]
sage: ParkingFunction([4,3,1,1]).ides_composition()
[3, 1]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).ides_
↪composition()
[2, 2]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).ides_
↪composition()
[2, 1, 1]
>>> ParkingFunction([Integer(4),Integer(3),Integer(1),Integer(1)]).ides_
↪composition()
[3, 1]
```

jump()

Return the sum of the differences between the parked and preferred parking spots.

See [Shin] p. 18.

OUTPUT:

- the sum of the differences between the parked and preferred parking spots

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.jump()
6
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.jump()
6
```

```
sage: ParkingFunction([3,1,1,4]).jump()
1
sage: ParkingFunction([4,1,1,1]).jump()
3
```

(continues on next page)

(continued from previous page)

```
sage: ParkingFunction([2,1,4,1]).jump()
2
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).jump()
1
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).jump()
3
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).jump()
2
```

jump_list()

Return the displacements of cars that corresponds to the parking function.

For example, `jump_list(PF) = [0, 0, 0, 0, 1, 3, 2]` means that car 1 through 4 parked in their preferred spots, car 5 had to park one spot farther (jumped or was displaced by one spot), car 6 had to jump 3 spots, and car 7 had to jump two spots.

OUTPUT:

- the displacements sequence of parked cars which corresponds to the parking function and which is the same size as parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.jump_list()
[0, 0, 0, 0, 1, 3, 2]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.jump_list()
[0, 0, 0, 0, 1, 3, 2]
```

```
sage: ParkingFunction([3,1,1,4]).jump_list()
[0, 0, 1, 0]
sage: ParkingFunction([4,1,1,1]).jump_list()
[0, 0, 1, 2]
sage: ParkingFunction([2,1,4,1]).jump_list()
[0, 0, 0, 2]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).jump_list()
[0, 0, 1, 0]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).jump_list()
[0, 0, 1, 2]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).jump_list()
[0, 0, 0, 2]
```

luck()

Return the number of cars that parked in their preferred parking spots (see [Shin] p. 33).

OUTPUT: the number of cars that parked in their preferred parking spots

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.luck()
4
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.luck()
4
```

```
sage: ParkingFunction([3,1,1,4]).luck()
3
sage: ParkingFunction([4,1,1,1]).luck()
2
sage: ParkingFunction([2,1,4,1]).luck()
3
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).luck()
3
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).luck()
2
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).luck()
3
```

lucky_cars()

Return the cars that can park in their preferred spots. For example, `lucky_cars(PF) = [1, 2, 7]` means that cars 1, 2 and 7 parked in their preferred spots and all the other cars did not.

OUTPUT: the cars that can park in their preferred spots

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.lucky_cars()
[1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.lucky_cars()
[1, 2, 3, 4]
```

```
sage: ParkingFunction([3,1,1,4]).lucky_cars()
[1, 2, 4]
sage: ParkingFunction([4,1,1,1]).lucky_cars()
[1, 2]
sage: ParkingFunction([2,1,4,1]).lucky_cars()
[1, 2, 3]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).lucky_
↪cars()
[1, 2, 4]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).lucky_
↪cars()
[1, 2]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).lucky_
↪cars()
[1, 2, 3]
```

parking_permutation()

Return the sequence of parking spots that are taken by cars 1 through n and corresponding to the parking function.

For example, `parking_permutation(PF) = [6, 1, 5, 2, 3, 4, 7]` means that spot 6 is taken by car 1, spot 1 by car 2, spot 5 by car 3, spot 2 is taken by car 4, spot 3 is taken by car 5, spot 4 is taken by car 6 and spot 7 is taken by car 7.

OUTPUT:

- the permutation of parking spots that corresponds to the parking function and which is the same size as parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.parking_permutation()
[6, 1, 5, 2, 3, 4, 7]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.parking_permutation()
[6, 1, 5, 2, 3, 4, 7]
```

```
sage: ParkingFunction([3,1,1,4]).parking_permutation()
[3, 1, 2, 4]
sage: ParkingFunction([4,1,1,1]).parking_permutation()
[4, 1, 2, 3]
sage: ParkingFunction([2,1,4,1]).parking_permutation()
[2, 1, 4, 3]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).parking_
↪permutation()
[3, 1, 2, 4]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).parking_
↪permutation()
[4, 1, 2, 3]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).parking_
↪permutation()
[2, 1, 4, 3]
```

pretty_print(*underpath=True*)

Displays a parking function as a lattice path consisting of a Dyck path and a labelling with the labels displayed along the edges of the Dyck path.

INPUT:

- `underpath` – if the length of the parking function is less than or equal to 9 then display the labels under the path if `underpath` is `True` otherwise display them to the right of the path (default: `True`)

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print()
          ___
         _|1x
        |7x  .
   _____|3 . .
  |5x x  . . .
 _|4x  . . . .
|6x  . . . . .
|2 . . . . . .

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print(underpath = false)
          ___
         _| x  1
        | x  . 7
   _____|  . . 3
  | x x  . . . 5
 _| x  . . . . 4
| x  . . . . . 6
|  . . . . . . 2
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.pretty_print()
          ___
         _|1x
        |7x  .
   _____|3 . .
  |5x x  . . .
 _|4x  . . . .
|6x  . . . . .
|2 . . . . . .

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.pretty_print(underpath = false)
          ___
         _| x  1
        | x  . 7
   _____|  . . 3
  | x x  . . . 5
```

(continues on next page)

(continued from previous page)

```
 _| x  . . . . 4
| x  . . . . . 6
|  . . . . . . 2
```

```
sage: ParkingFunction([3, 1, 1, 4]).pretty_print()

```

(continues on next page)

(continued from previous page)

```
| x  . . . . . .  7
|  . . . . . .  1
```

primary_dinversion_pairs()

Return the primary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

OUTPUT:

The pairs (i, j) such that $i < j$, and i-th area = j-th area, and i-th label < j-th label

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.primary_dinversion_pairs()
[(0, 4), (1, 5), (2, 5)]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.primary_dinversion_pairs()
[(0, 4), (1, 5), (2, 5)]
```

```
sage: ParkingFunction([3,1,1,4]).primary_dinversion_pairs()
[(0, 3), (2, 3)]
sage: ParkingFunction([4,1,1,1]).primary_dinversion_pairs()
[]
sage: ParkingFunction([2,1,4,1]).primary_dinversion_pairs()
[(0, 3)]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).primary_
↪dinversion_pairs()
[(0, 3), (2, 3)]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).primary_
↪dinversion_pairs()
[]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).primary_
↪dinversion_pairs()
[(0, 3)]
```

secondary_dinversion_pairs()

Return the secondary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

OUTPUT:

The pairs (i, j) such that $i < j$, and i-th area = j-th area +1, and i-th label > j-th label

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.secondary_dinversion_pairs()
[(1, 4), (2, 4), (3, 6)]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.secondary_dinversion_pairs()
[(1, 4), (2, 4), (3, 6)]
```

```
sage: ParkingFunction([3,1,1,4]).secondary_dinversion_pairs()
[(1, 2)]
sage: ParkingFunction([4,1,1,1]).secondary_dinversion_pairs()
[(1, 3)]
sage: ParkingFunction([2,1,4,1]).secondary_dinversion_pairs()
[(1, 3)]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).secondary_
↪dinversion_pairs()
[(1, 2)]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).secondary_
↪dinversion_pairs()
[(1, 3)]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).secondary_
↪dinversion_pairs()
[(1, 3)]
```

to_NonDecreasingParkingFunction()

Return the non-decreasing parking function which underlies the parking function.

OUTPUT: a sorted parking function

See also

NonDecreasingParkingFunction()

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_NonDecreasingParkingFunction()
[1, 1, 2, 2, 5, 5, 6]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.to_NonDecreasingParkingFunction()
[1, 1, 2, 2, 5, 5, 6]
```

```
sage: ParkingFunction([3,1,1,4]).to_NonDecreasingParkingFunction()
[1, 1, 3, 4]
sage: ParkingFunction([4,1,1,1]).to_NonDecreasingParkingFunction()
[1, 1, 1, 4]
sage: ParkingFunction([2,1,4,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
```

(continues on next page)

(continued from previous page)

```
sage: ParkingFunction([4,1,2,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).to_
↪NonDecreasingParkingFunction()
[1, 1, 3, 4]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).to_
↪NonDecreasingParkingFunction()
[1, 1, 1, 4]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).to_
↪NonDecreasingParkingFunction()
[1, 1, 2, 4]
>>> ParkingFunction([Integer(4),Integer(1),Integer(2),Integer(1)]).to_
↪NonDecreasingParkingFunction()
[1, 1, 2, 4]
```

to_area_sequence()

Return the area sequence of the support Dyck path of the parking function.

OUTPUT: the area sequence of the Dyck path

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_area_sequence()
[0, 1, 1, 2, 0, 1, 1]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.to_area_sequence()
[0, 1, 1, 2, 0, 1, 1]
```

```
sage: ParkingFunction([3,1,1,4]).to_area_sequence()
[0, 1, 0, 0]
sage: ParkingFunction([4,1,1,1]).to_area_sequence()
[0, 1, 2, 0]
sage: ParkingFunction([2,1,4,1]).to_area_sequence()
[0, 1, 1, 0]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).to_area_
↪sequence()
[0, 1, 0, 0]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).to_area_
↪sequence()
[0, 1, 2, 0]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).to_area_
↪sequence()
[0, 1, 1, 0]
```

to_dyck_word()

Return the support Dyck word of the parking function.

OUTPUT: the Dyck word of the corresponding parking function

See also

DyckWord()

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_dyck_word()
[1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.to_dyck_word()
[1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0]
```

```
sage: ParkingFunction([3,1,1,4]).to_dyck_word()
[1, 1, 0, 0, 1, 0, 1, 0]
sage: ParkingFunction([4,1,1,1]).to_dyck_word()
[1, 1, 1, 0, 0, 0, 1, 0]
sage: ParkingFunction([2,1,4,1]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).to_dyck_
↪word()
[1, 1, 0, 0, 1, 0, 1, 0]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).to_dyck_
↪word()
[1, 1, 1, 0, 0, 0, 1, 0]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).to_dyck_
↪word()
[1, 1, 0, 1, 0, 0, 1, 0]
```

to_labelled_dyck_word()

Return the labelled Dyck word corresponding to the parking function.

This is a representation of the parking function as a list where the entries of 1 in the Dyck word are replaced with the corresponding label.

OUTPUT:

- the labelled Dyck word of the corresponding parking function which is twice the size of parking function word

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelled_dyck_word()
[2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.to_labelled_dyck_word()
[2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]
```

```
sage: ParkingFunction([3,1,1,4]).to_labelled_dyck_word()
[2, 3, 0, 0, 1, 0, 4, 0]
sage: ParkingFunction([4,1,1,1]).to_labelled_dyck_word()
[2, 3, 4, 0, 0, 0, 1, 0]
sage: ParkingFunction([2,1,4,1]).to_labelled_dyck_word()
[2, 4, 0, 1, 0, 0, 3, 0]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).to_
↪labelled_dyck_word()
[2, 3, 0, 0, 1, 0, 4, 0]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).to_
↪labelled_dyck_word()
[2, 3, 4, 0, 0, 0, 1, 0]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).to_
↪labelled_dyck_word()
[2, 4, 0, 1, 0, 0, 3, 0]
```

to_labelling_area_sequence_pair()

Return a pair consisting of a labelling and an area sequence of a Dyck path which corresponds to the given parking function.

OUTPUT:

- returns a pair `(L, D)` where `L` is a labelling and `D` is the area sequence of the underlying Dyck path

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_area_sequence_pair()
([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.to_labelling_area_sequence_pair()
([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])
```

```
sage: ParkingFunction([1, 1, 1]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 1, 2])
sage: ParkingFunction([1, 2, 3]).to_labelling_area_sequence_pair()
([1, 2, 3], [0, 0, 0])
sage: ParkingFunction([1, 1, 2]).to_labelling_area_sequence_pair()
```

(continues on next page)

(continued from previous page)

```
([1, 2, 3], [0, 1, 1])
sage: ParkingFunction([1, 1, 3, 1]).to_labelling_area_sequence_pair()
([1, 2, 4, 3], [0, 1, 2, 1])
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(1), Integer(1), Integer(1)]).to_labelling_area_
↪sequence_pair()
([1, 2, 3], [0, 1, 2])
>>> ParkingFunction([Integer(1), Integer(2), Integer(3)]).to_labelling_area_
↪sequence_pair()
([1, 2, 3], [0, 0, 0])
>>> ParkingFunction([Integer(1), Integer(1), Integer(2)]).to_labelling_area_
↪sequence_pair()
([1, 2, 3], [0, 1, 1])
>>> ParkingFunction([Integer(1), Integer(1), Integer(3), Integer(1)]).to_
↪labelling_area_sequence_pair()
([1, 2, 4, 3], [0, 1, 2, 1])
```

to_labelling_dyck_word_pair()

Return the pair `(L, D)` where `L` is a labelling and `D` is the Dyck word of the parking function.

OUTPUT:

- the pair `(L, D)`, where `L` is the labelling and `D` is the Dyck word of the parking function

See also

DyckWord()

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_dyck_word_pair()
([2, 6, 4, 5, 3, 7, 1], [1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0])
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.to_labelling_dyck_word_pair()
([2, 6, 4, 5, 3, 7, 1], [1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0])
```

```
sage: ParkingFunction([3,1,1,4]).to_labelling_dyck_word_pair()
([2, 3, 1, 4], [1, 1, 0, 0, 1, 0, 1, 0])
sage: ParkingFunction([4,1,1,1]).to_labelling_dyck_word_pair()
([2, 3, 4, 1], [1, 1, 1, 0, 0, 0, 1, 0])
sage: ParkingFunction([2,1,4,1]).to_labelling_dyck_word_pair()
([2, 4, 1, 3], [1, 1, 0, 1, 0, 0, 1, 0])
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).to_
↪labelling_dyck_word_pair()
```

(continues on next page)

(continued from previous page)

```
([2, 3, 1, 4], [1, 1, 0, 0, 1, 0, 1, 0])
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).to_
↪labelling_dyck_word_pair()
([2, 3, 4, 1], [1, 1, 1, 0, 0, 0, 1, 0])
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).to_
↪labelling_dyck_word_pair()
([2, 4, 1, 3], [1, 1, 0, 1, 0, 0, 1, 0])
```

to_labelling_permutation()

Return the labelling of the support Dyck path of the parking function.

OUTPUT: the labelling of the Dyck path

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_permutation()
[2, 6, 4, 5, 3, 7, 1]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.to_labelling_permutation()
[2, 6, 4, 5, 3, 7, 1]
```

```
sage: ParkingFunction([3,1,1,4]).to_labelling_permutation()
[2, 3, 1, 4]
sage: ParkingFunction([4,1,1,1]).to_labelling_permutation()
[2, 3, 4, 1]
sage: ParkingFunction([2,1,4,1]).to_labelling_permutation()
[2, 4, 1, 3]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).to_
↪labelling_permutation()
[2, 3, 1, 4]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).to_
↪labelling_permutation()
[2, 3, 4, 1]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).to_
↪labelling_permutation()
[2, 4, 1, 3]
```

touch_composition()

Return the composition of the labelled Dyck path corresponding to the parking function.

For example, `touch_composition(PF) = [4, 3]` means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

OUTPUT:

- the length between the corresponding touch points which of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_composition()
[4, 3]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.touch_composition()
[4, 3]
```

```
sage: ParkingFunction([3,1,1,4]).touch_composition()
[2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition()
[3, 1]
sage: ParkingFunction([2,1,4,1]).touch_composition()
[3, 1]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).touch_
↪composition()
[2, 1, 1]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).touch_
↪composition()
[3, 1]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).touch_
↪composition()
[3, 1]
```

touch_points()

Return the sequence of touch points which corresponds to the labelled Dyck path after initial step.

For example, `touch_points(PF) = [4, 7]` means that after the initial step, the path touches the main diagonal at points $(4, 4)$ and $(7, 7)$.

OUTPUT:

- the sequence of touch points after the initial step of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_points()
[4, 7]
```

```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),␣
↪Integer(2), Integer(1), Integer(5)])
>>> PF.touch_points()
[4, 7]
```

```
sage: ParkingFunction([3,1,1,4]).touch_points()
[2, 3, 4]
```

(continues on next page)

(continued from previous page)

```
sage: ParkingFunction([4,1,1,1]).touch_points()
[3, 4]
sage: ParkingFunction([2,1,4,1]).touch_points()
[3, 4]
```

```
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).touch_
↪points()
[2, 3, 4]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).touch_
↪points()
[3, 4]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).touch_
↪points()
[3, 4]
```

class sage.combinat.parking_functions.**ParkingFunctions**

Bases: UniqueRepresentation, Parent

Return the combinatorial class of Parking Functions.

A *parking function* of size n is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A *parking function* of size n is a pair (L, D) of two sequences L and D where L is a permutation and D is an area sequence of a Dyck Path of size n such that $D[i] \geq 0$, $D[i+1] \leq D[i] + 1$ and if $D[i+1] = D[i] + 1$ then $L[i+1] > L[i]$.

The number of parking functions of size n is equal to the number of rooted forests on n vertices and is equal to $(n+1)^{n-1}$.

EXAMPLES:

Here are all parking functions of size 3:

```
sage: from sage.combinat.parking_functions import ParkingFunctions
sage: ParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3], [1, 3, 1],
 [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1], [1, 2, 3], [1, 3, 2],
 [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.parking_functions import ParkingFunctions
>>> ParkingFunctions(Integer(3)).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3], [1, 3, 1],
 [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1], [1, 2, 3], [1, 3, 2],
 [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

If no size is specified, then ParkingFunctions returns the combinatorial class of all parking functions.

```
sage: PF = ParkingFunctions(); PF
Parking functions
sage: [] in PF
True
sage: [1] in PF
```

(continues on next page)

(continued from previous page)

```
True
sage: [2] in PF
False
sage: [1,3,1] in PF
True
sage: [1,4,1] in PF
False
```

```
>>> from sage.all import *
>>> PF = ParkingFunctions(); PF
Parking functions
>>> [] in PF
True
>>> [Integer(1)] in PF
True
>>> [Integer(2)] in PF
False
>>> [Integer(1),Integer(3),Integer(1)] in PF
True
>>> [Integer(1),Integer(4),Integer(1)] in PF
False
```

If the size n is specified, then ParkingFunctions returns the combinatorial class of all parking functions of size n.

```
sage: PF = ParkingFunctions(0)
sage: PF.list()
[[]]
sage: PF = ParkingFunctions(1)
sage: PF.list()
[[1]]
sage: PF = ParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
 [1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
 [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```
>>> from sage.all import *
>>> PF = ParkingFunctions(Integer(0))
>>> PF.list()
[[]]
>>> PF = ParkingFunctions(Integer(1))
>>> PF.list()
[[1]]
>>> PF = ParkingFunctions(Integer(3))
>>> PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
 [1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
 [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```
sage: PF3 = ParkingFunctions(3); PF3
Parking functions of size 3
```

(continues on next page)

(continued from previous page)

```
sage: [] in PF3
False
sage: [1] in PF3
False
sage: [1,3,1] in PF3
True
sage: [1,4,1] in PF3
False
```

```
>>> from sage.all import *
>>> PF3 = ParkingFunctions(Integer(3)); PF3
Parking functions of size 3
>>> [] in PF3
False
>>> [Integer(1)] in PF3
False
>>> [Integer(1),Integer(3),Integer(1)] in PF3
True
>>> [Integer(1),Integer(4),Integer(1)] in PF3
False
```

class sage.combinat.parking_functions.**ParkingFunctions_all**

Bases: *ParkingFunctions*

Element

alias of *ParkingFunction*

graded_component(*n*)

Return the graded component.

EXAMPLES:

```
sage: PF = ParkingFunctions()
sage: PF.graded_component(4) == ParkingFunctions(4)
True
sage: it = iter(ParkingFunctions()) # indirect doctest
sage: [next(it) for i in range(8)]
[[], [1], [1, 1], [1, 2], [2, 1], [1, 1, 1], [1, 1, 2], [1, 2, 1]]
```

```
>>> from sage.all import *
>>> PF = ParkingFunctions()
>>> PF.graded_component(Integer(4)) == ParkingFunctions(Integer(4))
True
>>> it = iter(ParkingFunctions()) # indirect doctest
>>> [next(it) for i in range(Integer(8))]
[[], [1], [1, 1], [1, 2], [2, 1], [1, 1, 1], [1, 1, 2], [1, 2, 1]]
```

class sage.combinat.parking_functions.**ParkingFunctions_n**(*n*)

Bases: *ParkingFunctions*

The combinatorial class of parking functions of size n.

A *parking function* of size n is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A *parking function* of size n is a pair (L, D) of two sequences L and D where L is a permutation and D is an area sequence of a Dyck Path of size n such that $D[i] \geq 0$, $D[i+1] \leq D[i]+1$ and if $D[i+1] = D[i]+1$ then $L[i+1] > L[i]$.

The number of parking functions of size n is equal to the number of rooted forests on n vertices and is equal to $(n+1)^{n-1}$.

EXAMPLES:

```
sage: PF = ParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
[1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]
```

```
>>> from sage.all import *
>>> PF = ParkingFunctions(Integer(3))
>>> PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3],
[1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

>>> [ParkingFunctions(i).cardinality() for i in range(Integer(6))]
[1, 1, 3, 16, 125, 1296]
```

Warning

The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

Element

alias of *ParkingFunction*

cardinality()

Return the number of parking functions of size n.

The cardinality is equal to $(n+1)^{n-1}$.

EXAMPLES:

```
sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]
```

```
>>> from sage.all import *
>>> [ParkingFunctions(i).cardinality() for i in range(Integer(6))]
[1, 1, 3, 16, 125, 1296]
```

random_element()

Return a random parking function of size n.

The algorithm uses a circular parking space with $n+1$ spots. Then all n cars can park and there remains one empty spot. Spots are then renumbered so that the empty spot is 0.

The probability distribution is uniform on the set of $(n+1)^{n-1}$ parking functions of size n.

EXAMPLES:

```
sage: pf = ParkingFunctions(8)
sage: a = pf.random_element(); a  # random
[5, 7, 2, 4, 2, 5, 1, 3]
sage: a in pf
True
```

```
>>> from sage.all import *
>>> pf = ParkingFunctions(Integer(8))
>>> a = pf.random_element(); a  # random
[5, 7, 2, 4, 2, 5, 1, 3]
>>> a in pf
True
```

sage.combinat.parking_functions.**from_labelled_dyck_word**(*LDW*)

Return the parking function corresponding to the labelled Dyck word.

INPUT:

- LDW – labelled Dyck word

OUTPUT:

- the parking function corresponding to the labelled Dyck word that is half the size of LDW

EXAMPLES:

```
sage: from sage.combinat.parking_functions import from_labelled_dyck_word
sage: LDW = [2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]
sage: from_labelled_dyck_word(LDW)
[6, 1, 5, 2, 2, 1, 5]
```

```
>>> from sage.all import *
>>> from sage.combinat.parking_functions import from_labelled_dyck_word
>>> LDW = [Integer(2), Integer(6), Integer(0), Integer(4), Integer(5), Integer(0),
 ↪ Integer(0), Integer(0), Integer(3), Integer(7), Integer(0), Integer(1),␣
↪Integer(0), Integer(0)]
>>> from_labelled_dyck_word(LDW)
[6, 1, 5, 2, 2, 1, 5]
```

```
sage: from_labelled_dyck_word([2, 3, 0, 0, 1, 0, 4, 0])
[3, 1, 1, 4]
sage: from_labelled_dyck_word([2, 3, 4, 0, 0, 0, 1, 0])
[4, 1, 1, 1]
sage: from_labelled_dyck_word([2, 4, 0, 1, 0, 0, 3, 0])
[2, 1, 4, 1]
```

```
>>> from sage.all import *
>>> from_labelled_dyck_word([Integer(2), Integer(3), Integer(0), Integer(0),␣
↪Integer(1), Integer(0), Integer(4), Integer(0)])
[3, 1, 1, 4]
>>> from_labelled_dyck_word([Integer(2), Integer(3), Integer(4), Integer(0),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(0), Integer(0), Integer(1), Integer(0)])
[4, 1, 1, 1]
>>> from_labelled_dyck_word([Integer(2), Integer(4), Integer(0), Integer(1),␣
↪Integer(0), Integer(0), Integer(3), Integer(0)])
[2, 1, 4, 1]
```

sage.combinat.parking_functions.**from_labelling_and_area_sequence**(L, D)

Return the parking function corresponding to the labelling area sequence pair.

INPUT:

- `L` – a labelling permutation
- `D` – an area sequence for a Dyck word

OUTPUT:

- the parking function corresponding the labelling permutation `L` and `D` an area sequence of the corresponding Dyck path

EXAMPLES:

```
sage: from sage.combinat.parking_functions import from_labelling_and_area_sequence
sage: from_labelling_and_area_sequence([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1,␣
↪1])
[6, 1, 5, 2, 2, 1, 5]
```

```
>>> from sage.all import *
>>> from sage.combinat.parking_functions import from_labelling_and_area_sequence
>>> from_labelling_and_area_sequence([Integer(2), Integer(6), Integer(4),␣
↪Integer(5), Integer(3), Integer(7), Integer(1)], [Integer(0), Integer(1),␣
↪Integer(1), Integer(2), Integer(0), Integer(1), Integer(1)])
[6, 1, 5, 2, 2, 1, 5]
```

```
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 2])
[1, 1, 1]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 0, 0])
[1, 2, 3]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 1])
[1, 1, 2]
sage: from_labelling_and_area_sequence([1, 2, 4, 3], [0, 1, 2, 1])
[1, 1, 3, 1]
```

```
>>> from sage.all import *
>>> from_labelling_and_area_sequence([Integer(1), Integer(2), Integer(3)],␣
↪[Integer(0), Integer(1), Integer(2)])
[1, 1, 1]
>>> from_labelling_and_area_sequence([Integer(1), Integer(2), Integer(3)],␣
↪[Integer(0), Integer(0), Integer(0)])
[1, 2, 3]
>>> from_labelling_and_area_sequence([Integer(1), Integer(2), Integer(3)],␣
↪[Integer(0), Integer(1), Integer(1)])
[1, 1, 2]
>>> from_labelling_and_area_sequence([Integer(1), Integer(2), Integer(4),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(3)], [Integer(0), Integer(1), Integer(2), Integer(1)])
[1, 1, 3, 1]
```

sage.combinat.parking_functions.**is_a**(*x*, *n=None*)

Check whether a list is a parking function.

If a size n is specified, checks if a list is a parking function of size n.

Partition shifting algebras

This module contains families of operators that act on partitions or, more generally, integer sequences. In particular, this includes Young's raising operators R_{ij}, which act on integer sequences by adding 1 to the i-th entry and subtracting 1 to the j-th entry. A special case is acting on partitions.

AUTHORS:

- Matthew Lancellotti, George H. Seelinger (2018): initial version

class sage.combinat.partition_shifting_algebras.**ShiftingOperatorAlgebra**(*base_ring=Univariate Polynomial Ring in t over Rational Field*, *prefix='S'*)

Bases: *CombinatorialFreeModule*

An algebra of shifting operators.

Let R be a commutative ring. The algebra of shifting operators is isomorphic as an R-algebra to the Laurent polynomial ring $R[x_1^{\pm}, x_2^{\pm}, x_3^{\pm}, \ldots]$. Moreover, the monomials of the shifting operator algebra act on any integer sequence $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ as follows. Let S be our algebra of shifting operators. Then, for any monomial $s = x_1^{a_1} x_2^{a_2} \cdots x_r^{a_r} \in S$ where $a_i \in \mathbf{Z}$ and $r \geq \ell$, we get that $s.\lambda = (\lambda_1 + a_1, \lambda_2 + a_2, \ldots, \lambda_r + a_r)$ where we pad λ with $r - \ell$ zeros. In particular, we can recover Young's raising operator, R_{ij}, for $i < j$, acting on partitions by having $\frac{x_i}{x_j}$ act on a partition λ.

One can extend the action of these shifting operators to a basis of symmetric functions, but at the expense of no longer actually having a well-defined operator. Formally, to extend the action of the shifting operators on a symmetric function basis $B = \{b_\lambda\}_\lambda$, we define an R-module homomorphism $\phi : R[x_1^{\pm}, x_2^{\pm}, \ldots] \to B$. Then we compute $x_1^{a_1} \cdots x_r^{a_r}.b_\lambda$ by first computing $(x_1^{a_1} \cdots x_r^{a_r}) x_1^{\lambda_1} \cdots x_\ell^{\lambda_\ell}$ and then applying ϕ to the result. For examples of what this looks like with specific bases, see below.

This implementation is consistent with how many references work formally with raising operators. For instance, see exposition surrounding [BMPS2018] Equation (4.1).

We follow the following convention for creating elements: `S(1, 0, -1, 2)` is the shifting operator that raises the first part by 1, lowers the third part by 1, and raises the fourth part by 2.

In addition to acting on partitions (or any integer sequence), the shifting operators can also act on symmetric functions in a basis B when a conversion to B has been registered, preferably using *build_and_register_conversion()*.

For a definition of raising operators, see [BMPS2018] Definition 2.1. See *ij()* to create operators using the notation in [BMPS2018].

INPUT:

- `base_ring` – (default: `QQ['t']`) the base ring
- `prefix` – (default: `'S'`) the label for the shifting operators

EXAMPLES:

```
sage: S = ShiftingOperatorAlgebra()

sage: elm = S[1, -1, 2]; elm
S(1, -1, 2)
sage: elm([5, 4])
[([6, 3, 2], 1)]
```

```
>>> from sage.all import *
>>> S = ShiftingOperatorAlgebra()

>>> elm = S[Integer(1), -Integer(1), Integer(2)]; elm
S(1, -1, 2)
>>> elm([Integer(5), Integer(4)])
[([6, 3, 2], 1)]
```

The shifting operator monomials can act on a complete homogeneous symmetric function or a Schur function:

```
sage: s = SymmetricFunctions(QQ['t']).s()
sage: h = SymmetricFunctions(QQ['t']).h()

sage: elm(s[5, 4])
s[6, 3, 2]
sage: elm(h[5, 4])
h[6, 3, 2]

sage: S[1, -1](s[5, 4])
s[6, 3]
sage: S[1, -1](h[5, 4])
h[6, 3]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ['t']).s()
>>> h = SymmetricFunctions(QQ['t']).h()

>>> elm(s[Integer(5), Integer(4)])
s[6, 3, 2]
>>> elm(h[Integer(5), Integer(4)])
h[6, 3, 2]

>>> S[Integer(1), -Integer(1)](s[Integer(5), Integer(4)])
s[6, 3]
>>> S[Integer(1), -Integer(1)](h[Integer(5), Integer(4)])
h[6, 3]
```

In fact, we can extend this action by linearity:

```
sage: elm = (1 - S[1,-1]) * (1 - S[4])
sage: elm == S([]) - S([1, -1]) - S([4]) + S([5, -1])
True
sage: elm(s[2, 2, 1])
s[2, 2, 1] - s[3, 1, 1] - s[6, 2, 1] + s[7, 1, 1]

sage: elm = (1 - S[1,-1]) * (1 - S[0,1,-1])
```

(continues on next page)

(continued from previous page)

```
sage: elm == 1 - S[0,1,-1] - S[1,-1] + S[1,0,-1]
True
sage: elm(s[2, 2, 1])
s[2, 2, 1] - s[3, 1, 1] + s[3, 2]
```

```
>>> from sage.all import *
>>> elm = (Integer(1) - S[Integer(1),-Integer(1)]) * (Integer(1) - S[Integer(4)])
>>> elm == S([]) - S([Integer(1), -Integer(1)]) - S([Integer(4)]) + S([Integer(5),
↪ -Integer(1)])
True
>>> elm(s[Integer(2), Integer(2), Integer(1)])
s[2, 2, 1] - s[3, 1, 1] - s[6, 2, 1] + s[7, 1, 1]

>>> elm = (Integer(1) - S[Integer(1),-Integer(1)]) * (Integer(1) - S[Integer(0),
↪Integer(1),-Integer(1)])
>>> elm == Integer(1) - S[Integer(0),Integer(1),-Integer(1)] - S[Integer(1),-
↪Integer(1)] + S[Integer(1),Integer(0),-Integer(1)]
True
>>> elm(s[Integer(2), Integer(2), Integer(1)])
s[2, 2, 1] - s[3, 1, 1] + s[3, 2]
```

The algebra also comes equipped with homomorphisms to various symmetric function bases; these homomorphisms are how the action of `S` on the specific symmetric function bases is implemented:

```
sage: elm = S([3,1,2]); elm
S(3, 1, 2)
sage: h(elm)
h[3, 2, 1]
sage: s(elm)
0
```

```
>>> from sage.all import *
>>> elm = S([Integer(3),Integer(1),Integer(2)]); elm
S(3, 1, 2)
>>> h(elm)
h[3, 2, 1]
>>> s(elm)
0
```

However, not all homomorphisms are equivalent, so the action is basis dependent:

```
sage: elm = S([3,2,1]); elm
S(3, 2, 1)
sage: h(elm)
h[3, 2, 1]
sage: s(elm)
s[3, 2, 1]
sage: s(elm) == s(h(elm))
False
```

```
>>> from sage.all import *
>>> elm = S([Integer(3),Integer(2),Integer(1)]); elm
```

(continues on next page)

(continued from previous page)

```
S(3, 2, 1)
>>> h(elm)
h[3, 2, 1]
>>> s(elm)
s[3, 2, 1]
>>> s(elm) == s(h(elm))
False
```

We can also use raising operators to implement the Jacobi-Trudi identity:

```
sage: op = (1-S[(1,-1)]) * (1-S[(1,0,-1)]) * (1-S[(0,1,-1)])
sage: s(op(h[3,2,1]))
s[3, 2, 1]
```

```
>>> from sage.all import *
>>> op = (Integer(1)-S[(Integer(1),-Integer(1))]) * (Integer(1)-S[(Integer(1),
↪Integer(0),-Integer(1))]) * (Integer(1)-S[(Integer(0),Integer(1),-Integer(1))])
>>> s(op(h[Integer(3),Integer(2),Integer(1)]))
s[3, 2, 1]
```

class Element

Bases: IndexedFreeModuleElement

An element of a *ShiftingOperatorAlgebra*.

build_and_register_conversion(*support_map*, *codomain*)

Build a module homomorphism from a map sending integer sequences to `codomain` and registers the result into Sage's conversion model.

The intended use is to define a morphism from `self` to a basis B of symmetric functions that will be used by *ShiftingOperatorAlgebra* to define the action of the operators on B.

Note

The actions on the complete homogeneous symmetric functions and on the Schur functions by morphisms are already registered.

Warning

Because *ShiftingOperatorAlgebra* inherits from UniqueRepresentation, once you register a conversion, this will apply to all instances of *ShiftingOperatorAlgebra* over the same base ring with the same prefix.

INPUT:

- `support_map` – a map from integer sequences to `codomain`
- `codomain` – the codomain of `support_map`, usually a basis of symmetric functions

EXAMPLES:

```
sage: S = ShiftingOperatorAlgebra(QQ)
sage: sym = SymmetricFunctions(QQ)
sage: p = sym.p()
sage: zero_map = lambda part: p.zero()
sage: S.build_and_register_conversion(zero_map, p)
sage: p(2*S([1,0,-1]) + S([2,1,0]) - 3*S([0,1,3]))
0
sage: op = S((1, -1))
sage: op(2*p[4,3] + 5*p[2,2] + 7*p[2]) == p.zero()
True
```

```
>>> from sage.all import *
>>> S = ShiftingOperatorAlgebra(QQ)
>>> sym = SymmetricFunctions(QQ)
>>> p = sym.p()
>>> zero_map = lambda part: p.zero()
>>> S.build_and_register_conversion(zero_map, p)
>>> p(Integer(2)*S([Integer(1),Integer(0),-Integer(1)]) + S([Integer(2),
↪Integer(1),Integer(0)]) - Integer(3)*S([Integer(0),Integer(1),Integer(3)]))
0
>>> op = S((Integer(1), -Integer(1)))
>>> op(Integer(2)*p[Integer(4),Integer(3)] + Integer(5)*p[Integer(2),
↪Integer(2)] + Integer(7)*p[Integer(2)]) == p.zero()
True
```

For a more illustrative example, we can implement a simple (but not mathematically justified!) conversion on the monomial basis:

```
sage: S = ShiftingOperatorAlgebra(QQ)
sage: sym = SymmetricFunctions(QQ)
sage: m = sym.m()
sage: def supp_map(gamma):
....:     gsort = sorted(gamma, reverse=True)
....:     return m(gsort) if gsort in Partitions() else m.zero()
sage: S.build_and_register_conversion(supp_map, m)
sage: op = S.ij(0, 1)
sage: op(2*m[4,3] + 5*m[2,2] + 7*m[2]) == 2*m[5, 2] + 5*m[3, 1]
True
```

```
>>> from sage.all import *
>>> S = ShiftingOperatorAlgebra(QQ)
>>> sym = SymmetricFunctions(QQ)
>>> m = sym.m()
>>> def supp_map(gamma):
...     gsort = sorted(gamma, reverse=True)
...     return m(gsort) if gsort in Partitions() else m.zero()
>>> S.build_and_register_conversion(supp_map, m)
>>> op = S.ij(Integer(0), Integer(1))
>>> op(Integer(2)*m[Integer(4),Integer(3)] + Integer(5)*m[Integer(2),
↪Integer(2)] + Integer(7)*m[Integer(2)]) == Integer(2)*m[Integer(5),␣
↪Integer(2)] + Integer(5)*m[Integer(3), Integer(1)]
True
```

ij(*i*, *j*)

Return the raising operator R_{ij} as notated in [BMPS2018] Definition 2.1.

Shorthand element constructor that allows you to create raising operators using the familiar R_{ij} notation found in [BMPS2018] Definition 2.1, with the exception that indices here are 0-based, not 1-based.

EXAMPLES:

Create the raising operator which raises part 0 and lowers part 2 (indices are 0-based):

```
sage: R = ShiftingOperatorAlgebra()
sage: R.ij(0, 2)
S(1, 0, -1)
```

```
>>> from sage.all import *
>>> R = ShiftingOperatorAlgebra()
>>> R.ij(Integer(0), Integer(2))
S(1, 0, -1)
```

one_basis()

Return the index of the basis element for 1.

EXAMPLES:

```
sage: S = ShiftingOperatorAlgebra()
sage: S.one_basis()
()
```

```
>>> from sage.all import *
>>> S = ShiftingOperatorAlgebra()
>>> S.one_basis()
()
```

product_on_basis(*x*, *y*)

Return the product of basis elements indexed by `x` and `y`.

EXAMPLES:

```
sage: S = ShiftingOperatorAlgebra()
sage: S.product_on_basis((0, 5, 2), (3, 2, -2, 5))
S(3, 7, 0, 5)
sage: S.product_on_basis((1, -2, 0, 3, -6), (-1, 2, 2))
S(0, 0, 2, 3, -6)
sage: S.product_on_basis((1, -2, -2), (-1, 2, 2))
S()
```

```
>>> from sage.all import *
>>> S = ShiftingOperatorAlgebra()
>>> S.product_on_basis((Integer(0), Integer(5), Integer(2)), (Integer(3),␣
↪Integer(2), -Integer(2), Integer(5)))
S(3, 7, 0, 5)
>>> S.product_on_basis((Integer(1), -Integer(2), Integer(0), Integer(3), -
↪Integer(6)), (-Integer(1), Integer(2), Integer(2)))
S(0, 0, 2, 3, -6)
>>> S.product_on_basis((Integer(1), -Integer(2), -Integer(2)), (-Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(2), Integer(2)))
S()
```

class sage.combinat.partition_shifting_algebras.**ShiftingSequenceSpace**

Bases: Singleton, Parent

A helper for *ShiftingOperatorAlgebra* that contains all tuples with entries in **Z** of finite support with no trailing 0's.

EXAMPLES:

```
sage: from sage.combinat.partition_shifting_algebras import ShiftingSequenceSpace
sage: S = ShiftingSequenceSpace()
sage: (1, -1) in S
True
sage: (1, -1, 0, 9) in S
True
sage: [1, -1] in S
False
sage: (0.5, 1) in S
False
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_shifting_algebras import ShiftingSequenceSpace
>>> S = ShiftingSequenceSpace()
>>> (Integer(1), -Integer(1)) in S
True
>>> (Integer(1), -Integer(1), Integer(0), Integer(9)) in S
True
>>> [Integer(1), -Integer(1)] in S
False
>>> (RealNumber('0.5'), Integer(1)) in S
False
```

check(*seq*)

Verify that `seq` is a valid shifting sequence.

If it is not, raise a `ValueError`.

EXAMPLES:

```
sage: from sage.combinat.partition_shifting_algebras import␣
↪ShiftingSequenceSpace
sage: S = ShiftingSequenceSpace()
sage: S.check((1, -1))
sage: S.check((1, -1, 0, 9))
sage: S.check([1, -1])
Traceback (most recent call last):
...
ValueError: invalid index [1, -1]
sage: S.check((0.5, 1))
Traceback (most recent call last):
...
ValueError: invalid index (0.500000000000000, 1)
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_shifting_algebras import␣
↪ShiftingSequenceSpace
>>> S = ShiftingSequenceSpace()
>>> S.check((Integer(1), -Integer(1)))
>>> S.check((Integer(1), -Integer(1), Integer(0), Integer(9)))
>>> S.check([Integer(1), -Integer(1)])
Traceback (most recent call last):
...
ValueError: invalid index [1, -1]
>>> S.check((RealNumber('0.5'), Integer(1)))
Traceback (most recent call last):
...
ValueError: invalid index (0.500000000000000, 1)
```

Partition tuples

A *PartitionTuple* is a tuple of partitions. That is, an ordered k-tuple of partitions $\mu = (\mu^{(1)}, \mu^{(2)}, ..., \mu^{(k)})$. If

$$n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}|$$

then we say that μ is a k-partition of n.

In representation theory partition tuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups,
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type $G(r, 1, n)$,
- the degenerate cyclotomic Hecke algebras of type $G(r, 1, n)$.

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras, which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to partition tuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

A *PartitionTuple* belongs to *PartitionTuples* and its derived classes. *PartitionTuples* is the parent class for all partitions tuples. Four different classes of tuples of partitions are currently supported:

- `PartitionTuples(level=k,size=n)` are k-tuple of partitions of n.
- `PartitionTuples(level=k)` are k-tuple of partitions.
- `PartitionTuples(size=n)` are tuples of partitions of n.
- `PartitionTuples()` are tuples of partitions.

Note

As with *Partitions*, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is $[0, 0, 0]$.

EXAMPLES:

```
sage: PartitionTuple([[2,2],[1,1],[2]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (1, 0, 0), (1, 1, 0), (2, 0, 0), (2, 0,
↪ 1)]
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(1),Integer(1)],[Integer(2)]]).
↪cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (1, 0, 0), (1, 1, 0), (2, 0, 0), (2, 0,
↪ 1)]
```

Note

Many *PartitionTuple* methods take the individual coordinates (k, r, c) as their arguments, here k is the component, r is the row index and c is the column index. If your coordinates are in the form `(k,r,c)` then use Python's *-operator.

EXAMPLES:

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.arm_length(*c) for c in mu.cells()]
[0, 0, 1, 0, 1, 0, 0]
```

```
>>> from sage.all import *
>>> mu=PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),
↪Integer(1)]])
>>> [ mu.arm_length(*c) for c in mu.cells()]
[0, 0, 1, 0, 1, 0, 0]
```

Warning

In sage, if `mu` is a partition tuple then `mu[k]` most naturally refers to the k-th component of `mu`, so we use the convention of the (k, r, c)-th cell in a partition tuple refers to the cell in component k, row r, and column c. In the literature, the cells of a partition tuple are usually written in the form (r, c, k), where r is the row index, c is the column index, and k is the component index.

 ([1], [2]),
 ([1], [1, 1]),
 ([], [3]),
 ([], [2, 1]),
 ([], [1, 1, 1])]
```

One tuples of partitions are naturally in bijection with partitions and, as far as possible, partition tuples attempts to identify one tuples with partitions:

```
sage: Partition([4,3]) == PartitionTuple([[4,3]])
True
sage: Partition([4,3]) == PartitionTuple([4,3])
True
sage: PartitionTuple([4,3])
[4, 3]
sage: Partition([4,3]) in PartitionTuples()
True
```

```
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3)]) == PartitionTuple([[Integer(4),Integer(3)]])
True
>>> Partition([Integer(4),Integer(3)]) == PartitionTuple([Integer(4),Integer(3)])
True
>>> PartitionTuple([Integer(4),Integer(3)])
[4, 3]
>>> Partition([Integer(4),Integer(3)]) in PartitionTuples()
True
```

Partition tuples come equipped with many of the corresponding methods for partitions. For example, it is possible to add and remove cells, to conjugate partition tuples, to work with their diagrams, compare partition tuples in dominance and so:

```
sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).pp()
   ****   _   **   ***
   *          **
              *
sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).conjugate()
([1, 1, 1], [3, 2], [], [2, 1, 1, 1])
sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).conjugate().pp()
   *   ***   _   **
   *   **        *
   *             *
                 *

↪Integer(1)]]))
True
```

Every partition tuple behaves every much like a tuple of partitions:

```
sage: mu = PartitionTuple([[4,1],[],[2,2,1],[3]])
sage: [ nu for nu in mu ]
[[4, 1], [], [2, 2, 1], [3]]
sage: Set([ type(nu) for nu in mu ])
{<class 'sage.combinat.partition.Partitions_all_with_category.element_class'>}
sage: mu[2][2]
1
sage: mu[3]
[3]
sage: mu.components()
[[4, 1], [], [2, 2, 1], [3]]
sage: mu.components() == [ nu for nu in mu ]
True
sage: mu[0]
[4, 1]
sage: mu[1]
[]
sage: mu[2]

class sage.combinat.partition_tuple.**PartitionTuple**(*parent*, *mu*)

Bases: *CombinatorialElement*

A tuple of *Partition*.

A tuple of partition comes equipped with many of methods available to partitions. The `level` of the PartitionTuple is the length of the tuple.

This is an ordered k-tuple of partitions $\mu = (\mu^{(1)}, \mu^{(2)}, ..., \mu^{(k)})$. If

$$n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}|$$

then μ is a k-partition of n.

In representation theory PartitionTuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type $G(r, 1, n)$
- the degenerate cyclotomic Hecke algebras of type $G(r, 1, n)$

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to PartitionTuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

Warning

In the literature, the cells of a partition tuple are usually written in the form (r, c, k), where r is the row index, c is the column index, and k is the component index. In sage, if `mu` is a partition tuple then `mu[k]` most naturally refers to the k-th component of `mu`, so we use the convention of the (k, r, c)-th cell in a partition tuple refers to the cell in component k, row r, and column c.

INPUT:

Anything which can reasonably be interpreted as a tuple of partitions. That is, a list or tuple of partitions or valid input to *Partition*.

EXAMPLES:

```
sage: mu=PartitionTuple( [[3,2],[2,1],[],[1,1,1,1]] ); mu
([3, 2], [2, 1], [], [1, 1, 1, 1])
sage: nu=PartitionTuple( ([3,2],[2,1],[],[1,1,1,1]) ); nu
([3, 2], [2, 1], [], [1, 1, 1, 1])
sage: mu == nu

Element

alias of *Partition*

add_cell(k, r, c)

Return the partition tuple obtained by adding a cell in row `r`, column `c`, and component `k`.

This does not change `self`.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).add_cell(0,0,1)
([2, 1], [4, 3], [2, 1, 1])
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(4),Integer(3)],
↪[Integer(2),Integer(1),Integer(1)]]).add_cell(Integer(0),Integer(0),
↪Integer(1))
([2, 1], [4, 3], [2, 1, 1])
```

addable_cells()

Return a list of the removable cells of this partition tuple.

All indices are of the form `(k, r, c)`, where `r` is the row-index, `c` is the column index and `k` is the component.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1),␣
↪(2, 3, 0)]
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),
↪Integer(1)]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(4),Integer(3)],
↪[Integer(2),Integer(1),Integer(1)]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1),␣
↪(2, 3, 0)]
```

arm_length(k, r, c)

Return the length of the arm of cell `(k, r, c)` in `self`.

INPUT:

- `k` – the component
- `r` – the row
- `c` – the cell

OUTPUT: the arm length as an integer

The arm of cell `(k, r, c)` is the number of cells in the `k`-th component which are to the right of the cell in row `r` and column `c`.

EXAMPLES:

```
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,0)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,1)
0
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,2,0)
0
```

```
>>> from sage.all import *
>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)],[Integer(3)]]).arm_length(Integer(2),Integer(0),Integer(0))
1
>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)],[Integer(3)]]).arm_length(Integer(2),Integer(0),Integer(1))
0
>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)],[Integer(3)]]).arm_length(Integer(2),Integer(2),Integer(0))
0
```

block(*e*, *multicharge*)

Return a dictionary β that determines the block associated to the partition `self` and the *quantum_characteristic()* `e`.

INPUT:

- `e` – the quantum characteristic
- `multicharge` – the multicharge (default: $(0,)$)

OUTPUT:

- a dictionary giving the multiplicities of the residues in the partition tuple `self`

In more detail, the value `beta[i]` is equal to the number of nodes of residue `i`. This corresponds to the positive root

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+,$$

a element of the positive root lattice of the corresponding Kac-Moody algebra. See [DJM1998] and [BK2009] for more details.

This is a useful statistics because two Specht modules for a cyclotomic Hecke algebra of type A belong to the same block if and only if they correspond to same element β of the root lattice, given above.

We return a dictionary because when the quantum characteristic is 0, the Cartan type is A_∞, in which case the simple roots are indexed by the integers.

EXAMPLES:

```
sage: PartitionTuple([[2,2],[2,2]]).block(0,(0,0))
{-1: 2, 0: 4, 1: 2}
sage: PartitionTuple([[2,2],[2,2]]).block(2,(0,0))
{0: 4, 1: 4}
sage: PartitionTuple([[2,2],[2,2]]).block(2,(0,1))
{0: 4, 1: 4}
sage: PartitionTuple([[2,2],[2,2]]).block(3,(0,2))
{0: 3, 1: 2, 2: 3}
sage: PartitionTuple([[2,2],[2,2]]).block(3,(0,2))
{0: 3, 1: 2, 2: 3}
sage: PartitionTuple([[2,2],[2,2]]).block(3,(3,2))
{0: 3, 1: 2, 2: 3}
sage: PartitionTuple([[2,2],[2,2]]).block(4,(0,0))
{0: 4, 1: 2, 3: 2}
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪block(Integer(0),(Integer(0),Integer(0)))
{-1: 2, 0: 4, 1: 2}
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪block(Integer(2),(Integer(0),Integer(0)))
{0: 4, 1: 4}
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪block(Integer(2),(Integer(0),Integer(1)))
{0: 4, 1: 4}
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪block(Integer(3),(Integer(0),Integer(2)))
{0: 3, 1: 2, 2: 3}
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪block(Integer(3),(Integer(0),Integer(2)))
{0: 3, 1: 2, 2: 3}
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪block(Integer(3),(Integer(3),Integer(2)))
{0: 3, 1: 2, 2: 3}
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪block(Integer(4),(Integer(0),Integer(0)))
{0: 4, 1: 2, 3: 2}
```

cells()

Return the coordinates of the cells of `self`. Coordinates are given as (component index, row index, column index) and are 0 based.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[1],[1,1,1]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 2, 0)]
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(1)],[Integer(1),
↪Integer(1),Integer(1)]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 2, 0)]
```

components()

Return a list containing the shape of this partition.

This function exists in order to give a uniform way of iterating over the "components" of partition tuples of level 1 (partitions) and for higher levels.

EXAMPLES:

```
sage: for t in PartitionTuple([[2,1],[3,2],[3]]).components():
....:     print('%s\n' % t.ferrers_diagram())
**
*

***
**

***
```

(continues on next page)

(continued from previous page)

```
sage: for t in PartitionTuple([3,2]).components():
....:     print('%s\n' % t.ferrers_diagram())
***
**
```

```
>>> from sage.all import *
>>> for t in PartitionTuple([[Integer(2),Integer(1)],[Integer(3),Integer(2)],
↪[Integer(3)]]).components():
...     print('%s\n' % t.ferrers_diagram())
**
*
<BLANKLINE>
***
**
<BLANKLINE>
***
<BLANKLINE>
>>> for t in PartitionTuple([Integer(3),Integer(2)]).components():
...     print('%s\n' % t.ferrers_diagram())
***
**
```

conjugate()

Return the conjugate partition tuple of `self`.

The conjugate partition tuple is obtained by reversing the order of the components and then swapping the rows and columns in each component.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[1],[1,1,1]]).conjugate()
([3], [1], [2, 1])
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(1)],[Integer(1),
↪Integer(1),Integer(1)]]).conjugate()
([3], [1], [2, 1])
```

contains(*mu*)

Return `True` if this partition tuple contains μ.

If $\lambda = (\lambda^{(1)}, \ldots, \lambda^{(l)})$ and $\mu = (\mu^{(1)}, \ldots, \mu^{(m)})$ are two partition tuples then λ contains μ if $m \leq l$ and $\mu_r^{(i)} \leq \lambda_r^{(i)}$ for $1 \leq i \leq m$ and $r \geq 0$.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).contains( PartitionTuple([[1,1],[2],
↪[2,1]]) )
True
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1)]]).contains( PartitionTuple([[Integer(1),Integer(1)],
↪[Integer(2)],[Integer(2),Integer(1)]]) )
True
```

content(*k*, *r*, *c*, *multicharge*)

Return the content of the cell.

Let $m_k =$ `multicharge[k]`, then the content of a cell is $m_k + c - r$.

If the `multicharge` is a list of integers then it simply offsets the values of the contents in each component. On the other hand, if the `multicharge` belongs to $\mathbf{Z}/e\mathbf{Z}$ then the corresponding e-residue is returned (that is, the content mod e).

As with the content method for partitions, the content of a cell does not technically depend on the partition tuple, but this method is included because it is often useful.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [0,0,0])
-1
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [1,0,0])
0
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(2,1,0, [0,0,0])
-1
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),
↪Integer(1),Integer(1)]]).content(Integer(0),Integer(1),Integer(0),␣
↪[Integer(0),Integer(0),Integer(0)])
-1
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),
↪Integer(1),Integer(1)]]).content(Integer(0),Integer(1),Integer(0),␣
↪[Integer(1),Integer(0),Integer(0)])
0
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),
↪Integer(1),Integer(1)]]).content(Integer(2),Integer(1),Integer(0),␣
↪[Integer(0),Integer(0),Integer(0)])
-1
```

and now we return the 3-residue of a cell:

```
sage: multicharge = [IntegerModRing(3)(c) for c in [0,0,0]]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, multicharge)
2
```

```
>>> from sage.all import *
>>> multicharge = [IntegerModRing(Integer(3))(c) for c in [Integer(0),
↪Integer(0),Integer(0)]]
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),
↪Integer(1),Integer(1)]]).content(Integer(0),Integer(1),Integer(0),␣
↪multicharge)
2
```

content_tableau(*multicharge*)

Return the tableau which has (k,r,c)th entry equal to the content `multicharge[k]-r+c` of this cell.

As with the content function, by setting the `multicharge` appropriately the tableau containing the residues is returned.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau([0,0,0])
([[0, 1], [-1]], [[0, 1]], [[0], [-1], [-2]])
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau([0,0,1]).pp()
    0  1     0  1     1
   -1                 0
                     -1
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),
↪Integer(1),Integer(1)]]).content_tableau([Integer(0),Integer(0),Integer(0)])
([[0, 1], [-1]], [[0, 1]], [[0], [-1], [-2]])
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),
↪Integer(1),Integer(1)]]).content_tableau([Integer(0),Integer(0),
↪Integer(1)]).pp()
    0  1     0  1     1
   -1                 0
                     -1
```

as with the content function the multicharge can be used to return the tableau containing the residues of the cells:

```
sage: multicharge=[ IntegerModRing(3)(c) for c in [0,0,1] ]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau(multicharge).pp()
    0  1     0  1     1
    2                 0
                      2
```

```
>>> from sage.all import *
>>> multicharge=[ IntegerModRing(Integer(3))(c) for c in [Integer(0),
↪Integer(0),Integer(1)] ]
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),
↪Integer(1),Integer(1)]]).content_tableau(multicharge).pp()
    0  1     0  1     1
    2                 0
                      2
```

corners()

alias of *removable_cells()*.

defect(*e*, *multicharge*)

Return the e-defect or the e-weight `self`.

The e-defect is the number of (connected) e-rim hooks that can be removed from the partition.

The defect of a partition tuple is given by

$$\text{defect}(\beta) = (\Lambda, \beta) - \tfrac{1}{2}(\beta, \beta),$$

where $\Lambda = \sum_r \Lambda_{\kappa_r}$ for the multicharge $(\kappa_1, \ldots, \kappa_\ell)$ and $\beta = \sum_{(r,c)} \alpha_{(c-r) \pmod e}$, with the sum being over the cells in the partition.

INPUT:

- `e` – the quantum characteristic
- `multicharge` – the multicharge (default: $(0,)$)

OUTPUT: a nonnegative integer, which is the defect of the block containing the partition tuple `self`

EXAMPLES:

```
sage: PartitionTuple([[2,2],[2,2]]).defect(0,(0,0))
0
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,0))
8
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,1))
8
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(0,2))
5
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(0,2))
5
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(3,2))
2
sage: PartitionTuple([[2,2],[2,2]]).defect(4,(0,0))
0
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪defect(Integer(0),(Integer(0),Integer(0)))
0
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪defect(Integer(2),(Integer(0),Integer(0)))
8
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪defect(Integer(2),(Integer(0),Integer(1)))
8
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪defect(Integer(3),(Integer(0),Integer(2)))
5
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪defect(Integer(3),(Integer(0),Integer(2)))
5
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪defect(Integer(3),(Integer(3),Integer(2)))
2
>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(2),Integer(2)]]).
↪defect(Integer(4),(Integer(0),Integer(0)))
0
```

degree(*e*)

Return the `e`-th degree of `self`.

The e-th degree is the sum of the degrees of the standard tableaux of shape λ. The e-th degree is the exponent of $\Phi_e(q)$ in the Gram determinant of the Specht module for a semisimple cyclotomic Hecke algebra of type A with parameter q.

For this calculation the multicharge $(\kappa_1, \ldots, \kappa_l)$ is chosen so that $\kappa_{r+1} - \kappa_r > n$, where n is the *size()* of λ as this ensures that the Hecke algebra is semisimple.

INPUT:

- `e` – integer $e > 1$

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: PartitionTuple([[2,1],[2,2]]).degree(2)
532
sage: PartitionTuple([[2,1],[2,2]]).degree(3)
259
sage: PartitionTuple([[2,1],[2,2]]).degree(4)
196
sage: PartitionTuple([[2,1],[2,2]]).degree(5)
105
sage: PartitionTuple([[2,1],[2,2]]).degree(6)
105
sage: PartitionTuple([[2,1],[2,2]]).degree(7)
0
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
↪degree(Integer(2))
532
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
↪degree(Integer(3))
259
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
↪degree(Integer(4))
196
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
↪degree(Integer(5))
105
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
↪degree(Integer(6))
105
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
↪degree(Integer(7))
0
```

Therefore, the Gram determinant of $S(2,1|2,2)$ when the Hecke parameter q is "generic" is

$$q^N \Phi_2(q)^{532} \Phi_3(q)^{259} \Phi_4(q)^{196} \Phi_5(q)^{105} \Phi_6(q)^{105}$$

for some integer N. Compare with *prime_degree()*.

diagram()

Return a string for the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print(PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram())
   **    ***    *
   *     **     *
                *
sage: print(PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram())
   ***    **    _    *
   **     *          *
                     *
                     *
sage: PartitionTuples.options(convention='french')
sage: print(PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram())
                     *
                     *
   **     *          *
   ***    **    _    *
sage: PartitionTuples.options._reset()
```

```
>>> from sage.all import *
>>> print(PartitionTuple([[Integer(2),Integer(1)],[Integer(3),Integer(2)],
↪[Integer(1),Integer(1),Integer(1)]]).diagram())
   **    ***    *
   *     **     *
                *
>>> print(PartitionTuple([[Integer(3),Integer(2)],[Integer(2),Integer(1)],[],
↪[Integer(1),Integer(1),Integer(1),Integer(1)]]).diagram())
   ***    **    _    *
   **     *          *
                     *
                     *
>>> PartitionTuples.options(convention='french')
>>> print(PartitionTuple([[Integer(3),Integer(2)],[Integer(2),Integer(1)],[],
↪[Integer(1),Integer(1),Integer(1),Integer(1)]]).diagram())
                     *
                     *
   **     *          *
   ***    **    _    *
>>> PartitionTuples.options._reset()
```

dominates(*mu*)

Return `True` if the PartitionTuple dominates or equals μ and `False` otherwise.

Given partition tuples $\mu = (\mu^{(1)}, ..., \mu^{(m)})$ and $\nu = (\nu^{(1)}, ..., \nu^{(n)})$ then μ dominates ν if

$$\sum_{k=1}^{l-1} |\mu^{(k)}| + \sum_{r \geq 1} \mu_r^{(l)} \geq \sum_{k=1}^{l-1} |\nu^{(k)}| + \sum_{r \geq 1} \nu_r^{(l)}$$

EXAMPLES:

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: nu=PartitionTuple([[1,1],[1,1],[2,1]])
sage: mu.dominates(mu)
True
sage: mu.dominates(nu)
```

(continues on next page)

(continued from previous page)

```
True
sage: nu.dominates(mu)
False
sage: tau=PartitionTuple([[],[2,1],[]])
sage: tau.dominates([[2,1],[],[]])
False
sage: tau.dominates([[],[],[2,1]])
True
```

```
>>> from sage.all import *
>>> mu=PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),
↪Integer(1)]])
>>> nu=PartitionTuple([[Integer(1),Integer(1)],[Integer(1),Integer(1)],
↪[Integer(2),Integer(1)]])
>>> mu.dominates(mu)
True
>>> mu.dominates(nu)
True
>>> nu.dominates(mu)
False
>>> tau=PartitionTuple([[],[Integer(2),Integer(1)],[]])
>>> tau.dominates([[Integer(2),Integer(1)],[],[]])
False
>>> tau.dominates([[],[],[Integer(2),Integer(1)]])
True
```

down()

Generator (iterator) for the partition tuples that are obtained from `self` by removing a cell.

EXAMPLES:

```
sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).down()]
[([], [2, 1], [1, 1]), ([], [3], [1, 1]), ([], [3, 1], [1])]
sage: [mu for mu in PartitionTuple([[],[],[]]).down()]
[]
```

```
>>> from sage.all import *
>>> [mu for mu in PartitionTuple([[],[Integer(3),Integer(1)],[Integer(1),
↪Integer(1)]]).down()]
[([], [2, 1], [1, 1]), ([], [3], [1, 1]), ([], [3, 1], [1])]
>>> [mu for mu in PartitionTuple([[],[],[]]).down()]
[]
```

down_list()

Return a list of the partition tuples that can be formed from `self` by removing a cell.

EXAMPLES:

```
sage: PartitionTuple([[],[3,1],[1,1]]).down_list()
[([], [2, 1], [1, 1]), ([], [3], [1, 1]), ([], [3, 1], [1])]
sage: PartitionTuple([[],[],[]]).down_list()
[]
```

```
>>> from sage.all import *
>>> PartitionTuple([[],[Integer(3),Integer(1)],[Integer(1),Integer(1)]]).down_
↪list()
[([], [2, 1], [1, 1]), ([], [3], [1, 1]), ([], [3, 1], [1])]
>>> PartitionTuple([[],[],[]]).down_list()
[]
```

ferrers_diagram()

alias of *diagram()*.

garnir_tableau(**cell*)

Return the Garnir tableau of shape `self` corresponding to the cell `cell`.

If `cell` $= (k, a, c)$ then $(k, a+1, c)$ must belong to the diagram of the *PartitionTuple*. If this is not the case then we return `False`.

Note

The function also sets `g._garnir_cell` equal to `cell` which is used by some other functions.

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules over an arbitrary ring.

The Garnir tableau are the "first" non-standard tableaux which arise when you act by simple transpositions. If (k, a, c) is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers $1, 2, \ldots, n$ entered in order from left to right along the rows of the diagram up to the cell $(k, a, c-1)$, then along the cells $(k, a+1, 1)$ to $(k, a+1, c)$, then (k, a, c) until the end of row a and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

EXAMPLES:

```
sage: PartitionTuple([[5,3],[2,2],[4,3]]).garnir_tableau((0,0,2)).pp()
     1  2  6  7  8     9 10    13 14 15 16
     3  4  5          11 12    17 18 19
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((0,0,2)).pp()
     1  2  6  7  8    12 13    16 17 18 19
     3  4  5          14 15    20 21 22
     9 10 11
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((0,1,2)).pp()
     1  2  3  4  5    12 13    16 17 18 19
     6  7 11          14 15    20 21 22
     8  9 10
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((1,0,0)).pp()
     1  2  3  4  5    13 14    16 17 18 19
     6  7  8          12 15    20 21 22
     9 10 11
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((1,0,1)).pp()
     1  2  3  4  5    12 15    16 17 18 19
     6  7  8          13 14    20 21 22
     9 10 11
sage: PartitionTuple([[5,3,3],[2,2],[4,3]]).garnir_tableau((2,0,1)).pp()
     1  2  3  4  5    12 13    16 19 20 21
```

(continues on next page)

(continued from previous page)

```

↪Integer(1))).pp()
Traceback (most recent call last):
...
ValueError: (comp, row+1, col) must be inside the diagram
```

> **See also**
>
> - *top_garnir_tableau()*

hook_length(k, r, c)

Return the length of the hook of cell `(k, r, c)` in the partition.

The hook of cell `(k, r, c)` is defined as the cells to the right or below (in the English convention). If your coordinates are in the form `(k,r,c)`, use Python's *-operator.

EXAMPLES:

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.hook_length(*c) for c in mu.cells()]
[2, 1, 2, 1, 3, 1, 1]
```

```
>>> from sage.all import *
>>> mu=PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),
↪Integer(1)]])
>>> [ mu.hook_length(*c) for c in mu.cells()]
[2, 1, 2, 1, 3, 1, 1]
```

initial_column_tableau()

Return the initial column tableau of shape `self`.

The initial column tableau of shape λ is the standard tableau that has the numbers 1 to n, where n is the *size()* of λ, entered in order from top to bottom, and then left to right, down the columns of each component, starting from the rightmost component and working to the left.

EXAMPLES:

```
sage: PartitionTuple([ [3,1],[3,2] ]).initial_column_tableau()
([[6, 8, 9], [7]], [[1, 3, 5], [2, 4]])
```

```
>>> from sage.all import *
>>> PartitionTuple([ [Integer(3),Integer(1)],[Integer(3),Integer(2)] ]).
↪initial_column_tableau()
([[6, 8, 9], [7]], [[1, 3, 5], [2, 4]])
```

initial_tableau()

Return the *StandardTableauTuple* which has the numbers $1, 2, \ldots, n$, where n is the *size()* of `self`, entered in order from left to right along the rows of each component, where the components are ordered from left to right.

EXAMPLES:

```
sage: PartitionTuple([ [2,1],[3,2] ]).initial_tableau()
([[1, 2], [3]], [[4, 5, 6], [7, 8]])
```

```
>>> from sage.all import *
>>> PartitionTuple([ [Integer(2),Integer(1)],[Integer(3),Integer(2)] ]).
↪initial_tableau()
([[1, 2], [3]], [[4, 5, 6], [7, 8]])
```

leg_length(*k*, *r*, *c*)

Return the length of the leg of cell `(k, r, c)` in `self`.

INPUT:

- `k` – the component
- `r` – the row
- `c` – the cell

OUTPUT: the leg length as an integer

The leg of cell `(k, r, c)` is the number of cells in the `k`-th component which are below the node in row `r` and column `c`.

EXAMPLES:

```
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,0)
2
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,1)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,2,0)
0
```

```
>>> from sage.all import *
>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)],[Integer(3)]]).leg_length(Integer(2),Integer(0),Integer(0))
2
>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)],[Integer(3)]]).leg_length(Integer(2),Integer(0),Integer(1))
1
>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)],[Integer(3)]]).leg_length(Integer(2),Integer(2),Integer(0))
0
```

level()

Return the level of this partition tuple.

The level is the length of the tuple.

EXAMPLES:

```
sage: PartitionTuple([[2,1,1,0],[2,1]]).level()
2
sage: PartitionTuple([[],[],[2,1,1]]).level()
3
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1),Integer(1),Integer(0)],[Integer(2),
↪Integer(1)]]).level()
2
>>> PartitionTuple([[],[],[Integer(2),Integer(1),Integer(1)]]).level()
3
```

outside_corners()

alias of *addable_cells()*.

pp()

Pretty print this partition tuple. See *diagram()*.

EXAMPLES:

```
sage: PartitionTuple([[5,5,2,1],[3,2]]).pp()
*****   ***
*****   **
**
*
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(5),Integer(5),Integer(2),Integer(1)],[Integer(3),
↪Integer(2)]]).pp()
*****   ***
*****   **
**
*
```

prime_degree(p)

Return the `p`-th prime degree of `self`.

The degree of a partition λ is the sum of the e-degrees` of the standard tableaux of shape λ (see *degree()*), for e a power of the prime p. The prime degree gives the exponent of p in the Gram determinant of the integral Specht module of the symmetric group.

The p-th degree is the sum of the degrees of the standard tableaux of shape λ. The p-th degree is the exponent of p in the Gram determinant of a semisimple cyclotomic Hecke algebra of type A with parameter $q = 1$.

As with *degree()*, for this calculation the multicharge $(\kappa_1, \ldots, \kappa_l)$ is chosen so that $\kappa_{r+1} - \kappa_r > n$, where n is the *size()* of λ as this ensures that the Hecke algebra is semisimple.

INPUT:

- `e` – an integer $e > 1$
- `multicharge` – an l-tuple of integers, where l is the *level()* of `self`

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(2)
728
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(3)
259
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(5)
105
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(7)
0
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).prime_
↪degree(Integer(2))
728
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).prime_
↪degree(Integer(3))
```

(continues on next page)

(continued from previous page)

```
259
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).prime_
↪degree(Integer(5))
105
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).prime_
↪degree(Integer(7))
0
```

Therefore, the Gram determinant of $S(2,1|2,2)$ when $q=1$ is $2^{728}3^{259}5^{105}$. Compare with *degree()*.

removable_cells()

Return a list of the removable cells of this partition tuple.

All indices are of the form `(k, r, c)`, where `r` is the row-index, `c` is the column index and `k` is the component.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).removable_cells()
[(0, 1, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).removable_cells()
[(0, 1, 0), (1, 0, 3), (1, 1, 2), (2, 0, 1), (2, 2, 0)]
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),
↪Integer(1)]]).removable_cells()
[(0, 1, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(4),Integer(3)],
↪[Integer(2),Integer(1),Integer(1)]]).removable_cells()
[(0, 1, 0), (1, 0, 3), (1, 1, 2), (2, 0, 1), (2, 2, 0)]
```

remove_cell(k, r, c)

Return the partition tuple obtained by removing a cell in row `r`, column `c`, and component `k`.

This does not change `self`.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).remove_cell(0,1,0)
([1], [4, 3], [2, 1, 1])
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(4),Integer(3)],
↪[Integer(2),Integer(1),Integer(1)]]).remove_cell(Integer(0),Integer(1),
↪Integer(0))
([1], [4, 3], [2, 1, 1])
```

row_standard_tableaux()

Return the *row standard tableau tuples* of shape `self`.

EXAMPLES:

```
sage: PartitionTuple([[],[3,2,2,1],[2,2,1],[3]]).row_standard_tableaux()
Row standard tableau tuples of shape ([], [3, 2, 2, 1], [2, 2, 1], [3])
```

```
>>> from sage.all import *
>>> PartitionTuple([[],[Integer(3),Integer(2),Integer(2),Integer(1)],
↪[Integer(2),Integer(2),Integer(1)],[Integer(3)]]).row_standard_tableaux()
Row standard tableau tuples of shape ([], [3, 2, 2, 1], [2, 2, 1], [3])
```

size()

Return the size of a partition tuple.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[],[2,2]]).size()
7
sage: PartitionTuple([[],[],[1],[3,2,1]]).size()
7
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[],[Integer(2),Integer(2)]]).
↪size()
7
>>> PartitionTuple([[],[],[Integer(1)],[Integer(3),Integer(2),Integer(1)]]).
↪size()
7
```

standard_tableaux()

Return the *standard tableau tuples* of shape `self`.

EXAMPLES:

```
sage: PartitionTuple([[],[3,2,2,1],[2,2,1],[3]]).standard_tableaux()
Standard tableau tuples of shape ([], [3, 2, 2, 1], [2, 2, 1], [3])
```

```
>>> from sage.all import *
>>> PartitionTuple([[],[Integer(3),Integer(2),Integer(2),Integer(1)],
↪[Integer(2),Integer(2),Integer(1)],[Integer(3)]]).standard_tableaux()
Standard tableau tuples of shape ([], [3, 2, 2, 1], [2, 2, 1], [3])
```

to_exp(*k=0*)

Return a tuple of the multiplicities of the parts of a partition.

Use the optional parameter `k` to get a return list of length at least `k`.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[2],[2,1]]).to_exp()
([2], [0, 1], [1, 1])
sage: PartitionTuple([[1,1],[2,2,2,2],[2,1]]).to_exp()
([2], [0, 4], [1, 1])
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),
↪Integer(1)]]).to_exp()
([2], [0, 1], [1, 1])
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(2),Integer(2),Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2)],[Integer(2),Integer(1)]]).to_exp()
([2], [0, 4], [1, 1])
```

to_list()

Return `self` as a list of lists.

EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).to_list()
[[1, 1], [4, 3], [2, 1, 1]]
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(4),Integer(3)],
↪[Integer(2),Integer(1),Integer(1)]]).to_list()
[[1, 1], [4, 3], [2, 1, 1]]
```

top_garnir_tableau(*e*, *cell*)

Return the most dominant *standard* tableau which dominates the corresponding Garnir tableau and has the same residue that has shape `self` and is determined by `e` and `cell`.

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the "straightening" rules for the Specht modules over an arbitrary ring. The *top Garnir tableaux* arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR2012].

If the Garnir node is `cell=(k,r,c)` and m and M are the entries in the cells `(k,r,c)` and `(k,r+1, c)`, respectively, in the initial tableau then the top `e`-Garnir tableau is obtained by inserting the numbers $m, m+1, \ldots, M$ in order from left to right first in the cells in row `r+1` which are not in the `e`-Garnir belt, then in the cell in rows `r` and `r+1` which are in the Garnir belt and then, finally, in the remaining cells in row `r` which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If `e = 0`, or if there are no `e`-bricks in either row `r` or `r+1`, then the top Garnir tableau is the corresponding Garnir tableau.

EXAMPLES:

```
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,2)).pp()
    1  2  3     9 10 12 13 16
    4  5  6    11 14 15 17
    7  8       18 19 20
               21 22
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,1)).pp()
    1  2  3     9 10 11 12 13
    4  5  6    14 15 16 17
    7  8       18 19 20
               21 22
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(1,0,1)).pp()
    1  2  3     9 12 13 14 15
    4  5  6    10 11 16 17
    7  8       18 19 20
               21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(3,0,1)).pp()
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: (comp, row+1, col) must be inside the diagram
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(3),Integer(3),Integer(2)],[Integer(5),Integer(4),

```

See also

- *garnir_tableau()*

up()

Generator (iterator) for the partition tuples that are obtained from `self` by adding a cell.

EXAMPLES:

```
sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).up()]
[([1], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3,␣
↪1, 1], [1, 1]), ([], [3, 1], [2, 1]), ([], [3, 1], [1, 1, 1])]
sage: [mu for mu in PartitionTuple([[],[],[],[]]).up()]
[([1], [], [], []), ([], [1], [], []), ([], [], [1], []), ([], [], [], [1])]
```

```
>>> from sage.all import *
>>> [mu for mu in PartitionTuple([[],[Integer(3),Integer(1)],[Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1)]]).up()]
[([1], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3,␣
↪1, 1], [1, 1]), ([], [3, 1], [2, 1]), ([], [3, 1], [1, 1, 1])]
>>> [mu for mu in PartitionTuple([[],[],[],[]]).up()]
[([1], [], [], []), ([], [1], [], []), ([], [], [1], []), ([], [], [], [1])]
```

up_list()

Return a list of the partition tuples that can be formed from `self` by adding a cell.

EXAMPLES:

```
sage: PartitionTuple([[],[3,1],[1,1]]).up_list()
[([1], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3,␣
↪1, 1], [1, 1]), ([], [3, 1], [2, 1]), ([], [3, 1], [1, 1, 1])]
sage: PartitionTuple([[],[],[],[]]).up_list()
[([1], [], [], []), ([], [1], [], []), ([], [], [1], []), ([], [], [], [1])]
```

```
>>> from sage.all import *
>>> PartitionTuple([[],[Integer(3),Integer(1)],[Integer(1),Integer(1)]]).up_
↪list()
[([1], [3, 1], [1, 1]), ([], [4, 1], [1, 1]), ([], [3, 2], [1, 1]), ([], [3,␣
↪1, 1], [1, 1]), ([], [3, 1], [2, 1]), ([], [3, 1], [1, 1, 1])]
>>> PartitionTuple([[],[],[],[]]).up_list()
[([1], [], [], []), ([], [1], [], []), ([], [], [1], []), ([], [], [], [1])]
```

young_subgroup()

Return the corresponding Young, or parabolic, subgroup of the symmetric group.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[4,2],[1]]).young_subgroup()                    #␣
↪needs sage.groups
Permutation Group with generators [(), (8,9), (6,7), (5,6), (4,5), (1,2)]
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(4),Integer(2)],
↪[Integer(1)]]).young_subgroup()                    # needs sage.groups
Permutation Group with generators [(), (8,9), (6,7), (5,6), (4,5), (1,2)]
```

young_subgroup_generators()

Return an indexing set for the generators of the corresponding Young subgroup.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[4,2],[1]]).young_subgroup_generators()
[1, 4, 5, 6, 8]
```

```
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(4),Integer(2)],
↪[Integer(1)]]).young_subgroup_generators()
[1, 4, 5, 6, 8]
```

class sage.combinat.partition_tuple.**PartitionTuples**

Bases: UniqueRepresentation, Parent

Class of all partition tuples.

For more information about partition tuples, see *PartitionTuple*.

This is a factory class which returns the appropriate parent based on the values of `level`, `size`, and `regular`

INPUT:

- `level` – the length of the tuple
- `size` – the total number of cells
- `regular` – positive integer or a tuple of nonnegative integers; if an integer, the highest multiplicity an entry may have in a component plus 1

If a level k is specified and `regular` is a tuple of integers $\ell_1, \ldots, \ell_k$, then this specifies partition tuples μ such that μ_i is ℓ_i-regular, where 0 here represents ∞-regular partitions (equivalently, partitions without restrictions). If `regular` is an integer ℓ, then we set $\ell_i = \ell$ for all i.

Element

alias of *PartitionTuple*

level()

Return the level or `None` if it is not defined.

EXAMPLES:

```
sage: PartitionTuples().level() is None
True
sage: PartitionTuples(7).level()
7
```

```
>>> from sage.all import *
>>> PartitionTuples().level() is None
True
>>> PartitionTuples(Integer(7)).level()
7
```

options = Current options for Partitions - convention: English - diagram_str: * - display: list - latex: young_diagram - latex_diagram_str: \ast

size()

Return the size or `None` if it is not defined.

EXAMPLES:

```
sage: PartitionTuples().size() is None
True
sage: PartitionTuples(size=7).size()
7
```

```
>>> from sage.all import *
>>> PartitionTuples().size() is None
True
>>> PartitionTuples(size=Integer(7)).size()
7
```

class sage.combinat.partition_tuple.**PartitionTuples_all**

Bases: *PartitionTuples*

Class of partition tuples of a arbitrary level and arbitrary sum.

class sage.combinat.partition_tuple.**PartitionTuples_level**(*level*, *category=None*)

Bases: *PartitionTuples*

Class of partition tuples of a fixed level, but summing to an arbitrary integer.

class sage.combinat.partition_tuple.**PartitionTuples_level_size**(*level*, *size*)

Bases: *PartitionTuples*

Class of partition tuples with a fixed level and a fixed size.

cardinality()

Return the number of `level`-tuples of partitions of size `n`.

Wraps a pari function call using pari:eta.

EXAMPLES:

```
sage: PartitionTuples(2,3).cardinality()                                    #␣
↪needs sage.libs.pari
10
sage: PartitionTuples(2,8).cardinality()                                    #␣
↪needs sage.libs.pari
185
```

```
>>> from sage.all import *
>>> PartitionTuples(Integer(2),Integer(3)).cardinality()                    ␣
↪              # needs sage.libs.pari
10
>>> PartitionTuples(Integer(2),Integer(8)).cardinality()                    ␣
↪              # needs sage.libs.pari
185
```

class sage.combinat.partition_tuple.**PartitionTuples_size**(*size*)

Bases: *PartitionTuples*

Class of partition tuples of a fixed size, but arbitrary level.

class sage.combinat.partition_tuple.**RegularPartitionTuples**(*regular*, ***kwds*)

Bases: *PartitionTuples*

Abstract base class for ℓ-regular partition tuples.

class sage.combinat.partition_tuple.**RegularPartitionTuples_all**(*regular*)

Bases: *RegularPartitionTuples*

Class of ℓ-regular partition tuples.

class sage.combinat.partition_tuple.**RegularPartitionTuples_level**(*level*, *regular*)

Bases: *PartitionTuples_level*

Regular Partition tuples of a fixed level.

INPUT:

- `level` – nonnegative integer; the level

- `regular` – positive integer or a tuple of nonnegative integers; if an integer, the highest multiplicity an entry may have in a component plus 1 with 0 representing ∞-regular (equivalently, partitions without restrictions)

`regular` is a tuple of integers $(\ell_1, \ldots, \ell_k)$ that specifies partition tuples μ such that μ_i is ℓ_i-regular. If `regular` is an integer ℓ, then we set $\ell_i = \ell$ for all i.

EXAMPLES:

```
sage: RPT = PartitionTuples(level=4, regular=(2,3,0,2))
sage: RPT[:24]                                                              #␣
↪needs sage.libs.flint

class sage.combinat.partition_tuple.**RegularPartitionTuples_level_size**(*level*, *size*, *regular*)

Bases: *PartitionTuples_level_size*

Class of ℓ-regular partition tuples with a fixed level and a fixed size.

INPUT:

- `level` – nonnegative integer; the level
- `size` – nonnegative integer; the size
- `regular` – positive integer or a tuple of nonnegative integers; if an integer, the highest multiplicity an entry may have in a component plus 1 with 0 representing ∞-regular (equivalently, partitions without restrictions)

`regular` is a tuple of integers $(\ell_1, \ldots, \ell_k)$ that specifies partition tuples μ such that μ_i is ℓ_i-regular. If `regular` is an integer ℓ, then we set $\ell_i = \ell$ for all i.

EXAMPLES:

```
sage: PartitionTuples(level=3, size=7, regular=(2,1,3))[0:24]                 #␣
 ↪needs sage.libs.flint
[([7], [], []),

>>> p = PartitionAlgebra_bk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_generic**(*R*, *cclass*, *n*, *k*, *name=None*, *prefix=None*)

Bases: *CombinatorialFreeModule*

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: s = PartitionAlgebra_sk(QQ, 3, 1)
sage: TestSuite(s).run()
sage: s == loads(dumps(s))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> s = PartitionAlgebra_sk(QQ, Integer(3), Integer(1))
>>> TestSuite(s).run()
>>> s == loads(dumps(s))
True
```

one_basis()

Return the basis index for the unit of the algebra.

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: s = PartitionAlgebra_sk(ZZ, 3, 1)
sage: len(s.one().support())    # indirect doctest
1
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> s = PartitionAlgebra_sk(ZZ, Integer(3), Integer(1))
>>> len(s.one().support())    # indirect doctest
1
```

product_on_basis(*left*, *right*)

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: s = PartitionAlgebra_sk(QQ, 3, 1)
sage: t12 = s(Set([Set([1,-2]),Set([2,-1]),Set([3,-3])]))
sage: t12^2 == s(1) #indirect doctest
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> s = PartitionAlgebra_sk(QQ, Integer(3), Integer(1))
>>> t12 = s(Set([Set([Integer(1),-Integer(2)]),Set([Integer(2),-Integer(1)]),
↪Set([Integer(3),-Integer(3)])]))
>>> t12**Integer(2) == s(Integer(1)) #indirect doctest
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_pk**(*R*, *k*, *n*, *name=None*)

Bases: *PartitionAlgebra_generic*

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_pk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_pk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_prk**(*R*, *k*, *n*, *name=None*)

Bases: *PartitionAlgebra_generic*

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_prk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_prk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_rk**(*R*, *k*, *n*, *name=None*)

Bases: *PartitionAlgebra_generic*

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_rk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_rk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_sk**(*R*, *k*, *n*, *name=None*)

Bases: *PartitionAlgebra_generic*

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_sk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_sk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.**PartitionAlgebra_tk**(*R*, *k*, *n*, *name=None*)

Bases: *PartitionAlgebra_generic*

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_tk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_tk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
```

sage.combinat.partition_algebra.**SetPartitionsAk**(*k*)

Return the combinatorial class of set partitions of type A_k.

EXAMPLES:

```
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}

sage: A3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: A3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: A3.random_element()  #random
{{1, 3, -3, -1}, {2, -2}}

sage: A3.cardinality()
203

sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5.cardinality()
52

sage: A2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: A2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
sage: A2p5.random_element() #random
{{-1}, {-2}, {3, -3}, {1, 2}}
```

```
>>> from sage.all import *
>>> A3 = SetPartitionsAk(Integer(3)); A3
Set partitions of {1, ..., 3, -1, ..., -3}

>>> A3.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> A3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
>>> A3.random_element()  #random
{{1, 3, -3, -1}, {2, -2}}

>>> A3.cardinality()
203

>>> A2p5 = SetPartitionsAk(RealNumber('2.5')); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
>>> A2p5.cardinality()
52

>>> A2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> A2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
>>> A2p5.random_element() #random
{{-1}, {-2}, {3, -3}, {1, 2}}
```

class sage.combinat.partition_algebra.**SetPartitionsAk_k**(k)

Bases: *SetPartitions_set*

Element

alias of *SetPartitionsXkElement*

class sage.combinat.partition_algebra.**SetPartitionsAkhalf_k**(k)

Bases: *SetPartitions_set*

Element

alias of *SetPartitionsXkElement*

sage.combinat.partition_algebra.**SetPartitionsBk**(k)

Return the combinatorial class of set partitions of type B_k.

These are the set partitions where every block has size 2.

EXAMPLES:

```
sage: B3 = SetPartitionsBk(3); B3
Set partitions of {1, ..., 3, -1, ..., -3} with block size 2

sage: B3.first() #random
{{2, -2}, {1, -3}, {3, -1}}
sage: B3.last() #random
{{1, 2}, {3, -2}, {-3, -1}}
sage: B3.random_element() #random
{{2, -1}, {1, -3}, {3, -2}}
```

(continues on next page)

(continued from previous page)

```
sage: B3.cardinality()
15

sage: B2p5 = SetPartitionsBk(2.5); B2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and␣
↪with block size 2

sage: B2p5.first() #random
{{2, -1}, {3, -3}, {1, -2}}
sage: B2p5.last() #random
{{1, 2}, {3, -3}, {-1, -2}}
sage: B2p5.random_element() #random
{{2, -2}, {3, -3}, {1, -1}}

sage: B2p5.cardinality()
3
```

```
>>> from sage.all import *
>>> B3 = SetPartitionsBk(Integer(3)); B3
Set partitions of {1, ..., 3, -1, ..., -3} with block size 2

>>> B3.first() #random
{{2, -2}, {1, -3}, {3, -1}}
>>> B3.last() #random
{{1, 2}, {3, -2}, {-3, -1}}
>>> B3.random_element() #random
{{2, -1}, {1, -3}, {3, -2}}

>>> B3.cardinality()
15

>>> B2p5 = SetPartitionsBk(RealNumber('2.5')); B2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and␣
↪with block size 2

>>> B2p5.first() #random
{{2, -1}, {3, -3}, {1, -2}}
>>> B2p5.last() #random
{{1, 2}, {3, -3}, {-1, -2}}
>>> B2p5.random_element() #random
{{2, -2}, {3, -3}, {1, -1}}

>>> B2p5.cardinality()
3
```

class sage.combinat.partition_algebra.**SetPartitionsBk_k**(k)

Bases: *SetPartitionsAk_k*

cardinality()

Return the number of set partitions in B_k where k is an integer.

This is given by (2k)!! = (2k-1)*(2k-3)*…*5*3*1.

EXAMPLES:

```
sage: SetPartitionsBk(3).cardinality()
15
sage: SetPartitionsBk(2).cardinality()
3
sage: SetPartitionsBk(1).cardinality()
1
sage: SetPartitionsBk(4).cardinality()
105
sage: SetPartitionsBk(5).cardinality()
945
```

```
>>> from sage.all import *
>>> SetPartitionsBk(Integer(3)).cardinality()
15
>>> SetPartitionsBk(Integer(2)).cardinality()
3
>>> SetPartitionsBk(Integer(1)).cardinality()
1
>>> SetPartitionsBk(Integer(4)).cardinality()
105
>>> SetPartitionsBk(Integer(5)).cardinality()
945
```

class sage.combinat.partition_algebra.**SetPartitionsBkhalf_k**(k)

Bases: *SetPartitionsAkhalf_k*

cardinality()

sage.combinat.partition_algebra.**SetPartitionsIk**(k)

Return the combinatorial class of set partitions of type I_k.

These are set partitions with a propagating number of less than k. Note that the identity set partition $\{\{1,-1\},\dots,\{k,-k\}\}$ is not in I_k.

EXAMPLES:

```
sage: I3 = SetPartitionsIk(3); I3
Set partitions of {1, ..., 3, -1, ..., -3} with propagating number < 3
sage: I3.cardinality()
197

sage: I3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: I3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: I3.random_element() #random
{{-1}, {-3, -2}, {2, 3}, {1}}

sage: I2p5 = SetPartitionsIk(2.5); I2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and␣
↪propagating number < 3
sage: I2p5.cardinality()
50
```

(continues on next page)

(continued from previous page)

```
sage: I2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: I2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
sage: I2p5.random_element() #random
{{-1}, {-2}, {1, 3, -3}, {2}}
```

```
>>> from sage.all import *
>>> I3 = SetPartitionsIk(Integer(3)); I3
Set partitions of {1, ..., 3, -1, ..., -3} with propagating number < 3
>>> I3.cardinality()
197

>>> I3.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> I3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
>>> I3.random_element() #random
{{-1}, {-3, -2}, {2, 3}, {1}}

>>> I2p5 = SetPartitionsIk(RealNumber('2.5')); I2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and␣
↪propagating number < 3
>>> I2p5.cardinality()
50

>>> I2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> I2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
>>> I2p5.random_element() #random
{{-1}, {-2}, {1, 3, -3}, {2}}
```

class sage.combinat.partition_algebra.**SetPartitionsIk_k**(k)

Bases: *SetPartitionsAk_k*

cardinality()

class sage.combinat.partition_algebra.**SetPartitionsIkhalf_k**(k)

Bases: *SetPartitionsAkhalf_k*

cardinality()

sage.combinat.partition_algebra.**SetPartitionsPRk**(k)

Return the combinatorial class of set partitions of type PR_k.

EXAMPLES:

```
sage: SetPartitionsPRk(3)
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive
 and negative entry in each block and that are planar
```

```
>>> from sage.all import *
>>> SetPartitionsPRk(Integer(3))
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive
 and negative entry in each block and that are planar
```

class sage.combinat.partition_algebra.**SetPartitionsPRk_k**(*k*)

Bases: *SetPartitionsRk_k*

cardinality()

class sage.combinat.partition_algebra.**SetPartitionsPRkhalf_k**(*k*)

Bases: *SetPartitionsRkhalf_k*

cardinality()

sage.combinat.partition_algebra.**SetPartitionsPk**(*k*)

Return the combinatorial class of set partitions of type P_k.

These are the planar set partitions.

EXAMPLES:

```
sage: P3 = SetPartitionsPk(3); P3
Set partitions of {1, ..., 3, -1, ..., -3} that are planar
sage: P3.cardinality()
132

sage: P3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: P3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: P3.random_element() #random
{{1, 2, -1}, {-3}, {3, -2}}

sage: P2p5 = SetPartitionsPk(2.5); P2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and␣
↪that are planar
sage: P2p5.cardinality()
42

sage: P2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: P2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
sage: P2p5.random_element() #random
{{1, 2, 3, -3}, {-1, -2}}
```

```
>>> from sage.all import *
>>> P3 = SetPartitionsPk(Integer(3)); P3
Set partitions of {1, ..., 3, -1, ..., -3} that are planar
>>> P3.cardinality()
132

>>> P3.first() #random
```

(continues on next page)

(continued from previous page)

```
{{1, 2, 3, -1, -3, -2}}
>>> P3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
>>> P3.random_element() #random
{{1, 2, -1}, {-3}, {3, -2}}

>>> P2p5 = SetPartitionsPk(RealNumber('2.5')); P2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and␣
↪that are planar
>>> P2p5.cardinality()
42

>>> P2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> P2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
>>> P2p5.random_element() #random
{{1, 2, 3, -3}, {-1, -2}}
```

class sage.combinat.partition_algebra.**SetPartitionsPk_k**(k)

Bases: *SetPartitionsAk_k*

cardinality()

class sage.combinat.partition_algebra.**SetPartitionsPkhalf_k**(k)

Bases: *SetPartitionsAkhalf_k*

cardinality()

sage.combinat.partition_algebra.**SetPartitionsRk**(k)

Return the combinatorial class of set partitions of type R_k.

EXAMPLES:

```
sage: SetPartitionsRk(3)
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive
 and negative entry in each block
```

```
>>> from sage.all import *
>>> SetPartitionsRk(Integer(3))
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive
 and negative entry in each block
```

class sage.combinat.partition_algebra.**SetPartitionsRk_k**(k)

Bases: *SetPartitionsAk_k*

cardinality()

class sage.combinat.partition_algebra.**SetPartitionsRkhalf_k**(k)

Bases: *SetPartitionsAkhalf_k*

cardinality()

sage.combinat.partition_algebra.**SetPartitionsSk**(k)

Return the combinatorial class of set partitions of type S_k.

There is a bijection between these set partitions and the permutations of $1, \ldots, k$.

EXAMPLES:

```
sage: S3 = SetPartitionsSk(3); S3
Set partitions of {1, ..., 3, -1, ..., -3} with propagating number 3
sage: S3.cardinality()
6

sage: S3.list()  #random
[{{2, -2}, {3, -3}, {1, -1}},
 {{1, -1}, {2, -3}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}},
 {{1, -2}, {2, -3}, {3, -1}},
 {{1, -3}, {2, -1}, {3, -2}},
 {{1, -3}, {2, -2}, {3, -1}}]
sage: S3.first() #random
{{2, -2}, {3, -3}, {1, -1}}
sage: S3.last() #random
{{1, -3}, {2, -2}, {3, -1}}
sage: S3.random_element() #random
{{1, -3}, {2, -1}, {3, -2}}

sage: S3p5 = SetPartitionsSk(3.5); S3p5
Set partitions of {1, ..., 4, -1, ..., -4} with 4 and -4 in the same block and␣
↪propagating number 4
sage: S3p5.cardinality()
6

sage: S3p5.list() #random
[{{2, -2}, {3, -3}, {1, -1}, {4, -4}},
 {{2, -3}, {1, -1}, {4, -4}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}, {4, -4}},
 {{2, -3}, {1, -2}, {4, -4}, {3, -1}},
 {{1, -3}, {2, -1}, {4, -4}, {3, -2}},
 {{1, -3}, {2, -2}, {4, -4}, {3, -1}}]
sage: S3p5.first() #random
{{2, -2}, {3, -3}, {1, -1}, {4, -4}}
sage: S3p5.last() #random
{{1, -3}, {2, -2}, {4, -4}, {3, -1}}
sage: S3p5.random_element() #random
{{1, -3}, {2, -2}, {4, -4}, {3, -1}}
```

```
>>> from sage.all import *
>>> S3 = SetPartitionsSk(Integer(3)); S3
Set partitions of {1, ..., 3, -1, ..., -3} with propagating number 3
>>> S3.cardinality()
6

>>> S3.list()  #random
[{{2, -2}, {3, -3}, {1, -1}},
```

(continues on next page)

(continued from previous page)

```
 {{1, -1}, {2, -3}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}},
 {{1, -2}, {2, -3}, {3, -1}},
 {{1, -3}, {2, -1}, {3, -2}},
 {{1, -3}, {2, -2}, {3, -1}}]
>>> S3.first() #random
{{2, -2}, {3, -3}, {1, -1}}
>>> S3.last() #random
{{1, -3}, {2, -2}, {3, -1}}
>>> S3.random_element() #random
{{1, -3}, {2, -1}, {3, -2}}

>>> S3p5 = SetPartitionsSk(RealNumber('3.5')); S3p5
Set partitions of {1, ..., 4, -1, ..., -4} with 4 and -4 in the same block and␣
↪propagating number 4
>>> S3p5.cardinality()
6

>>> S3p5.list() #random
[{{2, -2}, {3, -3}, {1, -1}, {4, -4}},
 {{2, -3}, {1, -1}, {4, -4}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}, {4, -4}},
 {{2, -3}, {1, -2}, {4, -4}, {3, -1}},
 {{1, -3}, {2, -1}, {4, -4}, {3, -2}},
 {{1, -3}, {2, -2}, {4, -4}, {3, -1}}]
>>> S3p5.first() #random
{{2, -2}, {3, -3}, {1, -1}, {4, -4}}
>>> S3p5.last() #random
{{1, -3}, {2, -2}, {4, -4}, {3, -1}}
>>> S3p5.random_element() #random
{{1, -3}, {2, -2}, {4, -4}, {3, -1}}
```

class sage.combinat.partition_algebra.**SetPartitionsSk_k**(k)

Bases: *SetPartitionsAk_k*

cardinality()

Return k!.

class sage.combinat.partition_algebra.**SetPartitionsSkhalf_k**(k)

Bases: *SetPartitionsAkhalf_k*

cardinality()

sage.combinat.partition_algebra.**SetPartitionsTk**(k)

Return the combinatorial class of set partitions of type T_k.

These are planar set partitions where every block is of size 2.

EXAMPLES:

```
sage: T3 = SetPartitionsTk(3); T3
Set partitions of {1, ..., 3, -1, ..., -3} with block size 2 and that are planar
sage: T3.cardinality()
5
```

(continues on next page)

(continued from previous page)

```
sage: T3.first() #random
{{1, -3}, {2, 3}, {-1, -2}}
sage: T3.last() #random
{{1, 2}, {3, -1}, {-3, -2}}
sage: T3.random_element() #random
{{1, -3}, {2, 3}, {-1, -2}}

sage: T2p5 = SetPartitionsTk(2.5); T2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and␣
↪with block size 2 and that are planar
sage: T2p5.cardinality()
2

sage: T2p5.first() #random
{{2, -2}, {3, -3}, {1, -1}}
sage: T2p5.last() #random
{{1, 2}, {3, -3}, {-1, -2}}
```

```
>>> from sage.all import *
>>> T3 = SetPartitionsTk(Integer(3)); T3
Set partitions of {1, ..., 3, -1, ..., -3} with block size 2 and that are planar
>>> T3.cardinality()
5

>>> T3.first() #random
{{1, -3}, {2, 3}, {-1, -2}}
>>> T3.last() #random
{{1, 2}, {3, -1}, {-3, -2}}
>>> T3.random_element() #random
{{1, -3}, {2, 3}, {-1, -2}}

>>> T2p5 = SetPartitionsTk(RealNumber('2.5')); T2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and␣
↪with block size 2 and that are planar
>>> T2p5.cardinality()
2

>>> T2p5.first() #random
{{2, -2}, {3, -3}, {1, -1}}
>>> T2p5.last() #random
{{1, 2}, {3, -3}, {-1, -2}}
```

class sage.combinat.partition_algebra.**SetPartitionsTk_k**(k)

Bases: *SetPartitionsBk_k*

cardinality()

class sage.combinat.partition_algebra.**SetPartitionsTkhalf_k**(k)

Bases: *SetPartitionsBkhalf_k*

cardinality()

class sage.combinat.partition_algebra.**SetPartitionsXkElement**(*parent*, *s*, *check=True*)

Bases: *SetPartition*

An element for the classes of SetPartitionXk where X is some letter.

check()

Check to make sure this is a set partition.

EXAMPLES:

```
sage: A2p5 = SetPartitionsAk(2.5)
sage: x = A2p5.first(); x
{{-3, -2, -1, 1, 2, 3}}
sage: x.check()
sage: y = A2p5.next(x); y
{{-3, 3}, {-2, -1, 1, 2}}
sage: y.check()
```

```
>>> from sage.all import *
>>> A2p5 = SetPartitionsAk(RealNumber('2.5'))
>>> x = A2p5.first(); x
{{-3, -2, -1, 1, 2, 3}}
>>> x.check()
>>> y = A2p5.next(x); y
{{-3, 3}, {-2, -1, 1, 2}}
>>> y.check()
```

sage.combinat.partition_algebra.**identity**(k)

Return the identity set partition $1, -1, \ldots, k, -k$.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.identity(2)
{{2, -2}, {1, -1}}
```

```
>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> pa.identity(Integer(2))
{{2, -2}, {1, -1}}
```

sage.combinat.partition_algebra.**is_planar**(*sp*)

Return True if the diagram corresponding to the set partition is planar; otherwise, it returns False.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.is_planar( pa.to_set_partition([[1,-2],[2,-1]]))
False
sage: pa.is_planar( pa.to_set_partition([[1,-1],[2,-2]]))
True
```

```
>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
```

(continues on next page)

(continued from previous page)

```
>>> pa.is_planar( pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-
↪Integer(1)]]))
False
>>> pa.is_planar( pa.to_set_partition([[Integer(1),-Integer(1)],[Integer(2),-
↪Integer(2)]]))
True
```

sage.combinat.partition_algebra.**pair_to_graph**(*sp1*, *sp2*)

Return a graph consisting of the disjoint union of the graphs of set partitions `sp1` and `sp2` along with edges joining the bottom row (negative numbers) of `sp1` to the top row (positive numbers) of `sp2`.

The vertices of the graph `sp1` appear in the result as pairs `(k, 1)`, whereas the vertices of the graph `sp2` appear as pairs `(k, 2)`.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: g = pa.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices
```

```
>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> sp1 = pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> sp2 = pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> g = pa.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices
```

```
sage: g.vertices(sort=False) #random
[(1, 2), (-1, 1), (-2, 2), (-1, 2), (-2, 1), (2, 1), (2, 2), (1, 1)]
sage: g.edges(sort=False) #random
[((1, 2), (-1, 1), None),
 ((1, 2), (-2, 2), None),
 ((-1, 1), (2, 1), None),
 ((-1, 2), (2, 2), None),
 ((-2, 1), (1, 1), None),
 ((-2, 1), (2, 2), None)]
```

```
>>> from sage.all import *
>>> g.vertices(sort=False) #random
[(1, 2), (-1, 1), (-2, 2), (-1, 2), (-2, 1), (2, 1), (2, 2), (1, 1)]
>>> g.edges(sort=False) #random
[((1, 2), (-1, 1), None),
 ((1, 2), (-2, 2), None),
 ((-1, 1), (2, 1), None),
 ((-1, 2), (2, 2), None),
 ((-2, 1), (1, 1), None),
 ((-2, 1), (2, 2), None)]
```

Another example which used to be wrong until Issue #15958:

```
sage: sp3 = pa.to_set_partition([[1, -1], [2], [-2]])
sage: sp4 = pa.to_set_partition([[1], [-1], [2], [-2]])
sage: g = pa.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices

sage: g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=True)
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
 ((-1, 1), (1, 2), None)]
```

```
>>> from sage.all import *
>>> sp3 = pa.to_set_partition([[Integer(1), -Integer(1)], [Integer(2)], [-
↪Integer(2)]])
>>> sp4 = pa.to_set_partition([[Integer(1)], [-Integer(1)], [Integer(2)], [-
↪Integer(2)]])
>>> g = pa.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices

>>> g.vertices(sort=True)
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
>>> g.edges(sort=True)
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None),
 ((-1, 1), (1, 2), None)]
```

sage.combinat.partition_algebra.**propagating_number**(*sp*)

Return the propagating number of the set partition `sp`.

The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,2],[-2,-1]])
sage: pa.propagating_number(sp1)
2
sage: pa.propagating_number(sp2)
0
```

```
>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> sp1 = pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> sp2 = pa.to_set_partition([[Integer(1),Integer(2)],[-Integer(2),-Integer(1)]])
>>> pa.propagating_number(sp1)
2
>>> pa.propagating_number(sp2)
0
```

sage.combinat.partition_algebra.**set_partition_composition**(*sp1*, *sp2*)

Return a tuple consisting of the composition of the set partitions sp1 and sp2 and the number of components removed from the middle rows of the graph.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: pa.set_partition_composition(sp1, sp2) == (pa.identity(2), 0)
True
```

```
>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> sp1 = pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> sp2 = pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
>>> pa.set_partition_composition(sp1, sp2) == (pa.identity(Integer(2)),␣
↪Integer(0))
True
```

sage.combinat.partition_algebra.**to_graph**(*sp*)

Return a graph representing the set partition `sp`.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: g = pa.to_graph( pa.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices

sage: g.vertices(sort=False) #random
[1, 2, -2, -1]
sage: g.edges(sort=False) #random
[(1, -2, None), (2, -1, None)]
```

```
>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> g = pa.to_graph( pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-
↪Integer(1)]])); g
Graph on 4 vertices

>>> g.vertices(sort=False) #random
[1, 2, -2, -1]
>>> g.edges(sort=False) #random
[(1, -2, None), (2, -1, None)]
```

sage.combinat.partition_algebra.**to_set_partition**(*l*, *k=None*)

Convert a list of a list of numbers to a set partitions.

Each list of numbers in the outer list specifies the numbers contained in one of the blocks in the set partition.

If k is specified, then the set partition will be a set partition of 1, …, k, -1, …, -k. Otherwise, k will default to the minimum number needed to contain all of the specified numbers.

EXAMPLES:

```
sage: import sage.combinat.partition_algebra as pa
sage: pa.to_set_partition([[1,-1],[2,-2]]) == pa.identity(2)
True
```

```
>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> pa.to_set_partition([[Integer(1),-Integer(1)],[Integer(2),-Integer(2)]]) ==␣
↪pa.identity(Integer(2))
True
```

Partitions, tableaux, and others

Partitions

- *Integer partitions*
- *Skew partitions*
- *Partition tuples*
- *Super partitions*
- *Tableaux*
- *TableauTuples*
- *Skew tableaux*
- *Ribbons*
- *Ribbon tableaux*
- *Strong and weak tableaux*
- *Shifted primed tableaux*
- *Residue sequences of tableaux*

RSK

- *Robinson-Schensted-Knuth correspondence*
- *Growth diagrams and dual graded graphs*

Paths in directed acyclic graphs

`sage.combinat.graph_path.`**`GraphPaths`**(*g*, *source=None*, *target=None*)

Return the combinatorial class of paths in the directed acyclic graph g.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
```

If source and target are not given, then the returned class contains all paths (including trivial paths containing only one vertex).

```
sage: p = GraphPaths(G); p
Paths in Multi-digraph on 5 vertices
sage: p.cardinality()
37
sage: path = p.random_element()
sage: all(G.has_edge(*path[i:i+2]) for i in range(len(path) -1))
True
```

```
>>> from sage.all import *
>>> p = GraphPaths(G); p
Paths in Multi-digraph on 5 vertices
>>> p.cardinality()
37
>>> path = p.random_element()
>>> all(G.has_edge(*path[i:i+Integer(2)]) for i in range(len(path) -Integer(1)))
True
```

If the source is specified, then the returned class contains all of the paths starting at the vertex source (including the trivial path).

```
sage: p = GraphPaths(G, source=3); p
Paths in Multi-digraph on 5 vertices starting at 3
sage: p.list()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
```

```
>>> from sage.all import *
>>> p = GraphPaths(G, source=Integer(3)); p
Paths in Multi-digraph on 5 vertices starting at 3
>>> p.list()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
```

If the target is specified, then the returned class contains all of the paths ending at the vertex target (including the trivial path).

```
sage: p = GraphPaths(G, target=3); p
Paths in Multi-digraph on 5 vertices ending at 3
sage: p.cardinality()
5
sage: p.list()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
```

```
>>> from sage.all import *
>>> p = GraphPaths(G, target=Integer(3)); p
Paths in Multi-digraph on 5 vertices ending at 3
>>> p.cardinality()
5
>>> p.list()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
```

If both the target and source are specified, then the returned class contains all of the paths from source to target.

```
sage: p = GraphPaths(G, source=1, target=3); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
```

(continues on next page)

(continued from previous page)

```
sage: p.cardinality()
3
sage: p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]
```

```
>>> from sage.all import *
>>> p = GraphPaths(G, source=Integer(1), target=Integer(3)); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
>>> p.cardinality()
3
>>> p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]
```

Note that G must be a directed acyclic graph.

```
sage: G = DiGraph({1:[2,2,3,5], 2:[3,4], 3:[4], 4:[2,5,7], 5:[6]},␣
↪multiedges=True)
sage: GraphPaths(G)
Traceback (most recent call last):
...
TypeError: g must be a directed acyclic graph
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3),Integer(5)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(2),Integer(5),Integer(7)], Integer(5):[Integer(6)]},␣
↪multiedges=True)
>>> GraphPaths(G)
Traceback (most recent call last):
...
TypeError: g must be a directed acyclic graph
```

class sage.combinat.graph_path.**GraphPaths_all**(*g*)

Bases: Parent, *GraphPaths_common*

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.cardinality()
37
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G)
>>> p.cardinality()
37
```

list()

Return a list of the paths of `self`.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: len(GraphPaths(G).list())
37
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> len(GraphPaths(G).list())
37
```

class sage.combinat.graph_path.**GraphPaths_common**

Bases: object

incoming_edges(*v*)

Return a list of v's incoming edges.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.incoming_edges(2)
[(1, 2, None), (1, 2, None)]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G)
>>> p.incoming_edges(Integer(2))
[(1, 2, None), (1, 2, None)]
```

incoming_paths(*v*)

Return a list of paths that end at v.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.incoming_paths(2)
[[2], [1, 2], [1, 2]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> gp.incoming_paths(Integer(2))
[[2], [1, 2], [1, 2]]
```

outgoing_edges(*v*)

Return a list of v's outgoing edges.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.outgoing_edges(2)
[(2, 3, None), (2, 4, None)]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G)
>>> p.outgoing_edges(Integer(2))
[(2, 3, None), (2, 4, None)]
```

outgoing_paths(*v*)

Return a list of the paths that start at v.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.outgoing_paths(3)
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
sage: gp.outgoing_paths(2)
[[2],
 [2, 3],
 [2, 3, 4],
 [2, 3, 4, 5],
 [2, 3, 4, 5],
 [2, 4],
 [2, 4, 5],
 [2, 4, 5]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> gp.outgoing_paths(Integer(3))
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
>>> gp.outgoing_paths(Integer(2))
[[2],
 [2, 3],
 [2, 3, 4],
 [2, 3, 4, 5],
 [2, 3, 4, 5],
 [2, 4],
 [2, 4, 5],
 [2, 4, 5]]
```

paths()

Return a list of all the paths of `self`.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: len(gp.paths())
37
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> len(gp.paths())
37
```

paths_from_source_to_target(*source*, *target*)

Return a list of paths from source to target.

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.paths_from_source_to_target(2,4)
[[2, 3, 4], [2, 4]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> gp.paths_from_source_to_target(Integer(2),Integer(4))
[[2, 3, 4], [2, 4]]
```

class sage.combinat.graph_path.**GraphPaths_s**(*g*, *source*)

Bases: Parent, *GraphPaths_common*

list()

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G, 4)
sage: p.list()
[[4], [4, 5], [4, 5]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G, Integer(4))
>>> p.list()
[[4], [4, 5], [4, 5]]
```

class sage.combinat.graph_path.**GraphPaths_st**(*g*, *source*, *target*)

Bases: Parent, *GraphPaths_common*

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: GraphPaths(G,1,2).cardinality()
2
sage: GraphPaths(G,1,3).cardinality()
3
sage: GraphPaths(G,1,4).cardinality()
5
sage: GraphPaths(G,1,5).cardinality()
10
sage: GraphPaths(G,2,3).cardinality()
1
sage: GraphPaths(G,2,4).cardinality()
2
sage: GraphPaths(G,2,5).cardinality()
4
sage: GraphPaths(G,3,4).cardinality()
1
sage: GraphPaths(G,3,5).cardinality()
2
sage: GraphPaths(G,4,5).cardinality()
2
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣
↪Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> GraphPaths(G,Integer(1),Integer(2)).cardinality()
2
>>> GraphPaths(G,Integer(1),Integer(3)).cardinality()
3
>>> GraphPaths(G,Integer(1),Integer(4)).cardinality()
5
>>> GraphPaths(G,Integer(1),Integer(5)).cardinality()
10
>>> GraphPaths(G,Integer(2),Integer(3)).cardinality()
1
>>> GraphPaths(G,Integer(2),Integer(4)).cardinality()
2
>>> GraphPaths(G,Integer(2),Integer(5)).cardinality()
4
>>> GraphPaths(G,Integer(3),Integer(4)).cardinality()
1
>>> GraphPaths(G,Integer(3),Integer(5)).cardinality()
2
>>> GraphPaths(G,Integer(4),Integer(5)).cardinality()
2
```

list()

EXAMPLES:

```
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G,1,2)
```

(continues on next page)

(continued from previous page)

```
sage: p.list()
[[1, 2], [1, 2]]
```

```
>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],␣
↪Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],␣

 [1, 3, 4],
 [2, 3, 4],
 [1, 2, 3, 4],
 [1, 2, 3, 4]]
```

Perfect matchings

A perfect matching of a set S is a partition into 2-element sets. If S is the set $\{1, ..., n\}$, it is equivalent to fixpoint-free involutions. These simple combinatorial objects appear in different domains such as combinatorics of orthogonal polynomials and of the hyperoctahedral groups (see [MV], Chapter VII of [Mac1995] and [CM]):

AUTHOR:

- Valentin Feray, 2010 : initial version
- Martin Rubey, 2017: inherit from SetPartition, move crossings and nestings to SetPartition

EXAMPLES:

Create a perfect matching:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')]);m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
```

```
>>> from sage.all import *
>>> m = PerfectMatching([('a','e'),('b','c'),('d','f')]);m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
```

Count its crossings, if the ground set is totally ordered:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1
```

```
>>> from sage.all import *
>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),Integer(6),
↪Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.number_of_crossings()
1
```

List the perfect matchings of a given ground set:

```
sage: PerfectMatchings(4).list()
[[(1, 2), (3, 4)], [(1, 3), (2, 4)], [(1, 4), (2, 3)]]
```

```
>>> from sage.all import *
>>> PerfectMatchings(Integer(4)).list()
[[(1, 2), (3, 4)], [(1, 3), (2, 4)], [(1, 4), (2, 3)]]
```

class sage.combinat.perfect_matching.**PerfectMatching**(*parent*, *s*, *check=True*, *sort=True*)

Bases: *SetPartition*

A perfect matching.

A *perfect matching* of a set X is a set partition of X where all parts have size 2.

A perfect matching can be created from a list of pairs or from a fixed point-free involution as follows:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')]);m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]);n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: isinstance(m,PerfectMatching)
True
```

```
>>> from sage.all import *
>>> m = PerfectMatching([('a','e'),('b','c'),('d','f')]);m
[('a', 'e'), ('b', 'c'), ('d', 'f')]
>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),Integer(6),
↪Integer(5),Integer(4),Integer(2)]);n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> isinstance(m,PerfectMatching)
True
```

The parent, which is the set of perfect matchings of the ground set, is automatically created:

```
sage: n.parent()
Perfect matchings of {1, 2, 3, 4, 5, 6, 7, 8}
```

```
>>> from sage.all import *
>>> n.parent()
Perfect matchings of {1, 2, 3, 4, 5, 6, 7, 8}
```

If the ground set is ordered, one can, for example, ask if the matching is non crossing:

```
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_noncrossing()
True
```

```
>>> from sage.all import *
>>> PerfectMatching([(Integer(1), Integer(4)), (Integer(2), Integer(3)),␣
↪(Integer(5), Integer(6))]).is_noncrossing()
True
```

Weingarten_function(*d*, *other=None*)

Return the Weingarten function of two pairings.

This function is the value of some integrals over the orthogonal groups O_N. With the convention of [CM], the method returns $Wg^{O(d)}(other, self)$.

EXAMPLES:

```
sage: var('N')                                                              #␣
↪needs sage.symbolic
N
sage: m = PerfectMatching([(1,3),(2,4)])
sage: n = PerfectMatching([(1,2),(3,4)])
sage: factor(m.Weingarten_function(N, n))                                   #␣
↪needs sage.symbolic
-1/((N + 2)*(N - 1)*N)
```

```
>>> from sage.all import *
>>> var('N')                                                                #␣
↪needs sage.symbolic
N
>>> m = PerfectMatching([(Integer(1),Integer(3)),(Integer(2),Integer(4))])
>>> n = PerfectMatching([(Integer(1),Integer(2)),(Integer(3),Integer(4))])
>>> factor(m.Weingarten_function(N, n))                                     #␣
↪needs sage.symbolic
-1/((N + 2)*(N - 1)*N)
```

loop_type(*other=None*)

Return the loop type of `self`.

INPUT:

- `other` – a perfect matching of the same set of `self` (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the ordered list of the semi-length of these cycles (considered as a partition)

EXAMPLES:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')])
sage: n = PerfectMatching([('a','b'),('d','f'),('e','c')])
sage: m.loop_type(n)
[2, 1]
```

```
>>> from sage.all import *
>>> m = PerfectMatching([('a','e'),('b','c'),('d','f')])
>>> n = PerfectMatching([('a','b'),('d','f'),('e','c')])
>>> m.loop_type(n)
[2, 1]
```

loops(*other=None*)

Return the loops of `self`.

INPUT:

- `other` – a perfect matching of the same set of `self` (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the list of these cycles (each cycle is given as a list).

EXAMPLES:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')])
sage: n = PerfectMatching([('a','b'),('d','f'),('e','c')])
sage: loops = m.loops(n)
sage: loops # random
[['a', 'e', 'c', 'b'], ['d', 'f']]

sage: o = PerfectMatching([(1, 7), (2, 4), (3, 8), (5, 6)])
sage: p = PerfectMatching([(1, 6), (2, 7), (3, 4), (5, 8)])
sage: o.loops(p)
[[1, 7, 2, 4, 3, 8, 5, 6]]
```

```
>>> from sage.all import *
>>> m = PerfectMatching([('a','e'),('b','c'),('d','f')])
>>> n = PerfectMatching([('a','b'),('d','f'),('e','c')])
>>> loops = m.loops(n)
```

(continues on next page)

(continued from previous page)

```
>>> loops # random
[['a', 'e', 'c', 'b'], ['d', 'f']]

>>> o = PerfectMatching([(Integer(1), Integer(7)), (Integer(2), Integer(4)),␣
↪(Integer(3), Integer(8)), (Integer(5), Integer(6))])
>>> p = PerfectMatching([(Integer(1), Integer(6)), (Integer(2), Integer(7)),␣
↪(Integer(3), Integer(4)), (Integer(5), Integer(8))])
>>> o.loops(p)
[[1, 7, 2, 4, 3, 8, 5, 6]]
```

loops_iterator(*other=None*)

Iterate through the loops of `self`.

INPUT:

- `other` – a perfect matching of the same set of `self` (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns an iterator for these cycles (each cycle is given as a list).

EXAMPLES:

```
sage: o = PerfectMatching([(1, 7), (2, 4), (3, 8), (5, 6)])
sage: p = PerfectMatching([(1, 6), (2, 7), (3, 4), (5, 8)])
sage: it = o.loops_iterator(p)
sage: next(it)
[1, 7, 2, 4, 3, 8, 5, 6]
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

```
>>> from sage.all import *
>>> o = PerfectMatching([(Integer(1), Integer(7)), (Integer(2), Integer(4)),␣
↪(Integer(3), Integer(8)), (Integer(5), Integer(6))])
>>> p = PerfectMatching([(Integer(1), Integer(6)), (Integer(2), Integer(7)),␣
↪(Integer(3), Integer(4)), (Integer(5), Integer(8))])
>>> it = o.loops_iterator(p)
>>> next(it)
[1, 7, 2, 4, 3, 8, 5, 6]
>>> next(it)
Traceback (most recent call last):
...
StopIteration
```

number_of_loops(*other=None*)

Return the number of loops of `self`.

INPUT:

- `other` – a perfect matching of the same set of `self` (if the second argument is empty, the method `an_element()` is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns their numbers.

EXAMPLES:

```
sage: m = PerfectMatching([('a','e'),('b','c'),('d','f')])
sage: n = PerfectMatching([('a','b'),('d','f'),('e','c')])
sage: m.number_of_loops(n)
2
```

```
>>> from sage.all import *
>>> m = PerfectMatching([('a','e'),('b','c'),('d','f')])
>>> n = PerfectMatching([('a','b'),('d','f'),('e','c')])
>>> m.number_of_loops(n)
2
```

partner(*x*)

Return the element in the same pair than `x` in the matching `self`.

EXAMPLES:

```
sage: m = PerfectMatching([(-3, 1), (2, 4), (-2, 7)])
sage: m.partner(4)
2
sage: n = PerfectMatching([('c','b'),('d','f'),('e','a')])
sage: n.partner('c')
'b'
```

```
>>> from sage.all import *
>>> m = PerfectMatching([(-Integer(3), Integer(1)), (Integer(2), Integer(4)),␣
↪(-Integer(2), Integer(7))])
>>> m.partner(Integer(4))
2
>>> n = PerfectMatching([('c','b'),('d','f'),('e','a')])
>>> n.partner('c')
'b'
```

standardization()

Return the standardization of `self`.

See *standardization()* for details.

EXAMPLES:

```
sage: n = PerfectMatching([('c','b'),('d','f'),('e','a')])
sage: n.standardization()
[(1, 5), (2, 3), (4, 6)]
```

```
>>> from sage.all import *
>>> n = PerfectMatching([('c','b'),('d','f'),('e','a')])
>>> n.standardization()
[(1, 5), (2, 3), (4, 6)]
```

to_graph()

Return the graph corresponding to the perfect matching.

OUTPUT: the realization of `self` as a graph

EXAMPLES:

```
sage: PerfectMatching([[1,3], [4,2]]).to_graph().edges(sort=True,           #␣
↪needs sage.graphs
....:                                                 labels=False)
[(1, 3), (2, 4)]
sage: PerfectMatching([[1,4], [3,2]]).to_graph().edges(sort=True,           #␣
↪needs sage.graphs
....:                                                 labels=False)
[(1, 4), (2, 3)]
sage: PerfectMatching([]).to_graph().edges(sort=True, labels=False)         #␣
↪needs sage.graphs
[]
```

```
>>> from sage.all import *
>>> PerfectMatching([[Integer(1),Integer(3)], [Integer(4),Integer(2)]]).to_
↪graph().edges(sort=True,           # needs sage.graphs
...                                                 labels=False)
[(1, 3), (2, 4)]
>>> PerfectMatching([[Integer(1),Integer(4)], [Integer(3),Integer(2)]]).to_
↪graph().edges(sort=True,           # needs sage.graphs
...                                                 labels=False)
[(1, 4), (2, 3)]
>>> PerfectMatching([]).to_graph().edges(sort=True, labels=False)         #␣
↪needs sage.graphs
[]
```

to_noncrossing_set_partition()

Return the noncrossing set partition (on half as many elements) corresponding to the perfect matching if the perfect matching is noncrossing, and otherwise gives an error.

OUTPUT: the realization of `self` as a noncrossing set partition

EXAMPLES:

```
sage: PerfectMatching([[1,3], [4,2]]).to_noncrossing_set_partition()
Traceback (most recent call last):
...
ValueError: matching must be non-crossing
sage: PerfectMatching([[1,4], [3,2]]).to_noncrossing_set_partition()
{{1, 2}}
sage: PerfectMatching([]).to_noncrossing_set_partition()
{}
```

```
>>> from sage.all import *
>>> PerfectMatching([[Integer(1),Integer(3)], [Integer(4),Integer(2)]]).to_
↪noncrossing_set_partition()
Traceback (most recent call last):
...
ValueError: matching must be non-crossing
```

(continues on next page)

(continued from previous page)

```
>>> PerfectMatching([[Integer(1),Integer(4)], [Integer(3),Integer(2)]]).to_
↪noncrossing_set_partition()
{{1, 2}}
>>> PerfectMatching([]).to_noncrossing_set_partition()
{}
```

class sage.combinat.perfect_matching.**PerfectMatchings**(*s*)

Bases: *SetPartitions_set*

Perfect matchings of a ground set.

INPUT:

- s – an iterable of hashable objects or an integer

EXAMPLES:

If the argument s is an integer n, it will be transformed into the set $\{1, \ldots, n\}$:

```
sage: M = PerfectMatchings(6); M
Perfect matchings of {1, 2, 3, 4, 5, 6}
sage: PerfectMatchings([-1, -3, 1, 2])
Perfect matchings of {1, 2, -3, -1}
```

```
>>> from sage.all import *
>>> M = PerfectMatchings(Integer(6)); M
Perfect matchings of {1, 2, 3, 4, 5, 6}
>>> PerfectMatchings([-Integer(1), -Integer(3), Integer(1), Integer(2)])
Perfect matchings of {1, 2, -3, -1}
```

One can ask for the list, the cardinality or an element of a set of perfect matching:

```
sage: PerfectMatchings(4).list()
[[(1, 2), (3, 4)], [(1, 3), (2, 4)], [(1, 4), (2, 3)]]
sage: PerfectMatchings(8).cardinality()
105
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: x = M.an_element()
sage: x # random
[('a', 'c'), ('b', 'e'), ('d', 'f')]
sage: all(PerfectMatchings(i).an_element() in PerfectMatchings(i)
....:     for i in range(2,11,2))
True
```

```
>>> from sage.all import *
>>> PerfectMatchings(Integer(4)).list()
[[(1, 2), (3, 4)], [(1, 3), (2, 4)], [(1, 4), (2, 3)]]
>>> PerfectMatchings(Integer(8)).cardinality()
105
>>> M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
>>> x = M.an_element()
>>> x # random
[('a', 'c'), ('b', 'e'), ('d', 'f')]
>>> all(PerfectMatchings(i).an_element() in PerfectMatchings(i)
```

(continues on next page)

(continued from previous page)

```
...       for i in range(Integer(2),Integer(11),Integer(2)))
True
```

Element

alias of *PerfectMatching*

Weingarten_matrix(*N*)

Return the Weingarten matrix corresponding to the set of PerfectMatchings `self`.

It is a useful theoretical tool to compute polynomial integrals over the orthogonal group O_N (see [CM]).

EXAMPLES:

```
sage: M = PerfectMatchings(4).Weingarten_matrix(var('N'))                    #␣
↪needs sage.symbolic
sage: N*(N-1)*(N+2)*M.apply_map(factor)                                      #␣
↪needs sage.symbolic
[N + 1    -1    -1]
[   -1 N + 1    -1]
[   -1    -1 N + 1]
```

```
>>> from sage.all import *
>>> M = PerfectMatchings(Integer(4)).Weingarten_matrix(var('N'))             ␣
↪      # needs sage.symbolic
>>> N*(N-Integer(1))*(N+Integer(2))*M.apply_map(factor)                      ␣
↪               # needs sage.symbolic
[N + 1    -1    -1]
[   -1 N + 1    -1]
[   -1    -1 N + 1]
```

base_set()

Return the base set of `self`.

EXAMPLES:

```
sage: PerfectMatchings(3).base_set()
{1, 2, 3}
```

```
>>> from sage.all import *
>>> PerfectMatchings(Integer(3)).base_set()
{1, 2, 3}
```

base_set_cardinality()

Return the cardinality of the base set of `self`.

EXAMPLES:

```
sage: PerfectMatchings(3).base_set_cardinality()
3
```

```
>>> from sage.all import *
>>> PerfectMatchings(Integer(3)).base_set_cardinality()
3
```

cardinality()

Return the cardinality of the set of perfect matchings `self`.

This is $1 * 3 * 5 * ... * (2n - 1)$, where $2n$ is the size of the ground set.

EXAMPLES:

```
sage: PerfectMatchings(8).cardinality()
105
sage: PerfectMatchings([1,2,3,4]).cardinality()
3
sage: PerfectMatchings(3).cardinality()
0
sage: PerfectMatchings([]).cardinality()
1
```

```
>>> from sage.all import *
>>> PerfectMatchings(Integer(8)).cardinality()
105
>>> PerfectMatchings([Integer(1),Integer(2),Integer(3),Integer(4)]).
↪cardinality()
3
>>> PerfectMatchings(Integer(3)).cardinality()
0
>>> PerfectMatchings([]).cardinality()
1
```

random_element()

Return a random element of `self`.

EXAMPLES:

```
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: x = M.random_element()
sage: x # random
[('a', 'b'), ('c', 'd'), ('e', 'f')]
```

```
>>> from sage.all import *
>>> M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
>>> x = M.random_element()
>>> x # random
[('a', 'b'), ('c', 'd'), ('e', 'f')]
```

Permutations

The Permutations module. Use `Permutation?` to get information about the Permutation class, and `Permutations?` to get information about the combinatorial class of permutations.

Warning

This file defined *Permutation* which depends upon *CombinatorialElement* despite it being deprecated (see Issue #13742). This is dangerous. In particular, the `Permutation._left_to_right_multiply_on_right` method (which can be called through multiplication) disables the input checks (see *Permutation()*). This should not happen. Do not trust the results.

What does this file define ?

The main part of this file consists in the definition of permutation objects, i.e. the *Permutation()* method and the *Permutation* class. Global options for elements of the permutation class can be set through the *Permutations.options()* object.

Below are listed all methods and classes defined in this file.

Methods of Permutations objects

left_action_product()	Return the product of `self` with another permutation, in which the other permutation is applied first.
right_action_product()	Return the product of `self` with another permutation, in which `self` is applied first.
size()	Return the size of the permutation `self`.
cycle_string()	Return the disjoint-cycles representation of `self` as string.
next()	Return the permutation that follows `self` in lexicographic order (in the same symmetric group as `self`).
prev()	Return the permutation that comes directly before `self` in lexicographic order (in the same symmetric group as `self`).
to_tableau_by_shape()	Return a tableau of shape `shape` with the entries in `self`.
to_cycles()	Return the permutation `self` as a list of disjoint cycles.
forget_cycles()	Return `self` under the forget cycle map.
to_permutation_group_element()	Return a `PermutationGroupElement` equal to `self`.
signature()	Return the signature of the permutation `sef`.
is_even()	Return `True` if the permutation `self` is even, and `False` otherwise.
to_matrix()	Return a matrix representing the permutation `self`.
rank()	Return the rank of `self` in lexicographic ordering (on the symmetric group containing `self`).
to_inversion_vector()	Return the inversion vector of a permutation `self`.
inversions()	Return a list of the inversions of permutation `self`.
stack_sort()	Return the permutation obtained by sorting `self` through one stack.
to_digraph()	Return a digraph representation of `self`.
show()	Display the permutation as a drawing.
number_of_inversions()	Return the number of inversions in the permutation `self`.
noninversions()	Return the `k`-noninversions in the permutation `self`.
number_of_noninversions()	Return the number of `k`-noninversions in the permutation `self`.
length()	Return the Coxeter length of a permutation `self`.
inverse()	Return the inverse of a permutation `self`.
ishift()	Return the `i`-shift of `self`.
iswitch()	Return the `i`-switch of `self`.
runs()	Return a list of the runs in the permutation `self`.
longest_increasing_subsequence_length()	Return the length of the longest increasing subsequences of `self`.
longest_increasing_subsequences()	Return the list of the longest increasing subsequences of `self`.
number_of_longest_increasing_subsequences()	Return the number of longest increasing subsequences
cycle_type()	Return the cycle type of `self` as a partition of `len(self)`.
foata_bijection()	Return the image of the permutation `self` under the Foata bijection ϕ.
foata_bijection_inverse()	Return the image of the permutation `self` under the inverse of the Foata bijection ϕ.

continues on next page

Table 1 – continued from previous page

fundamental_transformation()	Return the image of the permutation `self` under the Renyi-Foata-Schuetzenberger fundamental transformation.
fundamental_transformation_inverse()	Return the image of the permutation `self` under the inverse of the Renyi-Foata-Schuetzenberger fundamental transformation.
destandardize()	Return destandardization of `self` with respect to `weight` and `ordered_alphabet`.
to_lehmer_code()	Return the Lehmer code of the permutation `self`.
to_lehmer_cocode()	Return the Lehmer cocode of `self`.
reduced_word()	Return the reduced word of the permutation `self`.
reduced_words()	Return a list of the reduced words of the permutation `self`.
reduced_words_iterator()	An iterator for the reduced words of the permutation `self`.
reduced_word_lexmin()	Return a lexicographically minimal reduced word of a permutation `self`.
fixed_points()	Return a list of the fixed points of the permutation `self`.
is_derangement()	Return `True` if the permutation `self` is a derangement, and `False` otherwise.
is_simple()	Return `True` if the permutation `self` is simple, and `False` otherwise.
number_of_fixed_points()	Return the number of fixed points of the permutation `self`.
recoils()	Return the list of the positions of the recoils of the permutation `self`.
number_of_recoils()	Return the number of recoils of the permutation `self`.
recoils_composition()	Return the composition corresponding to the recoils of `self`.
descents()	Return the list of the descents of the permutation `self`.
idescents()	Return a list of the idescents of `self`.
idescents_signature()	Return the list obtained by mapping each position in `self` to -1 if it is an idescent and 1 if it is not an idescent.
number_of_descents()	Return the number of descents of the permutation `self`.
number_of_idescents()	Return the number of idescents of the permutation `self`.
descents_composition()	Return the composition corresponding to the descents of `self`.
descent_polynomial()	Return the descent polynomial of the permutation `self`.
major_index()	Return the major index of the permutation `self`.
imajor_index()	Return the inverse major index of the permutation `self`.
to_major_code()	Return the major code of the permutation `self`.
peaks()	Return a list of the peaks of the permutation `self`.
number_of_peaks()	Return the number of peaks of the permutation `self`.
saliances()	Return a list of the saliances of the permutation `self`.
number_of_saliances()	Return the number of saliances of the permutation `self`.
bruhat_lequal()	Return `True` if `self` is less or equal to `p2` in the Bruhat order.
weak_excedences()	Return all the numbers `self[i]` such that `self[i] >= i+1`.
bruhat_inversions()	Return the list of inversions of `self` such that the application of this inversion to `self` decrements its number of inversions.
bruhat_inversions_iterator()	Return an iterator over Bruhat inversions of `self`.
bruhat_succ()	Return a list of the permutations covering `self` in the Bruhat order.
bruhat_succ_iterator()	An iterator for the permutations covering `self` in the Bruhat order.
bruhat_pred()	Return a list of the permutations covered by `self` in the Bruhat order.
bruhat_pred_iterator()	An iterator for the permutations covered by `self` in the Bruhat order.
bruhat_smaller()	Return the combinatorial class of permutations smaller than or equal to `self` in the Bruhat order.
bruhat_greater()	Return the combinatorial class of permutations greater than or equal to `self` in the Bruhat order.
permutohedron_lequal()	Return `True` if `self` is less or equal to `p2` in the permutohedron order.
permutohedron_succ()	Return a list of the permutations covering `self` in the permutohedron order.

continues on next page

Table 1 – continued from previous page

permutohedron_pred()	Return a list of the permutations covered by `self` in the permutohedron order.
permutohedron_smaller()	Return a list of permutations smaller than or equal to `self` in the permutohedron order.
permutohedron_greater()	Return a list of permutations greater than or equal to `self` in the permutohedron order.
right_permutohedron_interval_iterator()	Return an iterator over permutations in an interval of the permutohedron order.
right_permutohedron_interval()	Return a list of permutations in an interval of the permutohedron order.
has_pattern()	Test whether the permutation `self` matches the pattern.
avoids()	Test whether the permutation `self` avoids the pattern.
pattern_positions()	Return the list of positions where the pattern `patt` appears in `self`.
reverse()	Return the permutation obtained by reversing the 1-line notation of `self`.
complement()	Return the complement of the permutation which is obtained by replacing each value x in the 1-line notation of `self` with $n - x + 1$.
permutation_poset()	Return the permutation poset of `self`.
dict()	Return a dictionary corresponding to the permutation `self`.
action()	Return the action of the permutation `self` on a list.
robinson_schensted()	Return the pair of standard tableaux obtained by running the Robinson-Schensted Algorithm on `self`.
left_tableau()	Return the left standard tableau after performing the RSK algorithm.
right_tableau()	Return the right standard tableau after performing the RSK algorithm.
increasing_tree()	Return the increasing tree of `self`.
increasing_tree_shape()	Return the shape of the increasing tree of `self`.
binary_search_tree()	Return the binary search tree of `self`.
sylvester_class()	Iterate over the equivalence class of `self` under sylvester congruence
RS_partition()	Return the shape of the tableaux obtained by the RSK algorithm.
remove_extra_fixed_points()	Return the permutation obtained by removing any fixed points at the end of `self`.
retract_plain()	Return the plain retract of `self` to a smaller symmetric group S_m.
retract_direct_product()	Return the direct-product retract of `self` to a smaller symmetric group S_m.
retract_okounkov_vershik()	Return the Okounkov-Vershik retract of `self` to a smaller symmetric group S_m.
hyperoctahedral_double_coset_type()	Return the coset-type of `self` as a partition.
binary_search_tree_shape()	Return the shape of the binary search tree of `self` (a non labelled binary tree).
shifted_concatenation()	Return the right (or left) shifted concatenation of `self` with a permutation `other`.
shifted_shuffle()	Return the shifted shuffle of `self` with a permutation `other`.

Functions defined in this file

from_major_code()	Return the permutation corresponding to major code mc.
from_permutation_group_element()	Return a Permutation give a PermutationGroupElement pge.
from_rank()	Return the permutation with the specified lexicographic rank.
from_inversion_vector()	Return the permutation corresponding to inversion vector iv.
from_cycles()	Return the permutation with given disjoint-cycle representation cycles.
from_lehmer_code()	Return the permutation with Lehmer code lehmer.
from_reduced_word()	Return the permutation corresponding to the reduced word rw.
bistochastic_as_sum_of_permutations()	Return a given bistochastic matrix as a nonnegative linear combination of permutations.
bounded_affine_permutation()	Return a partial permutation representing the bounded affine permutation of a matrix.
descents_composition_list()	Return a list of all the permutations in a given descent class (i. e., having a given descents composition).
descents_composition_first()	Return the smallest element of a descent class.
descents_composition_last()	Return the largest element of a descent class.
bruhat_lequal()	Return True if p1 is less or equal to p2 in the Bruhat order.
permutohedron_lequal()	Return True if p1 is less or equal to p2 in the permutohedron order.
to_standard()	Return a standard permutation corresponding to the permutation self.

AUTHORS:

- Mike Hansen
- Dan Drake (2008-04-07): allow Permutation() to take lists of tuples
- Sébastien Labbé (2009-03-17): added robinson_schensted_inverse
- Travis Scrimshaw:
  - (2012-08-16): to_standard() no longer modifies input
  - (2013-01-19): Removed RSK implementation and moved to *rsk*.
  - (2013-07-13): Removed CombinatorialClass and moved permutations to the category framework.
- Darij Grinberg (2013-09-07): added methods; ameliorated Issue #14885 by exposing and documenting methods for global-independent multiplication.
- Travis Scrimshaw (2014-02-05): Made *StandardPermutations_n* a finite Weyl group to make it more uniform with SymmetricGroup. Added ability to compute the conjugacy classes.
- Trevor K. Karn (2022-08-05): Add reduced-word counting
- Amrutha P, Shriya M, Divya Aggarwal (2022-08-16): Added Multimajor Index.

Classes and methods

class sage.combinat.permutation.**Arrangements**

Bases: *Permutations*

An arrangement of a multiset mset is an ordered selection without repetitions. It is represented by a list that contains only elements from mset, but maybe in a different order.

Arrangements returns the combinatorial class of arrangements of the multiset mset that contain k elements.

EXAMPLES:

```
sage: mset = [1,1,2,3,4,4,5]
sage: Arrangements(mset, 2).list()                                              #␣
↪needs sage.libs.gap

  ['a', 't', 'c'],
  ['t', 'c', 'a'],
  ['t', 'a', 'c']]
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: A = Arrangements([1,1,2,3,4,4,5], 2)
sage: A.cardinality()                                                        #␣
↪needs sage.libs.gap

↪Integer(4),Integer(5)], Integer(2))
>>> A.cardinality()                                                          #␣
↪needs sage.libs.gap
22
```

class sage.combinat.permutation.**Arrangements_msetk**(*mset*, *k*)

Bases: *Arrangements*, *Permutations_msetk*

Arrangements of length k of a multiset M.

class sage.combinat.permutation.**Arrangements_setk**(*s*, *k*)

Bases: *Arrangements*, *Permutations_setk*

Arrangements of length k of a set S.

class sage.combinat.permutation.**CyclicPermutations**(*mset*)

Bases: *Permutations_mset*

Return the class of all cyclic permutations of `mset` in cycle notation. These are the same as necklaces.

INPUT:

- `mset` – a multiset

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list()                                   #␣
↪needs sage.combinat
[(0, 1, 2, 3),
 (0, 1, 3, 2),
 (0, 2, 1, 3),
 (0, 2, 3, 1),
 (0, 3, 1, 2),
 (0, 3, 2, 1)]
sage: CyclicPermutations([1,1,1]).list()                                    #␣
↪needs sage.combinat
[(1, 1, 1)]
```

```
>>> from sage.all import *
>>> CyclicPermutations(range(Integer(4))).list()                            ␣
↪     # needs sage.combinat
[(0, 1, 2, 3),
 (0, 1, 3, 2),
 (0, 2, 1, 3),
 (0, 2, 3, 1),
 (0, 3, 1, 2),
 (0, 3, 2, 1)]
>>> CyclicPermutations([Integer(1),Integer(1),Integer(1)]).list()           ␣
↪                        # needs sage.combinat
[(1, 1, 1)]
```

iterator(*distinct=False*)

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list()  # indirect doctest              #␣
↪needs sage.combinat
[(0, 1, 2, 3),
 (0, 1, 3, 2),
 (0, 2, 1, 3),
 (0, 2, 3, 1),
 (0, 3, 1, 2),
 (0, 3, 2, 1)]
 sage: CyclicPermutations([1,1,1]).list()                                   #␣
↪needs sage.combinat
 [(1, 1, 1)]
 sage: CyclicPermutations([1,1,1]).list(distinct=True)                      #␣
↪needs sage.combinat
 [(1, 1, 1), (1, 1, 1)]
```

```
>>> from sage.all import *
>>> CyclicPermutations(range(Integer(4))).list()  # indirect doctest
↪     # needs sage.combinat
[(0, 1, 2, 3),
 (0, 1, 3, 2),
 (0, 2, 1, 3),
 (0, 2, 3, 1),
 (0, 3, 1, 2),
 (0, 3, 2, 1)]
>>> CyclicPermutations([Integer(1),Integer(1),Integer(1)]).list()
↪                     # needs sage.combinat
 [(1, 1, 1)]
>>> CyclicPermutations([Integer(1),Integer(1),Integer(1)]).
↪list(distinct=True)                      # needs sage.combinat
 [(1, 1, 1), (1, 1, 1)]
```

list(*distinct=False*)

EXAMPLES:

```
sage: CyclicPermutations(range(4)).list()                                   #
↪needs sage.combinat
[(0, 1, 2, 3),
 (0, 1, 3, 2),
 (0, 2, 1, 3),
 (0, 2, 3, 1),
 (0, 3, 1, 2),
 (0, 3, 2, 1)]
```

```
>>> from sage.all import *
>>> CyclicPermutations(range(Integer(4))).list()
↪     # needs sage.combinat
[(0, 1, 2, 3),
 (0, 1, 3, 2),
 (0, 2, 1, 3),
 (0, 2, 3, 1),
 (0, 3, 1, 2),
 (0, 3, 2, 1)]
```

class sage.combinat.permutation.**CyclicPermutationsOfPartition**(*partition*)

Bases: *Permutations*

Combinations of cyclic permutations of each cell of a given partition.

This is the same as a Cartesian product of necklaces.

EXAMPLES:

```
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list()             #
↪needs sage.combinat
[[(1, 2, 3, 4), (5, 6, 7)],
 [(1, 2, 4, 3), (5, 6, 7)],
 [(1, 3, 2, 4), (5, 6, 7)],
 [(1, 3, 4, 2), (5, 6, 7)],
 [(1, 4, 2, 3), (5, 6, 7)],
```

(continues on next page)

(continued from previous page)

```

class Element

Bases: ClonableArray

A cyclic permutation of a partition.

check()

Check that self is a valid element.

EXAMPLES:

```
sage: CP = CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]])
sage: elt = CP[0]                                                              #␣
↪needs sage.combinat
sage: elt.check()                                                              #␣
↪needs sage.combinat
```

```
>>> from sage.all import *
>>> CP = CyclicPermutationsOfPartition([[Integer(1),Integer(2),Integer(3),
↪Integer(4)],[Integer(5),Integer(6),Integer(7)]])
>>> elt = CP[Integer(0)]                                                        ␣
↪     # needs sage.combinat
>>> elt.check()                                                              #␣
↪needs sage.combinat
```

iterator(*distinct=False*)

AUTHORS:

class sage.combinat.permutation.**PatternAvoider**(*parent*, *patterns*)

Bases: *GenericBacktracker*

EXAMPLES:

```
sage: from sage.combinat.permutation import PatternAvoider
sage: P = Permutations(4)
sage: p = PatternAvoider(P, [[1,2,3]])
sage: loads(dumps(p))
<sage.combinat.permutation.PatternAvoider object at 0x...>
```

```
>>> from sage.all import *
>>> from sage.combinat.permutation import PatternAvoider
>>> P = Permutations(Integer(4))
>>> p = PatternAvoider(P, [[Integer(1),Integer(2),Integer(3)]])
>>> loads(dumps(p))
<sage.combinat.permutation.PatternAvoider object at 0x...>
```

class sage.combinat.permutation.**Permutation**(*parent*, *l*, *algorithm='lex'*, *sjt=None*, *check=True*)

Bases: *CombinatorialElement*

A permutation.

Converts `l` to a permutation on $\{1, 2, \ldots, n\}$.

INPUT:

- `l` – can be any one of the following:
  - an instance of *Permutation*,
  - list of integers, viewed as one-line permutation notation. The construction checks that you give an acceptable entry. To avoid the check, use the `check` option.
  - string, expressing the permutation in cycle notation.
  - list of tuples of integers, expressing the permutation in cycle notation.
  - a `PermutationGroupElement`
  - a pair of two standard tableaux of the same shape. This yields the permutation obtained from the pair using the inverse of the Robinson-Schensted algorithm.
- `check` – boolean (default: `True`); whether to check that input is correct; slows the function down, but ensures that nothing bad happens
- `algorithm` – string (default: `'lex'`); the algorithm used to generate the permutations. Supported algorithms are:
  - `'lex'`: lexicographic order generation, this is the default algorithm
  - `'sjt'`: Steinhaus-Johnson-Trotter algorithm to generate permutations using only transposition of two elements in the list. It is highly recommended to set `check=True` (default value).
- `sjt` – SJT (default: `None`); the `SJT` object holding the permutation internal state. This should only be specified when initializing with non-identity permutation.

Warning

Since Issue #13742 the input is checked for correctness : it is not accepted unless it actually is a permutation on $\{1, \ldots, n\}$. It means that some *Permutation()* objects cannot be created anymore without setting `check=False`, as there is no certainty that its functions can handle them, and this should be fixed in a much better way ASAP (the functions should be rewritten to handle those cases, and new tests be added).

Warning

There are two possible conventions for multiplying permutations, and the one currently enabled in Sage by default is the one which has $(pq)(i) = q(p(i))$ for any permutations $p \in S_n$ and $q \in S_n$ and any $1 \leq i \leq n$. (This equation looks less strange when the action of permutations on numbers is written from the right: then it takes the form $i^{pq} = (i^p)^q$, which is an associativity law). There is an alternative convention, which has $(pq)(i) = p(q(i))$ instead. The conventions can be switched at runtime using *sage.combinat.permutation.Permutations.options()*. It is best for code not to rely on this setting being set to a particular standard, but rather use the methods *left_action_product()* and *right_action_product()* for multiplying permutations (these methods don't depend on the setting). See Issue #14885 for more details.

Note

The `bruhat*` methods refer to the *strong* Bruhat order. To use the *weak* Bruhat order, look under `permutohedron*`.

EXAMPLES:

```
sage: Permutation([2,1])
[2, 1]
sage: Permutation([2, 1, 4, 5, 3])
[2, 1, 4, 5, 3]
sage: Permutation('(1,2)')
[2, 1]
sage: Permutation('(1,2)(3,4,5)')
[2, 1, 4, 5, 3]
sage: Permutation( ((1,2),(3,4,5)) )
[2, 1, 4, 5, 3]
sage: Permutation( [(1,2),(3,4,5)] )
[2, 1, 4, 5, 3]
sage: Permutation( ((1,2)) )
[2, 1]
sage: Permutation( (1,2) )
[2, 1]
sage: Permutation( ((1,2),) )
[2, 1]
sage: Permutation( ((1,),) )
[1]
sage: Permutation( (1,) )
[1]
sage: Permutation( () )
[]
sage: Permutation( ((),) )
[]
sage: p = Permutation((1, 2, 5)); p
[2, 5, 3, 4, 1]
sage: type(p)
<class 'sage.combinat.permutation.StandardPermutations_n_with_category.element_
↪class'>
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1)])
[2, 1]
>>> Permutation([Integer(2), Integer(1), Integer(4), Integer(5), Integer(3)])
[2, 1, 4, 5, 3]
>>> Permutation('(1,2)')
[2, 1]
>>> Permutation('(1,2)(3,4,5)')
[2, 1, 4, 5, 3]
>>> Permutation( ((Integer(1),Integer(2)),(Integer(3),Integer(4),Integer(5))) )
[2, 1, 4, 5, 3]
>>> Permutation( [(Integer(1),Integer(2)),(Integer(3),Integer(4),Integer(5))] )
[2, 1, 4, 5, 3]
>>> Permutation( ((Integer(1),Integer(2))) )
[2, 1]
>>> Permutation( (Integer(1),Integer(2)) )
[2, 1]
>>> Permutation( ((Integer(1),Integer(2)),) )
[2, 1]
>>> Permutation( ((Integer(1),),) )

>>> Permutation( (Integer(1),) )
[1]
>>> Permutation( () )
[]
>>> Permutation( ((),) )
[]
>>> p = Permutation((Integer(1), Integer(2), Integer(5))); p
[2, 5, 3, 4, 1]
>>> type(p)
<class 'sage.combinat.permutation.StandardPermutations_n_with_category.element_
↪class'>
```

Generate permutations using the Steinhaus-Johnson Trotter algorithm. The output is not in lexicographic order:

```
sage: p = Permutation([1, 2, 3, 4], algorithm='sjt'); p
[1, 2, 3, 4]
sage: p = p.next(); p
[1, 2, 4, 3]
sage: p = p.next(); p
[1, 4, 2, 3]
sage: p = Permutation([1, 2, 3], algorithm='sjt')
sage: for _ in range(6):
....:     p = p.next()
sage: p
False

sage: Permutation([1, 3, 2, 4], algorithm='sjt')
Traceback (most recent call last):
...
ValueError: no internal state directions were given for non-identity
starting permutation for Steinhaus-Johnson-Trotter algorithm
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(1), Integer(2), Integer(3), Integer(4)], algorithm=
↪'sjt'); p
[1, 2, 3, 4]
>>> p = p.next(); p
[1, 2, 4, 3]
>>> p = p.next(); p
[1, 4, 2, 3]
>>> p = Permutation([Integer(1), Integer(2), Integer(3)], algorithm='sjt')
>>> for _ in range(Integer(6)):
...     p = p.next()
>>> p
False

>>> Permutation([Integer(1), Integer(3), Integer(2), Integer(4)], algorithm='sjt')
Traceback (most recent call last):
...
ValueError: no internal state directions were given for non-identity
starting permutation for Steinhaus-Johnson-Trotter algorithm
```

Construction from a string in cycle notation:

```
sage: p = Permutation( '(4,5)' ); p
[1, 2, 3, 5, 4]
```

```
>>> from sage.all import *
>>> p = Permutation( '(4,5)' ); p
[1, 2, 3, 5, 4]
```

The size of the permutation is the maximum integer appearing; add a 1-cycle to increase this:

```
sage: p2 = Permutation( '(4,5)(10)' ); p2
[1, 2, 3, 5, 4, 6, 7, 8, 9, 10]
sage: len(p); len(p2)
5
10
```

```
>>> from sage.all import *
>>> p2 = Permutation( '(4,5)(10)' ); p2
[1, 2, 3, 5, 4, 6, 7, 8, 9, 10]
>>> len(p); len(p2)
5
10
```

We construct a *Permutation* from a PermutationGroupElement:

```
sage: g = PermutationGroupElement([2,1,3])                                  #␣
↪needs sage.groups
sage: Permutation(g)                                                        #␣
↪needs sage.groups
[2, 1, 3]
```

```
>>> from sage.all import *
>>> g = PermutationGroupElement([Integer(2),Integer(1),Integer(3)])
↪                        # needs sage.groups
>>> Permutation(g)
↪needs sage.groups
[2, 1, 3]
```

From a pair of tableaux of the same shape. This uses the inverse of the Robinson-Schensted algorithm:

```
sage: # needs sage.combinat
sage: p = [[1, 4, 7], [2, 5], [3], [6]]
sage: q = [[1, 2, 5], [3, 6], [4], [7]]
sage: P = Tableau(p)
sage: Q = Tableau(q)
sage: Permutation( (p, q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [p, q] )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( (P, Q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [P, Q] )
[3, 6, 5, 2, 7, 4, 1]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> p = [[Integer(1), Integer(4), Integer(7)], [Integer(2), Integer(5)],
↪[Integer(3)], [Integer(6)]]
>>> q = [[Integer(1), Integer(2), Integer(5)], [Integer(3), Integer(6)],
↪[Integer(4)], [Integer(7)]]
>>> P = Tableau(p)
>>> Q = Tableau(q)
>>> Permutation( (p, q) )
[3, 6, 5, 2, 7, 4, 1]
>>> Permutation( [p, q] )
[3, 6, 5, 2, 7, 4, 1]
>>> Permutation( (P, Q) )
[3, 6, 5, 2, 7, 4, 1]
>>> Permutation( [P, Q] )
[3, 6, 5, 2, 7, 4, 1]
```

RS_partition()

Return the shape of the tableaux obtained by applying the RSK algorithm to `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).RS_partition()
↪needs sage.combinat
[2, 1, 1]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).RS_partition()
↪                                  # needs sage.combinat
[2, 1, 1]
```

absolute_length()

Return the absolute length of `self`

The absolute length is the length of the shortest expression of the element as a product of reflections.

For permutations in the symmetric groups, the absolute length is the size minus the number of its disjoint cycles.

EXAMPLES:

```
sage: Permutation([4,2,3,1]).absolute_length()                                #␣
↪needs sage.combinat
1
```

```
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(2),Integer(3),Integer(1)]).absolute_
↪length()                                  # needs sage.combinat
1
```

action(a)

Return the action of the permutation `self` on a list `a`.

The action of a permutation $p \in S_n$ on an n-element list $(a_1, a_2, \ldots, a_n)$ is defined to be $(a_{p(1)}, a_{p(2)}, \ldots, a_{p(n)})$.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: a = list(range(3))
sage: p.action(a)
[1, 0, 2]
sage: b = [1,2,3,4]
sage: p.action(b)
Traceback (most recent call last):
...
ValueError: len(a) must equal len(self)

sage: q = Permutation([2,3,1])
sage: a = list(range(3))
sage: q.action(a)
[1, 2, 0]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> a = list(range(Integer(3)))
>>> p.action(a)
[1, 0, 2]
>>> b = [Integer(1),Integer(2),Integer(3),Integer(4)]
>>> p.action(b)
Traceback (most recent call last):
...
ValueError: len(a) must equal len(self)

>>> q = Permutation([Integer(2),Integer(3),Integer(1)])
>>> a = list(range(Integer(3)))
```

(continues on next page)

(continued from previous page)

```
>>> q.action(a)
[1, 2, 0]
```

avoids(*patt*)

Test whether the permutation `self` avoids the pattern `patt`.

EXAMPLES:

```
sage: Permutation([6,2,5,4,3,1]).avoids([4,2,3,1])                              #␣
↪needs sage.combinat
False
sage: Permutation([6,1,2,5,4,3]).avoids([4,2,3,1])                              #␣
↪needs sage.combinat
True
sage: Permutation([6,1,2,5,4,3]).avoids([3,4,1,2])                              #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> Permutation([Integer(6),Integer(2),Integer(5),Integer(4),Integer(3),
↪Integer(1)]).avoids([Integer(4),Integer(2),Integer(3),Integer(1)])          ␣
↪                # needs sage.combinat
False
>>> Permutation([Integer(6),Integer(1),Integer(2),Integer(5),Integer(4),
↪Integer(3)]).avoids([Integer(4),Integer(2),Integer(3),Integer(1)])          ␣
↪                # needs sage.combinat
True
>>> Permutation([Integer(6),Integer(1),Integer(2),Integer(5),Integer(4),
↪Integer(3)]).avoids([Integer(3),Integer(4),Integer(1),Integer(2)])          ␣
↪                # needs sage.combinat
True
```

binary_search_tree(*left_to_right=True*)

Return the binary search tree associated to `self`.

If w is a word, then the binary search tree associated to w is defined as the result of starting with an empty binary tree, and then inserting the letters of w one by one into this tree. Here, the insertion is being done according to the method *binary_search_insert()*, and the word w is being traversed from left to right.

A permutation is regarded as a word (using one-line notation), and thus a binary search tree associated to a permutation is defined.

If the optional keyword variable `left_to_right` is set to `False`, the word w is being traversed from right to left instead.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).binary_search_tree()                               #␣
↪needs sage.graphs
1[., 4[3[2[., .], .], .]]
sage: Permutation([4,1,3,2]).binary_search_tree()                               #␣
↪needs sage.graphs
4[1[., 3[2[., .], .]], .]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).binary_search_
↪tree()                          # needs sage.graphs
1[., 4[3[2[., .], .], .]]
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2)]).binary_search_
↪tree()                          # needs sage.graphs
4[1[., 3[2[., .], .]], .]
```

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```
sage: Permutation([1,4,3,2]).binary_search_tree(False)                    #␣
↪needs sage.graphs
2[1[., .], 3[., 4[., .]]]
sage: Permutation([4,1,3,2]).binary_search_tree(False)                    #␣
↪needs sage.graphs
2[1[., .], 3[., 4[., .]]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).binary_search_
↪tree(False)                     # needs sage.graphs
2[1[., .], 3[., 4[., .]]]
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2)]).binary_search_
↪tree(False)                     # needs sage.graphs
2[1[., .], 3[., 4[., .]]]
```

binary_search_tree_shape(*left_to_right=True*)

Return the shape of the binary search tree of the permutation (a non labelled binary tree).

EXAMPLES:

```
sage: Permutation([1,4,3,2]).binary_search_tree_shape()                   #␣
↪needs sage.graphs
[., [[., .], .], .]]
sage: Permutation([4,1,3,2]).binary_search_tree_shape()                   #␣
↪needs sage.graphs
[[., [[., .], .]], .]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).binary_search_
↪tree_shape()                    # needs sage.graphs
[., [[., .], .], .]]
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2)]).binary_search_
↪tree_shape()                    # needs sage.graphs
[[., [[., .], .]], .]
```

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```
sage: Permutation([1,4,3,2]).binary_search_tree_shape(False)              #␣
↪needs sage.graphs
[[., .], [., [., .]]]
sage: Permutation([4,1,3,2]).binary_search_tree_shape(False)              #␣
↪needs sage.graphs
[[., .], [., [., .]]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).binary_search_
↪tree_shape(False)                # needs sage.graphs
[[., .], [., [., .]]]
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2)]).binary_search_
↪tree_shape(False)                # needs sage.graphs
[[., .], [., [., .]]]
```

bruhat_greater()

Return the combinatorial class of permutations greater than or equal to `self` in the Bruhat order (on the symmetric group containing `self`).

See *bruhat_lequal()* for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_greater().list()
[[4, 1, 2, 3],
 [4, 1, 3, 2],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(1),Integer(2),Integer(3)]).bruhat_
↪greater().list()
[[4, 1, 2, 3],
 [4, 1, 3, 2],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

bruhat_inversions()

Return the list of inversions of `self` such that the application of this inversion to `self` decreases its number of inversions by exactly 1.

Equivalently, it returns the list of pairs (i, j) such that $i < j$, such that $p(i) > p(j)$ and such that there exists no k (strictly) between i and j satisfying $p(i) > p(k) > p(j)$.

EXAMPLES:

```
sage: Permutation([5,2,3,4,1]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: Permutation([6,1,4,5,2,3]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(5),Integer(2),Integer(3),Integer(4),Integer(1)]).
↪bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
>>> Permutation([Integer(6),Integer(1),Integer(4),Integer(5),Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(3)]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_inversions_iterator()

Return the iterator for the inversions of `self` such that the application of this inversion to `self` decreases its number of inversions by exactly 1.

EXAMPLES:

```
sage: list(Permutation([5,2,3,4,1]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: list(Permutation([6,1,4,5,2,3]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

```
>>> from sage.all import *
>>> list(Permutation([Integer(5),Integer(2),Integer(3),Integer(4),
↪Integer(1)]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
>>> list(Permutation([Integer(6),Integer(1),Integer(4),Integer(5),Integer(2),
↪Integer(3)]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]
```

bruhat_lequal(*p2*)

Return `True` if `self` is less or equal to `p2` in the Bruhat order.

The Bruhat order (also called strong Bruhat order or Chevalley order) on the symmetric group S_n is the partial order on S_n determined by the following condition: If p is a permutation, and i and j are two indices satisfying $p(i) > p(j)$ and $i < j$ (that is, (i, j) is an inversion of p with $i < j$), then $p \circ (i, j)$ (the permutation obtained by first switching i with j and then applying p) is smaller than p in the Bruhat order.

One can show that a permutation $p \in S_n$ is less or equal to a permutation $q \in S_n$ in the Bruhat order if and only if for every $i \in \{0, 1, \cdots, n\}$ and $j \in \{1, 2, \cdots, n\}$, the number of the elements among $p(1), p(2), \cdots, p(j)$ that are greater than i is $\leq$ to the number of the elements among $q(1), q(2), \cdots, q(j)$ that are greater than i.

This method assumes that `self` and `p2` are permutations of the same integer n.

EXAMPLES:

```
sage: Permutation([2,4,3,1]).bruhat_lequal(Permutation([3,4,2,1]))
True

sage: Permutation([2,1,3]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([3,1,2]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([1,2,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,1,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,3,1]).bruhat_lequal(Permutation([1,3,2]))
False
```

(continues on next page)

(continued from previous page)

```
sage: sorted( [len([b for b in Permutations(3) if a.bruhat_lequal(b)])
....:          for a in Permutations(3)] )
[1, 2, 2, 4, 4, 6]

sage: Permutation([]).bruhat_lequal(Permutation([]))
True
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(4),Integer(3),Integer(1)]).bruhat_
↪lequal(Permutation([Integer(3),Integer(4),Integer(2),Integer(1)]))
True

>>> Permutation([Integer(2),Integer(1),Integer(3)]).bruhat_
↪lequal(Permutation([Integer(2),Integer(3),Integer(1)]))
True
>>> Permutation([Integer(2),Integer(1),Integer(3)]).bruhat_
↪lequal(Permutation([Integer(3),Integer(1),Integer(2)]))
True
>>> Permutation([Integer(2),Integer(1),Integer(3)]).bruhat_
↪lequal(Permutation([Integer(1),Integer(2),Integer(3)]))
False
>>> Permutation([Integer(1),Integer(3),Integer(2)]).bruhat_
↪lequal(Permutation([Integer(2),Integer(1),Integer(3)]))
False
>>> Permutation([Integer(1),Integer(3),Integer(2)]).bruhat_
↪lequal(Permutation([Integer(2),Integer(3),Integer(1)]))
True
>>> Permutation([Integer(2),Integer(3),Integer(1)]).bruhat_
↪lequal(Permutation([Integer(1),Integer(3),Integer(2)]))
False
>>> sorted( [len([b for b in Permutations(Integer(3)) if a.bruhat_lequal(b)])
...           for a in Permutations(Integer(3))] )
[1, 2, 2, 4, 4, 6]

>>> Permutation([]).bruhat_lequal(Permutation([]))
True
```

bruhat_pred()

Return a list of the permutations strictly smaller than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See *bruhat_lequal()* for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([6,1,4,5,2,3]).bruhat_pred()
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(6),Integer(1),Integer(4),Integer(5),Integer(2),
↪Integer(3)]).bruhat_pred()
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

bruhat_pred_iterator()

An iterator for the permutations strictly smaller than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See *bruhat_lequal()* for the definition of the Bruhat order.

EXAMPLES:

```
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_pred_iterator()]
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

```
>>> from sage.all import *
>>> [x for x in Permutation([Integer(6),Integer(1),Integer(4),Integer(5),
↪Integer(2),Integer(3)]).bruhat_pred_iterator()]
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

bruhat_smaller()

Return the combinatorial class of permutations smaller than or equal to `self` in the Bruhat order (on the symmetric group containing `self`).

See *bruhat_lequal()* for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([4,1,2,3]).bruhat_smaller().list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
```

(continues on next page)

(continued from previous page)

```
 [3, 1, 2, 4],
 [4, 1, 2, 3]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(1),Integer(2),Integer(3)]).bruhat_
↪smaller().list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [3, 1, 2, 4],
 [4, 1, 2, 3]]
```

bruhat_succ()

Return a list of the permutations strictly greater than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See *bruhat_lequal()* for the definition of the Bruhat order.

EXAMPLES:

```
sage: Permutation([6,1,4,5,2,3]).bruhat_succ()
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(6),Integer(1),Integer(4),Integer(5),Integer(2),
↪Integer(3)]).bruhat_succ()
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

bruhat_succ_iterator()

An iterator for the permutations that are strictly greater than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See *bruhat_lequal()* for the definition of the Bruhat order.

EXAMPLES:

```
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_succ_iterator()]
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

```
>>> from sage.all import *
>>> [x for x in Permutation([Integer(6),Integer(1),Integer(4),Integer(5),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2),Integer(3)]).bruhat_succ_iterator()]
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

complement()

Return the complement of the permutation `self`.

The complement of a permutation $w \in S_n$ is defined as the permutation in S_n sending each i to $n+1-w(i)$.

EXAMPLES:

```
sage: Permutation([1,2,3]).complement()
[3, 2, 1]
sage: Permutation([1, 3, 2]).complement()
[3, 1, 2]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).complement()
[3, 2, 1]
>>> Permutation([Integer(1), Integer(3), Integer(2)]).complement()
[3, 1, 2]
```

cycle_string(*singletons=False*)

Return a string of the permutation in cycle notation.

If `singletons=True`, it includes 1-cycles in the string.

EXAMPLES:

```
sage: Permutation([1,2,3]).cycle_string()
'()'
sage: Permutation([2,1,3]).cycle_string()
'(1,2)'
sage: Permutation([2,3,1]).cycle_string()
'(1,2,3)'
sage: Permutation([2,1,3]).cycle_string(singletons=True)
'(1,2)(3)'
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).cycle_string()
'()'
>>> Permutation([Integer(2),Integer(1),Integer(3)]).cycle_string()
'(1,2)'
>>> Permutation([Integer(2),Integer(3),Integer(1)]).cycle_string()
'(1,2,3)'
>>> Permutation([Integer(2),Integer(1),Integer(3)]).cycle_
↪string(singletons=True)
'(1,2)(3)'
```

cycle_tuples(*singletons=True*, *use_min=True*)

alias of *to_cycles()*.

cycle_type()

Return a partition of `len(self)` corresponding to the cycle type of `self`.

This is a non-increasing sequence of the cycle lengths of `self`.

EXAMPLES:

```
sage: Permutation([3,1,2,4]).cycle_type()                                   #␣
↪needs sage.combinat
[3, 1]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(1),Integer(2),Integer(4)]).cycle_type()  ␣
↪                                  # needs sage.combinat
[3, 1]
```

decreasing_runs(*as_tuple=False*)

Decreasing runs of the permutation.

INPUT:

- `as_tuple` – boolean (default: `False`); choice of output format

OUTPUT: list of lists or a tuple of tuples

See also

runs()

EXAMPLES:

```
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
sage: s.decreasing_runs()
[[2], [8, 3], [9, 6, 4], [5, 1], [7]]
sage: s.decreasing_runs(as_tuple=True)
((2,), (8, 3), (9, 6, 4), (5, 1), (7,))
```

```
>>> from sage.all import *
>>> s = Permutation([Integer(2),Integer(8),Integer(3),Integer(9),Integer(6),
↪Integer(4),Integer(5),Integer(1),Integer(7)])
>>> s.decreasing_runs()
[[2], [8, 3], [9, 6, 4], [5, 1], [7]]
>>> s.decreasing_runs(as_tuple=True)
((2,), (8, 3), (9, 6, 4), (5, 1), (7,))
```

descent_polynomial()

Return the descent polynomial of the permutation `self`.

The descent polynomial of a permutation p is the product of all the `z[p(i)]` where `i` ranges over the descents of `p`.

A descent of a permutation `p` is an integer `i` such that `p(i) > p(i+1)`.

REFERENCES:

- [GS1984]

EXAMPLES:

```
sage: Permutation([2,1,3]).descent_polynomial()
z2
sage: Permutation([4,3,2,1]).descent_polynomial()
z2*z3*z4
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).descent_polynomial()
z2
>>> Permutation([Integer(4),Integer(3),Integer(2),Integer(1)]).descent_
↪polynomial()
z2*z3*z4
```

Todo

This docstring needs to be fixed. This is not defined in [GS1984] (the descent monomial in their (7.23) is different).

descents(*final_descent=False*, *side='right'*, *positive=False*, *from_zero=False*, *index_set=None*)

Return the list of the descents of `self`.

A descent of a permutation p is an integer i such that $p(i) > p(i+1)$.

Warning

By default, the descents are returned as elements in the index set, i.e., starting at 1. If you want them to start at 0, set the keyword `from_zero` to `True`.

INPUT:

- `final_descent` – boolean (default: `False`); if `True`, the last position of a non-empty permutation is also considered as a descent
- `side` – `'right'` (default) or `'left'`; if `'left'`, return the descents of the inverse permutation
- `positive` – boolean (default: `False`); if `True`, return the positions that are not descents
- `from_zero` – boolean (default: `False`); if `True`, return the positions starting from 0
- `index_set` – list (default: `[1, ..., n-1]` where `self` is a permutation of `n`); the index set to check for descents

EXAMPLES:

```
sage: Permutation([3,1,2]).descents()
[1]
sage: Permutation([1,4,3,2]).descents()
[2, 3]
sage: Permutation([1,4,3,2]).descents(final_descent=True)
[2, 3, 4]
sage: Permutation([1,4,3,2]).descents(index_set=[1,2])
[2]
```

(continues on next page)

(continued from previous page)

```
sage: Permutation([1,4,3,2]).descents(from_zero=True)
[1, 2]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(1),Integer(2)]).descents()
[1]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).descents()
[2, 3]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).descents(final_
↪descent=True)
[2, 3, 4]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).descents(index_
↪set=[Integer(1),Integer(2)])
[2]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).descents(from_
↪zero=True)
[1, 2]
```

descents_composition()

Return the descent composition of `self`.

The descent composition of a permutation $p \in S_n$ is defined as the composition of n whose descent set equals the descent set of p. Here, the descent set of p is defined as the set of all $i \in \{1, 2, \ldots, n-1\}$ satisfying $p(i) > p(i+1)$. The descent set of a composition $c = (i_1, i_2, \ldots, i_k)$ is defined as the set $\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + i_2 + \cdots + i_{k-1}\}$.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).descents_composition()
[2, 2]
sage: Permutation([4,1,6,7,2,3,8,5]).descents_composition()
[1, 3, 3, 1]
sage: Permutation([]).descents_composition()
[]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4)]).descents_
↪composition()
[2, 2]
>>> Permutation([Integer(4),Integer(1),Integer(6),Integer(7),Integer(2),
↪Integer(3),Integer(8),Integer(5)]).descents_composition()
[1, 3, 3, 1]
>>> Permutation([]).descents_composition()
[]
```

destandardize(*weight*, *ordered_alphabet=None*)

Return destandardization of `self` with respect to `weight` and `ordered_alphabet`.

INPUT:

- `weight` – list or tuple of nonnegative integers that sum to n if `self` is a permutation in S_n
- `ordered_alphabet` – (default: `None`) a list or tuple specifying the ordered alphabet the destandardized word is over

OUTPUT: word over the `ordered_alphabet` which standardizes to `self`

Let $weight = (w_1, w_2, \ldots, w_\ell)$. Then this methods looks for an increasing sequence of $1, 2, \ldots, w_1$ and labels all letters in it by 1, then an increasing sequence of $w_1 + 1, w_1 + 2, \ldots, w_1 + w_2$ and labels all these letters by 2, etc.. If an increasing sequence for the specified `weight` does not exist, an error is returned. The output is a word `w` over the specified ordered alphabet with evaluation `weight` such that `w.standard_permutation()` is `self`.

EXAMPLES:

```
sage: p = Permutation([1,2,5,3,6,4])
sage: p.destandardize([3,1,2])                                              #␣
↪needs sage.combinat
word: 113132
sage: p = Permutation([2,1,3])
sage: p.destandardize([2,1])
Traceback (most recent call last):
...
ValueError: Standardization with weight [2, 1] is not possible!
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(1),Integer(2),Integer(5),Integer(3),Integer(6),
↪Integer(4)])
>>> p.destandardize([Integer(3),Integer(1),Integer(2)])                      ␣
↪                        # needs sage.combinat
word: 113132
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> p.destandardize([Integer(2),Integer(1)])
Traceback (most recent call last):
...
ValueError: Standardization with weight [2, 1] is not possible!
```

dict()

Return a dictionary corresponding to the permutation.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: d = p.dict()
sage: d[1]
2
sage: d[2]
1
sage: d[3]
3
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> d = p.dict()
>>> d[Integer(1)]
2
>>> d[Integer(2)]
1
>>> d[Integer(3)]
3
```

fixed_points()

Return a list of the fixed points of `self`.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).fixed_points()
[1, 4]
sage: Permutation([1,2,3,4]).fixed_points()
[1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4)]).fixed_points()
[1, 4]
>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4)]).fixed_points()
[1, 2, 3, 4]
```

foata_bijection()

Return the image of the permutation `self` under the Foata bijection ϕ.

The bijection shows that maj (the major index) and inv (the number of inversions) are equidistributed: if $\phi(P) = Q$, then $\mathrm{maj}(P) = \mathrm{inv}(Q)$.

The Foata bijection ϕ is a bijection on the set of words with no two equal letters. It can be defined by induction on the size of the word: Given a word $w_1 w_2 \cdots w_n$, start with $\phi(w_1) = w_1$. At the i-th step, if $\phi(w_1 w_2 \cdots w_i) = v_1 v_2 \cdots v_i$, we define $\phi(w_1 w_2 \cdots w_i w_{i+1})$ by placing w_{i+1} on the end of the word $v_1 v_2 \cdots v_i$ and breaking the word up into blocks as follows. If $w_{i+1} > v_i$, place a vertical line to the right of each v_k for which $w_{i+1} > v_k$. Otherwise, if $w_{i+1} < v_i$, place a vertical line to the right of each v_k for which $w_{i+1} < v_k$. In either case, place a vertical line at the start of the word as well. Now, within each block between vertical lines, cyclically shift the entries one place to the right.

For instance, to compute $\phi([1, 4, 2, 5, 3])$, the sequence of words is

- 1,
- $|1|4 \to 14$,
- $|14|2 \to 412$,
- $|4|1|2|5 \to 4125$,
- $|4|125|3 \to 45123$.

So $\phi([1, 4, 2, 5, 3]) = [4, 5, 1, 2, 3]$.

See section 2 of [FS1978], and the proof of Proposition 1.4.6 in [EnumComb1].

See also

foata_bijection_inverse() for the inverse map.

EXAMPLES:

```
sage: Permutation([1,2,4,3]).foata_bijection()
[4, 1, 2, 3]
sage: Permutation([2,5,1,3,4]).foata_bijection()
[2, 1, 3, 5, 4]
```

(continues on next page)

(continued from previous page)

```
sage: P = Permutation([2,5,1,3,4])
sage: P.major_index() == P.foata_bijection().number_of_inversions()
True

sage: all( P.major_index() == P.foata_bijection().number_of_inversions()
....:      for P in Permutations(4) )
True
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(4),Integer(3)]).foata_
↪bijection()
[4, 1, 2, 3]
>>> Permutation([Integer(2),Integer(5),Integer(1),Integer(3),Integer(4)]).
↪foata_bijection()
[2, 1, 3, 5, 4]

>>> P = Permutation([Integer(2),Integer(5),Integer(1),Integer(3),Integer(4)])
>>> P.major_index() == P.foata_bijection().number_of_inversions()
True

>>> all( P.major_index() == P.foata_bijection().number_of_inversions()
...      for P in Permutations(Integer(4)) )
True
```

The example from [FS1978]:

```
sage: Permutation([7,4,9,2,6,1,5,8,3]).foata_bijection()
[4, 7, 2, 6, 1, 9, 5, 8, 3]
```

```
>>> from sage.all import *
>>> Permutation([Integer(7),Integer(4),Integer(9),Integer(2),Integer(6),
↪Integer(1),Integer(5),Integer(8),Integer(3)]).foata_bijection()
[4, 7, 2, 6, 1, 9, 5, 8, 3]
```

Border cases:

```
sage: Permutation([]).foata_bijection()
[]
sage: Permutation([1]).foata_bijection()
[1]
```

```
>>> from sage.all import *
>>> Permutation([]).foata_bijection()
[]
>>> Permutation([Integer(1)]).foata_bijection()
[1]
```

foata_bijection_inverse()

Return the image of the permutation `self` under the inverse of the Foata bijection ϕ.

See *foata_bijection()* for the definition of the Foata bijection.

EXAMPLES:

```
sage: Permutation([4, 1, 2, 3]).foata_bijection()
[1, 2, 4, 3]
```

```
>>> from sage.all import *
>>> Permutation([Integer(4), Integer(1), Integer(2), Integer(3)]).foata_
↪bijection()
[1, 2, 4, 3]
```

forget_cycles()

Return the image of `self` under the map which forgets cycles.

Consider a permutation σ written in standard cyclic form:

$$\sigma = (a_{1,1}, \ldots, a_{1,k_1})(a_{2,1}, \ldots, a_{2,k_2}) \cdots (a_{m,1}, \ldots, a_{m,k_m}),$$

where $a_{1,1} < a_{2,1} < \cdots < a_{m,1}$ and $a_{j,1} < a_{j,i}$ for all $1 \leq j \leq m$ and $2 \leq i \leq k_j$ where we include cycles of length 1 as well. The image of the forget cycle map ϕ is given by

$$\phi(\sigma) = [a_{1,1}, \ldots, a_{1,k_1}, a_{2,1}, \ldots, a_{2,k_2}, \ldots, a_{m,1}, \ldots, a_{m,k_m}],$$

considered as a permutation in 1-line notation.

See also

fundamental_transformation(), which is a similar map that is defined by instead taking $a_{j,1} > a_{j,i}$ and is bijective.

EXAMPLES:

```
sage: P = Permutations(5)
sage: x = P([1, 5, 3, 4, 2])
sage: x.forget_cycles()
[1, 2, 5, 3, 4]
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(5))
>>> x = P([Integer(1), Integer(5), Integer(3), Integer(4), Integer(2)])
>>> x.forget_cycles()
[1, 2, 5, 3, 4]
```

We select all permutations with a cycle composition of $[2, 3, 1]$ in S_6:

```
sage: P = Permutations(6)
sage: l = [p for p in P if [len(t) for t in p.to_cycles()] == [1,3,2]]
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(6))
>>> l = [p for p in P if [len(t) for t in p.to_cycles()] == [Integer(1),
↪Integer(3),Integer(2)]]
```

Next we apply ϕ and then take the inverse, and then view the results as a poset under the Bruhat order:

```
sage: l = [p.forget_cycles().inverse() for p in l]
sage: B = Poset([l, lambda x,y: x.bruhat_lequal(y)])                    #␣
↪needs sage.combinat sage.graphs
sage: R.<q> = QQ[]
sage: sum(q^B.rank_function()(x) for x in B)                            #␣
↪needs sage.combinat sage.graphs
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
```

```
>>> from sage.all import *
>>> l = [p.forget_cycles().inverse() for p in l]
>>> B = Poset([l, lambda x,y: x.bruhat_lequal(y)])                     #␣
↪needs sage.combinat sage.graphs
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> sum(q**B.rank_function()(x) for x in B)                            #␣
↪needs sage.combinat sage.graphs
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
```

We check the statement in [CC2013] that the posets $C_{[1,3,1,1]}$ and $C_{[1,3,2]}$ are isomorphic:

```
sage: l2 = [p for p in P if [len(t) for t in p.to_cycles()] == [1,3,1,1]]
sage: l2 = [p.forget_cycles().inverse() for p in l2]
sage: B2 = Poset([l2, lambda x,y: x.bruhat_lequal(y)])                  #␣
↪needs sage.combinat sage.graphs
sage: B.is_isomorphic(B2)                                               #␣
↪needs sage.combinat sage.graphs
True
```

```
>>> from sage.all import *
>>> l2 = [p for p in P if [len(t) for t in p.to_cycles()] == [Integer(1),
↪Integer(3),Integer(1),Integer(1)]]
>>> l2 = [p.forget_cycles().inverse() for p in l2]
>>> B2 = Poset([l2, lambda x,y: x.bruhat_lequal(y)])                    #␣
↪needs sage.combinat sage.graphs
>>> B.is_isomorphic(B2)                                                #␣
↪needs sage.combinat sage.graphs
True
```

See also

fundamental_transformation().

fundamental_transformation()

Return the image of the permutation `self` under the Renyi-Foata-Schuetzenberger fundamental transformation.

The fundamental transformation is a bijection from the set of all permutations of $\{1, 2, \ldots, n\}$ to itself, which transforms any such permutation w as follows: Write w in cycle form, with each cycle starting with its highest element, and the cycles being sorted in increasing order of their highest elements. Drop the parentheses in the resulting expression, thus reading it as a one-line notation of a new permutation u. Then, u is the image of w under the fundamental transformation.

See [EnumComb1], Proposition 1.3.1.

See also

fundamental_transformation_inverse() for the inverse map.

forget_cycles() for a similar (but non-bijective) map where each cycle is starting from its lowest element.

EXAMPLES:

```
sage: Permutation([5, 1, 3, 4, 2]).fundamental_transformation()
[3, 4, 5, 2, 1]
sage: Permutations(5)([1, 5, 3, 4, 2]).fundamental_transformation()
[1, 3, 4, 5, 2]
sage: Permutation([8, 4, 7, 2, 9, 6, 5, 1, 3]).fundamental_transformation()
[4, 2, 6, 8, 1, 9, 3, 7, 5]
```

```
>>> from sage.all import *
>>> Permutation([Integer(5), Integer(1), Integer(3), Integer(4), Integer(2)]).
↪fundamental_transformation()
[3, 4, 5, 2, 1]
>>> Permutations(Integer(5))([Integer(1), Integer(5), Integer(3), Integer(4),␣
↪Integer(2)]).fundamental_transformation()
[1, 3, 4, 5, 2]
>>> Permutation([Integer(8), Integer(4), Integer(7), Integer(2), Integer(9),␣
↪Integer(6), Integer(5), Integer(1), Integer(3)]).fundamental_
↪transformation()
[4, 2, 6, 8, 1, 9, 3, 7, 5]
```

Comparison with *forget_cycles()*:

```
sage: P = Permutation([(1,3,4),(2,5)])
sage: P
[3, 5, 4, 1, 2]
sage: P.forget_cycles()
[1, 3, 4, 2, 5]
sage: P.fundamental_transformation()
[4, 1, 3, 5, 2]
```

```
>>> from sage.all import *
>>> P = Permutation([(Integer(1),Integer(3),Integer(4)),(Integer(2),
↪Integer(5))])
>>> P
[3, 5, 4, 1, 2]
>>> P.forget_cycles()
[1, 3, 4, 2, 5]
>>> P.fundamental_transformation()
[4, 1, 3, 5, 2]
```

fundamental_transformation_inverse()

Return the image of the permutation `self` under the inverse of the Renyi-Foata-Schuetzenberger fundamental transformation.

The inverse of the fundamental transformation is a bijection from the set of all permutations of $\{1, 2, \ldots, n\}$ to itself, which transforms any such permutation w as follows: Let $I = \{i_1 < i_2 < \cdots < i_k\}$ be the set of all

left-to-right maxima of w (that is, of all indices j such that $w(j)$ is bigger than each of $w(1), w(2), \ldots, w(j-1)$). The image of w under the inverse of the fundamental transformation is the permutation u that sends $w(i-1)$ to $w(i)$ for all $i \notin I$ (notice that this makes sense, since $1 \in I$ whenever $n > 0$), while sending each $w(i_p - 1)$ (with $p \geq 2$) to $w(i_{p-1})$. Here, we set $i_{k+1} = n + 1$.

See [EnumComb1], Proposition 1.3.1.

See also

fundamental_transformation() for the inverse map.

EXAMPLES:

```
sage: Permutation([3, 4, 5, 2, 1]).fundamental_transformation_inverse()
[5, 1, 3, 4, 2]
sage: Permutation([4, 2, 6, 8, 1, 9, 3, 7, 5]).fundamental_transformation_
↪inverse()
[8, 4, 7, 2, 9, 6, 5, 1, 3]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3), Integer(4), Integer(5), Integer(2), Integer(1)]).
↪fundamental_transformation_inverse()
[5, 1, 3, 4, 2]
>>> Permutation([Integer(4), Integer(2), Integer(6), Integer(8), Integer(1),␣
↪Integer(9), Integer(3), Integer(7), Integer(5)]).fundamental_transformation_
↪inverse()
[8, 4, 7, 2, 9, 6, 5, 1, 3]
```

grade()

alias of *size()*.

has_nth_root(n)

Check if `self` has n-th roots.

An n-th root of the permutation σ is a permutation γ such that $\gamma^n = \sigma$.

Note that the number of n-th roots only depends on the cycle type of `self`.

EXAMPLES:

```
sage: # needs sage.combinat
sage: sigma = Permutations(5).identity()
sage: sigma.has_nth_root(3)
True
sage: sigma = Permutation('(1, 3)')
sage: sigma.has_nth_root(2)
False
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> sigma = Permutations(Integer(5)).identity()
>>> sigma.has_nth_root(Integer(3))
True
>>> sigma = Permutation('(1, 3)')
```

(continues on next page)

(continued from previous page)

```
>>> sigma.has_nth_root(Integer(2))
False
```

See also

- *nth_roots()*
- *number_of_nth_roots()*

has_pattern(*patt*)

Test whether the permutation `self` contains the pattern `patt`.

EXAMPLES:

```
sage: Permutation([3,5,1,4,6,2]).has_pattern([1,3,2])                    #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(5),Integer(1),Integer(4),Integer(6),
↪Integer(2)]).has_pattern([Integer(1),Integer(3),Integer(2)])            ␣
↪       # needs sage.combinat
True
```

hyperoctahedral_double_coset_type()

Return the coset-type of `self` as a partition.

`self` must be a permutation of even size $2n$. The coset-type determines the double class of the permutation, that is its image in $H_n \backslash S_{2n} / H_n$, where H_n is the n-th hyperoctahedral group.

The coset-type is determined as follows. Consider the perfect matching $\{\{1,2\},\{3,4\},\ldots,\{2n-1,2n\}\}$ and its image by `self`, and draw them simultaneously as edges of a graph whose vertices are labeled by $1,2,\ldots,2n$. The coset-type is the ordered sequence of the semi-lengths of the cycles of this graph (see Chapter VII of [Mac1995] for more details, particularly Section VII.2).

EXAMPLES:

```
sage: # needs sage.combinat
sage: p = Permutation([3, 4, 6, 1, 5, 7, 2, 8])
sage: p.hyperoctahedral_double_coset_type()
[3, 1]
sage: all(p.hyperoctahedral_double_coset_type() ==
....:     p.inverse().hyperoctahedral_double_coset_type()
....:     for p in Permutations(4))
True
sage: Permutation([]).hyperoctahedral_double_coset_type()
[]
sage: Permutation([3,1,2]).hyperoctahedral_double_coset_type()
Traceback (most recent call last):
...
ValueError: [3, 1, 2] is a permutation of odd size and has no coset-type
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> p = Permutation([Integer(3), Integer(4), Integer(6), Integer(1),␣
↪Integer(5), Integer(7), Integer(2), Integer(8)])
>>> p.hyperoctahedral_double_coset_type()
[3, 1]
>>> all(p.hyperoctahedral_double_coset_type() ==
...     p.inverse().hyperoctahedral_double_coset_type()
...     for p in Permutations(Integer(4)))
True
>>> Permutation([]).hyperoctahedral_double_coset_type()
[]
>>> Permutation([Integer(3),Integer(1),Integer(2)]).hyperoctahedral_double_
↪coset_type()
Traceback (most recent call last):
...
ValueError: [3, 1, 2] is a permutation of odd size and has no coset-type
```

idescents(*final_descent=False*, *from_zero=False*)

Return a list of the idescents of `self`, that is the list of the descents of `self`'s inverse.

A descent of a permutation `p` is an integer `i` such that `p(i) > p(i+1)`.

Warning

By default, the descents are returned as elements in the index set, i.e., starting at 1. If you want them to start at 0, set the keyword `from_zero` to `True`.

INPUT:

- `final_descent` – boolean (default: `False`); if `True`, the last position of a non-empty permutation is also considered as a descent
- `from_zero` – boolean (default: `False`); if `False`, return the positions starting from 1

EXAMPLES:

```
sage: Permutation([2,3,1]).idescents()
[1]
sage: Permutation([1,4,3,2]).idescents()
[2, 3]
sage: Permutation([1,4,3,2]).idescents(final_descent=True)
[2, 3, 4]
sage: Permutation([1,4,3,2]).idescents(from_zero=True)
[1, 2]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(3),Integer(1)]).idescents()
[1]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).idescents()
[2, 3]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).
↪idescents(final_descent=True)
```

(continues on next page)

(continued from previous page)

```
[2, 3, 4]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).idescents(from_
↪zero=True)
[1, 2]
```

idescents_signature(*final_descent=False*)

Return the list obtained as follows: Each position in `self` is mapped to -1 if it is an idescent and 1 if it is not an idescent.

See *idescents()* for a definition of idescents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).idescents()
[2, 3]
sage: Permutation([1,4,3,2]).idescents_signature()
[1, -1, -1, 1]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).idescents()
[2, 3]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).idescents_
↪signature()
[1, -1, -1, 1]
```

imajor_index(*final_descent=False*)

Return the inverse major index of the permutation `self`, which is the major index of the inverse of `self`.

The major index of a permutation p is the sum of the descents of p. Since our permutation indices are 0-based, we need to add the number of descents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([2,1,3]).imajor_index()
1
sage: Permutation([3,4,1,2]).imajor_index()
2
sage: Permutation([4,3,2,1]).imajor_index()
6
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).imajor_index()
1
>>> Permutation([Integer(3),Integer(4),Integer(1),Integer(2)]).imajor_index()
2
>>> Permutation([Integer(4),Integer(3),Integer(2),Integer(1)]).imajor_index()
6
```

increasing_tree(*compare=<built-in function min>*)

Return the increasing tree associated to `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).increasing_tree()                                #␣
↪needs sage.graphs
1[., 2[3[4[., .], .], .]]
sage: Permutation([4,1,3,2]).increasing_tree()                                #␣
↪needs sage.graphs
1[4[., .], 2[3[., .], .]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).increasing_
↪tree()                                  # needs sage.graphs
1[., 2[3[4[., .], .], .]]
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2)]).increasing_
↪tree()                                  # needs sage.graphs
1[4[., .], 2[3[., .], .]]
```

By passing the option `compare=max` one can have the decreasing tree instead:

```
sage: Permutation([2,3,4,1]).increasing_tree(max)                             #␣
↪needs sage.graphs
4[3[2[., .], .], 1[., .]]
sage: Permutation([2,3,1,4]).increasing_tree(max)                             #␣
↪needs sage.graphs
4[3[2[., .], 1[., .]], .]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(3),Integer(4),Integer(1)]).increasing_
↪tree(max)                               # needs sage.graphs
4[3[2[., .], .], 1[., .]]
>>> Permutation([Integer(2),Integer(3),Integer(1),Integer(4)]).increasing_
↪tree(max)                               # needs sage.graphs
4[3[2[., .], 1[., .]], .]
```

increasing_tree_shape(*compare=<built-in function min>*)

Return the shape of the increasing tree associated with the permutation.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).increasing_tree_shape()                          #␣
↪needs sage.graphs
[., [[., .], .], .]]
sage: Permutation([4,1,3,2]).increasing_tree_shape()                          #␣
↪needs sage.graphs
[[., .], [[., .], .]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).increasing_
↪tree_shape()                            # needs sage.graphs
[., [[., .], .], .]]
```

(continues on next page)

(continued from previous page)

```
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2)]).increasing_
↪tree_shape()                          # needs sage.graphs
[[., .], [[., .], .]]
```

By passing the option `compare=max` one can have the decreasing tree instead:

```
sage: Permutation([2,3,4,1]).increasing_tree_shape(max)                    #␣
↪needs sage.graphs
[[[., .], .], [., .]]
sage: Permutation([2,3,1,4]).increasing_tree_shape(max)                    #␣
↪needs sage.graphs
[[[., .], [., .]], .]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(3),Integer(4),Integer(1)]).increasing_
↪tree_shape(max)                       # needs sage.graphs
[[[., .], .], [., .]]
>>> Permutation([Integer(2),Integer(3),Integer(1),Integer(4)]).increasing_
↪tree_shape(max)                       # needs sage.graphs
[[[., .], [., .]], .]
```

inverse()

Return the inverse of `self`.

EXAMPLES:

```
sage: Permutation([3,8,5,10,9,4,6,1,7,2]).inverse()
[8, 10, 1, 6, 3, 7, 9, 2, 5, 4]
sage: Permutation([2, 4, 1, 5, 3]).inverse()
[3, 1, 5, 2, 4]
sage: ~Permutation([2, 4, 1, 5, 3])
[3, 1, 5, 2, 4]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(8),Integer(5),Integer(10),Integer(9),
↪Integer(4),Integer(6),Integer(1),Integer(7),Integer(2)]).inverse()
[8, 10, 1, 6, 3, 7, 9, 2, 5, 4]
>>> Permutation([Integer(2), Integer(4), Integer(1), Integer(5), Integer(3)]).
↪inverse()
[3, 1, 5, 2, 4]
>>> ~Permutation([Integer(2), Integer(4), Integer(1), Integer(5), Integer(3)])
[3, 1, 5, 2, 4]
```

inversions()

Return a list of the inversions of `self`.

An inversion of a permutation p is a pair (i, j) such that $i < j$ and $p(i) > p(j)$.

EXAMPLES:

```
sage: Permutation([3,2,4,1,5]).inversions()
[(1, 2), (1, 4), (2, 4), (3, 4)]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(2),Integer(4),Integer(1),Integer(5)]).
↪inversions()
[(1, 2), (1, 4), (2, 4), (3, 4)]
```

is_derangement()

Return whether `self` is a derangement.

A permutation σ is a derangement if σ has no fixed points.

EXAMPLES:

```
sage: P = Permutation([1,4,2,3])
sage: P.is_derangement()
False
sage: P = Permutation([2,3,1])
sage: P.is_derangement()
True
```

```
>>> from sage.all import *
>>> P = Permutation([Integer(1),Integer(4),Integer(2),Integer(3)])
>>> P.is_derangement()
False
>>> P = Permutation([Integer(2),Integer(3),Integer(1)])
>>> P.is_derangement()
True
```

is_even()

Return `True` if the permutation `self` is even and `False` otherwise.

EXAMPLES:

```
sage: Permutation([1,2,3]).is_even()
True
sage: Permutation([2,1,3]).is_even()
False
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).is_even()
True
>>> Permutation([Integer(2),Integer(1),Integer(3)]).is_even()
False
```

is_simple()

Return whether `self` is simple.

A permutation is simple if it does not send any proper sub-interval to a sub-interval.

For instance, `[6,1,3,5,2,4]` is not simple because it maps the interval `[3,4,5,6]` to `[2,3,4,5]`, whereas `[2,6,3,5,1,4]` is simple.

See OEIS sequence A111111

EXAMPLES:

```
sage: g = Permutation([4,2,3,1])
sage: g.is_simple()
False

sage: g = Permutation([6,1,3,5,2,4])
sage: g.is_simple()
False

sage: g = Permutation([2,6,3,5,1,4])
sage: g.is_simple()
True

sage: [len([pi for pi in Permutations(n) if pi.is_simple()])
....:  for n in range(6)]
[1, 1, 2, 0, 2, 6]
```

```
>>> from sage.all import *
>>> g = Permutation([Integer(4),Integer(2),Integer(3),Integer(1)])
>>> g.is_simple()
False

>>> g = Permutation([Integer(6),Integer(1),Integer(3),Integer(5),Integer(2),
↪Integer(4)])
>>> g.is_simple()
False

>>> g = Permutation([Integer(2),Integer(6),Integer(3),Integer(5),Integer(1),
↪Integer(4)])
>>> g.is_simple()
True

>>> [len([pi for pi in Permutations(n) if pi.is_simple()])
...  for n in range(Integer(6))]
[1, 1, 2, 0, 2, 6]
```

ishift(*i*)

Return the `i`-shift of `self`. If an `i`-shift of `self` can't be performed, then `self` is returned.

An i-shift can be applied when i is not between $i-1$ and $i+1$. The i-shift moves i to the other side, and leaves the relative positions of $i-1$ and $i+1$ in place. All other entries of the permutations are also left in place.

EXAMPLES:

Here, 2 is to the left of both 1 and 3. A 2-shift can be applied which moves the 2 to the right and leaves 1 and 3 in their same relative order:

```
sage: Permutation([2,1,3]).ishift(2)
[1, 3, 2]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).ishift(Integer(2))
[1, 3, 2]
```

All entries other than i, $i-1$ and $i+1$ are unchanged:

```
sage: Permutation([2,4,1,3]).ishift(2)
[1, 4, 3, 2]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(4),Integer(1),Integer(3)]).
↪ishift(Integer(2))
[1, 4, 3, 2]
```

Since 2 is between 1 and 3 in `[1,2,3]`, a 2-shift cannot be applied to `[1,2,3]`

```
sage: Permutation([1,2,3]).ishift(2)
[1, 2, 3]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).ishift(Integer(2))
[1, 2, 3]
```

iswitch(i)

Return the `i`-switch of `self`. If an `i`-switch of `self` can't be performed, then `self` is returned.

An i-switch can be applied when the subsequence of `self` formed by the entries $i-1$, i and $i+1$ is neither increasing nor decreasing. In this case, this subsequence is reversed (i. e., its leftmost element and its rightmost element switch places), while all other letters of `self` are kept in place.

EXAMPLES:

Here, 2 is to the left of both 1 and 3. A 2-switch can be applied which moves the 2 to the right and switches the relative order between 1 and 3:

```
sage: Permutation([2,1,3]).iswitch(2)
[3, 1, 2]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).iswitch(Integer(2))
[3, 1, 2]
```

All entries other than $i-1$, i and $i+1$ are unchanged:

```
sage: Permutation([2,4,1,3]).iswitch(2)
[3, 4, 1, 2]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(4),Integer(1),Integer(3)]).
↪iswitch(Integer(2))
[3, 4, 1, 2]
```

Since 2 is between 1 and 3 in `[1,2,3]`, a 2-switch cannot be applied to `[1,2,3]`

```
sage: Permutation([1,2,3]).iswitch(2)
[1, 2, 3]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).iswitch(Integer(2))
[1, 2, 3]
```

left_action_product(*lp*)

Return the permutation obtained by composing `self` with `lp` in such an order that `lp` is applied first and `self` is applied afterwards.

This is usually denoted by either `self * lp` or `lp * self` depending on the conventions used by the author. If the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by $p(i)$, then this should be denoted by `self * lp` in order to have associativity (i.e., in order to have $(p \cdot q)(i) = p(q(i))$ for all p, q and i). If, on the other hand, the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by i^p, then this should be denoted by `lp * self` in order to have associativity (i.e., in order to have $i^{p \cdot q} = (i^p)^q$ for all p, q and i).

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.left_action_product(q)
[3, 2, 1]
sage: q.left_action_product(p)
[1, 3, 2]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> q = Permutation([Integer(3),Integer(1),Integer(2)])
>>> p.left_action_product(q)
[3, 2, 1]
>>> q.left_action_product(p)
[1, 3, 2]
```

left_tableau()

Return the left standard tableau after performing the RSK algorithm on `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).left_tableau()                                 #␣
↪needs sage.combinat
[[1, 2], [3], [4]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).left_tableau()␣
↪                                    # needs sage.combinat
[[1, 2], [3], [4]]
```

length()

Return the Coxeter length of `self`.

The length of a permutation p is given by the number of inversions of p.

EXAMPLES:

```
sage: Permutation([5, 1, 3, 4, 2]).length()
6
```

```
>>> from sage.all import *
>>> Permutation([Integer(5), Integer(1), Integer(3), Integer(4), Integer(2)]).
↪length()
6
```

longest_increasing_subsequence_length()

Return the length of the longest increasing subsequences of `self`.

EXAMPLES:

```
sage: Permutation([2,3,1,4]).longest_increasing_subsequence_length()
3
sage: all(i.longest_increasing_subsequence_length() == len(RSK(i)[0][0])    #␣
↪needs sage.combinat
....:     for i in Permutations(5))
True
sage: Permutation([]).longest_increasing_subsequence_length()
0
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(3),Integer(1),Integer(4)]).longest_
↪increasing_subsequence_length()
3
>>> all(i.longest_increasing_subsequence_length() ==␣
↪len(RSK(i)[Integer(0)][Integer(0)])    # needs sage.combinat
...     for i in Permutations(Integer(5)))
True
>>> Permutation([]).longest_increasing_subsequence_length()
0
```

longest_increasing_subsequences()

Return the list of the longest increasing subsequences of `self`.

A theorem of Schensted ([Sch1961]) states that an increasing subsequence of length i ends with the value entered in the i-th column of the p-tableau. The algorithm records which column of the p-tableau each value of the permutation is entered into, creates a digraph to record all increasing subsequences, and reads the paths from a source to a sink; these are the longest increasing subsequences.

EXAMPLES:

```
sage: Permutation([2,3,4,1]).longest_increasing_subsequences()              #␣
↪needs sage.graphs
[[2, 3, 4]]
sage: Permutation([5, 7, 1, 2, 6, 4, 3]).longest_increasing_subsequences()  #␣
↪needs sage.graphs
[[1, 2, 6], [1, 2, 4], [1, 2, 3]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(3),Integer(4),Integer(1)]).longest_
↪increasing_subsequences()              # needs sage.graphs
[[2, 3, 4]]
>>> Permutation([Integer(5), Integer(7), Integer(1), Integer(2), Integer(6),␣
↪Integer(4), Integer(3)]).longest_increasing_subsequences()  # needs sage.
```

(continues on next page)

(continued from previous page)

```
↪graphs
[[1, 2, 6], [1, 2, 4], [1, 2, 3]]
```

Note

This algorithm could be made faster using a balanced search tree for each column instead of sorted lists. See discussion on Issue #31451.

longest_increasing_subsequences_number()

alias of *number_of_longest_increasing_subsequences()*.

major_index(*final_descent=False*)

Return the major index of `self`.

The major index of a permutation p is the sum of the descents of p. Since our permutation indices are 0-based, we need to add the number of descents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([2,1,3]).major_index()
1
sage: Permutation([3,4,1,2]).major_index()
2
sage: Permutation([4,3,2,1]).major_index()
6
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).major_index()
1
>>> Permutation([Integer(3),Integer(4),Integer(1),Integer(2)]).major_index()
2
>>> Permutation([Integer(4),Integer(3),Integer(2),Integer(1)]).major_index()
6
```

multi_major_index(*composition*)

Return the multimajor index of this permutation with respect to `composition`.

INPUT:

- `composition` – a composition of the *size()* of this permutation

EXAMPLES:

```
sage: p = Permutation([5, 6, 2, 1, 3, 7, 4])
sage: p.multi_major_index([3, 2, 2])
[2, 0, 1]
sage: p.multi_major_index([7]) == [p.major_index()]
True
sage: p.multi_major_index([1]*7)
[0, 0, 0, 0, 0, 0, 0]
```

(continues on next page)

(continued from previous page)

```
sage: Permutation([]).multi_major_index([])
[]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(5), Integer(6), Integer(2), Integer(1),␣
↪Integer(3), Integer(7), Integer(4)])
>>> p.multi_major_index([Integer(3), Integer(2), Integer(2)])
[2, 0, 1]
>>> p.multi_major_index([Integer(7)]) == [p.major_index()]
True
>>> p.multi_major_index([Integer(1)]*Integer(7))
[0, 0, 0, 0, 0, 0, 0]
>>> Permutation([]).multi_major_index([])
[]
```

REFERENCES:

- [JS2000]

next()

Return the permutation that follows `self` on the symmetric group containing `self`. If `self` is the last permutation, then `next` returns `False`. If the `algorithm` parameter is specified, the permutations will be generated according to it. Supported algorithms are:

- `lex`: lexicographic order generation, this is the default algorithm.
- `sjt`: Steinhaus-Johnson-Trotter algorithm to generate permutations using only transposition of two elements in the list. It is highly recommended to set `check=True` (default value).

EXAMPLES:

```
sage: p = Permutation([1, 3, 2])
sage: next(p)
[2, 1, 3]
sage: p = Permutation([4,3,2,1])
sage: next(p)
False
sage: p = Permutation([1, 2, 3], algorithm='sjt')
sage: p = next(p); p
[1, 3, 2]
sage: p = next(p); p
[3, 1, 2]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(1), Integer(3), Integer(2)])
>>> next(p)
[2, 1, 3]
>>> p = Permutation([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> next(p)
False
>>> p = Permutation([Integer(1), Integer(2), Integer(3)], algorithm='sjt')
>>> p = next(p); p
[1, 3, 2]
```

(continues on next page)

(continued from previous page)

```
>>> p = next(p); p
[3, 1, 2]
```

noninversions(k)

Return the list of all k-noninversions in self.

If k is an integer and $p \in S_n$ is a permutation, then a k-noninversion in p is defined as a strictly increasing sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n\}$ satisfying $p(i_1) < p(i_2) < \cdots < p(i_k)$. (In other words, a k-noninversion in p can be regarded as a k-element subset of $\{1, 2, \ldots, n\}$ on which p restricts to an increasing map.)

EXAMPLES:

```
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.noninversions(1)
[[3], [2], [4], [1], [5]]
sage: p.noninversions(2)
[[3, 4], [3, 5], [2, 4], [2, 5], [4, 5], [1, 5]]
sage: p.noninversions(3)
[[3, 4, 5], [2, 4, 5]]
sage: p.noninversions(4)
[]
sage: p.noninversions(5)
[]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3), Integer(2), Integer(4), Integer(1),␣
↪Integer(5)])
>>> p.noninversions(Integer(1))
[[3], [2], [4], [1], [5]]
>>> p.noninversions(Integer(2))
[[3, 4], [3, 5], [2, 4], [2, 5], [4, 5], [1, 5]]
>>> p.noninversions(Integer(3))
[[3, 4, 5], [2, 4, 5]]
>>> p.noninversions(Integer(4))
[]
>>> p.noninversions(Integer(5))
[]
```

nth_roots(n)

Return all n-th roots of self (as a generator).

An n-th root of the permutation σ is a permutation γ such that $\gamma^n = \sigma$.

Note that the number of n-th roots only depends on the cycle type of self.

EXAMPLES:

```
sage: # needs sage.combinat
sage: sigma = Permutations(5).identity()
sage: list(sigma.nth_roots(3))
[[1, 4, 3, 5, 2], [1, 5, 3, 2, 4], [1, 2, 4, 5, 3], [1, 2, 5, 3, 4],
 [4, 2, 3, 5, 1], [5, 2, 3, 1, 4], [3, 2, 5, 4, 1], [5, 2, 1, 4, 3],
 [2, 5, 3, 4, 1], [5, 1, 3, 4, 2], [2, 3, 1, 4, 5], [3, 1, 2, 4, 5],
```

(continues on next page)

(continued from previous page)

```
 [2, 4, 3, 1, 5], [4, 1, 3, 2, 5], [3, 2, 4, 1, 5], [4, 2, 1, 3, 5],
 [1, 3, 4, 2, 5], [1, 4, 2, 3, 5], [1, 3, 5, 4, 2], [1, 5, 2, 4, 3],
 [1, 2, 3, 4, 5]]
sage: sigma = Permutation('(1, 3)')
sage: list(sigma.nth_roots(2))
[]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> sigma = Permutations(Integer(5)).identity()
>>> list(sigma.nth_roots(Integer(3)))
[[1, 4, 3, 5, 2], [1, 5, 3, 2, 4], [1, 2, 4, 5, 3], [1, 2, 5, 3, 4],
 [4, 2, 3, 5, 1], [5, 2, 3, 1, 4], [3, 2, 5, 4, 1], [5, 2, 1, 4, 3],
 [2, 5, 3, 4, 1], [5, 1, 3, 4, 2], [2, 3, 1, 4, 5], [3, 1, 2, 4, 5],
 [2, 4, 3, 1, 5], [4, 1, 3, 2, 5], [3, 2, 4, 1, 5], [4, 2, 1, 3, 5],
 [1, 3, 4, 2, 5], [1, 4, 2, 3, 5], [1, 3, 5, 4, 2], [1, 5, 2, 4, 3],
 [1, 2, 3, 4, 5]]
>>> sigma = Permutation('(1, 3)')
>>> list(sigma.nth_roots(Integer(2)))
[]
```

For $n \geq 6$, this algorithm begins to be more efficient than naive search (look at all permutations and test their n-th power).

See also

- *has_nth_root()*
- *number_of_nth_roots()*

number_of_descents(*final_descent=False*)

Return the number of descents of `self`.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_descents()
2
sage: Permutation([1,4,3,2]).number_of_descents(final_descent=True)
3
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).number_of_
↪descents()
2
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).number_of_
↪descents(final_descent=True)
3
```

number_of_fixed_points()

Return the number of fixed points of `self`.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).number_of_fixed_points()
2
sage: Permutation([1,2,3,4]).number_of_fixed_points()
4
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4)]).number_of_
↪fixed_points()
2
>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4)]).number_of_
↪fixed_points()
4
```

number_of_idescents(*final_descent=False*)

Return the number of idescents of `self`.

See *idescents()* for a definition of idescents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_idescents()
2
sage: Permutation([1,4,3,2]).number_of_idescents(final_descent=True)
3
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).number_of_
↪idescents()
2
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).number_of_
↪idescents(final_descent=True)
3
```

number_of_inversions()

Return the number of inversions in `self`.

An inversion of a permutation is a pair of elements (i, j) with $i < j$ and $p(i) > p(j)$.

REFERENCES:

- http://mathworld.wolfram.com/PermutationInversion.html

EXAMPLES:

```
sage: Permutation([3, 2, 4, 1, 5]).number_of_inversions()
4
sage: Permutation([1, 2, 6, 4, 7, 3, 5]).number_of_inversions()
6
```

```
>>> from sage.all import *
>>> Permutation([Integer(3), Integer(2), Integer(4), Integer(1), Integer(5)]).
↪number_of_inversions()
4
>>> Permutation([Integer(1), Integer(2), Integer(6), Integer(4), Integer(7),␣
↪Integer(3), Integer(5)]).number_of_inversions()
6
```

number_of_longest_increasing_subsequences()

Return the number of increasing subsequences of maximal length in `self`.

The list of longest increasing subsequences of a permutation is given by *longest_increasing_subsequences()*, and the length of these subsequences is given by *longest_increasing_subsequence_length()*.

The algorithm is similar to *longest_increasing_subsequences()*. Namely, the longest increasing subsequences are encoded as increasing sequences in a ranked poset from a smallest to a largest element. Their number can be obtained via dynamic programming: for each v in the poset we compute the number of paths from a smallest element to v.

EXAMPLES:

```
sage: sum(p.number_of_longest_increasing_subsequences()
....:     for p in Permutations(8))
120770

sage: p = Permutations(50).random_element()
sage: (len(p.longest_increasing_subsequences()) ==                              #␣
↪needs sage.graphs
....:  p.number_of_longest_increasing_subsequences())
True
```

```
>>> from sage.all import *
>>> sum(p.number_of_longest_increasing_subsequences()
...     for p in Permutations(Integer(8)))
120770

>>> p = Permutations(Integer(50)).random_element()
>>> (len(p.longest_increasing_subsequences()) ==                               #␣
↪needs sage.graphs
...  p.number_of_longest_increasing_subsequences())
True
```

number_of_noninversions(k)

Return the number of `k`-noninversions in `self`.

If k is an integer and $p \in S_n$ is a permutation, then a k-noninversion in p is defined as a strictly increasing sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n\}$ satisfying $p(i_1) < p(i_2) < \cdots < p(i_k)$. (In other words, a k-noninversion in p can be regarded as a k-element subset of $\{1, 2, \ldots, n\}$ on which p restricts to an increasing map.)

The number of k-noninversions in p has been denoted by $\mathrm{noninv}_k(p)$ in [RSW2011], where conjectures and results regarding this number have been stated.

EXAMPLES:

```
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.number_of_noninversions(1)
5
sage: p.number_of_noninversions(2)
6
sage: p.number_of_noninversions(3)
2
sage: p.number_of_noninversions(4)
0
sage: p.number_of_noninversions(5)
0
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3), Integer(2), Integer(4), Integer(1),␣
↪Integer(5)])
>>> p.number_of_noninversions(Integer(1))
5
>>> p.number_of_noninversions(Integer(2))
6
>>> p.number_of_noninversions(Integer(3))
2
>>> p.number_of_noninversions(Integer(4))
0
>>> p.number_of_noninversions(Integer(5))
0
```

The number of 2-noninversions of a permutation $p \in S_n$ is $\binom{n}{2}$ minus its number of inversions:

```
sage: b = binomial(5, 2)                                                    #␣
↪needs sage.symbolic
sage: all( x.number_of_noninversions(2) == b - x.number_of_inversions()     #␣
↪needs sage.symbolic
....:      for x in Permutations(5) )
True
```

```
>>> from sage.all import *
>>> b = binomial(Integer(5), Integer(2))                                    ␣
↪              # needs sage.symbolic
>>> all( x.number_of_noninversions(Integer(2)) == b - x.number_of_
↪inversions()     # needs sage.symbolic
...      for x in Permutations(Integer(5)) )
True
```

We also check some corner cases:

```
sage: all( x.number_of_noninversions(1) == 5 for x in Permutations(5) )
True
sage: all( x.number_of_noninversions(0) == 1 for x in Permutations(5) )
True
sage: Permutation([]).number_of_noninversions(1)
0
sage: Permutation([]).number_of_noninversions(0)
1
```

(continues on next page)

(continued from previous page)

```
sage: Permutation([2, 1]).number_of_noninversions(3)
0
```

```
>>> from sage.all import *
>>> all( x.number_of_noninversions(Integer(1)) == Integer(5) for x in␣
↪Permutations(Integer(5)) )
True
>>> all( x.number_of_noninversions(Integer(0)) == Integer(1) for x in␣
↪Permutations(Integer(5)) )
True
>>> Permutation([]).number_of_noninversions(Integer(1))
0
>>> Permutation([]).number_of_noninversions(Integer(0))
1
>>> Permutation([Integer(2), Integer(1)]).number_of_noninversions(Integer(3))
0
```

number_of_nth_roots(*n*)

Return the number of n-th roots of `self`.

An n-th root of the permutation σ is a permutation γ such that $\gamma^n = \sigma$.

Note that the number of n-th roots only depends on the cycle type of `self`.

EXAMPLES:

```
sage: # needs sage.combinat
sage: Sigma = Permutations(5).identity()
sage: Sigma.number_of_nth_roots(3)
21
sage: Sigma = Permutation('(1, 3)')
sage: Sigma.number_of_nth_roots(2)
0
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> Sigma = Permutations(Integer(5)).identity()
>>> Sigma.number_of_nth_roots(Integer(3))
21
>>> Sigma = Permutation('(1, 3)')
>>> Sigma.number_of_nth_roots(Integer(2))
0
```

See also

- *nth_roots()*
- *has_nth_root()*

number_of_peaks()

Return the number of peaks of the permutation `self`.

A peak of a permutation p is an integer i such that $p(i-1) < p(i)$ and $p(i) > p(i+1)$.

EXAMPLES:

```
sage: Permutation([1,3,2,4,5]).number_of_peaks()
1
sage: Permutation([4,1,3,2,6,5]).number_of_peaks()
2
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4),Integer(5)]).
↪number_of_peaks()
1
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2),Integer(6),
↪Integer(5)]).number_of_peaks()
2
```

number_of_recoils()

Return the number of recoils of the permutation `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).number_of_recoils()
2
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).number_of_
↪recoils()
2
```

number_of_reduced_words()

Return the number of reduced words of `self` without explicitly computing them all.

EXAMPLES:

```
sage: p = Permutation([6,4,2,5,1,8,3,7])
sage: len(p.reduced_words()) == p.number_of_reduced_words()                    #␣
↪needs sage.combinat
True
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(6),Integer(4),Integer(2),Integer(5),Integer(1),
↪Integer(8),Integer(3),Integer(7)])
>>> len(p.reduced_words()) == p.number_of_reduced_words()                      #␣
↪needs sage.combinat
True
```

number_of_saliances()

Return the number of saliances of `self`.

A saliance of a permutation p is an integer i such that $p(i) > p(j)$ for all $j > i$.

EXAMPLES:

```
sage: Permutation([2,3,1,5,4]).number_of_saliances()
2
```

(continues on next page)

(continued from previous page)

```
sage: Permutation([5,4,3,2,1]).number_of_saliances()
5
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(3),Integer(1),Integer(5),Integer(4)]).
↪number_of_saliances()
2
>>> Permutation([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)]).
↪number_of_saliances()
5
```

order()

Return the order of `self`.

EXAMPLES:

```
sage: sigma = Permutation([3,4,1,2,5])
sage: sigma.order()
2
sage: sigma * sigma
[1, 2, 3, 4, 5]
```

```
>>> from sage.all import *
>>> sigma = Permutation([Integer(3),Integer(4),Integer(1),Integer(2),
↪Integer(5)])
>>> sigma.order()
2
>>> sigma * sigma
[1, 2, 3, 4, 5]
```

pattern_positions(*patt*)

Return the list of positions where the pattern `patt` appears in the permutation `self`.

EXAMPLES:

```
sage: Permutation([3,5,1,4,6,2]).pattern_positions([1,3,2])                #␣
↪needs sage.combinat
[[0, 1, 3], [2, 3, 5], [2, 4, 5]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(5),Integer(1),Integer(4),Integer(6),
↪Integer(2)]).pattern_positions([Integer(1),Integer(3),Integer(2)])        ␣
↪       # needs sage.combinat
[[0, 1, 3], [2, 3, 5], [2, 4, 5]]
```

peaks()

Return a list of the peaks of the permutation `self`.

A peak of a permutation p is an integer i such that $p(i-1) < p(i)$ and $p(i) > p(i+1)$.

EXAMPLES:

```
sage: Permutation([1,3,2,4,5]).peaks()
[1]
sage: Permutation([4,1,3,2,6,5]).peaks()
[2, 4]
sage: Permutation([]).peaks()
[]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4),Integer(5)]).
↪peaks()
[1]
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2),Integer(6),
↪Integer(5)]).peaks()
[2, 4]
>>> Permutation([]).peaks()
[]
```

permutation_poset()

Return the permutation poset of `self`.

The permutation poset of a permutation p is the poset with vertices $(i, p(i))$ for $i = 1, 2, \ldots, n$ (where n is the size of p) and order inherited from $\mathbf{Z} \times \mathbf{Z}$.

EXAMPLES:

```
sage: # needs sage.combinat sage.graphs
sage: Permutation([3,1,5,4,2]).permutation_poset().cover_relations()
[[(2, 1), (5, 2)],
 [(2, 1), (3, 5)],
 [(2, 1), (4, 4)],
 [(1, 3), (3, 5)],
 [(1, 3), (4, 4)]]
sage: Permutation([]).permutation_poset().cover_relations()
[]
sage: Permutation([1,3,2]).permutation_poset().cover_relations()
[[(1, 1), (2, 3)], [(1, 1), (3, 2)]]
sage: Permutation([1,2]).permutation_poset().cover_relations()
[[(1, 1), (2, 2)]]
sage: P = Permutation([1,5,2,4,3])
```

```
>>> from sage.all import *
>>> # needs sage.combinat sage.graphs
>>> Permutation([Integer(3),Integer(1),Integer(5),Integer(4),Integer(2)]).
↪permutation_poset().cover_relations()
[[(2, 1), (5, 2)],
 [(2, 1), (3, 5)],
 [(2, 1), (4, 4)],
 [(1, 3), (3, 5)],
 [(1, 3), (4, 4)]]
>>> Permutation([]).permutation_poset().cover_relations()
[]
>>> Permutation([Integer(1),Integer(3),Integer(2)]).permutation_poset().cover_
↪relations()
```

(continues on next page)

(continued from previous page)

```
[[(1, 1), (2, 3)], [(1, 1), (3, 2)]]
>>> Permutation([Integer(1),Integer(2)]).permutation_poset().cover_relations()
[[(1, 1), (2, 2)]]
>>> P = Permutation([Integer(1),Integer(5),Integer(2),Integer(4),Integer(3)])
```

This should hold for any P:

```
sage: P.permutation_poset().greene_shape() == P.RS_partition()                #␣
↪needs sage.combinat sage.graphs
True
```

```
>>> from sage.all import *
>>> P.permutation_poset().greene_shape() == P.RS_partition()                  #␣
↪needs sage.combinat sage.graphs
True
```

permutohedron_greater(*side='right'*)

Return a list of permutations greater than or equal to `self` in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See *permutohedron_lequal()* for the definition of the permutohedron orders.

EXAMPLES:

```
sage: Permutation([4,2,1,3]).permutohedron_greater()
[[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1]]
sage: Permutation([4,2,1,3]).permutohedron_greater(side='left')
[[4, 2, 1, 3], [4, 3, 1, 2], [4, 3, 2, 1]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(2),Integer(1),Integer(3)]).permutohedron_
↪greater()
[[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1]]
>>> Permutation([Integer(4),Integer(2),Integer(1),Integer(3)]).permutohedron_
↪greater(side='left')
[[4, 2, 1, 3], [4, 3, 1, 2], [4, 3, 2, 1]]
```

permutohedron_join(*other*, *side='right'*)

Return the join of the permutations `self` and `other` in the right permutohedron order (or, if `side` is set to `'left'`, in the left permutohedron order).

The permutohedron orders (see *permutohedron_lequal()*) are lattices; the join operation refers to this lattice structure. In more elementary terms, the join of two permutations π and ψ in the symmetric group S_n is the permutation in S_n whose set of inversion is the transitive closure of the union of the set of inversions of π with the set of inversions of ψ.

See also

permutohedron_lequal(), *permutohedron_meet()*.

ALGORITHM:

It is enough to construct the join of any two permutations π and ψ in S_n with respect to the right weak order. (The join of π and ψ with respect to the left weak order is the inverse of the join of π^{-1} and ψ^{-1} with respect to the right weak order.) Start with an empty list l (denoted `xs` in the actual code). For $i = 1, 2, \ldots, n$ (in this order), we insert i into this list in the rightmost possible position such that any letter in $\{1, 2, ..., i-1\}$ which appears further right than i in either π or ψ (or both) must appear further right than i in the resulting list. After all numbers are inserted, we are left with a list which is precisely the join of π and ψ (in one-line notation). This algorithm is due to Markowsky, [Mar1994] (Theorem 1 (a)).

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_join(q)
[3, 1, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_join(p)
[3, 2, 1]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(1),Integer(2)])
>>> q = Permutation([Integer(1),Integer(3),Integer(2)])
>>> p.permutohedron_join(q)
[3, 1, 2]
>>> r = Permutation([Integer(2),Integer(1),Integer(3)])
>>> r.permutohedron_join(p)
[3, 2, 1]
```

```
sage: p = Permutation([3,2,4,1])
sage: q = Permutation([4,2,1,3])
sage: p.permutohedron_join(q)
[4, 3, 2, 1]
sage: r = Permutation([3,1,2,4])
sage: p.permutohedron_join(r)
[3, 2, 4, 1]
sage: q.permutohedron_join(r)
[4, 3, 2, 1]
sage: s = Permutation([1,4,2,3])
sage: s.permutohedron_join(r)
[4, 3, 1, 2]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> q = Permutation([Integer(4),Integer(2),Integer(1),Integer(3)])
>>> p.permutohedron_join(q)
[4, 3, 2, 1]
>>> r = Permutation([Integer(3),Integer(1),Integer(2),Integer(4)])
>>> p.permutohedron_join(r)
[3, 2, 4, 1]
>>> q.permutohedron_join(r)
[4, 3, 2, 1]
```

(continues on next page)

(continued from previous page)

```
>>> s = Permutation([Integer(1),Integer(4),Integer(2),Integer(3)])
>>> s.permutohedron_join(r)
[4, 3, 1, 2]
```

The universal property of the join operation is satisfied:

```
sage: def test_uni_join(p, q):
....:     j = p.permutohedron_join(q)
....:     if not p.permutohedron_lequal(j):
....:         return False
....:     if not q.permutohedron_lequal(j):
....:         return False
....:     for r in p.permutohedron_greater():
....:         if q.permutohedron_lequal(r) and not j.permutohedron_lequal(r):
....:             return False
....:     return True
sage: all( test_uni_join(p, q) for p in Permutations(3) for q in␣
↪Permutations(3) )
True
sage: test_uni_join(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3,␣
↪1, 2, 5, 4, 6, 8]))
True
```

```
>>> from sage.all import *
>>> def test_uni_join(p, q):
...     j = p.permutohedron_join(q)
...     if not p.permutohedron_lequal(j):
...         return False
...     if not q.permutohedron_lequal(j):
...         return False
...     for r in p.permutohedron_greater():
...         if q.permutohedron_lequal(r) and not j.permutohedron_lequal(r):
...             return False
...     return True
>>> all( test_uni_join(p, q) for p in Permutations(Integer(3)) for q in␣
↪Permutations(Integer(3)) )
True
>>> test_uni_join(Permutation([Integer(6), Integer(4), Integer(7), Integer(3),
↪ Integer(2), Integer(5), Integer(8), Integer(1)]), Permutation([Integer(7),␣
↪Integer(3), Integer(1), Integer(2), Integer(5), Integer(4), Integer(6),␣
↪Integer(8)]))
True
```

Border cases:

```
sage: p = Permutation([])
sage: p.permutohedron_join(p)
[]
sage: p = Permutation([1])
sage: p.permutohedron_join(p)
[1]
```

```
>>> from sage.all import *
>>> p = Permutation([])
>>> p.permutohedron_join(p)
[]
>>> p = Permutation([Integer(1)])
>>> p.permutohedron_join(p)
[1]
```

The left permutohedron:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_join(q, side='left')
[3, 2, 1]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_join(p, side='left')
[3, 1, 2]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(1),Integer(2)])
>>> q = Permutation([Integer(1),Integer(3),Integer(2)])
>>> p.permutohedron_join(q, side='left')
[3, 2, 1]
>>> r = Permutation([Integer(2),Integer(1),Integer(3)])
>>> r.permutohedron_join(p, side='left')
[3, 1, 2]
```

permutohedron_lequal(*p2*, *side='right'*)

Return `True` if `self` is less or equal to `p2` in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

For every nonnegative integer n, the right (resp. left) permutohedron order (also called the right (resp. left) weak order, or the right (resp. left) weak Bruhat order) is a partial order on the symmetric group S_n. It can be defined in various ways, including the following ones:

- Two permutations u and v in S_n satisfy $u \leq v$ in the right (resp. left) permutohedron order if and only if the (Coxeter) length of the permutation $v^{-1} \circ u$ (resp. of the permutation $u \circ v^{-1}$) equals the length of v minus the length of u. Here, $p \circ q$ means the permutation obtained by applying q first and then p. (Recall that the Coxeter length of a permutation is its number of inversions.)
- Two permutations u and v in S_n satisfy $u \leq v$ in the right (resp. left) permutohedron order if and only if every pair (i, j) of elements of $\{1, 2, \cdots, n\}$ such that $i < j$ and $u^{-1}(i) > u^{-1}(j)$ (resp. $u(i) > u(j)$) also satisfies $v^{-1}(i) > v^{-1}(j)$ (resp. $v(i) > v(j)$).
- A permutation $v \in S_n$ covers a permutation $u \in S_n$ in the right (resp. left) permutohedron order if and only if we have $v = u \circ (i, i+1)$ (resp. $v = (i, i+1) \circ u$) for some $i \in \{1, 2, \cdots, n-1\}$ satisfying $u(i) < u(i+1)$ (resp. $u^{-1}(i) < u^{-1}(i+1)$). Here, again, $p \circ q$ means the permutation obtained by applying q first and then p.

The right and the left permutohedron order are mutually isomorphic, with the isomorphism being the map sending every permutation to its inverse. Each of these orders endows the symmetric group S_n with the structure of a graded poset (the rank function being the Coxeter length).

Warning

The permutohedron order is not to be mistaken for the strong Bruhat order (*bruhat_lequal()*), despite both orders being occasionally referred to as the Bruhat order.

EXAMPLES:

```
sage: p = Permutation([3,2,1,4])
sage: p.permutohedron_lequal(Permutation([4,2,1,3]))
False
sage: p.permutohedron_lequal(Permutation([4,2,1,3]), side='left')
True
sage: p.permutohedron_lequal(p)
True

sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([3,1,2]))
False
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([1,2,3]))
False
sage: Permutation([1,3,2]).permutohedron_lequal(Permutation([2,1,3]))
False
sage: Permutation([1,3,2]).permutohedron_lequal(Permutation([2,3,1]))
False
sage: Permutation([2,3,1]).permutohedron_lequal(Permutation([1,3,2]))

[1, 2, 2, 3, 3, 6]

>>> Permutation([]).permutohedron_lequal(Permutation([]))
True
```

permutohedron_meet(*other*, *side='right'*)

Return the meet of the permutations `self` and `other` in the right permutohedron order (or, if `side` is set to `'left'`, in the left permutohedron order).

The permutohedron orders (see *permutohedron_lequal()*) are lattices; the meet operation refers to this lattice structure. It is connected to the join operation by the following simple symmetry property: If π and ψ are two permutations π and ψ in the symmetric group S_n, and if w_0 denotes the permutation $(n, n-1, \ldots, 1) \in S_n$, then

$$\pi \wedge \psi = w_0 \circ ((w_0 \circ \pi) \vee (w_0 \circ \psi)) = ((\pi \circ w_0) \vee (\psi \circ w_0)) \circ w_0$$

and

$$\pi \vee \psi = w_0 \circ ((w_0 \circ \pi) \wedge (w_0 \circ \psi)) = ((\pi \circ w_0) \wedge (\psi \circ w_0)) \circ w_0,$$

where $\wedge$ means meet and $\vee$ means join.

permutohedron_lequal(), *permutohedron_join()*.

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_meet(q)
[1, 3, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_meet(p)
[1, 2, 3]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(1),Integer(2)])
>>> q = Permutation([Integer(1),Integer(3),Integer(2)])
>>> p.permutohedron_meet(q)
[1, 3, 2]
>>> r = Permutation([Integer(2),Integer(1),Integer(3)])
>>> r.permutohedron_meet(p)
[1, 2, 3]
```

```
sage: p = Permutation([3,2,4,1])
sage: q = Permutation([4,2,1,3])
sage: p.permutohedron_meet(q)
[2, 1, 3, 4]
sage: r = Permutation([3,1,2,4])
sage: p.permutohedron_meet(r)
[3, 1, 2, 4]
sage: q.permutohedron_meet(r)
[1, 2, 3, 4]
sage: s = Permutation([1,4,2,3])
sage: s.permutohedron_meet(r)
[1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> q = Permutation([Integer(4),Integer(2),Integer(1),Integer(3)])
>>> p.permutohedron_meet(q)
[2, 1, 3, 4]
>>> r = Permutation([Integer(3),Integer(1),Integer(2),Integer(4)])
>>> p.permutohedron_meet(r)
[3, 1, 2, 4]
>>> q.permutohedron_meet(r)
[1, 2, 3, 4]
>>> s = Permutation([Integer(1),Integer(4),Integer(2),Integer(3)])
>>> s.permutohedron_meet(r)
[1, 2, 3, 4]
```

The universal property of the meet operation is satisfied:

```
sage: def test_uni_meet(p, q):
....:     m = p.permutohedron_meet(q)
....:     if not m.permutohedron_lequal(p):
....:         return False
....:     if not m.permutohedron_lequal(q):

....:     for r in p.permutohedron_smaller():
....:         if r.permutohedron_lequal(q) and not r.permutohedron_lequal(m):
....:             return False
....:     return True
sage: all( test_uni_meet(p, q) for p in Permutations(3) for q in␣
↪Permutations(3) )
True
sage: test_uni_meet(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3,␣
↪1, 2, 5, 4, 6, 8]))
True
```

```
>>> from sage.all import *
>>> def test_uni_meet(p, q):
...     m = p.permutohedron_meet(q)
...     if not m.permutohedron_lequal(p):
...         return False
...     if not m.permutohedron_lequal(q):
...         return False
...     for r in p.permutohedron_smaller():
...         if r.permutohedron_lequal(q) and not r.permutohedron_lequal(m):
...             return False
...     return True
>>> all( test_uni_meet(p, q) for p in Permutations(Integer(3)) for q in␣
↪Permutations(Integer(3)) )
True
>>> test_uni_meet(Permutation([Integer(6), Integer(4), Integer(7), Integer(3),
↪ Integer(2), Integer(5), Integer(8), Integer(1)]), Permutation([Integer(7),␣
↪Integer(3), Integer(1), Integer(2), Integer(5), Integer(4), Integer(6),␣
↪Integer(8)]))
True
```

Border cases:

```
sage: p = Permutation([])
sage: p.permutohedron_meet(p)
[]
sage: p = Permutation([1])
sage: p.permutohedron_meet(p)
[1]
```

```
>>> from sage.all import *
>>> p = Permutation([])
>>> p.permutohedron_meet(p)
[]
>>> p = Permutation([Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> p.permutohedron_meet(p)
[1]
```

The left permutohedron:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_meet(q, side='left')
[1, 2, 3]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_meet(p, side='left')
[2, 1, 3]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(1),Integer(2)])
>>> q = Permutation([Integer(1),Integer(3),Integer(2)])
>>> p.permutohedron_meet(q, side='left')
[1, 2, 3]
>>> r = Permutation([Integer(2),Integer(1),Integer(3)])
>>> r.permutohedron_meet(p, side='left')
[2, 1, 3]
```

permutohedron_pred(*side='right'*)

Return a list of the permutations strictly smaller than `self` in the permutohedron order such that there is no permutation between any of those and `self`.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See *permutohedron_lequal()* for the definition of the permutohedron orders.

EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_pred()
[[2, 4, 1, 3], [4, 1, 2, 3]]
sage: p.permutohedron_pred(side='left')
[[4, 1, 2, 3], [3, 2, 1, 4]]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(4),Integer(2),Integer(1),Integer(3)])
>>> p.permutohedron_pred()
[[2, 4, 1, 3], [4, 1, 2, 3]]
>>> p.permutohedron_pred(side='left')
[[4, 1, 2, 3], [3, 2, 1, 4]]
```

permutohedron_smaller(*side='right'*)

Return a list of permutations smaller than or equal to `self` in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See *permutohedron_lequal()* for the definition of the permutohedron orders.

EXAMPLES:

```
sage: Permutation([4,2,1,3]).permutohedron_smaller()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 4, 1, 3],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(2),Integer(1),Integer(3)]).permutohedron_
↪smaller()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 4, 1, 3],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

```
sage: Permutation([4,2,1,3]).permutohedron_smaller(side='left')
[[1, 2, 3, 4],
 [1, 3, 2, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(2),Integer(1),Integer(3)]).permutohedron_
↪smaller(side='left')
[[1, 2, 3, 4],
 [1, 3, 2, 4],
 [2, 1, 3, 4],
 [2, 3, 1, 4],
 [3, 1, 2, 4],
 [3, 2, 1, 4],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

permutohedron_succ(*side='right'*)

Return a list of the permutations strictly greater than `self` in the permutohedron order such that there is no permutation between any of those and `self`.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See *permutohedron_lequal()* for the definition of the permutohedron orders.

EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_succ()
[[4, 2, 3, 1]]
sage: p.permutohedron_succ(side='left')
[[4, 3, 1, 2]]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(4),Integer(2),Integer(1),Integer(3)])
>>> p.permutohedron_succ()
[[4, 2, 3, 1]]
>>> p.permutohedron_succ(side='left')
[[4, 3, 1, 2]]
```

prev()

Return the permutation that comes directly before `self` in lexicographic order on the symmetric group containing `self`. If `self` is the first permutation, then it returns `False`. Does not support the Steinhaus-Johnson-Trotter algorithm for the moment.

EXAMPLES:

```
sage: p = Permutation([1,2,3])
sage: p.prev()
False
sage: p = Permutation([1,3,2])
sage: p.prev()
[1, 2, 3]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(1),Integer(2),Integer(3)])
>>> p.prev()
False
>>> p = Permutation([Integer(1),Integer(3),Integer(2)])
>>> p.prev()
[1, 2, 3]
```

Todo

Implement the previous permutation for the Steinhaus-Johnson-Trotter algorithm.

rank()

Return the rank of `self` in the lexicographic ordering on the symmetric group to which `self` belongs.

EXAMPLES:

```
sage: Permutation([1,2,3]).rank()
0
sage: Permutation([1, 2, 4, 6, 3, 5]).rank()
10
sage: perms = Permutations(6).list()
sage: [p.rank() for p in perms] == list(range(factorial(6)))
True
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).rank()
0
>>> Permutation([Integer(1), Integer(2), Integer(4), Integer(6), Integer(3),␣
↪Integer(5)]).rank()
10
>>> perms = Permutations(Integer(6)).list()
>>> [p.rank() for p in perms] == list(range(factorial(Integer(6))))
True
```

rank_matrix()

Return the rank matrix of `self`.

Let $P = [P_{ij}]_{i,j=1}^{n}$ be the permutation matrix of $w \in S_n$. The rank matrix is the $n \times n$ matrix with entries

$$r_w(i,j) = \sum_{a=1}^{i} \sum_{b=1}^{j} P_{ij}.$$

EXAMPLES:

```
sage: w = Permutation([2, 1, 5, 4, 3])
sage: w.to_matrix()
[0 1 0 0 0]
[1 0 0 0 0]
[0 0 0 0 1]
[0 0 0 1 0]
[0 0 1 0 0]
sage: w.rank_matrix()
[0 1 1 1 1]
[1 2 2 2 2]
[1 2 2 2 3]
[1 2 2 3 4]
[1 2 3 4 5]
```

```
>>> from sage.all import *
>>> w = Permutation([Integer(2), Integer(1), Integer(5), Integer(4),␣
↪Integer(3)])
>>> w.to_matrix()
[0 1 0 0 0]
[1 0 0 0 0]
[0 0 0 0 1]
[0 0 0 1 0]
[0 0 1 0 0]
>>> w.rank_matrix()
[0 1 1 1 1]
[1 2 2 2 2]
[1 2 2 2 3]
[1 2 2 3 4]
[1 2 3 4 5]
```

recoils()

Return the list of the positions of the recoils of `self`.

A recoil of a permutation p is an integer i such that $i+1$ appears to the left of i in p. Here, the positions are being counted starting at 0. (Note that it is the positions, not the recoils themselves, which are being listed.)

EXAMPLES:

```
sage: Permutation([1,4,3,2]).recoils()
[2, 3]
sage: Permutation([]).recoils()
[]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).recoils()
[2, 3]
>>> Permutation([]).recoils()
[]
```

recoils_composition()

Return the recoils composition of `self`.

The recoils composition of a permutation $p \in S_n$ is the composition of n whose descent set is the set of the recoils of p (not their positions). In other words, this is the descents composition of p^{-1}.

EXAMPLES:

```
sage: Permutation([1,3,2,4]).recoils_composition()
[2, 2]
sage: Permutation([]).recoils_composition()
[]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4)]).recoils_
↪composition()
[2, 2]
>>> Permutation([]).recoils_composition()
[]
```

reduced_word()

Return a reduced word of the permutation `self`.

See *reduced_words()* for the definition of reduced words and a way to compute them all.

Warning

This does not respect the multiplication convention.

EXAMPLES:

```
sage: Permutation([3,5,4,6,2,1]).reduced_word()
[2, 1, 4, 3, 2, 4, 3, 5, 4, 5]

Permutation([1]).reduced_word_lexmin()
[]
Permutation([]).reduced_word_lexmin()
[]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(5),Integer(4),Integer(6),Integer(2),
↪Integer(1)]).reduced_word()
[2, 1, 4, 3, 2, 4, 3, 5, 4, 5]

Permutation([1]).reduced_word_lexmin()
[]
Permutation([]).reduced_word_lexmin()
[]
```

reduced_word_lexmin()

Return a lexicographically minimal reduced word of the permutation `self`.

See *reduced_words()* for the definition of reduced words and a way to compute them all.

EXAMPLES:

```
sage: Permutation([3,4,2,1]).reduced_word_lexmin()
[1, 2, 1, 3, 2]

Permutation([1]).reduced_word_lexmin()
[]
Permutation([]).reduced_word_lexmin()
[]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(4),Integer(2),Integer(1)]).reduced_word_
↪lexmin()
[1, 2, 1, 3, 2]

Permutation([1]).reduced_word_lexmin()
[]
Permutation([]).reduced_word_lexmin()
[]
```

reduced_words()

Return a list of the reduced words of `self`.

The notion of a reduced word is based on the well-known fact that every permutation can be written as a product of adjacent transpositions. In more detail: If n is a nonnegative integer, we can define the transpositions $s_i = (i, i+1) \in S_n$ for all $i \in \{1, 2, \ldots, n-1\}$, and every $p \in S_n$ can then be written as a product $s_{i_1} s_{i_2} \cdots s_{i_k}$ for some sequence $(i_1, i_2, \ldots, i_k)$ of elements of $\{1, 2, \ldots, n-1\}$ (here $\{1, 2, \ldots, n-1\}$ denotes the empty set when $n \leq 1$). Fixing a p, the sequences $(i_1, i_2, \ldots, i_k)$ of smallest length satisfying $p = s_{i_1} s_{i_2} \cdots s_{i_k}$ are called the reduced words of p. (Their length is the Coxeter length of p, and can be computed using *length()*.)

Note that the product of permutations is defined here in such a way that $(pq)(i) = p(q(i))$ for all permutations p and q and each $i \in \{1, 2, \ldots, n\}$ (this is the same convention as in *left_action_product()*, but not the default semantics of the $*$ operator on permutations in Sage). Thus, for instance, $s_2 s_1$ is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3.

reduced_word(), *reduced_word_lexmin()*

EXAMPLES:

```
sage: Permutation([2,1,3]).reduced_words()
[[1]]
sage: Permutation([3,1,2]).reduced_words()
[[2, 1]]
sage: Permutation([3,2,1]).reduced_words()
[[1, 2, 1], [2, 1, 2]]
sage: Permutation([3,2,4,1]).reduced_words()
[[1, 2, 3, 1], [1, 2, 1, 3], [2, 1, 2, 3]]

Permutation([1]).reduced_words()
[[]]
Permutation([]).reduced_words()
[[]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).reduced_words()
[[1]]
>>> Permutation([Integer(3),Integer(1),Integer(2)]).reduced_words()
[[2, 1]]
>>> Permutation([Integer(3),Integer(2),Integer(1)]).reduced_words()
[[1, 2, 1], [2, 1, 2]]
>>> Permutation([Integer(3),Integer(2),Integer(4),Integer(1)]).reduced_words()
[[1, 2, 3, 1], [1, 2, 1, 3], [2, 1, 2, 3]]

Permutation([1]).reduced_words()
[[]]
Permutation([]).reduced_words()
[[]]
```

reduced_words_iterator()

Return an iterator for the reduced words of `self`.

EXAMPLES:

```
sage: next(Permutation([5,2,3,4,1]).reduced_words_iterator())
[1, 2, 3, 4, 3, 2, 1]
```

```
>>> from sage.all import *
>>> next(Permutation([Integer(5),Integer(2),Integer(3),Integer(4),
↪Integer(1)]).reduced_words_iterator())
[1, 2, 3, 4, 3, 2, 1]
```

remove_extra_fixed_points()

Return the permutation obtained by removing any fixed points at the end of `self`.

However, return `[1]` rather than `[]` if `self` is the identity permutation.

This is mostly a helper method for *sage.combinat.schubert_polynomial*, where it is used to normalize finitary permutations of $\{1, 2, 3, \ldots\}$.

EXAMPLES:

```
sage: Permutation([2,1,3]).remove_extra_fixed_points()
[2, 1]
sage: Permutation([1,2,3,4]).remove_extra_fixed_points()
[1]
sage: Permutation([2,1]).remove_extra_fixed_points()
[2, 1]
sage: Permutation([]).remove_extra_fixed_points()
[1]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).remove_extra_fixed_
↪points()
[2, 1]
>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4)]).remove_extra_
↪fixed_points()
[1]
>>> Permutation([Integer(2),Integer(1)]).remove_extra_fixed_points()
[2, 1]
>>> Permutation([]).remove_extra_fixed_points()
[1]
```

retract_plain()

retract_direct_product(*m*)

Return the direct-product retract of the permutation `self` $\in S_n$ to S_m, where $m \leq n$. If this retract is undefined, then `None` is returned.

If $p \in S_n$ is a permutation, and m is a nonnegative integer less or equal to n, then the direct-product retract of p to S_m is defined only if $p([m]) = [m]$, where $[m]$ denotes the interval $\{1, 2, \ldots, m\}$. In this case, it is defined as the permutation written $(p(1), p(2), \ldots, p(m))$ in one-line notation.

EXAMPLES:

```
sage: Permutation([4,1,2,3,5]).retract_direct_product(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_direct_product(3)

sage: Permutation([1,4,2,3,6,5]).retract_direct_product(5)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(4)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(3)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(2)
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(1)
[1]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(0)
[]
```

retract_plain(), *retract_okounkov_vershik()*

retract_okounkov_vershik(*m*)

Return the Okounkov-Vershik retract of the permutation `self` $\in S_n$ to S_m, where $m \leq n$.

If $p \in S_n$ is a permutation, and m is a nonnegative integer less or equal to n, then the Okounkov-Vershik retract of p to S_m is defined as the permutation in S_m which sends every $i \in \{1, 2, \ldots, m\}$ to $p^{k_i}(i)$, where k_i is the smallest positive integer k satisfying $p^k(i) \leq m$.

In other words, the Okounkov-Vershik retract of p is the permutation whose disjoint cycle decomposition is obtained by removing all letters strictly greater than m from the decomposition of p into disjoint cycles (and removing all cycles which are emptied in the process).

When $m = n-1$, the Okounkov-Vershik retract (as a map $S_n \to S_{n-1}$) is the map $\widetilde{p}_n$ introduced in Section 7 of [VO2005], and appears as (3.20) in [CST2010]. In the general case, the Okounkov-Vershik retract of a permutation in S_n to S_m can be obtained by first taking its Okounkov-Vershik retract to S_{n-1}, then that of the resulting permutation to S_{n-2}, etc. until arriving in S_m.

EXAMPLES:

```
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(3)

See also

retract_plain(), *retract_direct_product()*

retract_plain(*m*)

Return the plain retract of the permutation `self` in S_n to S_m, where $m \leq n$. If this retract is undefined, then `None` is returned.

If $p \in S_n$ is a permutation, and m is a nonnegative integer less or equal to n, then the plain retract of p to S_m is defined only if every $i > m$ satisfies $p(i) = i$. In this case, it is defined as the permutation written $(p(1), p(2), \ldots, p(m))$ in one-line notation.

EXAMPLES:

```
sage: Permutation([4,1,2,3,5]).retract_plain(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_plain(3)
```

(continues on next page)

(continued from previous page)

```
sage: Permutation([1,3,2,4,5,6]).retract_plain(3)
[1, 3, 2]
sage: Permutation([1,3,2,4,5,6]).retract_plain(2)

sage: Permutation([1,2,3,4,5]).retract_plain(1)
[1]
sage: Permutation([1,2,3,4,5]).retract_plain(0)
[]

sage: all( p.retract_plain(3) == p for p in Permutations(3) )
True

↪Integer(6)]).retract_plain(Integer(2))

>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]).
↪retract_plain(Integer(1))
[1]
>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]).
↪retract_plain(Integer(0))
[]

>>> all( p.retract_plain(Integer(3)) == p for p in Permutations(Integer(3)) )
True
```

See also

retract_direct_product(), *retract_okounkov_vershik()*, *remove_extra_fixed_points()*

reverse()

Return the permutation obtained by reversing the list.

EXAMPLES:

```
sage: Permutation([3,4,1,2]).reverse()
[2, 1, 4, 3]
sage: Permutation([1,2,3,4,5]).reverse()
[5, 4, 3, 2, 1]
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(4),Integer(1),Integer(2)]).reverse()
[2, 1, 4, 3]
>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]).
↪reverse()
[5, 4, 3, 2, 1]
```

right_action_product(*rp*)

Return the permutation obtained by composing `self` with `rp` in such an order that `self` is applied first and `rp` is applied afterwards.

This is usually denoted by either `self * rp` or `rp * self` depending on the conventions used by the author. If the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by $p(i)$, then this should be denoted by `rp * self` in order to have associativity (i.e., in order to have $(p \cdot q)(i) = p(q(i))$ for all p, q and i). If, on the other hand, the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \cdots, n\}$ is denoted by i^p, then this should be denoted by `self * rp` in order to have associativity (i.e., in order to have $i^{p \cdot q} = (i^p)^q$ for all p, q and i).

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.right_action_product(q)
[1, 3, 2]
sage: q.right_action_product(p)
[3, 2, 1]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> q = Permutation([Integer(3),Integer(1),Integer(2)])
>>> p.right_action_product(q)
[1, 3, 2]
>>> q.right_action_product(p)
[3, 2, 1]
```

right_permutohedron_interval(*other*)

Return the list of the permutations belonging to the right permutohedron interval where `self` is the minimal element and `other` the maximal element.

See *permutohedron_lequal()* for the definition of the permutohedron orders.

EXAMPLES:

```
sage: p = Permutation([2, 1, 4, 5, 3]); q = Permutation([2, 5, 4, 1, 3])
sage: p.right_permutohedron_interval(q)                                    #␣
↪needs sage.graphs sage.modules
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3],
 [2, 1, 5, 4, 3], [2, 5, 1, 4, 3], [2, 5, 4, 1, 3]]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2), Integer(1), Integer(4), Integer(5),␣
↪Integer(3)]); q = Permutation([Integer(2), Integer(5), Integer(4),␣
↪Integer(1), Integer(3)])
>>> p.right_permutohedron_interval(q)                                      #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.graphs sage.modules
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3],
 [2, 1, 5, 4, 3], [2, 5, 1, 4, 3], [2, 5, 4, 1, 3]]
```

right_permutohedron_interval_iterator(*other*)

Return an iterator on the permutations (represented as integer lists) belonging to the right permutohedron interval where `self` is the minimal element and `other` the maximal element.

See *permutohedron_lequal()* for the definition of the permutohedron orders.

EXAMPLES:

```
sage: p = Permutation([2, 1, 4, 5, 3]); q = Permutation([2, 5, 4, 1, 3])
sage: p.right_permutohedron_interval(q)  # indirect doctest                #␣
↪needs sage.graphs sage.modules
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3],
 [2, 1, 5, 4, 3], [2, 5, 1, 4, 3], [2, 5, 4, 1, 3]]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2), Integer(1), Integer(4), Integer(5),␣
↪Integer(3)]); q = Permutation([Integer(2), Integer(5), Integer(4),␣
↪Integer(1), Integer(3)])
>>> p.right_permutohedron_interval(q)  # indirect doctest                #␣
↪needs sage.graphs sage.modules
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3],
 [2, 1, 5, 4, 3], [2, 5, 1, 4, 3], [2, 5, 4, 1, 3]]
```

right_tableau()

Return the right standard tableau after performing the RSK algorithm on `self`.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).right_tableau()                                #␣
↪needs sage.combinat
[[1, 2], [3], [4]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).right_
↪tableau()                                  # needs sage.combinat
[[1, 2], [3], [4]]
```

robinson_schensted()

Return the pair of standard tableaux obtained by running the Robinson-Schensted algorithm on `self`.

This can also be done by running *RSK()* on `self` (with the optional argument `check_standard=True` to return standard Young tableaux).

EXAMPLES:

```
sage: Permutation([6,2,3,1,7,5,4]).robinson_schensted()                     #␣
↪needs sage.combinat
[[[1, 3, 4], [2, 5], [6, 7]], [[1, 3, 5], [2, 6], [4, 7]]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(6),Integer(2),Integer(3),Integer(1),Integer(7),
↪Integer(5),Integer(4)]).robinson_schensted()                    # needs␣
↪sage.combinat
[[[1, 3, 4], [2, 5], [6, 7]], [[1, 3, 5], [2, 6], [4, 7]]]
```

rothe_diagram()

Return the Rothe diagram of `self`.

EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: D = p.rothe_diagram(); D                                          #␣
↪needs sage.combinat
[(0, 0), (0, 1), (0, 2), (1, 0)]
sage: D.pp()                                                            #␣
↪needs sage.combinat
O O O .
O . . .
. . . .
. . . .
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(4),Integer(2),Integer(1),Integer(3)])
>>> D = p.rothe_diagram(); D                                            #␣
↪needs sage.combinat
[(0, 0), (0, 1), (0, 2), (1, 0)]
>>> D.pp()                                                              #␣
↪needs sage.combinat
O O O .
O . . .
. . . .
. . . .
```

runs(*as_tuple=False*)

Return a list of the runs in the nonempty permutation `self`.

A run in a permutation is defined to be a maximal (with respect to inclusion) nonempty increasing substring (i. e., contiguous subsequence). For instance, the runs in the permutation `[6,1,7,3,4,5,2]` are `[6]`, `[1,7]`, `[3,4,5]` and `[2]`.

Runs in an empty permutation are not defined.

INPUT:

- `as_tuple` – boolean (default: `False`); choice of output format

OUTPUT: list of lists or a tuple of tuples

REFERENCES:

- http://mathworld.wolfram.com/PermutationRun.html

EXAMPLES:

```
sage: Permutation([1,2,3,4]).runs()
[[1, 2, 3, 4]]
```

(continues on next page)

(continued from previous page)

```
sage: Permutation([4,3,2,1]).runs()
[[4], [3], [2], [1]]
sage: Permutation([2,4,1,3]).runs()
[[2, 4], [1, 3]]
sage: Permutation([1]).runs()
[[1]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4)]).runs()
[[1, 2, 3, 4]]
>>> Permutation([Integer(4),Integer(3),Integer(2),Integer(1)]).runs()
[[4], [3], [2], [1]]
>>> Permutation([Integer(2),Integer(4),Integer(1),Integer(3)]).runs()
[[2, 4], [1, 3]]
>>> Permutation([Integer(1)]).runs()
[[1]]
```

The example from above:

```
sage: Permutation([6,1,7,3,4,5,2]).runs()
[[6], [1, 7], [3, 4, 5], [2]]
sage: Permutation([6,1,7,3,4,5,2]).runs(as_tuple=True)
((6,), (1, 7), (3, 4, 5), (2,))
```

```
>>> from sage.all import *
>>> Permutation([Integer(6),Integer(1),Integer(7),Integer(3),Integer(4),
↪Integer(5),Integer(2)]).runs()
[[6], [1, 7], [3, 4, 5], [2]]
>>> Permutation([Integer(6),Integer(1),Integer(7),Integer(3),Integer(4),
↪Integer(5),Integer(2)]).runs(as_tuple=True)
((6,), (1, 7), (3, 4, 5), (2,))
```

The number of runs in a nonempty permutation equals its number of descents plus 1:

```
sage: all( len(p.runs()) == p.number_of_descents() + 1
....:      for p in Permutations(6) )
True
```

```
>>> from sage.all import *
>>> all( len(p.runs()) == p.number_of_descents() + Integer(1)
...      for p in Permutations(Integer(6)) )
True
```

saliances()

Return a list of the saliances of the permutation `self`.

A saliance of a permutation p is an integer i such that $p(i) > p(j)$ for all $j > i$.

EXAMPLES:

```
sage: Permutation([2,3,1,5,4]).saliances()
[3, 4]
```

(continues on next page)

(continued from previous page)

```
sage: Permutation([5,4,3,2,1]).saliances()
[0, 1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(3),Integer(1),Integer(5),Integer(4)]).
↪saliances()
[3, 4]
>>> Permutation([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)]).
↪saliances()
[0, 1, 2, 3, 4]
```

schubert_determinant_ideal()

Return the Schubert determinant ideal of `self`.

From Lemma 3.10 [Ful1992], the matrix Schubert variety of a permutation $w \in S_n$ is defined by the ideal

$$I_w = \sum_{(i,j)} I_{r_w(i,j)+1}(i,j),$$

where the sum is over the *essential set*, $[r_w(i,j)]_{i,j}$ is the *rank_matrix()* of w, and $I_k(i,j)$ is the ideal generated by the $k \times k$ minors of the $i \times j$ matrix $[z_{ab}]_{a,b}$.

These ideals are known to be prime of codimension equal to $\ell(w)$ (the length of w) such that R/I_w is Cohen-Macaulay, where R is the polynomial ring $\mathbf{Q}[z_{ab} | 1 \leq a, b \leq n]$ from Prop. 3.10 of [Ful1992].

EXAMPLES:

```
sage: w = Permutation([3, 1, 4, 2])
sage: Iw = w.schubert_determinant_ideal()
sage: Iw.gens()
[z00, z01, -z01*z10 + z00*z11, -z01*z20 + z00*z21, -z11*z20 + z10*z21]
sage: Iw.dimension()
13
sage: Iw.dimension() + w.length()
16
sage: Iw.is_prime()
True

sage: w = Permutation([2, 1, 5, 4, 3])
sage: Iw = w.schubert_determinant_ideal()
sage: Iw.dimension()
21
sage: w.length() + Iw.dimension()
25
sage: Iw.is_prime()
True
```

```
>>> from sage.all import *
>>> w = Permutation([Integer(3), Integer(1), Integer(4), Integer(2)])
>>> Iw = w.schubert_determinant_ideal()
>>> Iw.gens()
[z00, z01, -z01*z10 + z00*z11, -z01*z20 + z00*z21, -z11*z20 + z10*z21]
>>> Iw.dimension()
```

(continues on next page)

(continued from previous page)

```
13
>>> Iw.dimension() + w.length()
16
>>> Iw.is_prime()
True

>>> w = Permutation([Integer(2), Integer(1), Integer(5), Integer(4),␣
↪Integer(3)])
>>> Iw = w.schubert_determinant_ideal()
>>> Iw.dimension()
21
>>> w.length() + Iw.dimension()
25
>>> Iw.is_prime()
True
```

shifted_concatenation(*other*, *side='right'*)

Return the right (or left) shifted concatenation of `self` with a permutation `other`. These operations are also known as the Loday-Ronco over and under operations.

INPUT:

- `other` – a permutation, a list, a tuple, or any iterable representing a permutation
- `side` – string (default: `'right'`); `'left'` or `'right'`

OUTPUT:

If `side` is `'right'`, the method returns the permutation obtained by concatenating `self` with the letters of `other` incremented by the size of `self`. This is what is called `side / other` in [LR0102066], and denoted as the "over" operation. Otherwise, i. e., when `side` is `'left'`, the method returns the permutation obtained by concatenating the letters of `other` incremented by the size of `self` with `self`. This is what is called `side \ other` in [LR0102066] (which seems to use the $(\sigma\pi)(i) = \pi(\sigma(i))$ convention for the product of permutations).

EXAMPLES:

```
sage: Permutation([]).shifted_concatenation(Permutation([]), "right")
[]
sage: Permutation([]).shifted_concatenation(Permutation([]), "left")
[]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]),
↪"right")
[2, 4, 1, 3, 7, 5, 6]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]),
↪"left")
[7, 5, 6, 2, 4, 1, 3]
```

```
>>> from sage.all import *
>>> Permutation([]).shifted_concatenation(Permutation([]), "right")
[]
>>> Permutation([]).shifted_concatenation(Permutation([]), "left")
[]
>>> Permutation([Integer(2), Integer(4), Integer(1), Integer(3)]).shifted_
↪concatenation(Permutation([Integer(3), Integer(1), Integer(2)]), "right")
```

(continues on next page)

(continued from previous page)

```
[2, 4, 1, 3, 7, 5, 6]
>>> Permutation([Integer(2), Integer(4), Integer(1), Integer(3)]).shifted_
↪concatenation(Permutation([Integer(3), Integer(1), Integer(2)]), "left")
[7, 5, 6, 2, 4, 1, 3]
```

shifted_shuffle(*other*)

Return the shifted shuffle of two permutations `self` and `other`.

INPUT:

- `other` – a permutation, a list, a tuple, or any iterable representing a permutation

OUTPUT:

The list of the permutations appearing in the shifted shuffle of the permutations `self` and `other`.

EXAMPLES:

```
sage: # needs sage.graphs sage.modules
sage: Permutation([]).shifted_shuffle(Permutation([]))
[[]]
sage: Permutation([1, 2, 3]).shifted_shuffle(Permutation([1]))
[[4, 1, 2, 3], [1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3]]
sage: Permutation([1, 2]).shifted_shuffle(Permutation([2, 1]))
[[4, 1, 3, 2], [4, 3, 1, 2], [1, 4, 3, 2],
 [1, 4, 2, 3], [1, 2, 4, 3], [4, 1, 2, 3]]
sage: Permutation([1]).shifted_shuffle([1])
[[2, 1], [1, 2]]
sage: p = Permutation([3, 1, 5, 4, 2])
sage: len(p.shifted_shuffle(Permutation([2, 1, 4, 3])))
126
```

```
>>> from sage.all import *
>>> # needs sage.graphs sage.modules
>>> Permutation([]).shifted_shuffle(Permutation([]))
[[]]
>>> Permutation([Integer(1), Integer(2), Integer(3)]).shifted_
↪shuffle(Permutation([Integer(1)]))
[[4, 1, 2, 3], [1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3]]
>>> Permutation([Integer(1), Integer(2)]).shifted_
↪shuffle(Permutation([Integer(2), Integer(1)]))
[[4, 1, 3, 2], [4, 3, 1, 2], [1, 4, 3, 2],
 [1, 4, 2, 3], [1, 2, 4, 3], [4, 1, 2, 3]]
>>> Permutation([Integer(1)]).shifted_shuffle([Integer(1)])
[[2, 1], [1, 2]]
>>> p = Permutation([Integer(3), Integer(1), Integer(5), Integer(4),␣
↪Integer(2)])
>>> len(p.shifted_shuffle(Permutation([Integer(2), Integer(1), Integer(4),␣
↪Integer(3)])))
126
```

The shifted shuffle product is associative. We can test this on an admittedly toy example:

```
sage: all( all( all( sorted(flatten([abs.shifted_shuffle(c)                    #␣
↪needs sage.graphs sage.modules
....:                                  for abs in a.shifted_shuffle(b)]))
....:                 == sorted(flatten([a.shifted_shuffle(bcs)
....:                                    for bcs in b.shifted_shuffle(c)]))
....:                 for c in Permutations(2) )
....:             for b in Permutations(2) )
....:         for a in Permutations(2) )
True
```

```
>>> from sage.all import *
>>> all( all( all( sorted(flatten([abs.shifted_shuffle(c)                    #␣
↪needs sage.graphs sage.modules
...                                  for abs in a.shifted_shuffle(b)]))
...                 == sorted(flatten([a.shifted_shuffle(bcs)
...                                    for bcs in b.shifted_shuffle(c)]))
...                 for c in Permutations(Integer(2)) )
...             for b in Permutations(Integer(2)) )
...         for a in Permutations(Integer(2)) )
True
```

The `shifted_shuffle` method on permutations gives the same permutations as the `shifted_shuffle` method on words (but is faster):

```
sage: all( all( sorted(p1.shifted_shuffle(p2))                                 #␣
↪needs sage.combinat sage.graphs sage.modules sage.rings.finite_rings
....:             == sorted([Permutation(p) for p in
....:                        Word(p1).shifted_shuffle(Word(p2))])
....:             for p2 in Permutations(3) )
....:         for p1 in Permutations(2) )
True
```

```
>>> from sage.all import *
>>> all( all( sorted(p1.shifted_shuffle(p2))                                   #␣
↪needs sage.combinat sage.graphs sage.modules sage.rings.finite_rings
...             == sorted([Permutation(p) for p in
...                        Word(p1).shifted_shuffle(Word(p2))])
...             for p2 in Permutations(Integer(3)) )
...         for p1 in Permutations(Integer(2)) )
True
```

show(*representation='cycles'*, *orientation='landscape'*, ***args*)

Display the permutation as a drawing.

INPUT:

- `representation` – different kinds of drawings are available
  - `'cycles'` – default; the permutation is displayed as a collection of directed cycles
  - `'braid'` – the permutation is displayed as segments linking each element $1, ..., n$ to its image on a parallel line

    When using this drawing, it is also possible to display the permutation horizontally (`orientation = "landscape"`, default option) or vertically (`orientation = "portrait"`).

– `'chord-diagram'` – the permutation is displayed as a directed graph, all of its vertices being located on a circle

All additional arguments are forwarded to the `show` subcalls.

EXAMPLES:

```
sage: P20 = Permutations(20)
sage: P20.random_element().show(representation='cycles')                    #␣
↪needs sage.graphs sage.plot
sage: P20.random_element().show(representation='chord-diagram')             #␣
↪needs sage.graphs sage.plot
sage: P20.random_element().show(representation='braid')                     #␣
↪needs sage.plot
sage: P20.random_element().show(representation='braid',                     #␣
↪needs sage.plot
....:                           orientation='portrait')
```

```
>>> from sage.all import *
>>> P20 = Permutations(Integer(20))
>>> P20.random_element().show(representation='cycles')                    #␣
↪needs sage.graphs sage.plot
>>> P20.random_element().show(representation='chord-diagram')             #␣
↪needs sage.graphs sage.plot
>>> P20.random_element().show(representation='braid')                     #␣
↪needs sage.plot
>>> P20.random_element().show(representation='braid',                     #␣
↪needs sage.plot
...                            orientation='portrait')
```

sign()

alias of *signature()*.

signature()

Return the signature of the permutation `self`. This is $(-1)^l$, where l is the number of inversions of `self`.

Note

sign() can be used as an alias for *signature()*.

EXAMPLES:

```
sage: Permutation([4, 2, 3, 1, 5]).signature()
-1
sage: Permutation([1,3,2,5,4]).sign()
1
sage: Permutation([]).sign()
1
```

```
>>> from sage.all import *
>>> Permutation([Integer(4), Integer(2), Integer(3), Integer(1), Integer(5)]).
↪signature()
-1
```

(continues on next page)

(continued from previous page)

```
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(5),Integer(4)]).
↪sign()
1
>>> Permutation([]).sign()
1
```

simion_schmidt (*avoid=[1, 2, 3]*)

Implement the Simion-Schmidt map which sends an arbitrary permutation to a pattern avoiding permutation, where the permutation pattern is one of four length-three patterns. This method also implements the bijection between (for example) `[1,2,3]`- and `[1,3,2]`-avoiding permutations.

INPUT:

- `avoid` – one of the patterns `[1,2,3]`, `[1,3,2]`, `[3,1,2]`, `[3,2,1]`

EXAMPLES:

```
sage: P = Permutations(6)
sage: p = P([4,5,1,6,3,2])
sage: pl = [ [1,2,3], [1,3,2], [3,1,2], [3,2,1] ]
sage: for q in pl:                                                          #␣
↪needs sage.combinat
....:     s = p.simion_schmidt(q)
....:     print("{} {}".format(s, s.has_pattern(q)))
[4, 6, 1, 5, 3, 2] False
[4, 2, 1, 3, 5, 6] False
[4, 5, 3, 6, 2, 1] False
[4, 5, 1, 6, 2, 3] False
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(6))
>>> p = P([Integer(4),Integer(5),Integer(1),Integer(6),Integer(3),Integer(2)])
>>> pl = [ [Integer(1),Integer(2),Integer(3)], [Integer(1),Integer(3),
↪Integer(2)], [Integer(3),Integer(1),Integer(2)], [Integer(3),Integer(2),
↪Integer(1)] ]
>>> for q in pl:                                                            #␣
↪needs sage.combinat
...     s = p.simion_schmidt(q)
...     print("{} {}".format(s, s.has_pattern(q)))
[4, 6, 1, 5, 3, 2] False
[4, 2, 1, 3, 5, 6] False
[4, 5, 3, 6, 2, 1] False
[4, 5, 1, 6, 2, 3] False
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: Permutation([3,4,1,2,5]).size()
5
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(4),Integer(1),Integer(2),Integer(5)]).
↪size()
5
```

stack_sort()

Return the stack sort of a permutation.

This is another permutation obtained through the process of sorting using one stack. If the result is the identity permutation, the original permutation is *stack-sortable*.

See Wikipedia article Stack-sortable_permutation

EXAMPLES:

```
sage: p = Permutation([2,1,5,3,4,9,7,8,6])
sage: p.stack_sort()
[1, 2, 3, 4, 5, 7, 6, 8, 9]

sage: S5 = Permutations(5)
sage: len([1 for s in S5 if s.stack_sort() == S5.one()])
42
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(5),Integer(3),Integer(4),
↪Integer(9),Integer(7),Integer(8),Integer(6)])
>>> p.stack_sort()
[1, 2, 3, 4, 5, 7, 6, 8, 9]

>>> S5 = Permutations(Integer(5))
>>> len([Integer(1) for s in S5 if s.stack_sort() == S5.one()])
42
```

sylvester_class(*left_to_right=False*)

Iterate over the equivalence class of the permutation `self` under sylvester congruence.

Sylvester congruence is an equivalence relation on the set S_n of all permutations of n. It is defined as the smallest equivalence relation such that every permutation of the form $uacvbw$ with u, v and w being words and a, b and c being letters satisfying $a \leq b < c$ is equivalent to the permutation $ucavbw$. (Here, permutations are regarded as words by way of one-line notation.) This definition comes from [HNT2005], Definition 8, where it is more generally applied to arbitrary words.

The equivalence class of a permutation $p \in S_n$ under sylvester congruence is called the *sylvester class* of p. It is an interval in the right permutohedron order (see *permutohedron_lequal()*) on S_n.

This is related to the *sylvester_class()* method in that the equivalence class of a permutation π under sylvester congruence is the sylvester class of the right-to-left binary search tree of π. However, the present method yields permutations, while the method on labelled binary trees yields plain lists.

If the variable `left_to_right` is set to `True`, the method instead iterates over the equivalence class of `self` with respect to the *left* sylvester congruence. The left sylvester congruence is easiest to define by saying that two permutations are equivalent under it if and only if their reverses (*reverse()*) are equivalent under (standard) sylvester congruence.

EXAMPLES:

The sylvester class of a permutation in S_5:

```
sage: p = Permutation([3, 5, 1, 2, 4])
sage: sorted(p.sylvester_class())                                           #␣
↪needs sage.combinat sage.graphs
[[1, 3, 2, 5, 4],
 [1, 3, 5, 2, 4],
 [1, 5, 3, 2, 4],
 [3, 1, 2, 5, 4],
 [3, 1, 5, 2, 4],
 [3, 5, 1, 2, 4],
 [5, 1, 3, 2, 4],
 [5, 3, 1, 2, 4]]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3), Integer(5), Integer(1), Integer(2),␣
↪Integer(4)])
>>> sorted(p.sylvester_class())                                             #␣
↪needs sage.combinat sage.graphs
[[1, 3, 2, 5, 4],
 [1, 3, 5, 2, 4],
 [1, 5, 3, 2, 4],
 [3, 1, 2, 5, 4],
 [3, 1, 5, 2, 4],
 [3, 5, 1, 2, 4],
 [5, 1, 3, 2, 4],
 [5, 3, 1, 2, 4]]
```

The sylvester class of a permutation p contains p:

```
sage: all(p in p.sylvester_class() for p in Permutations(4))                #␣
↪needs sage.combinat sage.graphs
True
```

```
>>> from sage.all import *
>>> all(p in p.sylvester_class() for p in Permutations(Integer(4)))          ␣
↪     # needs sage.combinat sage.graphs
True
```

Small cases:

```
sage: list(Permutation([]).sylvester_class())                               #␣
↪needs sage.combinat sage.graphs
[[]]

sage: list(Permutation([1]).sylvester_class())                              #␣
↪needs sage.combinat sage.graphs
[[1]]
```

```
>>> from sage.all import *
>>> list(Permutation([]).sylvester_class())                                 #␣
↪needs sage.combinat sage.graphs
[[]]
```

(continues on next page)

(continued from previous page)

```
>>> list(Permutation([Integer(1)]).sylvester_class())                    ␣
↪     # needs sage.combinat sage.graphs
[[1]]
```

The sylvester classes in S_3:

```
sage: [sorted(p.sylvester_class()) for p in Permutations(3)]              #␣
↪needs sage.combinat sage.graphs
[[[1, 2, 3]],
 [[1, 3, 2], [3, 1, 2]],
 [[2, 1, 3]],
 [[2, 3, 1]],
 [[1, 3, 2], [3, 1, 2]],
 [[3, 2, 1]]]
```

```
>>> from sage.all import *
>>> [sorted(p.sylvester_class()) for p in Permutations(Integer(3))]      ␣
↪     # needs sage.combinat sage.graphs
[[[1, 2, 3]],
 [[1, 3, 2], [3, 1, 2]],
 [[2, 1, 3]],
 [[2, 3, 1]],
 [[1, 3, 2], [3, 1, 2]],
 [[3, 2, 1]]]
```

The left sylvester classes in S_3:

```
sage: [sorted(p.sylvester_class(left_to_right=True))                      #␣
↪needs sage.combinat sage.graphs
....:  for p in Permutations(3)]
[[[1, 2, 3]],
 [[1, 3, 2]],
 [[2, 1, 3], [2, 3, 1]],
 [[2, 1, 3], [2, 3, 1]],
 [[3, 1, 2]],
 [[3, 2, 1]]]
```

```
>>> from sage.all import *
>>> [sorted(p.sylvester_class(left_to_right=True))                        #␣
↪needs sage.combinat sage.graphs
...  for p in Permutations(Integer(3))]
[[[1, 2, 3]],
 [[1, 3, 2]],
 [[2, 1, 3], [2, 3, 1]],
 [[2, 1, 3], [2, 3, 1]],
 [[3, 1, 2]],
 [[3, 2, 1]]]
```

A left sylvester class in S_5:

```
sage: p = Permutation([4, 2, 1, 5, 3])
sage: sorted(p.sylvester_class(left_to_right=True))                       #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.combinat sage.graphs
[[4, 2, 1, 3, 5],
 [4, 2, 1, 5, 3],
 [4, 2, 3, 1, 5],
 [4, 2, 3, 5, 1],
 [4, 2, 5, 1, 3],
 [4, 2, 5, 3, 1],
 [4, 5, 2, 1, 3],
 [4, 5, 2, 3, 1]]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(4), Integer(2), Integer(1), Integer(5),␣
↪Integer(3)])
>>> sorted(p.sylvester_class(left_to_right=True))                          #␣
↪needs sage.combinat sage.graphs
[[4, 2, 1, 3, 5],
 [4, 2, 1, 5, 3],
 [4, 2, 3, 1, 5],
 [4, 2, 3, 5, 1],
 [4, 2, 5, 1, 3],
 [4, 2, 5, 3, 1],
 [4, 5, 2, 1, 3],
 [4, 5, 2, 3, 1]]
```

to_alternating_sign_matrix()

Return a matrix representing the permutation in the *AlternatingSignMatrix* class.

EXAMPLES:

```
sage: m = Permutation([1,2,3]).to_alternating_sign_matrix(); m             #␣
↪needs sage.combinat sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
sage: parent(m)                                                            #␣
↪needs sage.combinat sage.modules
Alternating sign matrices of size 3
```

```
>>> from sage.all import *
>>> m = Permutation([Integer(1),Integer(2),Integer(3)]).to_alternating_sign_
↪matrix(); m              # needs sage.combinat sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
>>> parent(m)                                                              #␣
↪needs sage.combinat sage.modules
Alternating sign matrices of size 3
```

to_cycles(*singletons=True*, *use_min=True*)

Return the permutation `self` as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If `singletons=False` is given, the list does not contain the singleton cycles.

If `use_min=False` is given, the cycles are returned in the order of increasing *largest* (not smallest) elements, and each cycle starts with its largest element.

EXAMPLES:

```
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]
sage: Permutation([2,1,3,4]).to_cycles(use_min=True)
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(use_min=False)
[(4,), (3,), (2, 1)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False, use_min=False)
[(2, 1)]

sage: Permutation([4,1,5,2,6,3]).to_cycles()
[(1, 4, 2), (3, 5, 6)]
sage: Permutation([4,1,5,2,6,3]).to_cycles(use_min=False)
[(6, 3, 5), (4, 2, 1)]

sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles()
[(1, 6), (2, 4), (3, 5)]
sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles(use_min=False)
[(6, 1), (5, 3), (4, 2)]
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3),Integer(4)]).to_cycles()
[(1, 2), (3,), (4,)]
>>> Permutation([Integer(2),Integer(1),Integer(3),Integer(4)]).to_
↪cycles(singletons=False)
[(1, 2)]
>>> Permutation([Integer(2),Integer(1),Integer(3),Integer(4)]).to_cycles(use_
↪min=True)
[(1, 2), (3,), (4,)]
>>> Permutation([Integer(2),Integer(1),Integer(3),Integer(4)]).to_cycles(use_
↪min=False)
[(4,), (3,), (2, 1)]
>>> Permutation([Integer(2),Integer(1),Integer(3),Integer(4)]).to_
↪cycles(singletons=False, use_min=False)
[(2, 1)]

>>> Permutation([Integer(4),Integer(1),Integer(5),Integer(2),Integer(6),
↪Integer(3)]).to_cycles()
[(1, 4, 2), (3, 5, 6)]
>>> Permutation([Integer(4),Integer(1),Integer(5),Integer(2),Integer(6),
↪Integer(3)]).to_cycles(use_min=False)
[(6, 3, 5), (4, 2, 1)]

>>> Permutation([Integer(6), Integer(4), Integer(5), Integer(2), Integer(3),␣
↪Integer(1)]).to_cycles()
[(1, 6), (2, 4), (3, 5)]
```

(continues on next page)

(continued from previous page)

```
>>> Permutation([Integer(6), Integer(4), Integer(5), Integer(2), Integer(3),␣
↪Integer(1)]).to_cycles(use_min=False)
[(6, 1), (5, 3), (4, 2)]
```

The algorithm is of complexity $O(n)$ where n is the size of the given permutation.

to_digraph()

Return a digraph representation of `self`.

EXAMPLES:

```
sage: d = Permutation([3, 1, 2]).to_digraph()                                  #␣
↪needs sage.graphs
sage: d.edges(sort=True, labels=False)                                         #␣
↪needs sage.graphs
[(1, 3), (2, 1), (3, 2)]
sage: P = Permutations(range(1, 10))
sage: d = Permutation(P.random_element()).to_digraph()                         #␣
↪needs sage.graphs
sage: all(c.is_cycle()                                                         #␣
↪needs sage.graphs
....:     for c in d.strongly_connected_components_subgraphs())
True
```

```
>>> from sage.all import *
>>> d = Permutation([Integer(3), Integer(1), Integer(2)]).to_digraph()       ␣
↪                       # needs sage.graphs
>>> d.edges(sort=True, labels=False)                                         #␣
↪needs sage.graphs
[(1, 3), (2, 1), (3, 2)]
>>> P = Permutations(range(Integer(1), Integer(10)))
>>> d = Permutation(P.random_element()).to_digraph()                         #␣
↪needs sage.graphs
>>> all(c.is_cycle()                                                         #␣
↪needs sage.graphs
...     for c in d.strongly_connected_components_subgraphs())
True
```

to_inversion_vector()

Return the inversion vector of `self`.

The inversion vector of a permutation $p \in S_n$ is defined as the vector $(v_1, v_2, \ldots, v_n)$, where v_i is the number of elements larger than i that appear to the left of i in the permutation p.

The algorithm is of complexity $O(n \log(n))$ where n is the size of the given permutation.

EXAMPLES:

```
sage: Permutation([5,9,1,8,2,6,4,7,3]).to_inversion_vector()
[2, 3, 6, 4, 0, 2, 2, 1, 0]
sage: Permutation([8,7,2,1,9,4,6,5,10,3]).to_inversion_vector()
[3, 2, 7, 3, 4, 3, 1, 0, 0, 0]
sage: Permutation([3,2,4,1,5]).to_inversion_vector()
[3, 1, 0, 0, 0]
```

```
>>> from sage.all import *
>>> Permutation([Integer(5),Integer(9),Integer(1),Integer(8),Integer(2),
↪Integer(6),Integer(4),Integer(7),Integer(3)]).to_inversion_vector()
[2, 3, 6, 4, 0, 2, 2, 1, 0]
>>> Permutation([Integer(8),Integer(7),Integer(2),Integer(1),Integer(9),
↪Integer(4),Integer(6),Integer(5),Integer(10),Integer(3)]).to_inversion_
↪vector()
[3, 2, 7, 3, 4, 3, 1, 0, 0, 0]
>>> Permutation([Integer(3),Integer(2),Integer(4),Integer(1),Integer(5)]).to_
↪inversion_vector()
[3, 1, 0, 0, 0]
```

to_lehmer_cocode()

Return the Lehmer cocode of the permutation `self`.

The Lehmer cocode of a permutation p is defined as the list $(c_1, c_2, \ldots, c_n)$, where c_i is the number of $j < i$ such that $p(j) > p(i)$.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_cocode()
[0, 1, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_cocode()
[0, 1, 1]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> p.to_lehmer_cocode()
[0, 1, 0]
>>> q = Permutation([Integer(3),Integer(1),Integer(2)])
>>> q.to_lehmer_cocode()
[0, 1, 1]
```

to_lehmer_code()

Return the Lehmer code of the permutation `self`.

The Lehmer code of a permutation p is defined as the list $[c[1], c[2], ..., c[n]]$, where $c[i]$ is the number of $j > i$ such that $p(j) < p(i)$.

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_code()
[1, 0, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_code()
[2, 0, 0]

sage: Permutation([1]).to_lehmer_code()
[0]
sage: Permutation([]).to_lehmer_code()
[]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> p.to_lehmer_code()
[1, 0, 0]
>>> q = Permutation([Integer(3),Integer(1),Integer(2)])
>>> q.to_lehmer_code()
[2, 0, 0]

>>> Permutation([Integer(1)]).to_lehmer_code()
[0]
>>> Permutation([]).to_lehmer_code()
[]
```

to_major_code(*final_descent=False*)

Return the major code of the permutation `self`.

The major code of a permutation p is defined as the sequence $(m_1 - m_2, m_2 - m_3, \ldots, m_n)$, where m_i is the major index of the permutation obtained by erasing all letters smaller than i from p.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent. This has an effect on the computation of major indices.

↪Integer(1),Integer(4),Integer(6),Integer(8)]).to_major_code()
[5, 0, 1, 0, 1, 2, 0, 1, 0]
>>> Permutation([Integer(2),Integer(8),Integer(4),Integer(3),Integer(6),
↪Integer(7),Integer(9),Integer(5),Integer(1)]).to_major_code()
[8, 3, 3, 1, 4, 0, 1, 0, 0]
```

to_matrix()

Return a matrix representing the permutation.

EXAMPLES:

```
sage: Permutation([1,2,3]).to_matrix()                                  #␣
↪needs sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).to_matrix()
↪                        # needs sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
```

Alternatively:

```
sage: matrix(Permutation([1,3,2]))
↪needs sage.modules
[1 0 0]
[0 0 1]
[0 1 0]
```

```
>>> from sage.all import *
>>> matrix(Permutation([Integer(1),Integer(3),Integer(2)]))
↪                        # needs sage.modules
[1 0 0]
[0 0 1]
[0 1 0]
```

Notice that matrix multiplication corresponds to permutation multiplication only when the permutation option mult='r2l'

```
sage: Permutations.options.mult='r2l'
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: (p*q).to_matrix()
↪needs sage.modules
[0 0 1]
[0 1 0]
[1 0 0]
sage: p.to_matrix()*q.to_matrix()
↪needs sage.modules
[0 0 1]
[0 1 0]
[1 0 0]
sage: Permutations.options.mult='l2r'
sage: (p*q).to_matrix()
↪needs sage.modules
[1 0 0]
[0 0 1]
[0 1 0]
```

```
>>> from sage.all import *
>>> Permutations.options.mult='r2l'
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> q = Permutation([Integer(3),Integer(1),Integer(2)])
>>> (p*q).to_matrix()
↪needs sage.modules
[0 0 1]
[0 1 0]
```

(continues on next page)

(continued from previous page)

```
[1 0 0]
>>> p.to_matrix()*q.to_matrix()                                    #␣
↪needs sage.modules
[0 0 1]
[0 1 0]
[1 0 0]
>>> Permutations.options.mult='l2r'
>>> (p*q).to_matrix()                                              #␣
↪needs sage.modules
[1 0 0]
[0 0 1]
[0 1 0]
```

to_permutation_group_element()

Return a PermutationGroupElement equal to `self`.

EXAMPLES:

```
sage: Permutation([2,1,4,3]).to_permutation_group_element()         #␣
↪needs sage.groups
(1,2)(3,4)
sage: Permutation([1,2,3]).to_permutation_group_element()           #␣
↪needs sage.groups
()
```

```
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(4),Integer(3)]).to_permutation_
↪group_element()                  # needs sage.groups
(1,2)(3,4)
>>> Permutation([Integer(1),Integer(2),Integer(3)]).to_permutation_group_
↪element()                      # needs sage.groups
()
```

to_tableau_by_shape(*shape*)

Return a tableau of shape `shape` with the entries in `self`.

The tableau is such that the reading word (i. e., the word obtained by reading the tableau row by row, starting from the top row in English notation, with each row being read from left to right) is `self`.

EXAMPLES:

```
sage: T = Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2]); T    #␣
↪needs sage.combinat
[[1, 2, 5], [3, 4]]
sage: T.reading_word_permutation()                                  #␣
↪needs sage.combinat
[3, 4, 1, 2, 5]
```

```
>>> from sage.all import *
>>> T = Permutation([Integer(3),Integer(4),Integer(1),Integer(2),Integer(5)]).
↪to_tableau_by_shape([Integer(3),Integer(2)]); T            # needs sage.
↪combinat
[[1, 2, 5], [3, 4]]
```

(continues on next page)

(continued from previous page)

```
>>> T.reading_word_permutation()                                    #␣
↪needs sage.combinat
[3, 4, 1, 2, 5]
```

weak_excedences()

Return all the numbers `self[i]` such that `self[i] >= i+1`.

EXAMPLES:

```
sage: Permutation([1,4,3,2,5]).weak_excedences()
[1, 4, 3, 5]
```

```
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2),Integer(5)]).
↪weak_excedences()
[1, 4, 3, 5]
```

class sage.combinat.permutation.**Permutations**

Bases: `UniqueRepresentation`, `Parent`

Permutations.

`Permutations(n)` returns the class of permutations of `n`, if `n` is an integer, list, set, or string.

`Permutations(n, k)` returns the class of length-`k` partial permutations of `n` (where `n` is any of the above things); `k` must be a nonnegative integer. A length-k partial permutation of n is defined as a k-tuple of pairwise distinct elements of $\{1, 2, \ldots, n\}$.

Valid keyword arguments are: 'descents', 'bruhat_smaller', 'bruhat_greater', 'recoils_finer', 'recoils_fatter', 'recoils', and 'avoiding'. With the exception of 'avoiding', you cannot specify `n` or `k` along with a keyword.

`Permutations(descents=(list,n))` returns the class of permutations of n with descents in the positions specified by `list`. This uses the slightly nonstandard convention that the images of $1, 2, ..., n$ under the permutation are regarded as positions $0, 1, ..., n-1$, so for example the presence of 1 in `list` signifies that the permutations π should satisfy $\pi(2) > \pi(3)$. Note that `list` is supposed to be a list of positions of the descents, not the descents composition. It does *not* return the class of permutations with descents composition `list`.

`Permutations(bruhat_smaller=p)` and `Permutations(bruhat_greater=p)` return the class of permutations smaller-or-equal or greater-or-equal, respectively, than the given permutation `p` in the Bruhat order. (The Bruhat order is defined in *bruhat_lequal()*. It is also referred to as the *strong* Bruhat order.)

`Permutations(recoils=p)` returns the class of permutations whose recoils composition is `p`. Unlike the `descents=(list, n)` syntax, this actually takes a *composition* as input.

`Permutations(recoils_fatter=p)` and `Permutations(recoils_finer=p)` return the class of permutations whose recoils composition is fatter or finer, respectively, than the given composition `p`.

`Permutations(n, avoiding=P)` returns the class of permutations of `n` avoiding `P`. Here `P` may be a single permutation or a list of permutations; the returned class will avoid all patterns in `P`.

EXAMPLES:

```
sage: p = Permutations(3); p
Standard permutations of 3
sage: p.list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```
>>> from sage.all import *
>>> p = Permutations(Integer(3)); p
Standard permutations of 3
>>> p.list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```
sage: p = Permutations(3, 2); p
Permutations of {1,...,3} of length 2
sage: p.list()
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
>>> from sage.all import *
>>> p = Permutations(Integer(3), Integer(2)); p
Permutations of {1,...,3} of length 2
>>> p.list()
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
sage: p = Permutations(['c', 'a', 't']); p
Permutations of the set ['c', 'a', 't']
sage: p.list()
[['c', 'a', 't'],
 ['c', 't', 'a'],
 ['a', 'c', 't'],
 ['a', 't', 'c'],
 ['t', 'c', 'a'],
 ['t', 'a', 'c']]
```

```
>>> from sage.all import *
>>> p = Permutations(['c', 'a', 't']); p
Permutations of the set ['c', 'a', 't']
>>> p.list()
[['c', 'a', 't'],
 ['c', 't', 'a'],
 ['a', 'c', 't'],
 ['a', 't', 'c'],
 ['t', 'c', 'a'],
 ['t', 'a', 'c']]
```

```
sage: p = Permutations(['c', 'a', 't'], 2); p
Permutations of the set ['c', 'a', 't'] of length 2
sage: p.list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]
```

```
>>> from sage.all import *
>>> p = Permutations(['c', 'a', 't'], Integer(2)); p
Permutations of the set ['c', 'a', 't'] of length 2
>>> p.list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]
```

```
sage: p = Permutations([1,1,2]); p
Permutations of the multi-set [1, 1, 2]
```

Element

alias of *Permutation*

options = Current options for Permutations - display: list - generator_name: s - latex: list - latex_empty_str: 1 - mult: l2r

class sage.combinat.permutation.**PermutationsNK**(*s*, *k*)

Bases: *Permutations_setk*

This exists solely for unpickling `PermutationsNK` objects created with Sage <= 6.3.

class sage.combinat.permutation.**Permutations_mset**(*mset*)

Bases: *Permutations*

Permutations of a multiset M.

A permutation of a multiset M is represented by a list that contains exactly the same elements as M (with the same multiplicities), but possibly in different order. If M is a proper set there are $|M|!$ such permutations. Otherwise, if the first element appears k_1 times, the second element appears k_2 times and so on, the number of permutations is $|M|!/(k_1!k_2!\ldots)$, which is sometimes called a multinomial coefficient.

EXAMPLES:

```
sage: mset = [1,1,2,2,2]
sage: from sage.combinat.permutation import Permutations_mset
sage: P = Permutations_mset(mset); P
Permutations of the multi-set [1, 1, 2, 2, 2]
sage: sorted(P)
[[1, 1, 2, 2, 2],
 [1, 2, 1, 2, 2],
 [1, 2, 2, 1, 2],
 [1, 2, 2, 2, 1],
 [2, 1, 1, 2, 2],
 [2, 1, 2, 1, 2],
 [2, 1, 2, 2, 1],
 [2, 2, 1, 1, 2],
 [2, 2, 1, 2, 1],
 [2, 2, 2, 1, 1]]

sage: # needs sage.modules
sage: MS = MatrixSpace(GF(2), 2, 2)
sage: A = MS([1,0,1,1])
sage: rows = A.rows()
sage: rows[0].set_immutable()
sage: rows[1].set_immutable()
sage: P = Permutations_mset(rows); P
Permutations of the multi-set [(1, 0), (1, 1)]
```

(continues on next page)

(continued from previous page)

```
sage: sorted(P)
[[(1, 0), (1, 1)], [(1, 1), (1, 0)]]
```

```
>>> from sage.all import *
>>> mset = [Integer(1),Integer(1),Integer(2),Integer(2),Integer(2)]
>>> from sage.combinat.permutation import Permutations_mset
>>> P = Permutations_mset(mset); P
Permutations of the multi-set [1, 1, 2, 2, 2]
>>> sorted(P)
[[1, 1, 2, 2, 2],
 [1, 2, 1, 2, 2],
 [1, 2, 2, 1, 2],
 [1, 2, 2, 2, 1],
 [2, 1, 1, 2, 2],
 [2, 1, 2, 1, 2],
 [2, 1, 2, 2, 1],
 [2, 2, 1, 1, 2],
 [2, 2, 1, 2, 1],
 [2, 2, 2, 1, 1]]

>>> # needs sage.modules

>>> A = MS([Integer(1),Integer(0),Integer(1),Integer(1)])
>>> rows = A.rows()
>>> rows[Integer(0)].set_immutable()
>>> rows[Integer(1)].set_immutable()
>>> P = Permutations_mset(rows); P
Permutations of the multi-set [(1, 0), (1, 1)]
>>> sorted(P)
[[(1, 0), (1, 1)], [(1, 1), (1, 0)]]
```

class Element

Bases: `ClonableArray`

A permutation of an arbitrary multiset.

check()

Verify that `self` is a valid permutation of the underlying multiset.

EXAMPLES:

```
sage: S = Permutations(['c','a','c'])
sage: elt = S(['c','c','a'])
sage: elt.check()
```

```
>>> from sage.all import *
>>> S = Permutations(['c','a','c'])
>>> elt = S(['c','c','a'])
>>> elt.check()
```

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations([1,2,2]).cardinality()
3
sage: Permutations([1,1,2,2,2]).cardinality()
10
```

```
>>> from sage.all import *
>>> Permutations([Integer(1),Integer(2),Integer(2)]).cardinality()
3
>>> Permutations([Integer(1),Integer(1),Integer(2),Integer(2),Integer(2)]).
↪cardinality()
10
```

rank(*p*)

Return the rank of `p` in lexicographic order.

INPUT:

- `p` – a permutation of M

ALGORITHM:

The algorithm uses the recurrence from the solution to exercise 4 in [Knu2011], Section 7.2.1.2:

$$\operatorname{rank}(p_1 \dots p_n) = \operatorname{rank}(p_2 \dots p_n) + \frac{1}{n}\binom{n}{n_1, \dots, n_t} \sum_{j=1}^{t} n_j \left[x_j < p_1\right],$$

where x_j, n_j are the distinct elements of p with their multiplicities, n is the sum of $n_1, \dots, n_t$, $\binom{n}{n_1,\dots,n_t}$ is the multinomial coefficient $\frac{n!}{n_1!\dots n_t!}$, and $\sum_{j=1}^{t} n_j \left[x_j < p_1\right]$ means "the number of elements to the right of the first element that are less than the first element".

EXAMPLES:

```
sage: mset = [1, 1, 2, 3, 4, 5, 5, 6, 9]
sage: p = Permutations(mset)
sage: p.rank(list(sorted(mset)))
0
sage: p.rank(list(reversed(sorted(mset)))) == p.cardinality() - 1
True
sage: p.rank([3, 1, 4, 1, 5, 9, 2, 6, 5])
30991
```

```
>>> from sage.all import *
>>> mset = [Integer(1), Integer(1), Integer(2), Integer(3), Integer(4),␣
↪Integer(5), Integer(5), Integer(6), Integer(9)]
>>> p = Permutations(mset)
>>> p.rank(list(sorted(mset)))
0
>>> p.rank(list(reversed(sorted(mset)))) == p.cardinality() - Integer(1)
True
>>> p.rank([Integer(3), Integer(1), Integer(4), Integer(1), Integer(5),␣
↪Integer(9), Integer(2), Integer(6), Integer(5)])
30991
```

unrank(*r*)

Return the permutation of M having lexicographic rank `r`.

INPUT:

- `r` – integer between `0` and `self.cardinality()-1` inclusive

ALGORITHM:

The algorithm is adapted from the solution to exercise 4 in [Knu2011], Section 7.2.1.2.

EXAMPLES:

```
sage: mset = [1, 1, 2, 3, 4, 5, 5, 6, 9]
sage: p = Permutations(mset)
sage: p.unrank(30991)
[3, 1, 4, 1, 5, 9, 2, 6, 5]
sage: p.rank(p.unrank(10))
10
sage: p.unrank(0) == p(sorted(mset))
True
sage: p.unrank(p.cardinality()-1) == p(reversed(sorted(mset)))
True
```

```
>>> from sage.all import *
>>> mset = [Integer(1), Integer(1), Integer(2), Integer(3), Integer(4),␣
↪Integer(5), Integer(5), Integer(6), Integer(9)]
>>> p = Permutations(mset)
>>> p.unrank(Integer(30991))
[3, 1, 4, 1, 5, 9, 2, 6, 5]
>>> p.rank(p.unrank(Integer(10)))
10
>>> p.unrank(Integer(0)) == p(sorted(mset))
True
>>> p.unrank(p.cardinality()-Integer(1)) == p(reversed(sorted(mset)))
True
```

class sage.combinat.permutation.**Permutations_msetk**(*mset*, *k*)

Bases: *Permutations_mset*

Length-k partial permutations of a multiset.

A length-k partial permutation of a multiset M is represented by a list of length k whose entries are elements of M, appearing in the list with a multiplicity not higher than their respective multiplicity in M.

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations([1,2,2], 2).cardinality()                                #␣
↪needs sage.libs.gap
3
```

```
>>> from sage.all import *
>>> Permutations([Integer(1),Integer(2),Integer(2)], Integer(2)).
↪cardinality()                                  # needs sage.libs.gap
3
```

rank(*x*)

The rank of an element of `self`.

EXAMPLES:

```
sage: P = Permutations([1,1,1,2,3], 3)
sage: P.rank(P([1,1,1]))
0
```

```
>>> from sage.all import *
>>> P = Permutations([Integer(1),Integer(1),Integer(1),Integer(2),Integer(3)],
↪ Integer(3))
>>> P.rank(P([Integer(1),Integer(1),Integer(1)]))
0
```

unrank(*r*)

The element of `self` with rank `r`.

EXAMPLES:

```
sage: P = Permutations([1,1,1,2,3], 3)
sage: P.unrank(P.rank(P([1,1,2])))
[1, 1, 2]
```

```
>>> from sage.all import *
>>> P = Permutations([Integer(1),Integer(1),Integer(1),Integer(2),Integer(3)],
↪ Integer(3))
>>> P.unrank(P.rank(P([Integer(1),Integer(1),Integer(2)])))
[1, 1, 2]
```

class sage.combinat.permutation.**Permutations_nk**(*n*, *k*)

Bases: *Permutations*

Length-k partial permutations of $\{1, 2, \ldots, n\}$.

class Element

Bases: ClonableArray

A length-k partial permutation of $[n]$.

check()

Verify that `self` is a valid length-k partial permutation of $[n]$.

EXAMPLES:

```
sage: S = Permutations(4, 2)
sage: elt = S([3, 1])
sage: elt.check()
```

```
>>> from sage.all import *
>>> S = Permutations(Integer(4), Integer(2))
>>> elt = S([Integer(3), Integer(1)])
>>> elt.check()
```

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations(3,0).cardinality()
1
sage: Permutations(3,1).cardinality()
3
sage: Permutations(3,2).cardinality()
6
sage: Permutations(3,3).cardinality()
6
sage: Permutations(3,4).cardinality()
0
```

```
>>> from sage.all import *
>>> Permutations(Integer(3),Integer(0)).cardinality()
1
>>> Permutations(Integer(3),Integer(1)).cardinality()
3
>>> Permutations(Integer(3),Integer(2)).cardinality()
6
>>> Permutations(Integer(3),Integer(3)).cardinality()
6
>>> Permutations(Integer(3),Integer(4)).cardinality()
0
```

random_element()

EXAMPLES:

```
sage: s = Permutations(3, 2).random_element()
sage: s in Permutations(3, 2)
True
```

```
>>> from sage.all import *
>>> s = Permutations(Integer(3), Integer(2)).random_element()
>>> s in Permutations(Integer(3), Integer(2))
True
```

class sage.combinat.permutation.**Permutations_set**(*s*)

Bases: *Permutations*

Permutations of an arbitrary given finite set.

Here, a "permutation of a finite set S" means a list of the elements of S in which every element of S occurs exactly once. This is not to be confused with bijections from S to S, which are also often called permutations in literature.

class Element

Bases: ClonableArray

A permutation of an arbitrary set.

check()

Verify that `self` is a valid permutation of the underlying set.

EXAMPLES:

```
sage: S = Permutations(['c','a','t'])
sage: elt = S(['t','c','a'])
sage: elt.check()
```

```
>>> from sage.all import *
>>> S = Permutations(['c','a','t'])
>>> elt = S(['t','c','a'])
>>> elt.check()
```

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations([1,2,3]).cardinality()
6
```

```
>>> from sage.all import *
>>> Permutations([Integer(1),Integer(2),Integer(3)]).cardinality()
6
```

random_element()

EXAMPLES:

```
sage: s = Permutations([1,2,3]).random_element()
sage: s.parent() is Permutations([1,2,3])
True
```

```
>>> from sage.all import *
>>> s = Permutations([Integer(1),Integer(2),Integer(3)]).random_element()
>>> s.parent() is Permutations([Integer(1),Integer(2),Integer(3)])
True
```

class sage.combinat.permutation.**Permutations_setk**(s, k)

Bases: *Permutations_set*

Length-k partial permutations of an arbitrary given finite set.

Here, a "length-k partial permutation of a finite set S" means a list of length k whose entries are pairwise distinct and all belong to S.

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations([1,2,4,5], 2).cardinality()
12
```

```
>>> from sage.all import *
>>> Permutations([Integer(1),Integer(2),Integer(4),Integer(5)], Integer(2)).
↪cardinality()
12
```

random_element()

EXAMPLES:

```
sage: s = Permutations([1,2,4], 2).random_element()
sage: s in Permutations([1,2,4], 2)
True
```

```
>>> from sage.all import *
>>> s = Permutations([Integer(1),Integer(2),Integer(4)], Integer(2)).random_
↪element()
>>> s in Permutations([Integer(1),Integer(2),Integer(4)], Integer(2))
True
```

class sage.combinat.permutation.**StandardPermutations_all**

Bases: *Permutations*

All standard permutations.

graded_component(n)

Return the graded component.

EXAMPLES:

```
sage: P = Permutations()
sage: P.graded_component(4) == Permutations(4)
True
```

```
>>> from sage.all import *
>>> P = Permutations()
>>> P.graded_component(Integer(4)) == Permutations(Integer(4))
True
```

class sage.combinat.permutation.**StandardPermutations_all_avoiding**(a)

Bases: *StandardPermutations_all*

All standard permutations avoiding a set of patterns.

patterns()

Return the patterns avoided by this class of permutations.

EXAMPLES:

```
sage: P = Permutations(avoiding=[[2,1,3],[1,2,3]])
sage: P.patterns()
([2, 1, 3], [1, 2, 3])
```

```
>>> from sage.all import *
>>> P = Permutations(avoiding=[[Integer(2),Integer(1),Integer(3)],[Integer(1),
↪Integer(2),Integer(3)]])
```

(continues on next page)

(continued from previous page)

```
>>> P.patterns()
([2, 1, 3], [1, 2, 3])
```

class sage.combinat.permutation.**StandardPermutations_avoiding_12**(*n*)

Bases: *StandardPermutations_avoiding_generic*

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Permutations(3, avoiding=[1, 2])
sage: P.cardinality()
1
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(3), avoiding=[Integer(1), Integer(2)])
>>> P.cardinality()
1
```

class sage.combinat.permutation.**StandardPermutations_avoiding_123**(*n*)

Bases: *StandardPermutations_avoiding_generic*

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations(5, avoiding=[1, 2, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 2, 3]).list() )
42
```

```
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(1), Integer(2), Integer(3)]).
↪cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(1), Integer(2),␣
↪Integer(3)]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_132**(*n*)

Bases: *StandardPermutations_avoiding_generic*

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations(5, avoiding=[1, 3, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 3, 2]).list() )
42
```

```
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(1), Integer(3), Integer(2)]).
↪cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(1), Integer(3),␣
↪Integer(2)]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_21**(*n*)

Bases: *StandardPermutations_avoiding_generic*

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Permutations(3, avoiding=[2, 1])
sage: P.cardinality()
1
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(3), avoiding=[Integer(2), Integer(1)])
>>> P.cardinality()
1
```

class sage.combinat.permutation.**StandardPermutations_avoiding_213**(*n*)

Bases: *StandardPermutations_avoiding_generic*

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations(5, avoiding=[2, 1, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 1, 3]).list() )
42
```

```
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(2), Integer(1), Integer(3)]).
↪cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(2), Integer(1),␣
↪Integer(3)]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_231**(*n*)

Bases: *StandardPermutations_avoiding_generic*

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations(5, avoiding=[2, 3, 1]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 3, 1]).list() )
42
```

```
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(2), Integer(3), Integer(1)]).
↪cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(2), Integer(3),␣
↪Integer(1)]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_312**(*n*)

Bases: *StandardPermutations_avoiding_generic*

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations(5, avoiding=[3, 1, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[3, 1, 2]).list() )
42
```

```
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(3), Integer(1), Integer(2)]).
↪cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(3), Integer(1),␣
↪Integer(2)]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_321**(*n*)

Bases: *StandardPermutations_avoiding_generic*

cardinality()

Return the cardinality of the set.

EXAMPLES:

```
sage: Permutations(5, avoiding=[3, 2, 1]).cardinality()
42
sage: len( Permutations(5, avoiding=[3, 2, 1]).list() )
42
```

```
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(3), Integer(2), Integer(1)]).
↪cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(3), Integer(2),␣
↪Integer(1)]).list() )
42
```

class sage.combinat.permutation.**StandardPermutations_avoiding_generic**(n, a)

Bases: *StandardPermutations_n_abstract*

Generic class for subset of permutations avoiding a set of patterns.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: P = Permutations(3, avoiding=[[2, 1, 3],[1,2,3]])
sage: P.cardinality()                                                    #␣
↪needs sage.combinat
4
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(3), avoiding=[[Integer(2), Integer(1),␣
↪Integer(3)],[Integer(1),Integer(2),Integer(3)]])
>>> P.cardinality()                                                      #␣
↪needs sage.combinat
4
```

patterns()

Return the patterns avoided by this class of permutations.

EXAMPLES:

```
sage: P = Permutations(3, avoiding=[[2,1,3],[1,2,3]])
sage: P.patterns()
([2, 1, 3], [1, 2, 3])
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(3), avoiding=[[Integer(2),Integer(1),Integer(3)],
↪[Integer(1),Integer(2),Integer(3)]])
>>> P.patterns()
([2, 1, 3], [1, 2, 3])
```

class sage.combinat.permutation.**StandardPermutations_bruhat_greater**(p)

Bases: *Permutations*

Permutations of $\{1, \ldots, n\}$ that are greater than or equal to a permutation p in the Bruhat order.

class sage.combinat.permutation.**StandardPermutations_bruhat_smaller**(p)

Bases: *Permutations*

Permutations of $\{1, \ldots, n\}$ that are less than or equal to a permutation p in the Bruhat order.

class sage.combinat.permutation.**StandardPermutations_descents**(d, n)

Bases: *StandardPermutations_n_abstract*

Permutations of $\{1, \ldots, n\}$ with a fixed set of descents.

cardinality()

Return the cardinality of `self`.

ALGORITHM:

The algorithm described in [Vie1979] is implemented naively.

EXAMPLES:

```
sage: P = Permutations(descents=([1,0,2], 5))
sage: P.cardinality()
4
```

```
>>> from sage.all import *
>>> P = Permutations(descents=([Integer(1),Integer(0),Integer(2)],␣
↪Integer(5)))
>>> P.cardinality()
4
```

first()

Return the first permutation with descents d.

EXAMPLES:

```
sage: Permutations(descents=([1,0,4,8],12)).first()
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

```
>>> from sage.all import *
>>> Permutations(descents=([Integer(1),Integer(0),Integer(4),Integer(8)],
↪Integer(12))).first()
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

last()

Return the last permutation with descents d.

EXAMPLES:

```
sage: Permutations(descents=([1,0,4,8],12)).last()
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

```
>>> from sage.all import *
>>> Permutations(descents=([Integer(1),Integer(0),Integer(4),Integer(8)],
↪Integer(12))).last()
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

class sage.combinat.permutation.**StandardPermutations_n**(n)

Bases: *StandardPermutations_n_abstract*

Permutations of the set $\{1, 2, \ldots, n\}$.

These are also called permutations of size n, or the elements of the n-th symmetric group.

Todo

Have a *reduced_word()* which works in both multiplication conventions.

class Element(*parent*, *l*, *algorithm='lex'*, *sjt=None*, *check=True*)

Bases: *Permutation*

apply_simple_reflection_left(*i*)

Return `self` multiplied by the simple reflection `s[i]` on the left.

This acts by switching the entries in positions i and $i+1$.

> **Warning**
>
> This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing *reduced_word()*).

EXAMPLES:

```
sage: W = Permutations(3)
sage: w = W([2,3,1])
sage: w.apply_simple_reflection_left(1)
[1, 3, 2]
sage: w.apply_simple_reflection_left(2)
[3, 2, 1]
```

```
>>> from sage.all import *
>>> W = Permutations(Integer(3))
>>> w = W([Integer(2),Integer(3),Integer(1)])
>>> w.apply_simple_reflection_left(Integer(1))
[1, 3, 2]
>>> w.apply_simple_reflection_left(Integer(2))
[3, 2, 1]
```

apply_simple_reflection_right(*i*)

Return `self` multiplied by the simple reflection `s[i]` on the right.

This acts by switching the entries i and $i+1$.

> **Warning**
>
> This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing *reduced_word()*).

EXAMPLES:

```
sage: W = Permutations(3)
sage: w = W([2,3,1])
sage: w.apply_simple_reflection_right(1)
[3, 2, 1]
sage: w.apply_simple_reflection_right(2)
[2, 1, 3]
```

```
>>> from sage.all import *
>>> W = Permutations(Integer(3))
>>> w = W([Integer(2),Integer(3),Integer(1)])
>>> w.apply_simple_reflection_right(Integer(1))
[3, 2, 1]
```

(continues on next page)

(continued from previous page)

```
>>> w.apply_simple_reflection_right(Integer(2))
[2, 1, 3]
```

has_left_descent(*i*)

Check if `i` is a left descent of `self`.

A *left descent* of a permutation $\pi \in S_n$ means an index $i \in \{1, 2, \ldots, n-1\}$ such that $s_i \circ \pi$ has smaller length than π. Thus, a left descent of π is an index $i \in \{1, 2, \ldots, n-1\}$ satisfying $\pi^{-1}(i) > \pi^{-1}(i+1)$.

Warning

The methods *descents()* and *sage.combinat.permutation.Permutation.idescents()* behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

Warning

This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing *reduced_word()*).

EXAMPLES:

```
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: (~x).descents()
[1, 2]
sage: [i for i in P.index_set() if x.has_left_descent(i)]
[1, 2]
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> x = P([Integer(3), Integer(2), Integer(4), Integer(1)])
>>> (~x).descents()
[1, 2]
>>> [i for i in P.index_set() if x.has_left_descent(i)]
[1, 2]
```

has_right_descent(*i*, *mult=None*)

Check if `i` is a right descent of `self`.

A *right descent* of a permutation $\pi \in S_n$ means an index $i \in \{1, 2, \ldots, n-1\}$ such that $\pi \circ s_i$ has smaller length than π. Thus, a right descent of π is an index $i \in \{1, 2, \ldots, n-1\}$ satisfying $\pi(i) > \pi(i+1)$.

Warning

The methods *descents()* and *sage.combinat.permutation.Permutation.idescents()* behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

> **Warning**
>
> This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing *reduced_word()*).

EXAMPLES:

```
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: x.descents()
[1, 3]
sage: [i for i in P.index_set() if x.has_right_descent(i)]
[1, 3]
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> x = P([Integer(3), Integer(2), Integer(4), Integer(1)])
>>> x.descents()
[1, 3]
>>> [i for i in P.index_set() if x.has_right_descent(i)]
[1, 3]
```

inverse()

Return the inverse of `self`.

EXAMPLES:

```
sage: P = Permutations(4)
sage: w0 = P([4,3,2,1])
sage: w0.inverse() == w0
True
sage: w0.inverse().parent() is P
True
sage: P([3,2,4,1]).inverse()
[4, 2, 1, 3]
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> w0 = P([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> w0.inverse() == w0
True
>>> w0.inverse().parent() is P
True
>>> P([Integer(3),Integer(2),Integer(4),Integer(1)]).inverse()
[4, 2, 1, 3]
```

algebra(*base_ring*, *category=None*)

Return the symmetric group algebra associated to `self`.

INPUT:

- `base_ring` – a ring
- `category` – a category (default: the category of `self`)

EXAMPLES:

```
sage: # needs sage.groups sage.modules
sage: P = Permutations(4)
sage: A = P.algebra(QQ); A
Symmetric group algebra of order 4 over Rational Field
sage: A.category()
Join of Category of Coxeter group algebras over Rational Field
    and Category of finite group algebras over Rational Field
    and Category of finite dimensional cellular algebras
        with basis over Rational Field
sage: A = P.algebra(QQ, category=Monoids())
sage: A.category()
Category of finite dimensional cellular monoid algebras over Rational Field
```

```
>>> from sage.all import *
>>> # needs sage.groups sage.modules
>>> P = Permutations(Integer(4))
>>> A = P.algebra(QQ); A
Symmetric group algebra of order 4 over Rational Field
>>> A.category()
Join of Category of Coxeter group algebras over Rational Field
    and Category of finite group algebras over Rational Field
    and Category of finite dimensional cellular algebras
        with basis over Rational Field
>>> A = P.algebra(QQ, category=Monoids())
>>> A.category()
Category of finite dimensional cellular monoid algebras over Rational Field
```

as_permutation_group()

Return `self` as a permutation group.

EXAMPLES:

```
sage: P = Permutations(4)
sage: PG = P.as_permutation_group(); PG                                     #␣
↪needs sage.groups
Symmetric group of order 4! as a permutation group

sage: G = SymmetricGroup(4)                                                 #␣
↪needs sage.groups
sage: PG is G                                                               #␣
↪needs sage.groups
True
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> PG = P.as_permutation_group(); PG                                       #␣
↪needs sage.groups
Symmetric group of order 4! as a permutation group

>>> G = SymmetricGroup(Integer(4))                                          ␣
↪     # needs sage.groups
```

(continues on next page)

(continued from previous page)

```
>>> PG is G                                                                    #␣
↪needs sage.groups
True
```

cardinality()

Return the number of permutations of size n, which is $n!$.

EXAMPLES:

```
sage: Permutations(0).cardinality()
1
sage: Permutations(3).cardinality()
6
sage: Permutations(4).cardinality()
24
```

```
>>> from sage.all import *
>>> Permutations(Integer(0)).cardinality()
1
>>> Permutations(Integer(3)).cardinality()
6
>>> Permutations(Integer(4)).cardinality()
24
```

cartan_type()

Return the Cartan type of `self`.

The symmetric group S_n is a Coxeter group of type A_{n-1}.

EXAMPLES:

```
sage: A = SymmetricGroup([2,3,7]); A.cartan_type()                            #␣
↪needs sage.combinat sage.groups
['A', 2]
sage: A = SymmetricGroup([]); A.cartan_type()                                 #␣
↪needs sage.combinat sage.groups
['A', 0]
```

```
>>> from sage.all import *
>>> A = SymmetricGroup([Integer(2),Integer(3),Integer(7)]); A.cartan_type()  ␣
↪                        # needs sage.combinat sage.groups
['A', 2]
>>> A = SymmetricGroup([]); A.cartan_type()                                   #␣
↪needs sage.combinat sage.groups
['A', 0]
```

codegrees()

Return the codegrees of `self`.

EXAMPLES:

```
sage: Permutations(3).codegrees()
(0, 1)
```

(continues on next page)

(continued from previous page)

```
sage: Permutations(7).codegrees()
(0, 1, 2, 3, 4, 5)
```

```
>>> from sage.all import *
>>> Permutations(Integer(3)).codegrees()
(0, 1)
>>> Permutations(Integer(7)).codegrees()
(0, 1, 2, 3, 4, 5)
```

conjugacy_class(*g*)

Return the conjugacy class of `g` in `self`.

INPUT:

- `g` – a partition or an element of `self`

EXAMPLES:

```
sage: G = Permutations(5)
sage: g = G([2,3,4,1,5])
sage: G.conjugacy_class(g)                                                  #␣
↪needs sage.combinat sage.graphs sage.groups
Conjugacy class of cycle type [4, 1] in Standard permutations of 5
sage: G.conjugacy_class(Partition([2, 1, 1, 1]))                            #␣
↪needs sage.combinat sage.graphs sage.groups
Conjugacy class of cycle type [2, 1, 1, 1] in Standard permutations of 5
```

```
>>> from sage.all import *
>>> G = Permutations(Integer(5))
>>> g = G([Integer(2),Integer(3),Integer(4),Integer(1),Integer(5)])
>>> G.conjugacy_class(g)                                                    #␣
↪needs sage.combinat sage.graphs sage.groups
Conjugacy class of cycle type [4, 1] in Standard permutations of 5
>>> G.conjugacy_class(Partition([Integer(2), Integer(1), Integer(1),␣
↪Integer(1)]))                              # needs sage.combinat sage.graphs␣
↪sage.groups
Conjugacy class of cycle type [2, 1, 1, 1] in Standard permutations of 5
```

conjugacy_classes()

Return a list of the conjugacy classes of `self`.

EXAMPLES:

```
sage: G = Permutations(4)
sage: G.conjugacy_classes()                                                 #␣
↪needs sage.combinat sage.graphs sage.groups
[Conjugacy class of cycle type [1, 1, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 2] in Standard permutations of 4,
 Conjugacy class of cycle type [3, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [4] in Standard permutations of 4]
```

```
>>> from sage.all import *
>>> G = Permutations(Integer(4))
>>> G.conjugacy_classes()                                                    #␣
↪needs sage.combinat sage.graphs sage.groups
[Conjugacy class of cycle type [1, 1, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 2] in Standard permutations of 4,
 Conjugacy class of cycle type [3, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [4] in Standard permutations of 4]
```

conjugacy_classes_iterator()

Iterate over the conjugacy classes of `self`.

EXAMPLES:

```
sage: G = Permutations(4)
sage: list(G.conjugacy_classes_iterator()) == G.conjugacy_classes()       #␣
↪needs sage.combinat sage.graphs sage.groups
True
```

```
>>> from sage.all import *
>>> G = Permutations(Integer(4))
>>> list(G.conjugacy_classes_iterator()) == G.conjugacy_classes()         #␣
↪needs sage.combinat sage.graphs sage.groups
True
```

conjugacy_classes_representatives()

Return a complete list of representatives of conjugacy classes in `self`.

Let S_n be the symmetric group on n letters. The conjugacy classes are indexed by partitions λ of n. The ordering of the conjugacy classes is reverse lexicographic order of the partitions.

EXAMPLES:

```
sage: G = Permutations(5)
sage: G.conjugacy_classes_representatives()                               #␣
↪needs sage.combinat sage.libs.flint
[[1, 2, 3, 4, 5],
 [2, 1, 3, 4, 5],
 [2, 1, 4, 3, 5],
 [2, 3, 1, 4, 5],
 [2, 3, 1, 5, 4],
 [2, 3, 4, 1, 5],
 [2, 3, 4, 5, 1]]
```

```
>>> from sage.all import *
>>> G = Permutations(Integer(5))
>>> G.conjugacy_classes_representatives()                                 #␣
↪needs sage.combinat sage.libs.flint
[[1, 2, 3, 4, 5],
 [2, 1, 3, 4, 5],
 [2, 1, 4, 3, 5],
 [2, 3, 1, 4, 5],
 [2, 3, 1, 5, 4],
```

(continues on next page)

(continued from previous page)

```
 [2, 3, 4, 1, 5],
 [2, 3, 4, 5, 1]]
```

degree()

Return the degree of `self`.

This is the cardinality n of the set `self` acts on.

EXAMPLES:

```
sage: Permutations(0).degree()
0
sage: Permutations(1).degree()
1
sage: Permutations(5).degree()
5
```

```
>>> from sage.all import *
>>> Permutations(Integer(0)).degree()
0
>>> Permutations(Integer(1)).degree()
1
>>> Permutations(Integer(5)).degree()
5
```

degrees()

Return the degrees of `self`.

These are the degrees of the fundamental invariants of the ring of polynomial invariants.

EXAMPLES:

```
sage: Permutations(3).degrees()
(2, 3)
sage: Permutations(7).degrees()
(2, 3, 4, 5, 6, 7)
```

```
>>> from sage.all import *
>>> Permutations(Integer(3)).degrees()
(2, 3)
>>> Permutations(Integer(7)).degrees()
(2, 3, 4, 5, 6, 7)
```

element_in_conjugacy_classes(*nu*)

Return a permutation with cycle type `nu`.

If the size of `nu` is smaller than the size of permutations in `self`, then some fixed points are added.

EXAMPLES:

```
sage: PP = Permutations(5)
sage: PP.element_in_conjugacy_classes([2,2])                    #␣
↪needs sage.combinat
[2, 1, 4, 3, 5]
```

(continues on next page)

(continued from previous page)

```
sage: PP.element_in_conjugacy_classes([5, 5])                                  #␣
↪needs sage.combinat
Traceback (most recent call last):
...
ValueError: the size of the partition (=10) should be at most the size of the␣
↪permutations (=5)
```

```
>>> from sage.all import *
>>> PP = Permutations(Integer(5))
>>> PP.element_in_conjugacy_classes([Integer(2),Integer(2)])                   ␣
↪              # needs sage.combinat
[2, 1, 4, 3, 5]
>>> PP.element_in_conjugacy_classes([Integer(5), Integer(5)])                  ␣
↪              # needs sage.combinat
Traceback (most recent call last):
...
ValueError: the size of the partition (=10) should be at most the size of the␣
↪permutations (=5)
```

gens()

Return a set of generators for `self` as a group.

EXAMPLES:

```
sage: P4 = Permutations(4)
sage: P4.gens()
([2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3])
```

```
>>> from sage.all import *
>>> P4 = Permutations(Integer(4))
>>> P4.gens()
([2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3])
```

identity()

Return the identity permutation of size n.

EXAMPLES:

```
sage: Permutations(4).identity()
[1, 2, 3, 4]
sage: Permutations(0).identity()
[]
```

```
>>> from sage.all import *
>>> Permutations(Integer(4)).identity()
[1, 2, 3, 4]
>>> Permutations(Integer(0)).identity()
[]
```

index_set()

Return the index set for the descents of the symmetric group `self`.

This is $\{1, 2, \ldots, n-1\}$, where `self` is S_n.

EXAMPLES:

```
sage: P = Permutations(8)
sage: P.index_set()
(1, 2, 3, 4, 5, 6, 7)
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(8))
>>> P.index_set()
(1, 2, 3, 4, 5, 6, 7)
```

one()

alias of *identity()*.

random_element()

EXAMPLES:

```
sage: s = Permutations(4).random_element(); s  # random
[1, 2, 4, 3]
sage: s in Permutations(4)
True
```

```
>>> from sage.all import *
>>> s = Permutations(Integer(4)).random_element(); s  # random
[1, 2, 4, 3]
>>> s in Permutations(Integer(4))
True
```

rank(*p=None*)

Return the rank of `self` or `p` depending on input.

If a permutation `p` is given, return the rank of `p` in `self`. Otherwise return the dimension of the underlying vector space spanned by the (simple) roots.

EXAMPLES:

```
sage: P = Permutations(5)
sage: P.rank()
4

sage: SP3 = Permutations(3)
sage: list(map(SP3.rank, SP3))
[0, 1, 2, 3, 4, 5]
sage: SP0 = Permutations(0)
sage: list(map(SP0.rank, SP0))
[0]
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(5))
>>> P.rank()
4

>>> SP3 = Permutations(Integer(3))
>>> list(map(SP3.rank, SP3))
```

(continues on next page)

(continued from previous page)

```
[0, 1, 2, 3, 4, 5]
>>> SP0 = Permutations(Integer(0))
>>> list(map(SP0.rank, SP0))
[0]
```

reflection(i)

Return the reflection indexed by `i` of `self`.

This returns the permutation with cycle $i = (a, b)$.

See also

- *reflection_index_set()*
- reflections()

EXAMPLES:

```
sage: P = Permutations(4)
sage: for i in P.reflection_index_set():
....:     print('%s %s'%(i, P.reflection(i)))
(1, 2) [2, 1, 3, 4]
(1, 3) [3, 2, 1, 4]
(1, 4) [4, 2, 3, 1]
(2, 3) [1, 3, 2, 4]
(2, 4) [1, 4, 3, 2]
(3, 4) [1, 2, 4, 3]
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> for i in P.reflection_index_set():
...     print('%s %s'%(i, P.reflection(i)))
(1, 2) [2, 1, 3, 4]
(1, 3) [3, 2, 1, 4]
(1, 4) [4, 2, 3, 1]
(2, 3) [1, 3, 2, 4]
(2, 4) [1, 4, 3, 2]
(3, 4) [1, 2, 4, 3]
```

reflection_index_set()

Return the index set of the reflections of `self`.

See also

- *reflection()*
- reflections()

EXAMPLES:

```
sage: P = Permutations(4)
sage: P.reflection_index_set()
((1, 2), (1, 3), (1, 4), (2, 3), (2, 4), (3, 4))
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> P.reflection_index_set()
((1, 2), (1, 3), (1, 4), (2, 3), (2, 4), (3, 4))
```

simple_reflection(*i*)

For i in the index set of `self` (that is, for i in $\{1, 2, \ldots, n-1\}$, where `self` is S_n), this returns the elementary transposition $s_i = (i, i+1)$.

EXAMPLES:

```
sage: P = Permutations(4)
sage: P.simple_reflection(2)
[1, 3, 2, 4]
sage: P.simple_reflections()
Finite family {1: [2, 1, 3, 4], 2: [1, 3, 2, 4], 3: [1, 2, 4, 3]}
```

```
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> P.simple_reflection(Integer(2))
[1, 3, 2, 4]
>>> P.simple_reflections()
Finite family {1: [2, 1, 3, 4], 2: [1, 3, 2, 4], 3: [1, 2, 4, 3]}
```

unrank(*r*)

EXAMPLES:

```
sage: SP3 = Permutations(3)
sage: l = list(map(SP3.unrank, range(6)))
sage: l == SP3.list()
True
sage: SP0 = Permutations(0)
sage: l = list(map(SP0.unrank, range(1)))
sage: l == SP0.list()
True
```

```
>>> from sage.all import *
>>> SP3 = Permutations(Integer(3))
>>> l = list(map(SP3.unrank, range(Integer(6))))
>>> l == SP3.list()
True
>>> SP0 = Permutations(Integer(0))
>>> l = list(map(SP0.unrank, range(Integer(1))))
>>> l == SP0.list()
True
```

class sage.combinat.permutation.**StandardPermutations_n_abstract**(*n*, *category=None*)

Bases: *Permutations*

Abstract base class for subsets of permutations of the set $\{1, 2, \ldots, n\}$.

Warning

Anything inheriting from this class should override the `__contains__` method.

class sage.combinat.permutation.**StandardPermutations_recoils**(*recoils*)

Bases: *Permutations*

Permutations of $\{1, \ldots, n\}$ with a fixed recoils composition.

class sage.combinat.permutation.**StandardPermutations_recoilsfatter**(*recoils*)

Bases: *Permutations*

class sage.combinat.permutation.**StandardPermutations_recoilsfiner**(*recoils*)

Bases: *Permutations*

sage.combinat.permutation.**bistochastic_as_sum_of_permutations**(*M*, *check=True*)

Return the positive sum of permutations corresponding to the bistochastic matrix `M`.

A stochastic matrix is a matrix with nonnegative real entries such that the sum of the elements of any row is equal to 1. A bistochastic matrix is a stochastic matrix whose transpose matrix is also stochastic (there are conditions both on the rows and on the columns).

According to the Birkhoff-von Neumann Theorem, any bistochastic matrix can be written as a convex combination of permutation matrices, which also means that the polytope of bistochastic matrices is integer.

As a non-bistochastic matrix can obviously not be written as a convex combination of permutations, this theorem is an equivalence.

This function, given a bistochastic matrix, returns the corresponding decomposition.

INPUT:

- `M` – a bistochastic matrix
- `check` – boolean; set to `True` (default) to check that the matrix is indeed bistochastic

OUTPUT:

- An element of `CombinatorialFreeModule`, which is a free F-module (where F is the ground ring of the given matrix) whose basis is indexed by the permutations.

Note

- In this function, we just assume 1 to be any constant : for us a matrix M is bistochastic if there exists $c > 0$ such that M/c is bistochastic.
- You can obtain a sequence of pairs `(permutation, coeff)`, where `permutation` is a Sage `Permutation` instance, and `coeff` its corresponding coefficient from the result of this function by applying the `list` function.
- If you are interested in the matrix corresponding to a `Permutation` you will be glad to learn about the `Permutation.to_matrix()` method.
- The base ring of the matrix can be anything that can be coerced to `RR`.

See also

- `as_sum_of_permutations()` to use this method through the `Matrix` class.

EXAMPLES:

We create a bistochastic matrix from a convex sum of permutations, then try to deduce the decomposition from the matrix:

```
sage: from sage.combinat.permutation import bistochastic_as_sum_of_permutations

sage: # needs networkx sage.graphs sage.modules
sage: L = []
sage: L.append((9,Permutation([4, 1, 3, 5, 2])))
sage: L.append((6,Permutation([5, 3, 4, 1, 2])))
sage: L.append((3,Permutation([3, 1, 4, 2, 5])))
sage: L.append((2,Permutation([1, 4, 2, 3, 5])))
sage: M = sum([c * p.to_matrix() for c, p in L])
sage: decomp = bistochastic_as_sum_of_permutations(M)
sage: print(decomp)
2*B[[1, 4, 2, 3, 5]] + 3*B[[3, 1, 4, 2, 5]]
 + 9*B[[4, 1, 3, 5, 2]] + 6*B[[5, 3, 4, 1, 2]]
```

```
>>> from sage.all import *
>>> from sage.combinat.permutation import bistochastic_as_sum_of_permutations

>>> # needs networkx sage.graphs sage.modules
>>> L = []
>>> L.append((Integer(9),Permutation([Integer(4), Integer(1), Integer(3),␣
↪Integer(5), Integer(2)])))
>>> L.append((Integer(6),Permutation([Integer(5), Integer(3), Integer(4),␣
↪Integer(1), Integer(2)])))
>>> L.append((Integer(3),Permutation([Integer(3), Integer(1), Integer(4),␣
↪Integer(2), Integer(5)])))
>>> L.append((Integer(2),Permutation([Integer(1), Integer(4), Integer(2),␣
↪Integer(3), Integer(5)])))
>>> M = sum([c * p.to_matrix() for c, p in L])
>>> decomp = bistochastic_as_sum_of_permutations(M)
>>> print(decomp)
2*B[[1, 4, 2, 3, 5]] + 3*B[[3, 1, 4, 2, 5]]
 + 9*B[[4, 1, 3, 5, 2]] + 6*B[[5, 3, 4, 1, 2]]
```

An exception is raised when the matrix is not positive and bistochastic:

```
sage: # needs sage.modules
sage: M = Matrix([[2,3],[2,2]])
sage: decomp = bistochastic_as_sum_of_permutations(M)
Traceback (most recent call last):
...
ValueError: the matrix is not bistochastic
sage: bistochastic_as_sum_of_permutations(Matrix(GF(7), 2, [2,1,1,2]))
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: the base ring of the matrix must have a coercion map to RR
sage: bistochastic_as_sum_of_permutations(Matrix(ZZ, 2, [2,-1,-1,2]))
Traceback (most recent call last):
...
ValueError: the matrix should have nonnegative entries
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> M = Matrix([[Integer(2),Integer(3)],[Integer(2),Integer(2)]])
>>> decomp = bistochastic_as_sum_of_permutations(M)
Traceback (most recent call last):
...
ValueError: the matrix is not bistochastic
>>> bistochastic_as_sum_of_permutations(Matrix(GF(Integer(7)), Integer(2),␣
↪[Integer(2),Integer(1),Integer(1),Integer(2)]))
Traceback (most recent call last):
...
ValueError: the base ring of the matrix must have a coercion map to RR
>>> bistochastic_as_sum_of_permutations(Matrix(ZZ, Integer(2), [Integer(2),-
↪Integer(1),-Integer(1),Integer(2)]))
Traceback (most recent call last):
...
ValueError: the matrix should have nonnegative entries
```

sage.combinat.permutation.**bounded_affine_permutation**(*A*)

Return the bounded affine permutation of a matrix.

The *bounded affine permutation* of a matrix A with entries in R is a partial permutation of length n, where n is the number of columns of A. The entry in position i is the smallest value j such that column i is in the span of columns $i+1, \ldots, j$, over R, where column indices are taken modulo n. If column i is the zero vector, then the permutation has a fixed point at i.

INPUT:

- `A` – matrix with entries in a ring R

EXAMPLES:

```
sage: from sage.combinat.permutation import bounded_affine_permutation
sage: A = Matrix(ZZ, [[1,0,0,0], [0,1,0,0]])                                #␣
↪needs sage.modules
sage: bounded_affine_permutation(A)                                         #␣
↪needs sage.libs.flint sage.modules
[5, 6, 3, 4]

sage: A = Matrix(ZZ, [[0,1,0,1,0], [0,0,1,1,0]])                            #␣
↪needs sage.modules
sage: bounded_affine_permutation(A)                                         #␣
↪needs sage.libs.flint sage.modules
[1, 4, 7, 8, 5]
```

```
>>> from sage.all import *
>>> from sage.combinat.permutation import bounded_affine_permutation
>>> A = Matrix(ZZ, [[Integer(1),Integer(0),Integer(0),Integer(0)], [Integer(0),
↪Integer(1),Integer(0),Integer(0)]])                                    # needs␣
↪sage.modules
>>> bounded_affine_permutation(A)                                        #␣
↪needs sage.libs.flint sage.modules
[5, 6, 3, 4]

>>> A = Matrix(ZZ, [[Integer(0),Integer(1),Integer(0),Integer(1),Integer(0)],␣
↪[Integer(0),Integer(0),Integer(1),Integer(1),Integer(0)]])                ␣
↪          # needs sage.modules
>>> bounded_affine_permutation(A)                                        #␣
↪needs sage.libs.flint sage.modules
[1, 4, 7, 8, 5]
```

REFERENCES:

- [KLS2013]

sage.combinat.permutation.**bruhat_lequal**(*p1*, *p2*)

Return `True` if `p1` is less than `p2` in the Bruhat order.

Algorithm from mupad-combinat.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.bruhat_lequal([2,4,3,1],[3,4,2,1])
True
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> permutation.bruhat_lequal([Integer(2),Integer(4),Integer(3),Integer(1)],
↪[Integer(3),Integer(4),Integer(2),Integer(1)])
True
```

sage.combinat.permutation.**descents_composition_first**(*dc*)

Compute the smallest element of a descent class having a descent composition `dc`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_first([1,1,3,4,3])
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> permutation.descents_composition_first([Integer(1),Integer(1),Integer(3),
↪Integer(4),Integer(3)])
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

sage.combinat.permutation.**descents_composition_last**(*dc*)

Return the largest element of a descent class having a descent composition `dc`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_last([1,1,3,4,3])
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> permutation.descents_composition_last([Integer(1),Integer(1),Integer(3),
↪Integer(4),Integer(3)])
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

sage.combinat.permutation.**descents_composition_list**(*dc*)

Return a list of all the permutations that have the descent composition dc.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_list([1,2,2])                    #␣
↪needs sage.graphs sage.modules

```
 [4, 2, 3, 1, 5],
 [5, 2, 3, 1, 4]]
```

sage.combinat.permutation.**from_cycles**(*n*, *cycles*, *parent=None*)

Return the permutation in the n-th symmetric group whose decomposition into disjoint cycles is `cycles`.

This function checks that its input is correct (i.e. that the cycles are disjoint and their elements integers among $1...n$). It raises an exception otherwise.

Warning

It assumes that the elements are of `int` type.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_cycles(4, [[1,2]])
[2, 1, 3, 4]
sage: permutation.from_cycles(4, [[1,2,4]])
[2, 4, 3, 1]
sage: permutation.from_cycles(10, [[3,1],[4,5],[6,8,9]])
[3, 2, 1, 5, 4, 8, 7, 9, 6, 10]
sage: permutation.from_cycles(10, ((2, 5), (6, 1, 3)))
[3, 5, 6, 4, 2, 1, 7, 8, 9, 10]
sage: permutation.from_cycles(4, [])
[1, 2, 3, 4]
sage: permutation.from_cycles(4, [[]])
[1, 2, 3, 4]
sage: permutation.from_cycles(0, [])
[]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> permutation.from_cycles(Integer(4), [[Integer(1),Integer(2)]])
[2, 1, 3, 4]
>>> permutation.from_cycles(Integer(4), [[Integer(1),Integer(2),Integer(4)]])
[2, 4, 3, 1]
>>> permutation.from_cycles(Integer(10), [[Integer(3),Integer(1)],[Integer(4),
↪Integer(5)],[Integer(6),Integer(8),Integer(9)]])
[3, 2, 1, 5, 4, 8, 7, 9, 6, 10]
>>> permutation.from_cycles(Integer(10), ((Integer(2), Integer(5)), (Integer(6),␣
↪Integer(1), Integer(3))))
[3, 5, 6, 4, 2, 1, 7, 8, 9, 10]
>>> permutation.from_cycles(Integer(4), [])
[1, 2, 3, 4]
>>> permutation.from_cycles(Integer(4), [[]])
[1, 2, 3, 4]
>>> permutation.from_cycles(Integer(0), [])
[]
```

Bad input (see Issue #13742):

```
sage: Permutation("(-12,2)(3,4)")
Traceback (most recent call last):
...
ValueError: all elements should be strictly positive integers, but I found -12
sage: Permutation("(1,2)(2,4)")
Traceback (most recent call last):
...
ValueError: the element 2 appears more than once in the input
sage: permutation.from_cycles(4, [[1,18]])
Traceback (most recent call last):
...
ValueError: you claimed that this is a permutation on 1...4, but it contains 18
```

```
>>> from sage.all import *
>>> Permutation("(-12,2)(3,4)")
Traceback (most recent call last):
...
ValueError: all elements should be strictly positive integers, but I found -12
>>> Permutation("(1,2)(2,4)")
Traceback (most recent call last):
...
ValueError: the element 2 appears more than once in the input
>>> permutation.from_cycles(Integer(4), [[Integer(1),Integer(18)]])
Traceback (most recent call last):
...
ValueError: you claimed that this is a permutation on 1...4, but it contains 18
```

sage.combinat.permutation.**from_inversion_vector**(*iv*, *parent=None*)

Return the permutation corresponding to inversion vector `iv`.

See *sage.combinat.permutation.Permutation.to_inversion_vector* for a definition of the inversion vector of a permutation.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_inversion_vector([3,1,0,0,0])
[3, 2, 4, 1, 5]
sage: permutation.from_inversion_vector([2,3,6,4,0,2,2,1,0])
[5, 9, 1, 8, 2, 6, 4, 7, 3]
sage: permutation.from_inversion_vector([0])
[1]
sage: permutation.from_inversion_vector([])
[]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> permutation.from_inversion_vector([Integer(3),Integer(1),Integer(0),
↪Integer(0),Integer(0)])
[3, 2, 4, 1, 5]
>>> permutation.from_inversion_vector([Integer(2),Integer(3),Integer(6),
↪Integer(4),Integer(0),Integer(2),Integer(2),Integer(1),Integer(0)])
[5, 9, 1, 8, 2, 6, 4, 7, 3]
```

(continues on next page)

(continued from previous page)

```
>>> permutation.from_inversion_vector([Integer(0)])
[1]
>>> permutation.from_inversion_vector([])
[]
```

sage.combinat.permutation.**from_lehmer_cocode**(*lehmer*, *parent=Standard permutations*)

Return the permutation with Lehmer cocode `lehmer`.

The Lehmer cocode of a permutation p is defined as the list $(c_1, c_2, \ldots, c_n)$, where c_i is the number of $j < i$ such that $p(j) > p(i)$.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: lcc = Permutation([2,1,5,4,3]).to_lehmer_cocode(); lcc
[0, 1, 0, 1, 2]
sage: permutation.from_lehmer_cocode(lcc)
[2, 1, 5, 4, 3]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> lcc = Permutation([Integer(2),Integer(1),Integer(5),Integer(4),Integer(3)]).
↪to_lehmer_cocode(); lcc
[0, 1, 0, 1, 2]
>>> permutation.from_lehmer_cocode(lcc)
[2, 1, 5, 4, 3]
```

sage.combinat.permutation.**from_lehmer_code**(*lehmer*, *parent=None*)

Return the permutation with Lehmer code `lehmer`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: lc = Permutation([2,1,5,4,3]).to_lehmer_code(); lc
[1, 0, 2, 1, 0]
sage: permutation.from_lehmer_code(lc)
[2, 1, 5, 4, 3]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> lc = Permutation([Integer(2),Integer(1),Integer(5),Integer(4),Integer(3)]).to_
↪lehmer_code(); lc
[1, 0, 2, 1, 0]
>>> permutation.from_lehmer_code(lc)
[2, 1, 5, 4, 3]
```

sage.combinat.permutation.**from_major_code**(*mc*, *final_descent=False*)

Return the permutation with major code `mc`.

The major code of a permutation is defined in *to_major_code()*.

Warning

This function creates illegal permutations (i.e. `Permutation([9])`, and this is dangerous as the *Permutation()* class is only designed to handle permutations on $1...n$. This will have to be changed when Sage permutations will be able to handle anything, but right now this should be fixed. Be careful with the results.

Warning

If `mc` is not a major index of a permutation, then the return value of this method can be anything. Garbage in, garbage out!

REFERENCES:

- Skandera, M. *An Eulerian Partner for Inversions*. Sem. Lothar. Combin. 46 (2001) B46d.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_major_code([5, 0, 1, 0, 1, 2, 0, 1, 0])
[9, 3, 5, 7, 2, 1, 4, 6, 8]
sage: permutation.from_major_code([8, 3, 3, 1, 4, 0, 1, 0, 0])
[2, 8, 4, 3, 6, 7, 9, 5, 1]
sage: Permutation([2,1,6,4,7,3,5]).to_major_code()
[3, 2, 0, 2, 2, 0, 0]
sage: permutation.from_major_code([3, 2, 0, 2, 2, 0, 0])
[2, 1, 6, 4, 7, 3, 5]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> permutation.from_major_code([Integer(5), Integer(0), Integer(1), Integer(0),␣
↪Integer(1), Integer(2), Integer(0), Integer(1), Integer(0)])
[9, 3, 5, 7, 2, 1, 4, 6, 8]
>>> permutation.from_major_code([Integer(8), Integer(3), Integer(3), Integer(1),␣
↪Integer(4), Integer(0), Integer(1), Integer(0), Integer(0)])
[2, 8, 4, 3, 6, 7, 9, 5, 1]
>>> Permutation([Integer(2),Integer(1),Integer(6),Integer(4),Integer(7),
↪Integer(3),Integer(5)]).to_major_code()
[3, 2, 0, 2, 2, 0, 0]
>>> permutation.from_major_code([Integer(3), Integer(2), Integer(0), Integer(2),␣
↪Integer(2), Integer(0), Integer(0)])
[2, 1, 6, 4, 7, 3, 5]
```

`sage.combinat.permutation.`**`from_permutation_group_element`**(*pge*, *parent=None*)

Return a *Permutation* given a `PermutationGroupElement` `pge`.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: pge = PermutationGroupElement([(1,2),(3,4)])                    #␣
↪needs sage.groups
sage: permutation.from_permutation_group_element(pge)                 #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.groups
[2, 1, 4, 3]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> pge = PermutationGroupElement([(Integer(1),Integer(2)),(Integer(3),
↪Integer(4))])                                  # needs sage.groups
>>> permutation.from_permutation_group_element(pge)                          #␣
↪needs sage.groups
[2, 1, 4, 3]
```

sage.combinat.permutation.**from_rank**(*n*, *rank*)

Return the permutation of the set $\{1, ..., n\}$ with lexicographic rank `rank`. This is the permutation whose Lehmer code is the factoradic representation of `rank`. In particular, the permutation with rank 0 is the identity permutation.

The permutation is computed without iterating through all of the permutations with lower rank. This makes it efficient for large permutations.

Note

The variable `rank` is not checked for being in the interval from 0 to $n! - 1$. When outside this interval, it acts as its residue modulo $n!$.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: Permutation([3, 6, 5, 4, 2, 1]).rank()
359
sage: [permutation.from_rank(3, i) for i in range(6)]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: Permutations(6)[10]
[1, 2, 4, 6, 3, 5]
sage: permutation.from_rank(6,10)
[1, 2, 4, 6, 3, 5]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> Permutation([Integer(3), Integer(6), Integer(5), Integer(4), Integer(2),␣
↪Integer(1)]).rank()
359
>>> [permutation.from_rank(Integer(3), i) for i in range(Integer(6))]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
>>> Permutations(Integer(6))[Integer(10)]
[1, 2, 4, 6, 3, 5]
>>> permutation.from_rank(Integer(6),Integer(10))
[1, 2, 4, 6, 3, 5]
```

sage.combinat.permutation.**from_reduced_word**(*rw*, *parent=None*)

Return the permutation corresponding to the reduced word `rw`.

See *reduced_words()* for a definition of reduced words and the convention on the order of multiplication used.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_reduced_word([3,2,3,1,2,3,1])
[3, 4, 2, 1]
sage: permutation.from_reduced_word([])
[]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> permutation.from_reduced_word([Integer(3),Integer(2),Integer(3),Integer(1),
↪Integer(2),Integer(3),Integer(1)])
[3, 4, 2, 1]
>>> permutation.from_reduced_word([])
[]
```

sage.combinat.permutation.**permutohedron_lequal**(*p1*, *p2*, *side='right'*)

Return `True` if `p1` is less than or equal to `p2` in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.permutohedron_lequal(Permutation([3,2,1,4]),Permutation([4,2,1,
↪3]))
False
sage: permutation.permutohedron_lequal(Permutation([3,2,1,4]),Permutation([4,2,1,
↪3]), side='left')
True
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>> permutation.permutohedron_lequal(Permutation([Integer(3),Integer(2),
↪Integer(1),Integer(4)]),Permutation([Integer(4),Integer(2),Integer(1),
↪Integer(3)]))
False
>>> permutation.permutohedron_lequal(Permutation([Integer(3),Integer(2),
↪Integer(1),Integer(4)]),Permutation([Integer(4),Integer(2),Integer(1),
↪Integer(3)]), side='left')
True
```

sage.combinat.permutation.**to_standard**(*p*, *key=None*)

Return a standard permutation corresponding to the iterable `p`.

INPUT:

- `p` – an iterable
- `key` – (optional) a comparison key for the element `x` of `p`

EXAMPLES:

```
sage: # needs sage.combinat
sage: import sage.combinat.permutation as permutation
sage: permutation.to_standard([4,2,7])
```

(continues on next page)

(continued from previous page)

```
[2, 1, 3]
sage: permutation.to_standard([1,2,3])
[1, 2, 3]
sage: permutation.to_standard([])
[]
sage: permutation.to_standard([1,2,3], key=lambda x: -x)
[3, 2, 1]
sage: permutation.to_standard([5,8,2,5], key=lambda x: -x)
[2, 1, 4, 3]
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> import sage.combinat.permutation as permutation
>>> permutation.to_standard([Integer(4),Integer(2),Integer(7)])
[2, 1, 3]
>>> permutation.to_standard([Integer(1),Integer(2),Integer(3)])
[1, 2, 3]
>>> permutation.to_standard([])
[]
>>> permutation.to_standard([Integer(1),Integer(2),Integer(3)], key=lambda x: -x)
[3, 2, 1]
>>> permutation.to_standard([Integer(5),Integer(8),Integer(2),Integer(5)],␣
↪key=lambda x: -x)
[2, 1, 4, 3]
```

Permutations (Cython file)

This is a nearly-straightforward implementation of what Knuth calls "Algorithm P" in TAOCP 7.2.1.2. The intent is to be able to enumerate permutation by "plain changes", or multiplication by adjacent transpositions, as a generator. This is useful when a class of objects is inherently enumerated by permutations, but it is faster to swap items in a permutation than construct the next object directly from the next permutation in a list. The backtracking algorithm in sage/graphs/genus.pyx is an example of this.

The lowest level is implemented as a struct with auxiliary methods. This is because Cython does not allow pointers to class instances, so a list of these objects is inherently slower than a list of structs. The author prefers ugly code to slow code.

For those willing to sacrifice a (very small) amount of speed, we provide a class that wraps our struct.

`sage.combinat.permutation_cython.`**`left_action_product`**`(`*S*, *lp*`)`

Return the permutation obtained by composing a permutation `S` with a permutation `lp` in such an order that `lp` is applied first and `S` is applied afterwards.

See also

sage.combinat.permutation.Permutation.left_action_product()

EXAMPLES:

```
sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_product
```

(continues on next page)

(continued from previous page)

```
sage: left_action_product(p, q)
[3, 2, 1, 4]
sage: left_action_product(q, p)
[1, 3, 2, 4]
sage: q
[3, 1, 2]
```

```
>>> from sage.all import *
>>> p = [Integer(2),Integer(1),Integer(3),Integer(4)]
>>> q = [Integer(3),Integer(1),Integer(2)]
>>> from sage.combinat.permutation_cython import left_action_product
>>> left_action_product(p, q)
[3, 2, 1, 4]
>>> left_action_product(q, p)
[1, 3, 2, 4]
>>> q
[3, 1, 2]
```

sage.combinat.permutation_cython.**left_action_same_n**(*S*, *lp*)

Return the permutation obtained by composing a permutation `s` with a permutation `lp` in such an order that `lp` is applied first and `s` is applied afterwards and `s` and `lp` are of the same length.

See also

sage.combinat.permutation.Permutation.left_action_product()

EXAMPLES:

```
sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_same_n
sage: left_action_same_n(p, q)
[3, 2, 1]
sage: left_action_same_n(q, p)
[1, 3, 2]
```

```
>>> from sage.all import *
>>> p = [Integer(2),Integer(1),Integer(3)]
>>> q = [Integer(3),Integer(1),Integer(2)]
>>> from sage.combinat.permutation_cython import left_action_same_n
>>> left_action_same_n(p, q)
[3, 2, 1]
>>> left_action_same_n(q, p)
[1, 3, 2]
```

sage.combinat.permutation_cython.**map_to_list**(*l*, *values*, *n*)

Build a list by mapping the array `l` using `values`.

> **Warning**
>
> There is no check of the input data at any point. Using wrong types or values with wrong length is likely to result in a Sage crash.

INPUT:

- `l` – array of unsigned int (i.e., type `'I'`)
- `values` – tuple; the values of the permutation
- `n` – integer; the length of the array `l`

OUTPUT: list representing the permutation

EXAMPLES:

```
sage: from array import array
sage: from sage.combinat.permutation_cython import map_to_list
sage: l = array('I', [0, 1, 0, 3, 3, 0, 1])
sage: map_to_list(l, ('a', 'b', 'c', 'd'), 7)
['a', 'b', 'a', 'd', 'd', 'a', 'b']
```

```
>>> from sage.all import *
>>> from array import array
>>> from sage.combinat.permutation_cython import map_to_list
>>> l = array('I', [Integer(0), Integer(1), Integer(0), Integer(3), Integer(3),␣
↪Integer(0), Integer(1)])
>>> map_to_list(l, ('a', 'b', 'c', 'd'), Integer(7))
['a', 'b', 'a', 'd', 'd', 'a', 'b']
```

sage.combinat.permutation_cython.**next_perm**(*l*)

Obtain the next permutation under lex order of `l` by mutating `l`.

Algorithm based on: http://marknelson.us/2002/03/01/next-permutation/

INPUT:

- `l` – array of unsigned int (i.e., type `'I'`)

> **Warning**
>
> This method mutates the array `l`.

OUTPUT: boolean; whether another permutation was obtained

EXAMPLES:

```
sage: from sage.combinat.permutation_cython import next_perm
sage: from array import array
sage: L = array('I', [1, 1, 2, 3])
sage: while next_perm(L):
....:     print(L)
array('I', [1, 1, 3, 2])
array('I', [1, 2, 1, 3])
```

(continues on next page)

(continued from previous page)

```
array('I', [1, 2, 3, 1])
array('I', [1, 3, 1, 2])
array('I', [1, 3, 2, 1])
array('I', [2, 1, 1, 3])
array('I', [2, 1, 3, 1])
array('I', [2, 3, 1, 1])
array('I', [3, 1, 1, 2])
array('I', [3, 1, 2, 1])
array('I', [3, 2, 1, 1])
```

```
>>> from sage.all import *
>>> from sage.combinat.permutation_cython import next_perm
>>> from array import array
>>> L = array('I', [Integer(1), Integer(1), Integer(2), Integer(3)])
>>> while next_perm(L):
...     print(L)
array('I', [1, 1, 3, 2])
array('I', [1, 2, 1, 3])
array('I', [1, 2, 3, 1])
array('I', [1, 3, 1, 2])
array('I', [1, 3, 2, 1])
array('I', [2, 1, 1, 3])
array('I', [2, 1, 3, 1])
array('I', [2, 3, 1, 1])
array('I', [3, 1, 1, 2])
array('I', [3, 1, 2, 1])
array('I', [3, 2, 1, 1])
```

sage.combinat.permutation_cython.**permutation_iterator_transposition_list**(n)

Return a list of transposition indices to enumerate the permutations on n letters by adjacent transpositions. Assumes zero-based lists. We artificially limit the argument to $n < 12$ to avoid overflowing 32-bit pointers. While the algorithm works for larger n, the user is encouraged to avoid filling anything more than 4GB of memory with the output of this function.

EXAMPLES:

```
sage: import sage.combinat.permutation_cython
sage: from sage.combinat.permutation_cython import permutation_iterator_
↪transposition_list
sage: permutation_iterator_transposition_list(4)
[2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2]
sage: permutation_iterator_transposition_list(200)
Traceback (most recent call last):
...
ValueError: Cowardly refusing to enumerate the permutations on more than 12␣
↪letters.
sage: permutation_iterator_transposition_list(1)
[]

sage: # Generate the permutations of [1,2,3,4] fixing 4.
sage: Q = [1,2,3,4]
sage: L = [copy(Q)]
```

(continues on next page)

(continued from previous page)

```
sage: for t in permutation_iterator_transposition_list(3):
....:     Q[t], Q[t+1] = Q[t+1], Q[t]
....:     L.append(copy(Q))
sage: print(L)
[[1, 2, 3, 4], [1, 3, 2, 4], [3, 1, 2, 4], [3, 2, 1, 4], [2, 3, 1, 4], [2, 1, 3,␣
↪4]]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation_cython
>>> from sage.combinat.permutation_cython import permutation_iterator_
↪transposition_list
>>> permutation_iterator_transposition_list(Integer(4))
[2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2]
>>> permutation_iterator_transposition_list(Integer(200))
Traceback (most recent call last):
...
ValueError: Cowardly refusing to enumerate the permutations on more than 12␣
↪letters.
>>> permutation_iterator_transposition_list(Integer(1))
[]

>>> # Generate the permutations of [1,2,3,4] fixing 4.
>>> Q = [Integer(1),Integer(2),Integer(3),Integer(4)]
>>> L = [copy(Q)]
>>> for t in permutation_iterator_transposition_list(Integer(3)):
...     Q[t], Q[t+Integer(1)] = Q[t+Integer(1)], Q[t]
...     L.append(copy(Q))
>>> print(L)
[[1, 2, 3, 4], [1, 3, 2, 4], [3, 1, 2, 4], [3, 2, 1, 4], [2, 3, 1, 4], [2, 1, 3,␣
↪4]]
```

sage.combinat.permutation_cython.**right_action_product**(*S*, *rp*)

Return the permutation obtained by composing a permutation `S` with a permutation `rp` in such an order that `S` is applied first and `rp` is applied afterwards.

See also

sage.combinat.permutation.Permutation.right_action_product()

EXAMPLES:

```
sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_product
sage: right_action_product(p, q)
[1, 3, 2, 4]
sage: right_action_product(q, p)
[3, 2, 1, 4]
sage: q
[3, 1, 2]
```

```
>>> from sage.all import *
>>> p = [Integer(2),Integer(1),Integer(3),Integer(4)]
>>> q = [Integer(3),Integer(1),Integer(2)]
>>> from sage.combinat.permutation_cython import right_action_product
>>> right_action_product(p, q)
[1, 3, 2, 4]
>>> right_action_product(q, p)
[3, 2, 1, 4]
>>> q
[3, 1, 2]
```

sage.combinat.permutation_cython.**right_action_same_n**(*S*, *rp*)

Return the permutation obtained by composing a permutation `S` with a permutation `rp` in such an order that `S` is applied first and `rp` is applied afterwards and `S` and `rp` are of the same length.

See also

sage.combinat.permutation.Permutation.right_action_product()

EXAMPLES:

```
sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_same_n
sage: right_action_same_n(p, q)
[1, 3, 2]
sage: right_action_same_n(q, p)
[3, 2, 1]
```

```
>>> from sage.all import *
>>> p = [Integer(2),Integer(1),Integer(3)]
>>> q = [Integer(3),Integer(1),Integer(2)]
>>> from sage.combinat.permutation_cython import right_action_same_n
>>> right_action_same_n(p, q)
[1, 3, 2]
>>> right_action_same_n(q, p)
[3, 2, 1]
```

Plane partitions

AUTHORS:

- Jang Soo Kim (2016): initial implementation
- Jessica Striker (2016): added additional methods
- Kevin Dilks (2021): added symmetry classes

class sage.combinat.plane_partition.**PlanePartition**(*parent*, *pp*, *check=True*)

Bases: `ClonableArray`

A plane partition.

A *plane partition* is a stack of cubes in the positive orthant.

INPUT:

- `PP` – list of lists which represents a tableau
- `box_size` – (optional) a list `[A, B, C]` of 3 positive integers, where `A`, `B`, `C` are the lengths of the box in the x-axis, y-axis, z-axis, respectively; if this is not given, it is determined by the smallest box bounding `PP`

OUTPUT: the plane partition whose tableau representation is `PP`

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP
Plane partition [[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP
Plane partition [[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

bounding_box()

Return the smallest box (a, b, c) that `self` is contained in.

EXAMPLES:

```
sage: PP = PlanePartition([[5,2,1,1], [2,2], [2]])
sage: PP.bounding_box()
(3, 4, 5)
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(5),Integer(2),Integer(1),Integer(1)],␣
↪[Integer(2),Integer(2)], [Integer(2)]])
>>> PP.bounding_box()
(3, 4, 5)
```

cells()

Return the list of cells inside `self`.

Each cell is a tuple.

EXAMPLES:

```
sage: PP = PlanePartition([[3,1],[2]])
sage: PP.cells()
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 0), (1, 0, 0), (1, 0, 1)]
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(3),Integer(1)],[Integer(2)]])
>>> PP.cells()
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 0), (1, 0, 0), (1, 0, 1)]
```

check()

Check to see that `self` is a valid plane partition.

EXAMPLES:

```
sage: a = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: a.check()
sage: b = PlanePartition([[1,2],[1]])
Traceback (most recent call last):
...
ValueError: not weakly decreasing along rows
sage: c = PlanePartition([[1,1],[2]])
Traceback (most recent call last):
...
ValueError: not weakly decreasing along columns
sage: d = PlanePartition([[2,-1],[-2]])
Traceback (most recent call last):
...
ValueError: entries not all nonnegative
sage: e = PlanePartition([[3/2,1],[.5]])
Traceback (most recent call last):
...
ValueError: entries not all integers
```

```
>>> from sage.all import *
>>> a = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> a.check()
>>> b = PlanePartition([[Integer(1),Integer(2)],[Integer(1)]])
Traceback (most recent call last):
...
ValueError: not weakly decreasing along rows
>>> c = PlanePartition([[Integer(1),Integer(1)],[Integer(2)]])
Traceback (most recent call last):
...
ValueError: not weakly decreasing along columns
>>> d = PlanePartition([[Integer(2),-Integer(1)],[-Integer(2)]])
Traceback (most recent call last):
...
ValueError: entries not all nonnegative
>>> e = PlanePartition([[Integer(3)/Integer(2),Integer(1)],[RealNumber('.5
↪')]])
Traceback (most recent call last):
...
ValueError: entries not all integers
```

complement(*tableau_only=False*)

Return the complement of `self`.

If the parent of `self` consists only of partitions inside a given box, then the complement is taken in this box. Otherwise, the complement is taken in the smallest box containing the plane partition. The empty plane partition with no box specified is its own complement.

If `tableau_only` is set to `True`, then only the tableau consisting of the projection of boxes size onto the xy-plane is returned instead of a *PlanePartition*. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.complement()
Plane partition [[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1]]
sage: PP.complement(True)
[[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1, 0]]
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.complement()
Plane partition [[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1]]
>>> PP.complement(True)
[[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1, 0]]
```

contains(*PP*)

Return `True` if `PP` is a plane partition that fits inside `self`.

Specifically, `self` contains `PP` if, for all i, j, the height of `PP` at ij is less than or equal to the height of `self` at ij.

EXAMPLES:

```
sage: P1 = PlanePartition([[5,4,3], [3,2,2], [1]])
sage: P2 = PlanePartition([[3,2], [1,1], [0,0], [0,0]])
sage: P3 = PlanePartition([[5,5,5], [2,1,0]])
sage: P1.contains(P2)
True
sage: P2.contains(P1)
False
sage: P1.contains(P3)
False
sage: P3.contains(P2)
True
```

```
>>> from sage.all import *
>>> P1 = PlanePartition([[Integer(5),Integer(4),Integer(3)], [Integer(3),
↪Integer(2),Integer(2)], [Integer(1)]])
>>> P2 = PlanePartition([[Integer(3),Integer(2)], [Integer(1),Integer(1)],␣
↪[Integer(0),Integer(0)], [Integer(0),Integer(0)]])
>>> P3 = PlanePartition([[Integer(5),Integer(5),Integer(5)], [Integer(2),
↪Integer(1),Integer(0)]])
>>> P1.contains(P2)
True
>>> P2.contains(P1)
False
>>> P1.contains(P3)
False
>>> P3.contains(P2)
True
```

cyclically_rotate(*preserve_parent=False*)

Return the cyclic rotation of `self`.

By default, if the parent of `self` consists of plane partitions inside an $a \times b \times c$ box, the result will have a

parent consisting of partitions inside a $c \times a \times b$ box, unless the optional parameter `preserve_parent` is set to `True`. Enabling this setting may give an element that is **not** an element of its parent.

EXAMPLES:

```
sage: PlanePartition([[3,2,1],[2,2],[2]]).cyclically_rotate()
Plane partition [[3, 3, 1], [2, 2], [1]]
sage: PP = PlanePartition([[4,1],[1],[1]])
sage: PP.cyclically_rotate()
Plane partition [[3, 1, 1, 1], [1]]
sage: PP == PP.cyclically_rotate().cyclically_rotate().cyclically_rotate()
True

sage: # needs sage.graphs sage.modules
sage: PP = PlanePartitions([4,3,2]).random_element()
sage: PP.cyclically_rotate().parent()
Plane partitions inside a 2 x 4 x 3 box
sage: PP = PlanePartitions([3,4,2])([[2,2,2,2],[2,2,2,2],[2,2,2,2]])
sage: PP_rotated = PP.cyclically_rotate(preserve_parent=True)
sage: PP_rotated in PP_rotated.parent()
False
```

```
>>> from sage.all import *
>>> PlanePartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(2)]]).cyclically_rotate()
Plane partition [[3, 3, 1], [2, 2], [1]]
>>> PP = PlanePartition([[Integer(4),Integer(1)],[Integer(1)],[Integer(1)]])
>>> PP.cyclically_rotate()
Plane partition [[3, 1, 1, 1], [1]]
>>> PP == PP.cyclically_rotate().cyclically_rotate().cyclically_rotate()
True

>>> # needs sage.graphs sage.modules
>>> PP = PlanePartitions([Integer(4),Integer(3),Integer(2)]).random_element()
>>> PP.cyclically_rotate().parent()
Plane partitions inside a 2 x 4 x 3 box
>>> PP = PlanePartitions([Integer(3),Integer(4),Integer(2)])([[Integer(2),
↪Integer(2),Integer(2),Integer(2)],[Integer(2),Integer(2),Integer(2),
↪Integer(2)],[Integer(2),Integer(2),Integer(2),Integer(2)]])
>>> PP_rotated = PP.cyclically_rotate(preserve_parent=True)
>>> PP_rotated in PP_rotated.parent()
False
```

is_CSPP()

Return whether `self` is a cyclically symmetric plane partition.

A plane partition is cyclically symmetric if its x, y, and z tableaux are all equal.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSPP()
False
sage: PP = PlanePartition([[3,2,2],[3,1,0],[1,1,0]])
```

(continues on next page)

(continued from previous page)

```
sage: PP.is_CSPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_CSPP()
False
>>> PP = PlanePartition([[Integer(3),Integer(2),Integer(2)],[Integer(3),
↪Integer(1),Integer(0)],[Integer(1),Integer(1),Integer(0)]])
>>> PP.is_CSPP()
True
```

is_CSSCPP()

Return whether `self` is a cyclically symmetric and self-complementary plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSSCPP()
False
sage: PP = PlanePartition([[4,4,4,1],[3,3,2,1],[3,2,1,1],[3,0,0,0]])
sage: PP.is_CSSCPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_CSSCPP()
False
>>> PP = PlanePartition([[Integer(4),Integer(4),Integer(4),Integer(1)],
↪[Integer(3),Integer(3),Integer(2),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(1)],[Integer(3),Integer(0),Integer(0),Integer(0)]])
>>> PP.is_CSSCPP()
True
```

is_CSTCPP()

Return whether `self` is a cyclically symmetric and transpose-complementary plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSTCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,3,2,1],[3,2,1,0],[2,1,0,0]])
sage: PP.is_CSTCPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_CSTCPP()
```

(continues on next page)

(continued from previous page)

```
False
>>> PP = PlanePartition([[Integer(4),Integer(4),Integer(3),Integer(2)],
↪[Integer(4),Integer(3),Integer(2),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(0)],[Integer(2),Integer(1),Integer(0),Integer(0)]])
>>> PP.is_CSTCPP()
True
```

is_SCPP()

Return whether `self` is a self-complementary plane partition.

Note that the complement of a plane partition (and thus the property of being self-complementary) is dependent on the choice of a box that it is contained in. If no parent/bounding box is specified, the box is taken to be the smallest box that contains the plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SCPP()
False
sage: PP = PlanePartition([[4,4,4,4],[4,4,2,0],[4,2,0,0],[0,0,0,0]])
sage: PP.is_SCPP()
False
sage: PP = PlanePartitions([4,4,4])([[4,4,4,4],[4,4,2,0],[4,2,0,0],[0,0,0,0]])
sage: PP.is_SCPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_SCPP()
False
>>> PP = PlanePartition([[Integer(4),Integer(4),Integer(4),Integer(4)],
↪[Integer(4),Integer(4),Integer(2),Integer(0)],[Integer(4),Integer(2),
↪Integer(0),Integer(0)],[Integer(0),Integer(0),Integer(0),Integer(0)]])
>>> PP.is_SCPP()
False
>>> PP = PlanePartitions([Integer(4),Integer(4),Integer(4)])([[Integer(4),
↪Integer(4),Integer(4),Integer(4)],[Integer(4),Integer(4),Integer(2),
↪Integer(0)],[Integer(4),Integer(2),Integer(0),Integer(0)],[Integer(0),
↪Integer(0),Integer(0),Integer(0)]])
>>> PP.is_SCPP()
True
```

is_SPP()

Return whether `self` is a symmetric plane partition.

A plane partition is symmetric if the corresponding tableau is symmetric about the diagonal.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,3,2],[3,3,2],[2,2,2]])
```

(continues on next page)

(continued from previous page)

```
sage: PP.is_SPP()
True
sage: PP = PlanePartition([[3,2,1],[2,0,0]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,2,0],[2,0,0]])
sage: PP.is_SPP()
True
sage: PP = PlanePartition([[3,2],[2,0],[1,0]])
sage: PP.is_SPP()
False
sage: PP = PlanePartition([[3,2],[2,0],[0,0]])
sage: PP.is_SPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_SPP()
False
>>> PP = PlanePartition([[Integer(3),Integer(3),Integer(2)],[Integer(3),
↪Integer(3),Integer(2)],[Integer(2),Integer(2),Integer(2)]])
>>> PP.is_SPP()
True
>>> PP = PlanePartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(0),Integer(0)]])
>>> PP.is_SPP()
False
>>> PP = PlanePartition([[Integer(3),Integer(2),Integer(0)],[Integer(2),
↪Integer(0),Integer(0)]])
>>> PP.is_SPP()
True
>>> PP = PlanePartition([[Integer(3),Integer(2)],[Integer(2),Integer(0)],
↪[Integer(1),Integer(0)]])
>>> PP.is_SPP()
False
>>> PP = PlanePartition([[Integer(3),Integer(2)],[Integer(2),Integer(0)],
↪[Integer(0),Integer(0)]])
>>> PP.is_SPP()
True
```

is_SSCPP()

Return whether `self` is a symmetric, self-complementary plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_SSCPP()
False
sage: PP = PlanePartition([[4,3,3,2],[3,2,2,1],[3,2,2,1],[2,1,1,0]])
sage: PP.is_SSCPP()
True
```

(continues on next page)

(continued from previous page)

```
sage: PP = PlanePartition([[2,1],[1,0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[4,3,2],[3,2,1],[2,1,0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[4,2,2,2],[2,2,2,2],[2,2,2,2],[2,2,2,0]])
sage: PP.is_SSCPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_SSCPP()
False
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(2)],
↪[Integer(3),Integer(2),Integer(2),Integer(1)],[Integer(3),Integer(2),
↪Integer(2),Integer(1)],[Integer(2),Integer(1),Integer(1),Integer(0)]])
>>> PP.is_SSCPP()
True
>>> PP = PlanePartition([[Integer(2),Integer(1)],[Integer(1),Integer(0)]])
>>> PP.is_SSCPP()
True
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(2)],[Integer(3),
↪Integer(2),Integer(1)],[Integer(2),Integer(1),Integer(0)]])
>>> PP.is_SSCPP()
True
>>> PP = PlanePartition([[Integer(4),Integer(2),Integer(2),Integer(2)],
↪[Integer(2),Integer(2),Integer(2),Integer(2)],[Integer(2),Integer(2),
↪Integer(2),Integer(2)],[Integer(2),Integer(2),Integer(2),Integer(0)]])
>>> PP.is_SSCPP()
True
```

is_TCPP()

Return whether `self` is a transpose-complementary plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,4,2,1],[4,2,0,0],[2,0,0,0]])
sage: PP.is_TCPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_TCPP()
False
>>> PP = PlanePartition([[Integer(4),Integer(4),Integer(3),Integer(2)],
↪[Integer(4),Integer(4),Integer(2),Integer(1)],[Integer(4),Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(0),Integer(0)],[Integer(2),Integer(0),Integer(0),Integer(0)]])
>>> PP.is_TCPP()
True
```

is_TSPP()

Return whether `self` is a totally symmetric plane partition.

A plane partition is totally symmetric if it is both symmetric and cyclically symmetric.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TSPP()
False
sage: PP = PlanePartition([[3,3,3],[3,3,2],[3,2,1]])
sage: PP.is_TSPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_TSPP()
False
>>> PP = PlanePartition([[Integer(3),Integer(3),Integer(3)],[Integer(3),
↪Integer(3),Integer(2)],[Integer(3),Integer(2),Integer(1)]])
>>> PP.is_TSPP()
True
```

is_TSSCPP()

Return whether `self` is a totally symmetric self-complementary plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TSSCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,3,2,1],[3,2,1,0],[2,1,0,0]])
sage: PP.is_TSSCPP()
True
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_TSSCPP()
False
>>> PP = PlanePartition([[Integer(4),Integer(4),Integer(3),Integer(2)],
↪[Integer(4),Integer(3),Integer(2),Integer(1)],[Integer(3),Integer(2),
↪Integer(1),Integer(0)],[Integer(2),Integer(1),Integer(0),Integer(0)]])
>>> PP.is_TSSCPP()
True
```

maximal_boxes()

Return the coordinates of the maximal boxes of `self`.

The maximal boxes of a plane partitions are the boxes that can be removed from a plane partition and still yield a valid plane partition.

EXAMPLES:

```
sage: sorted(PlanePartition([[3,2,1],[2,2],[2]]).maximal_boxes())
[[0, 0, 2], [0, 2, 0], [1, 1, 1], [2, 0, 1]]
sage: sorted(PlanePartition([[2,1],[1],[1]]).maximal_boxes())
[[0, 0, 1], [0, 1, 0], [2, 0, 0]]
```

```
>>> from sage.all import *
>>> sorted(PlanePartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
...Integer(2)],[Integer(2)]]).maximal_boxes())
[[0, 0, 2], [0, 2, 0], [1, 1, 1], [2, 0, 1]]
>>> sorted(PlanePartition([[Integer(2),Integer(1)],[Integer(1)],
...[Integer(1)]]).maximal_boxes())
[[0, 0, 1], [0, 1, 0], [2, 0, 0]]
```

number_of_boxes()

Return the number of boxes in the plane partition.

EXAMPLES:

```
sage: PP = PlanePartition([[3,1],[2]])
sage: PP.number_of_boxes()
6
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(3),Integer(1)],[Integer(2)]])
>>> PP.number_of_boxes()
6
```

plot(*show_box=False*, *colors=None*)

Return a plot of `self`.

INPUT:

- `show_box` – boolean (default: `False`); if `True`, also shows the visible tiles on the xy-, yz-, zx-planes
- `colors` – (default: `["white", "lightgray", "darkgray"]`) list `[A, B, C]` of 3 strings representing colors

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.plot()                                                             #␣
...needs sage.plot
Graphics object consisting of 27 graphics primitives
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
...[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.plot()                                                               #␣
...needs sage.plot
Graphics object consisting of 27 graphics primitives
```

plot3d(*colors=None*)

Return a 3D-plot of `self`.

INPUT:

- `colors` – (default: `["white", "lightgray", "darkgray"]`) list `[A, B, C]` of 3 strings representing colors

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.plot3d()                                                          #␣
↪needs sage.plot
Graphics3d Object
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.plot3d()                                                            #␣
↪needs sage.plot
Graphics3d Object
```

pp(*show_box=False*)

Return a pretty print of the plane partition.

INPUT:

- `show_box` – boolean (default: `False`); if `True`, also shows the visible tiles on the xy-, yz-, zx-planes

OUTPUT: a pretty print of the plane partition

EXAMPLES:

```
sage: PlanePartition([[4,3,3,1],[2,1,1],[1,1]]).pp()
        __
       /\_\
    __/\/_/
 __/\_\/\_\

   \_\_\/_/
```

to_order_ideal()

Return the order ideal corresponding to `self`.

Todo

As many families of symmetric plane partitions are in bijection with order ideals in an associated poset, this function could feasibly have options to send symmetric plane partitions to the associated order ideal in that poset, instead.

EXAMPLES:

```
sage: PlanePartition([[3,2,1],[2,2],[2]]).to_order_ideal()                    #␣
↪needs sage.graphs sage.modules
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 0), (0, 1, 1), (0, 2, 0),
 (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1), (2, 0, 0), (2, 0, 1)]
sage: PlanePartition([[2,1],[1],[1]]).to_order_ideal()                         #␣
↪needs sage.graphs sage.modules
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0)]
```

```
>>> from sage.all import *
>>> PlanePartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(2)]]).to_order_ideal()                  # needs sage.
↪graphs sage.modules
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 0), (0, 1, 1), (0, 2, 0),
 (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1), (2, 0, 0), (2, 0, 1)]
>>> PlanePartition([[Integer(2),Integer(1)],[Integer(1)],[Integer(1)]]).to_
↪order_ideal()                        # needs sage.graphs sage.modules
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0)]
```

to_tableau()

Return the tableau class of `self`.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.to_tableau()
[[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.to_tableau()
[[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

transpose(*tableau_only=False*)

Return the transpose of `self`.

If `tableau_only` is set to `True`, then only the tableau consisting of the projection of boxes size onto the xy-plane is returned instead of a *PlanePartition*. This will not necessarily have trailing rows or trailing zeros removed.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.transpose()
Plane partition [[4, 2, 1], [3, 1, 1], [3, 1], [1]]
sage: PP.transpose(True)
[[4, 2, 1], [3, 1, 1], [3, 1, 0], [1, 0, 0]]

sage: PPP = PlanePartitions([1, 2, 3])
sage: PP = PPP([[1, 1]])
sage: PT = PP.transpose(); PT
Plane partition [[1], [1]]
sage: PT.parent()
Plane partitions inside a 2 x 1 x 3 box
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.transpose()
Plane partition [[4, 2, 1], [3, 1, 1], [3, 1], [1]]
>>> PP.transpose(True)
[[4, 2, 1], [3, 1, 1], [3, 1, 0], [1, 0, 0]]

>>> PPP = PlanePartitions([Integer(1), Integer(2), Integer(3)])
>>> PP = PPP([[Integer(1), Integer(1)]])
>>> PT = PP.transpose(); PT
Plane partition [[1], [1]]
>>> PT.parent()
Plane partitions inside a 2 x 1 x 3 box
```

x_tableau(*tableau=True*)

Return the projection of `self` in the x direction.

If `tableau` is set to `False`, then only the list of lists consisting of the projection of boxes size onto the yz-plane is returned instead of a *Tableau* object. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.x_tableau()
[[3, 2, 1, 1], [3, 1, 1, 0], [2, 1, 1, 0], [1, 0, 0, 0]]
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.x_tableau()
[[3, 2, 1, 1], [3, 1, 1, 0], [2, 1, 1, 0], [1, 0, 0, 0]]
```

y_tableau(*tableau=True*)

Return the projection of `self` in the y direction.

If `tableau` is set to `False`, then only the list of lists consisting of the projection of boxes size onto the xz-plane is returned instead of a *Tableau* object. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.y_tableau()
[[4, 3, 2], [3, 1, 0], [3, 0, 0], [1, 0, 0]]
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.y_tableau()
[[4, 3, 2], [3, 1, 0], [3, 0, 0], [1, 0, 0]]
```

z_tableau(*tableau=True*)

Return the projection of `self` in the z direction.

If `tableau` is set to `False`, then only the list of lists consisting of the projection of boxes size onto the xy-plane is returned instead of a *Tableau* object. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.z_tableau()
[[4, 3, 3, 1], [2, 1, 1, 0], [1, 1, 0, 0]]
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
↪[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.z_tableau()
[[4, 3, 3, 1], [2, 1, 1, 0], [1, 1, 0, 0]]
```

class sage.combinat.plane_partition.**PlanePartitions**(*box_size=None*, *symmetry=None*, *category=None*)

Bases: UniqueRepresentation, Parent

Plane partitions.

PlanePartitions() returns the class of all plane partitions.

PlanePartitions(n) return the class of all plane partitions with precisely n boxes.

PlanePartitions([a, b, c]) returns the class of plane partitions that fit inside an $a \times b \times c$ box.

PlanePartitions([a, b, c]) has the optional keyword symmetry, which restricts the plane partitions inside a box of the specified size satisfying certain symmetry conditions.

- symmetry='SPP' gives the class of symmetric plane partitions. which is all plane partitions fixed under reflection across the diagonal. Requires that $a = b$.
- symmetry='CSPP' gives the class of cyclic plane partitions, which is all plane partitions fixed under cyclic rotation of coordinates. Requires that $a = b = c$.
- symmetry='TSPP' gives the class of totally symmetric plane partitions, which is all plane partitions fixed under any interchanging of coordinates. Requires that $a = b = c$.
- symmetry='SCPP' gives the class of self-complementary plane partitions. which is all plane partitions that are equal to their own complement in the specified box. Requires at least one of a, b, c be even.
- symmetry='TCPP' gives the class of transpose complement plane partitions, which is all plane partitions whose complement in the box of the specified size is equal to their transpose. Requires $a = b$ and at least one of a, b, c be even.
- symmetry='SSCPP' gives the class of symmetric self-complementary plane partitions, which is all plane partitions that are both symmetric and self-complementary. Requires $a = b$ and at least one of a, b, c be even.
- symmetry='CSTCPP' gives the class of cyclically symmetric transpose complement plane partitions, which is all plane partitions that are both symmetric and equal to the transpose of their complement. Requires $a = b = c$.
- symmetry='CSSCPP' gives the class of cyclically symmetric self-complementary plane partitions, which is all plane partitions that are both cyclically symmetric and self-complementary. Requires $a = b = c$ and all a, b, c be even.
- symmetry='TSSCPP' gives the class of totally symmetric self-complementary plane partitions, which is all plane partitions that are totally symmetric and also self-complementary. Requires $a = b = c$ and all a, b, c be even.

EXAMPLES:

If no arguments are passed, then the class of all plane partitions is returned:

```
sage: PlanePartitions()
Plane partitions
sage: [[2,1],[1]] in PlanePartitions()
True
```

```
>>> from sage.all import *
>>> PlanePartitions()
Plane partitions
>>> [[Integer(2),Integer(1)],[Integer(1)]] in PlanePartitions()
True
```

If an integer n is passed, then the class of plane partitions of n is returned:

```
sage: PlanePartitions(3)
Plane partitions of size 3
sage: PlanePartitions(3).list()
[Plane partition [[3]],
 Plane partition [[2, 1]],
 Plane partition [[1, 1, 1]],
 Plane partition [[2], [1]],
 Plane partition [[1, 1], [1]],
 Plane partition [[1], [1], [1]]]
```

```
>>> from sage.all import *
>>> PlanePartitions(Integer(3))
Plane partitions of size 3
>>> PlanePartitions(Integer(3)).list()
[Plane partition [[3]],
 Plane partition [[2, 1]],
 Plane partition [[1, 1, 1]],
 Plane partition [[2], [1]],
 Plane partition [[1, 1], [1]],
 Plane partition [[1], [1], [1]]]
```

If a three-element tuple or list $[a, b, c]$ is passed, then the class of all plane partitions that fit inside and $a \times b \times c$ box is returned:

```
sage: PlanePartitions([2,2,2])
Plane partitions inside a 2 x 2 x 2 box
sage: [[2,1],[1]] in PlanePartitions([2,2,2])
True
```

```
>>> from sage.all import *
>>> PlanePartitions([Integer(2),Integer(2),Integer(2)])
Plane partitions inside a 2 x 2 x 2 box
>>> [[Integer(2),Integer(1)],[Integer(1)]] in PlanePartitions([Integer(2),
↪Integer(2),Integer(2)])
True
```

If an additional keyword `symmetry` is pass along with a three-element tuple or list $[a, b, c]$, then the class of all plane partitions that fit inside an $a \times b \times c$ box with the specified symmetry is returned:

```
sage: PlanePartitions([2,2,2], symmetry='CSPP')
Cyclically symmetric plane partitions inside a 2 x 2 x 2 box
sage: [[2,1],[1]] in PlanePartitions([2,2,2], symmetry='CSPP')
True
```

```
>>> from sage.all import *
>>> PlanePartitions([Integer(2),Integer(2),Integer(2)], symmetry='CSPP')
Cyclically symmetric plane partitions inside a 2 x 2 x 2 box
>>> [[Integer(2),Integer(1)],[Integer(1)]] in PlanePartitions([Integer(2),
↪Integer(2),Integer(2)], symmetry='CSPP')
True
```

Element

alias of *PlanePartition*

box()

Return the size of the box of the plane partition of `self` is contained in.

EXAMPLES:

```
sage: P = PlanePartitions([4,3,5])
sage: P.box()
(4, 3, 5)

sage: PP = PlanePartitions()
sage: PP.box() is None
True
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(3),Integer(5)])
>>> P.box()
(4, 3, 5)

>>> PP = PlanePartitions()
>>> PP.box() is None
True
```

symmetry()

Return the symmetry class of `self`.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: PP.symmetry()
'SPP'
sage: PP = PlanePartitions()
sage: PP.symmetry() is None
True
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> PP.symmetry()
'SPP'
>>> PP = PlanePartitions()
>>> PP.symmetry() is None
True
```

class sage.combinat.plane_partition.**PlanePartitions_CSPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are cyclically symmetric.

cardinality()

Return the cardinality of `self`.

The number of cyclically symmetric plane partitions inside an $a \times a \times a$ box is equal to

$$\left(\prod_{i=1}^{a} \frac{3i-1}{3i-2}\right)\left(\prod_{1\le i<j\le a} \frac{i+j+a-1}{2i+j-1}\right).$$

EXAMPLES:

```
sage: P = PlanePartitions([4,4,4], symmetry='CSPP')
sage: P.cardinality()
132
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(4)], symmetry='CSPP')
>>> P.cardinality()
132
```

from_antichain(*acl*)

Return the cyclically symmetric plane partition corresponding to an antichain in the poset given in *to_poset()*.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: A = [(0, 2, 2), (1, 1, 1)]
sage: PP.from_antichain(A)
Plane partition [[3, 3, 3], [3, 2, 1], [3, 1, 1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='CSPP')
>>> A = [(Integer(0), Integer(2), Integer(2)), (Integer(1), Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(1))]
>>> PP.from_antichain(A)
Plane partition [[3, 3, 3], [3, 2, 1], [3, 1, 1]]
```

from_order_ideal(*I*)

Return the cyclically symmetric plane partition corresponding to an order ideal in the poset given in *to_poset()*.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: I = [(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 1), (0, 1, 2),
....:      (1, 0, 2), (0, 2, 2), (1, 1, 1), (1, 1, 2), (1, 2, 2)]
sage: PP.from_order_ideal(I)                                                #␣
↪needs sage.graphs
Plane partition [[3, 3, 3], [3, 3, 3], [3, 3, 2]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='CSPP')
>>> I = [(Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(0),␣
↪Integer(1)), (Integer(0), Integer(0), Integer(2)), (Integer(0), Integer(1),␣
↪Integer(1)), (Integer(0), Integer(1), Integer(2)),
...      (Integer(1), Integer(0), Integer(2)), (Integer(0), Integer(2),␣
↪Integer(2)), (Integer(1), Integer(1), Integer(1)), (Integer(1), Integer(1),␣
↪Integer(2)), (Integer(1), Integer(2), Integer(2))]
>>> PP.from_order_ideal(I)                                                  #␣
↪needs sage.graphs
Plane partition [[3, 3, 3], [3, 3, 3], [3, 3, 2]]
```

random_element()

Return a uniformly random element of `self`.

ALGORITHM:

This uses the *random_order_ideal()* method and the natural bijection between cyclically symmetric plane partitions and order ideals in an associated poset.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: PP.random_element()  # random                                         #␣
↪needs sage.graphs
Plane partition [[3, 2, 2], [3, 1], [1, 1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='CSPP')
>>> PP.random_element()  # random                                           #␣
↪needs sage.graphs
Plane partition [[3, 2, 2], [3, 1], [1, 1]]
```

to_poset()

Return a partially ordered set whose order ideals are in bijection with cyclically symmetric plane partitions.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: PP.to_poset()                                                    #␣
↪needs sage.graphs
Finite poset containing 11 elements
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality() ␣
↪          # needs sage.graphs
True
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='CSPP')
>>> PP.to_poset()                                                      #␣
↪needs sage.graphs
Finite poset containing 11 elements
>>> PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()  ␣
↪        # needs sage.graphs
True
```

class sage.combinat.plane_partition.**PlanePartitions_CSSCPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are cyclically symmetric self-complementary.

cardinality()

Return the cardinality of `self`.

The number of cyclically symmetric self-complementary plane partitions inside a $2a \times 2a \times 2a$ box is equal to

$$\left(\prod_{i=0}^{a-1} \frac{(3i+1)!}{(a+i)!}\right)^2.$$

EXAMPLES:

```
sage: P = PlanePartitions([6,6,6], symmetry='CSSCPP')
sage: P.cardinality()
49
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='CSSCPP')
>>> P.cardinality()
49
```

class sage.combinat.plane_partition.**PlanePartitions_CSTCPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are cyclically symmetric and transpose-complement.

cardinality()

Return the cardinality of `self`.

The number of cyclically symmetric transpose complement plane partitions inside a $2a \times 2a \times 2a$ box is equal to

$$\prod_{i=0}^{a-1} \frac{(3i+1)(6i)!(2i)!}{(4i+1)!(4i)!}.$$

EXAMPLES:

```
sage: P = PlanePartitions([6,6,6], symmetry='CSTCPP')
sage: P.cardinality()
11
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='CSTCPP')
>>> P.cardinality()
11
```

class sage.combinat.plane_partition.**PlanePartitions_SCPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are self-complementary.

cardinality()

Return the cardinality of `self`.

The number of self complementary plane partitions inside a $2a \times 2b \times 2c$ box is equal to

$$\left(\prod_{i=1}^{r}\prod_{j=1}^{b}\frac{i+j+c-1}{i+j-1}\right)^2.$$

The number of self complementary plane partitions inside an $(2a+1) \times 2b \times 2c$ box is equal to

$$\left(\prod_{i=1}^{a}\prod_{j=1}^{b}\frac{i+j+c-1}{i+j-1}\right)\left(\prod_{i=1}^{a+1}\prod_{j=1}^{b}\frac{i+j+c-1}{i+j-1}\right).$$

The number of self complementary plane partitions inside an $(2a+1) \times (2b+1) \times 2c$ box is equal to

$$\left(\prod_{i=1}^{a+1}\prod_{j=1}^{b}\frac{i+j+c-1}{i+j-1}\right)\left(\prod_{i=1}^{a}\prod_{j=1}^{b+1}\frac{i+j+c-1}{i+j-1}\right).$$

EXAMPLES:

```
sage: P = PlanePartitions([4,4,4], symmetry='SCPP')
sage: P.cardinality()
400

sage: P = PlanePartitions([5,4,4], symmetry='SCPP')
sage: P.cardinality()
1000
sage: P = PlanePartitions([4,5,4], symmetry='SCPP')
sage: P.cardinality()
1000
sage: P = PlanePartitions([4,4,5], symmetry='SCPP')
sage: P.cardinality()
1000

sage: P = PlanePartitions([5,5,4], symmetry='SCPP')
sage: P.cardinality()
2500
sage: P = PlanePartitions([5,4,5], symmetry='SCPP')
```

(continues on next page)

(continued from previous page)

```
sage: P.cardinality()
2500
sage: P = PlanePartitions([4,5,5], symmetry='SCPP')
sage: P.cardinality()
2500
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(4)], symmetry='SCPP')
>>> P.cardinality()
400

>>> P = PlanePartitions([Integer(5),Integer(4),Integer(4)], symmetry='SCPP')
>>> P.cardinality()
1000
>>> P = PlanePartitions([Integer(4),Integer(5),Integer(4)], symmetry='SCPP')
>>> P.cardinality()
1000
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(5)], symmetry='SCPP')
>>> P.cardinality()
1000

>>> P = PlanePartitions([Integer(5),Integer(5),Integer(4)], symmetry='SCPP')
>>> P.cardinality()
2500
>>> P = PlanePartitions([Integer(5),Integer(4),Integer(5)], symmetry='SCPP')
>>> P.cardinality()
2500
>>> P = PlanePartitions([Integer(4),Integer(5),Integer(5)], symmetry='SCPP')
>>> P.cardinality()
2500
```

class sage.combinat.plane_partition.**PlanePartitions_SPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are symmetric.

cardinality()

Return the cardinality of `self`.

The number of symmetric plane partitions inside an $a \times a \times b$ box is equal to

$$\left(\prod_{i=1}^{a} \frac{2i+b-1}{2i-1}\right)\left(\prod_{1\le i<j\le a} \frac{i+j+b-1}{i+j-1}\right).$$

EXAMPLES:

```
sage: P = PlanePartitions([3,3,2], symmetry='SPP')
sage: P.cardinality()
35
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
```

(continues on next page)

(continued from previous page)

```
>>> P.cardinality()
35
```

from_antichain(*A*)

Return the symmetric plane partition corresponding to an antichain in the poset given in *to_poset()*.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: A = [(2, 2, 0), (1, 0, 1), (1, 1, 0)]
sage: PP.from_antichain(A)
Plane partition [[2, 2, 1], [2, 1, 1], [1, 1, 1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> A = [(Integer(2), Integer(2), Integer(0)), (Integer(1), Integer(0),␣
↪Integer(1)), (Integer(1), Integer(1), Integer(0))]
>>> PP.from_antichain(A)
Plane partition [[2, 2, 1], [2, 1, 1], [1, 1, 1]]
```

from_order_ideal(*I*)

Return the symmetric plane partition corresponding to an order ideal in the poset given in *to_poset()*.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: I = [(0, 0, 0), (1, 0, 0), (1, 1, 0), (2, 0, 0)]
sage: PP.from_order_ideal(I)                                                #␣
↪needs sage.graphs
Plane partition [[1, 1, 1], [1, 1], [1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> I = [(Integer(0), Integer(0), Integer(0)), (Integer(1), Integer(0),␣
↪Integer(0)), (Integer(1), Integer(1), Integer(0)), (Integer(2), Integer(0),␣
↪Integer(0))]
>>> PP.from_order_ideal(I)                                                  #␣
↪needs sage.graphs
Plane partition [[1, 1, 1], [1, 1], [1]]
```

random_element()

Return a uniformly random element of `self`.

ALGORITHM:

This uses the *random_order_ideal()* method and the natural bijection between symmetric plane partitions and order ideals in an associated poset.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: PP.random_element()  # random                                         #␣
↪needs sage.graphs
Plane partition [[2, 2, 2], [2, 2], [2]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> PP.random_element()  # random                                          #␣
↪needs sage.graphs
Plane partition [[2, 2, 2], [2, 2], [2]]
```

to_poset()

Return a poset whose order ideals are in bijection with symmetric plane partitions.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: PP.to_poset()                                                       #␣
↪needs sage.graphs
Finite poset containing 12 elements
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality() ␣
↪          # needs sage.graphs sage.modules sage.rings.finite_rings
True
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> PP.to_poset()                                                         #␣
↪needs sage.graphs
Finite poset containing 12 elements
>>> PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()  ␣
↪        # needs sage.graphs sage.modules sage.rings.finite_rings
True
```

class sage.combinat.plane_partition.**PlanePartitions_SSCPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are symmetric self-complementary.

cardinality()

Return the cardinality of `self`.

The number of symmetric self-complementary plane partitions inside a $2a \times 2a \times 2b$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{a} \frac{i+j+b-1}{i+j-1}.$$

The number of symmetric self-complementary plane partitions inside a $(2a+1) \times (2a+1) \times 2b$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{a+1} \frac{i+j+b-1}{i+j-1}.$$

EXAMPLES:

```
sage: P = PlanePartitions([4,4,2], symmetry='SSCPP')
sage: P.cardinality()
6
sage: Q = PlanePartitions([3,3,2], symmetry='SSCPP')
sage: Q.cardinality()
3
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(2)], symmetry='SSCPP')
>>> P.cardinality()
6
>>> Q = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SSCPP')
>>> Q.cardinality()
3
```

class sage.combinat.plane_partition.**PlanePartitions_TCPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are transpose-complement.

cardinality()

Return the cardinality of `self`.

The number of transpose complement plane partitions inside an $a \times a \times 2b$ box is equal to

$$\binom{b+1-1}{a-1} \prod_{1 \le i,j \le a-2} \frac{i+j+2b-1}{i+j-1}.$$

EXAMPLES:

```
sage: P = PlanePartitions([3,3,2], symmetry='TCPP')
sage: P.cardinality()
5
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='TCPP')
>>> P.cardinality()
5
```

class sage.combinat.plane_partition.**PlanePartitions_TSPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are totally symmetric.

cardinality()

Return the cardinality of `self`.

The number of totally symmetric plane partitions inside an $a \times a \times a$ box is equal to

$$\prod_{1 \le i \le j \le a} \frac{i+j+a-1}{i+2j-2}.$$

EXAMPLES:

```
sage: P = PlanePartitions([4,4,4], symmetry='TSPP')
sage: P.cardinality()
66
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(4)], symmetry='TSPP')
>>> P.cardinality()
66
```

from_antichain(*acl*)

Return the totally symmetric plane partition corresponding to an antichain in the poset given in *to_poset()*.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='TSPP')
sage: A = [(0, 0, 2), (0, 1, 1)]
sage: PP.from_antichain(A)
Plane partition [[3, 2, 1], [2, 1], [1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='TSPP')
>>> A = [(Integer(0), Integer(0), Integer(2)), (Integer(0), Integer(1),␣
↪Integer(1))]
>>> PP.from_antichain(A)
Plane partition [[3, 2, 1], [2, 1], [1]]
```

from_order_ideal(*I*)

Return the totally symmetric plane partition corresponding to an order ideal in the poset given in *to_poset()*.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='TSPP')
sage: I = [(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 1)]
sage: PP.from_order_ideal(I)                                                #␣
↪needs sage.graphs
Plane partition [[3, 2, 1], [2, 1], [1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='TSPP')
>>> I = [(Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(0),␣
↪Integer(1)), (Integer(0), Integer(0), Integer(2)), (Integer(0), Integer(1),␣
↪Integer(1))]
>>> PP.from_order_ideal(I)                                                  #␣
↪needs sage.graphs
Plane partition [[3, 2, 1], [2, 1], [1]]
```

to_poset()

Return a poset whose order ideals are in bijection with totally symmetric plane partitions.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='TSPP')
sage: PP.to_poset()                                                         #␣
↪needs sage.graphs
Finite poset containing 10 elements
sage: (PP.to_poset().order_ideals_lattice().cardinality()                   #␣
↪needs sage.graphs sage.modules sage.rings.finite_rings
....:     == PP.cardinality())
True
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='TSPP')
```

(continues on next page)

(continued from previous page)

```
>>> PP.to_poset()                                                    #␣
↪needs sage.graphs
Finite poset containing 10 elements
>>> (PP.to_poset().order_ideals_lattice().cardinality()              #␣
↪needs sage.graphs sage.modules sage.rings.finite_rings
...      == PP.cardinality())
True
```

class sage.combinat.plane_partition.**PlanePartitions_TSSCPP**(*box_size*)

Bases: *PlanePartitions*

Plane partitions that fit inside a box of a specified size that are totally symmetric self-complementary.

cardinality()

Return the cardinality of `self`.

The number of totally symmetric self-complementary plane partitions inside a $2a \times 2a \times 2a$ box is equal to

$$\prod_{i=0}^{a-1} \frac{(3i+1)!}{(a+i)!}.$$

EXAMPLES:

```
sage: P = PlanePartitions([6,6,6], symmetry='TSSCPP')
sage: P.cardinality()
7
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='TSSCPP')
>>> P.cardinality()
7
```

from_antichain(*acl*)

Return the totally symmetric self-complementary plane partition corresponding to an antichain in the poset given in *to_poset()*.

EXAMPLES:

```
sage: PP = PlanePartitions([6,6,6], symmetry='TSSCPP')
sage: A = [(0, 0, 1), (1, 1, 0)]
sage: PP.from_antichain(A)
Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 4, 3, 1], [6, 5, 4, 3, 2, 1],
                 [5, 4, 3, 2, 1], [5, 3, 2, 1, 1], [3, 1, 1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='TSSCPP
↪')
>>> A = [(Integer(0), Integer(0), Integer(1)), (Integer(1), Integer(1),␣
↪Integer(0))]
>>> PP.from_antichain(A)
Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 4, 3, 1], [6, 5, 4, 3, 2, 1],
                 [5, 4, 3, 2, 1], [5, 3, 2, 1, 1], [3, 1, 1]]
```

from_order_ideal(*I*)

Return the totally symmetric self-complementary plane partition corresponding to an order ideal in the poset given in *to_poset()*.

EXAMPLES:

```
sage: PP = PlanePartitions([6,6,6], symmetry='TSSCPP')                    #␣
↪needs sage.graphs
sage: I = [(0, 0, 0), (0, 1, 0), (1, 1, 0)]
sage: PP.from_order_ideal(I)                                              #␣
↪needs sage.graphs
Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 3, 3, 1], [6, 5, 5, 3, 3, 1],
                 [5, 3, 3, 1, 1], [5, 3, 3, 1, 1], [3, 1, 1]]
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='TSSCPP
↪')                       # needs sage.graphs
>>> I = [(Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(1),␣
↪Integer(0)), (Integer(1), Integer(1), Integer(0))]
>>> PP.from_order_ideal(I)                                                #␣
↪needs sage.graphs
Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 3, 3, 1], [6, 5, 5, 3, 3, 1],
                 [5, 3, 3, 1, 1], [5, 3, 3, 1, 1], [3, 1, 1]]
```

to_poset()

Return a poset whose order ideals are in bijection with totally symmetric self-complementary plane partitions.

EXAMPLES:

```
sage: PP = PlanePartitions([6,6,6], symmetry='TSSCPP')
sage: PP.to_poset()                                                       #␣
↪needs sage.graphs sage.modules
Finite poset containing 4 elements
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality() ␣
↪          # needs sage.graphs sage.modules
True
```

```
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='TSSCPP
↪')
>>> PP.to_poset()                                                         #␣
↪needs sage.graphs sage.modules
Finite poset containing 4 elements
>>> PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()   ␣
↪        # needs sage.graphs sage.modules
True
```

class sage.combinat.plane_partition.**PlanePartitions_all**

Bases: *PlanePartitions*, DisjointUnionEnumeratedSets

All plane partitions.

an_element()

Return a particular element of the class.

class sage.combinat.plane_partition.**PlanePartitions_box**(*box_size*)

Bases: *PlanePartitions*

All plane partitions that fit inside a box of a specified size.

By convention, a plane partition in an $a \times b \times c$ box will have at most a rows, of lengths at most b, with entries at most c.

cardinality()

Return the cardinality of `self`.

The number of plane partitions inside an $a \times b \times c$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{b} \frac{i+j+c-1}{i+j-1}.$$

EXAMPLES:

```
sage: P = PlanePartitions([4,3,5])
sage: P.cardinality()
116424
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(3),Integer(5)])
>>> P.cardinality()
116424
```

from_antichain(*A*)

Return the plane partition corresponding to an antichain in the poset given in *to_poset()*.

EXAMPLES:

```
sage: A = [(1,0,1), (0,1,1), (1,1,0)]
sage: PlanePartitions([2,2,2]).from_antichain(A)
Plane partition [[2, 2], [2, 1]]
```

```
>>> from sage.all import *
>>> A = [(Integer(1),Integer(0),Integer(1)), (Integer(0),Integer(1),
↪Integer(1)), (Integer(1),Integer(1),Integer(0))]
>>> PlanePartitions([Integer(2),Integer(2),Integer(2)]).from_antichain(A)
Plane partition [[2, 2], [2, 1]]
```

from_order_ideal(*I*)

Return the plane partition corresponding to an order ideal in the poset given in *to_poset()*.

EXAMPLES:

```
sage: I = [(1, 0, 0), (1, 0, 1), (1, 1, 0), (0, 1, 0),
....:      (0, 0, 0), (0, 0, 1), (0, 1, 1)]
sage: PlanePartitions([2,2,2]).from_order_ideal(I)                    #␣
↪needs sage.graphs sage.modules
Plane partition [[2, 2], [2, 1]]
```

```
>>> from sage.all import *
>>> I = [(Integer(1), Integer(0), Integer(0)), (Integer(1), Integer(0),␣
↪Integer(1)), (Integer(1), Integer(1), Integer(0)), (Integer(0), Integer(1),␣
↪Integer(0)),
...       (Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(0),␣
↪Integer(1)), (Integer(0), Integer(1), Integer(1))]
>>> PlanePartitions([Integer(2),Integer(2),Integer(2)]).from_order_ideal(I)  ␣
↪                        # needs sage.graphs sage.modules
Plane partition [[2, 2], [2, 1]]
```

generating_series(*q=None*)

Return the generating function of plane partitions in this box.

The generating function of plane partitions inside an $a \times b \times c$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{b} \frac{1-q^{i+j+c-1}}{1-q^{i+j-1}}.$$

INPUT:

- `q` – (default: `None`) the variable q; if `None`, then use a default variable in $\mathbf{Z}[q]$

ALGORITHM:

This function computes the generating function $N_q(a,b,c)$ by factoring it into cyclotomic polynomials:

$$N_q(a,b,c) = \prod_{d=1}^{a+b+c-1} \Phi_d(q)^{e_d}$$

where

$$e_d = \sum_{i=0}^{a-1} \left\lfloor \frac{b+c+i}{d} \right\rfloor - \left\lfloor \frac{c+i}{d} \right\rfloor + \left\lfloor \frac{i}{d} \right\rfloor - \left\lfloor \frac{b+i}{d} \right\rfloor.$$

EXAMPLES:

```
sage: P = PlanePartitions([2, 2, 2])
sage: P.generating_series()
q^8 + q^7 + 3*q^6 + 3*q^5 + 4*q^4 + 3*q^3 + 3*q^2 + q + 1

sage: R.<t> = ZZ[]
sage: P = PlanePartitions([3, 1, 1])
sage: P.generating_series(q=t)
t^3 + t^2 + t + 1
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(2), Integer(2), Integer(2)])
>>> P.generating_series()
q^8 + q^7 + 3*q^6 + 3*q^5 + 4*q^4 + 3*q^3 + 3*q^2 + q + 1

>>> R = ZZ['t']; (t,) = R._first_ngens(1)
>>> P = PlanePartitions([Integer(3), Integer(1), Integer(1)])
>>> P.generating_series(q=t)
t^3 + t^2 + t + 1
```

random_element()

Return a uniformly random plane partition inside a box.

ALGORITHM:

This uses the *random_order_ideal()* method and the natural bijection with plane partitions.

EXAMPLES:

```
sage: P = PlanePartitions([4,3,5])
sage: P.random_element()  # random                                          #␣
↪needs sage.graphs sage.modules
Plane partition [[4, 3, 3], [4], [2]]
```

```
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(3),Integer(5)])
>>> P.random_element()  # random                                           #␣
↪needs sage.graphs sage.modules
Plane partition [[4, 3, 3], [4], [2]]
```

to_poset()

Return the product of three chains poset, whose order ideals are naturally in bijection with plane partitions inside a box.

EXAMPLES:

```
sage: PlanePartitions([2,2,2]).to_poset()                                   #␣
↪needs sage.graphs sage.modules
Finite lattice containing 8 elements
```

```
>>> from sage.all import *
>>> PlanePartitions([Integer(2),Integer(2),Integer(2)]).to_poset()          ␣
↪                        # needs sage.graphs sage.modules
Finite lattice containing 8 elements
```

class sage.combinat.plane_partition.**PlanePartitions_n**(*n*)

Bases: *PlanePartitions*

Plane partitions with a fixed number of boxes.

cardinality()

Return the number of plane partitions with `n` boxes.

Calculated using the recurrence relation

$$PL(n) = \sum_{k=1}^{n} PL(n-k)\sigma_2(k),$$

where $\sigma_k(n)$ is the sum of the k-th powers of divisors of n.

EXAMPLES:

```
sage: P = PlanePartitions(17)
sage: P.cardinality()
18334
```

```
>>> from sage.all import *
>>> P = PlanePartitions(Integer(17))
>>> P.cardinality()
18334
```

Rankers

sage.combinat.ranker.**from_list**(*l*)

Return a ranker from the list l.

INPUT:

- `l` – list

OUTPUT: `[rank, unrank]` – functions

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: r,u = ranker.from_list(l)
sage: r(1)
0
sage: r(3)
2
sage: u(2)
3
sage: u(0)
1
```

```
>>> from sage.all import *
>>> import sage.combinat.ranker as ranker
>>> l = [Integer(1),Integer(2),Integer(3)]
>>> r,u = ranker.from_list(l)
>>> r(Integer(1))
0
>>> r(Integer(3))
2
>>> u(Integer(2))
3
>>> u(Integer(0))
1
```

sage.combinat.ranker.**on_fly**()

Return a pair of enumeration functions rank / unrank.

rank assigns on the fly an integer, starting from 0, to any object passed as argument. The object should be hashable. unrank is the inverse function; it returns None for indices that have not yet been assigned.

EXAMPLES:

```
sage: [rank, unrank] = sage.combinat.ranker.on_fly()
sage: rank('a')
0
sage: rank('b')
```

(continues on next page)

(continued from previous page)

```
1
sage: rank('c')
2
sage: rank('a')
0
sage: unrank(2)
'c'
sage: unrank(3)
sage: rank('d')
3
sage: unrank(3)
'd'
```

```
>>> from sage.all import *
>>> [rank, unrank] = sage.combinat.ranker.on_fly()
>>> rank('a')
0
>>> rank('b')
1
>>> rank('c')
2
>>> rank('a')
0
>>> unrank(Integer(2))
'c'
>>> unrank(Integer(3))
>>> rank('d')
3
>>> unrank(Integer(3))
'd'
```

Todo

add tests as in combinat::rankers

sage.combinat.ranker.**rank_from_list**(*l*)

Return a rank function for the elements of `l`.

INPUT:

- `l` – a duplicate free list (or iterable) of hashable objects

OUTPUT:

- a function from the elements of `l` to `0,...,len(l)`

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = ['a', 'b', 'c']
sage: r = ranker.rank_from_list(l)
sage: r('a')
0
```

(continues on next page)

(continued from previous page)

```
sage: r('c')
2
```

```
>>> from sage.all import *
>>> import sage.combinat.ranker as ranker
>>> l = ['a', 'b', 'c']
>>> r = ranker.rank_from_list(l)
>>> r('a')
0
>>> r('c')
2
```

For non elements a `ValueError` is raised, as with the usual `index` method of lists:

```
sage: r('blah')
Traceback (most recent call last):
...
ValueError: 'blah' is not in dict
```

```
>>> from sage.all import *
>>> r('blah')
Traceback (most recent call last):
...
ValueError: 'blah' is not in dict
```

Currently, the rank function is a `CallableDict`; but this is an implementation detail:

```
sage: type(r)
<class 'sage.misc.callable_dict.CallableDict'>
sage: r
{'a': 0, 'b': 1, 'c': 2}
```

```
>>> from sage.all import *
>>> type(r)
<class 'sage.misc.callable_dict.CallableDict'>
>>> r
{'a': 0, 'b': 1, 'c': 2}
```

With the current implementation, no error is issued in case of duplicate value in `l`. Instead, the rank function returns the position of some of the duplicates:

```
sage: r = ranker.rank_from_list(['a', 'b', 'a', 'c'])
sage: r('a')
2
```

```
>>> from sage.all import *
>>> r = ranker.rank_from_list(['a', 'b', 'a', 'c'])
>>> r('a')
2
```

Constructing the rank function itself is of complexity `O(len(l))`. Then, each call to the rank function consists of an essentially constant time dictionary lookup.

sage.combinat.ranker.**unrank**(L, i)

Return the i-th element of L.

INPUT:

- `L` – list, tuple, finite enumerated set, etc.
- `i` – integer

The purpose of this utility is to give a uniform idiom to recover the i-th element of an object `L`, whether `L` is a list, tuple (or more generally a `collections.abc.Sequence`), an enumerated set, some old parent of Sage still implementing unranking in the method `__getitem__`, or an iterable (see `collections.abc.Iterable`). See Issue #15919.

EXAMPLES:

Lists, tuples, and other `sequences`:

```
sage: from sage.combinat.ranker import unrank
sage: unrank(['a','b','c'], 2)
'c'
sage: unrank(('a','b','c'), 1)
'b'
sage: unrank(range(3,13,2), 1)
5
```

```
>>> from sage.all import *
>>> from sage.combinat.ranker import unrank
>>> unrank(['a','b','c'], Integer(2))
'c'
>>> unrank(('a','b','c'), Integer(1))
'b'
>>> unrank(range(Integer(3),Integer(13),Integer(2)), Integer(1))
5
```

Enumerated sets:

```
sage: unrank(GF(7), 2)
2
sage: unrank(IntegerModRing(29), 10)
10
```

```
>>> from sage.all import *
>>> unrank(GF(Integer(7)), Integer(2))
2
>>> unrank(IntegerModRing(Integer(29)), Integer(10))
10
```

An iterable:

```
sage: unrank(NN,4)
4
```

```
>>> from sage.all import *
>>> unrank(NN,Integer(4))
4
```

An iterator:

```
sage: unrank(('a{}'.format(i) for i in range(20)), 0)
'a0'
sage: unrank(('a{}'.format(i) for i in range(20)), 2)
'a2'
```

```
>>> from sage.all import *
>>> unrank(('a{}'.format(i) for i in range(Integer(20))), Integer(0))
'a0'
>>> unrank(('a{}'.format(i) for i in range(Integer(20))), Integer(2))
'a2'
```

Warning

When unranking an iterator, it returns the `i`-th element beyond where it is currently at:

```
sage: from sage.combinat.ranker import unrank
sage: it = iter(range(20))
sage: unrank(it, 2)
2
sage: unrank(it, 2)
5
```

```
>>> from sage.all import *
>>> from sage.combinat.ranker import unrank
>>> it = iter(range(Integer(20)))
>>> unrank(it, Integer(2))
2
>>> unrank(it, Integer(2))
5
```

sage.combinat.ranker.**unrank_from_list**(*l*)

Return an unrank function from a list.

EXAMPLES:

```
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: u = ranker.unrank_from_list(l)
sage: u(2)
3
sage: u(0)
1
```

```
>>> from sage.all import *
>>> import sage.combinat.ranker as ranker
>>> l = [Integer(1),Integer(2),Integer(3)]
>>> u = ranker.unrank_from_list(l)
>>> u(Integer(2))
3
>>> u(Integer(0))
```

```

Recognizable series

Let A be an alphabet and K a semiring. Then a formal series S with coefficients in K and indices in the words A^* is called recognizable if it has a linear representation, i.e., there exists

- a nonnegative integer n

and there exist

- two vectors $left$ and $right$ of dimension n and
- a morphism of monoids μ from A^* to $n \times n$ matrices over K

such that the coefficient corresponding to a word $w \in A^*$ equals

$$left\, \mu(w)\, right.$$

Note

Whenever a minimization (*minimized()*) of a series needs to be computed, it is required that K is a field. In particular, minimization is called before checking if a series is nonzero.

See also

k-regular sequence, *sage.rings.cfinite_sequence*, *sage.combinat.binary_recurrence_sequences*.

class sage.combinat.recognizable_series.**PrefixClosedSet**(*words*)

Bases: object

A prefix-closed set.

Creation of this prefix-closed set is interactive iteratively.

INPUT:

- `words` – a class of words (instance of *Words*)

EXAMPLES:

```
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet(Words([0, 1], infinite=False)); P
[word: ]

sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
[word: ]
```

```
>>> from sage.all import *
>>> from sage.combinat.recognizable_series import PrefixClosedSet
>>> P = PrefixClosedSet(Words([Integer(0), Integer(1)], infinite=False)); P
[word: ]

>>> P = PrefixClosedSet.create_by_alphabet([Integer(0), Integer(1)]); P
[word: ]
```

See *iterate_possible_additions()* for further examples.

add(*w*, *check=True*)

Add a word to this prefix-closed set.

INPUT:

- `w` – a word
- `check` – boolean (default: `True`); if set, then it is verified whether all proper prefixes of `w` are already in this prefix-closed set

OUTPUT:

Nothing, but a RuntimeError is raised if the check fails.

EXAMPLES:

```
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1])
sage: W = P.words
sage: P.add(W([0])); P
[word: , word: 0]
sage: P.add(W([0, 1])); P
[word: , word: 0, word: 01]
sage: P.add(W([1, 1]))
Traceback (most recent call last):
...
ValueError: cannot add as not all prefixes of 11 are included yet
```

```
>>> from sage.all import *
>>> from sage.combinat.recognizable_series import PrefixClosedSet
>>> P = PrefixClosedSet.create_by_alphabet([Integer(0), Integer(1)])
>>> W = P.words
>>> P.add(W([Integer(0)])); P
[word: , word: 0]
>>> P.add(W([Integer(0), Integer(1)])); P
[word: , word: 0, word: 01]
>>> P.add(W([Integer(1), Integer(1)]))
Traceback (most recent call last):
...
ValueError: cannot add as not all prefixes of 11 are included yet
```

classmethod create_by_alphabet(*alphabet*)

A prefix-closed set.

This is a convenience method for the creation of prefix-closed sets by specifying an alphabet.

INPUT:

- `alphabet` – finite words over this `alphabet` will used

EXAMPLES:

```
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
[word: ]
```

```
>>> from sage.all import *
>>> from sage.combinat.recognizable_series import PrefixClosedSet
>>> P = PrefixClosedSet.create_by_alphabet([Integer(0), Integer(1)]); P
[word: ]
```

iterate_possible_additions()

Return an iterator over all elements including possible new elements.

OUTPUT: an iterator

EXAMPLES:

```
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
[word: ]
sage: for n, p in enumerate(P.iterate_possible_additions()):
....:     print('{}?'.format(p))
....:     if n in (0, 2, 3, 5):
....:         P.add(p)
....:         print('...added')
0?
...added
1?
00?
...added
01?
...added
000?
001?
...added
010?
011?
0010?
0011?
sage: P.elements
[word: , word: 0, word: 00, word: 01, word: 001]
```

```
>>> from sage.all import *
>>> from sage.combinat.recognizable_series import PrefixClosedSet
>>> P = PrefixClosedSet.create_by_alphabet([Integer(0), Integer(1)]); P
[word: ]
>>> for n, p in enumerate(P.iterate_possible_additions()):
...     print('{}?'.format(p))
...     if n in (Integer(0), Integer(2), Integer(3), Integer(5)):
...         P.add(p)
...         print('...added')
```

(continues on next page)

(continued from previous page)

```
0?
...added
1?
00?
...added
01?
...added
000?
001?
...added
010?
011?
0010?
0011?
>>> P.elements
[word: , word: 0, word: 00, word: 01, word: 001]
```

Calling the iterator once more, returns all elements:

```
sage: list(P.iterate_possible_additions())
[word: 0,
 word: 1,
 word: 00,
 word: 01,
 word: 000,
 word: 001,
 word: 010,
 word: 011,
 word: 0010,
 word: 0011]
```

```
>>> from sage.all import *
>>> list(P.iterate_possible_additions())
[word: 0,
 word: 1,
 word: 00,
 word: 01,
 word: 000,
 word: 001,
 word: 010,
 word: 011,
 word: 0010,
 word: 0011]
```

The method *iterate_possible_additions()* is roughly equivalent to

```
sage: list(p + a
....:      for p in P.elements
....:      for a in P.words.iterate_by_length(1))
[word: 0,
 word: 1,
 word: 00,
```

(continues on next page)

(continued from previous page)

```
 word: 01,
 word: 000,
 word: 001,
 word: 010,
 word: 011,
 word: 0010,
 word: 0011]
```

```
>>> from sage.all import *
>>> list(p + a
...       for p in P.elements
...       for a in P.words.iterate_by_length(Integer(1)))
[word: 0,
 word: 1,
 word: 00,
 word: 01,
 word: 000,
 word: 001,
 word: 010,
 word: 011,
 word: 0010,
 word: 0011]
```

However, the above does not allow to add elements during iteration, whereas *iterate_possible_additions()* does.

prefix_set()

Return the set of minimal (with respect to prefix ordering) elements of the complement of this prefix closed set.

See also Proposition 2.3.1 of [BR2010a].

OUTPUT: list

EXAMPLES:

```
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
[word: ]
sage: for n, p in enumerate(P.iterate_possible_additions()):
....:     if n in (0, 1, 2, 4, 6):
....:         P.add(p)
sage: P
[word: , word: 0, word: 1, word: 00, word: 10, word: 000]
sage: P.prefix_set()
[word: 01, word: 11, word: 001, word: 100,
 word: 101, word: 0000, word: 0001]
```

```
>>> from sage.all import *
>>> from sage.combinat.recognizable_series import PrefixClosedSet
>>> P = PrefixClosedSet.create_by_alphabet([Integer(0), Integer(1)]); P
[word: ]
>>> for n, p in enumerate(P.iterate_possible_additions()):
```

(continues on next page)

(continued from previous page)

```
...     if n in (Integer(0), Integer(1), Integer(2), Integer(4), Integer(6)):
...         P.add(p)
>>> P
[word: , word: 0, word: 1, word: 00, word: 10, word: 000]
>>> P.prefix_set()
[word: 01, word: 11, word: 001, word: 100,
 word: 101, word: 0000, word: 0001]
```

class sage.combinat.recognizable_series.**RecognizableSeries**(*parent*, *mu*, *left*, *right*)

Bases: ModuleElement

A recognizable series.

- parent – an instance of *RecognizableSeriesSpace*
- mu – a family of square matrices, all of which have the same dimension. The indices of this family are the elements of the alphabet. mu may be a list or tuple of the same cardinality as the alphabet as well. See also *mu*.
- left – a vector. When evaluating a coefficient, this vector is multiplied from the left to the matrix obtained from *mu* applying on a word. See also *left*.
- right – a vector. When evaluating a coefficient, this vector is multiplied from the right to the matrix obtained from *mu* applying on a word. See also *right*.

When created via the parent *RecognizableSeriesSpace*, then the following option is available.

EXAMPLES:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
....:         vector([0, 1]), vector([1, 0])).transposed(); S
[1] + 3*[01] + [10] + 5*[11] + 9*[001] + 3*[010] + ...
```

```
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> S = Rec((Matrix([[Integer(3), Integer(6)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(0), -Integer(6)], [Integer(1), Integer(5)]])),
...         vector([Integer(0), Integer(1)]), vector([Integer(1), Integer(0)])).
↪transposed(); S
[1] + 3*[01] + [10] + 5*[11] + 9*[001] + 3*[010] + ...
```

We can access coefficients by

```
sage: W = Rec.indices()
sage: S[W([0, 0, 1])]
9
```

```
>>> from sage.all import *
>>> W = Rec.indices()
>>> S[W([Integer(0), Integer(0), Integer(1)])]
9
```

See also

recognizable series, `RecognizableSeriesSpace`.

coefficient_of_word(*w*, *multiply_left=True*, *multiply_right=True*)

Return the coefficient to word w of this series.

INPUT:

- `w` – a word over the parent's *alphabet()*
- `multiply_left` – boolean (default: `True`); if `False`, then multiplication by *left* is skipped
- `multiply_right` – boolean (default: `True`); if `False`, then multiplication by *right* is skipped

OUTPUT:

An element in the parent's *coefficient_ring()*

EXAMPLES:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: W = Rec.indices()
sage: S = Rec((Matrix([[1, 0], [0, 1]]), Matrix([[0, -1], [1, 2]])),
....:           left=vector([0, 1]), right=vector([1, 0]))
sage: S[W(7.digits(2))]  # indirect doctest
3
```

```
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> W = Rec.indices()
>>> S = Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(0), -Integer(1)], [Integer(1), Integer(2)]])),
...           left=vector([Integer(0), Integer(1)]), right=vector([Integer(1),␣
↪Integer(0)]))
>>> S[W(Integer(7).digits(Integer(2)))]  # indirect doctest
3
```

dimension()

Return the dimension of this recognizable series.

EXAMPLES:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
....:     left=vector([0, 1]), right=vector([1, 0])).dimension()
2
```

```
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]])),
...      left=vector([Integer(0), Integer(1)]), right=vector([Integer(1),␣
↪Integer(0)])).dimension()
2
```

hadamard_product(**args*, ***kwds*)

Return the Hadamard product of this recognizable series and the `other` recognizable series, i.e., multiply the two series coefficient-wise.

INPUT:

- `other` – a *RecognizableSeries* with the same parent as this recognizable series
- `minimize` – (default: `None`) a boolean or `None`. If `True`, then *minimized()* is called after the operation, if `False`, then not. If this argument is `None`, then the default specified by the parent's `minimize_results` is used.

OUTPUT: a *RecognizableSeries*

EXAMPLES:

```
sage: Seq2 = RegularSequenceRing(2, ZZ)

sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
....:          vector([1, 0]), vector([1, 1]))
sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...

sage: O = Seq2((Matrix([[0, 0], [0, 1]]), Matrix([[0, 1], [0, 1]])),
....:          vector([1, 0]), vector([0, 1]))
sage: O
2-regular sequence 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, ...

sage: C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
....:          vector([1, 0]), vector([0, 1]))
sage: C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
```

```
>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)

>>> E = Seq2((Matrix([[Integer(0), Integer(1)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(0), Integer(0)], [Integer(0), Integer(1)]])),
...          vector([Integer(1), Integer(0)]), vector([Integer(1),␣
↪Integer(1)]))
>>> E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...

>>> O = Seq2((Matrix([[Integer(0), Integer(0)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(0), Integer(1)], [Integer(0), Integer(1)]])),
...          vector([Integer(1), Integer(0)]), vector([Integer(0),␣
↪Integer(1)]))
>>> O
2-regular sequence 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, ...

>>> C = Seq2((Matrix([[Integer(2), Integer(0)], [Integer(2), Integer(1)]]),␣
↪Matrix([[Integer(0), Integer(1)], [-Integer(2), Integer(3)]])),
...          vector([Integer(1), Integer(0)]), vector([Integer(0),␣
↪Integer(1)]))
>>> C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
```

```
sage: CE = C.hadamard_product(E)
sage: CE
2-regular sequence 0, 0, 2, 0, 4, 0, 6, 0, 8, 0, ...
sage: CE.linear_representation()
((1, 0, 0),
 Finite family {0: [0 1 0]
                   [0 2 0]
                   [0 2 1],
                1: [ 0  0  0]
                   [ 0  0  1]
                   [ 0 -2  3]},
 (0, 0, 2))

sage: Z = E.hadamard_product(O)
sage: Z
2-regular sequence 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, ...
sage: Z.linear_representation()
((),
 Finite family {0: [],
                1: []},
 ())
```

```
>>> from sage.all import *
>>> CE = C.hadamard_product(E)
>>> CE
2-regular sequence 0, 0, 2, 0, 4, 0, 6, 0, 8, 0, ...
>>> CE.linear_representation()
((1, 0, 0),
 Finite family {0: [0 1 0]
                   [0 2 0]
                   [0 2 1],
                1: [ 0  0  0]
                   [ 0  0  1]
                   [ 0 -2  3]},
 (0, 0, 2))

>>> Z = E.hadamard_product(O)
>>> Z
2-regular sequence 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, ...
>>> Z.linear_representation()
((),
 Finite family {0: [],
                1: []},
 ())
```

is_trivial_zero()

Return whether this recognizable series is trivially equal to zero (without any *minimization*).

EXAMPLES:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
....:     left=vector([0, 1]), right=vector([1, 0])).is_trivial_zero()
```

(continues on next page)

(continued from previous page)

```
False
sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
....:     left=vector([0, 0]), right=vector([1, 0])).is_trivial_zero()
True
sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
....:     left=vector([0, 1]), right=vector([0, 0])).is_trivial_zero()
True
```

```
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]])),
...     left=vector([Integer(0), Integer(1)]), right=vector([Integer(1),␣
↪Integer(0)])).is_trivial_zero()
False
>>> Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]])),
...     left=vector([Integer(0), Integer(0)]), right=vector([Integer(1),␣
↪Integer(0)])).is_trivial_zero()
True
>>> Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]])),
...     left=vector([Integer(0), Integer(1)]), right=vector([Integer(0),␣
↪Integer(0)])).is_trivial_zero()
True
```

The following two differ in the coefficient of the empty word:

```
sage: Rec((Matrix([[0, 0], [0, 0]]), Matrix([[0, 0], [0, 0]])),
....:     left=vector([0, 1]), right=vector([1, 0])).is_trivial_zero()
True
sage: Rec((Matrix([[0, 0], [0, 0]]), Matrix([[0, 0], [0, 0]])),
....:     left=vector([1, 1]), right=vector([1, 1])).is_trivial_zero()
False
```

```
>>> from sage.all import *
>>> Rec((Matrix([[Integer(0), Integer(0)], [Integer(0), Integer(0)]]),␣
↪Matrix([[Integer(0), Integer(0)], [Integer(0), Integer(0)]])),
...     left=vector([Integer(0), Integer(1)]), right=vector([Integer(1),␣
↪Integer(0)])).is_trivial_zero()
True
>>> Rec((Matrix([[Integer(0), Integer(0)], [Integer(0), Integer(0)]]),␣
↪Matrix([[Integer(0), Integer(0)], [Integer(0), Integer(0)]])),
...     left=vector([Integer(1), Integer(1)]), right=vector([Integer(1),␣
↪Integer(1)])).is_trivial_zero()
False
```

property left

When evaluating a coefficient, this vector is multiplied from the left to the matrix obtained from *mu* applied on a word.

linear_representation()

Return the linear representation of this series.

OUTPUT:

A triple `(left, mu, right)` containing the vectors *left* and *right*, and the family of matrices *mu*.

EXAMPLES:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
....:     vector([0, 1]), vector([1, 0])
....:    ).transposed().linear_representation()
((1, 0),
 Finite family {0: [3 0]
                   [6 1],
                1: [ 0  1]
                   [-6  5]},
 (0, 1))
```

```
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> Rec((Matrix([[Integer(3), Integer(6)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(0), -Integer(6)], [Integer(1), Integer(5)]])),
...      vector([Integer(0), Integer(1)]), vector([Integer(1), Integer(0)])
...     ).transposed().linear_representation()
((1, 0),
 Finite family {0: [3 0]
                   [6 1],
                1: [ 0  1]
                   [-6  5]},
 (0, 1))
```

minimized()

Return a recognizable series equivalent to this series, but with a minimized linear representation.

The coefficients of the involved matrices need be in a field. If this is not the case, then the coefficients are automatically coerced to their fraction field.

OUTPUT: a *RecognizableSeries*

ALGORITHM:

This method implements the minimization algorithm presented in Chapter 2 of [BR2010a].

Note

Due to the algorithm, the left vector of the result is always $(1, 0, \ldots, 0)$, i.e., the first vector of the standard basis.

EXAMPLES:

```
sage: from itertools import islice
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])

sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
....:         vector([0, 1]), vector([1, 0])).transposed()
sage: S
```

(continues on next page)

(continued from previous page)

```
[1] + 3*[01] + [10] + 5*[11] + 9*[001] + 3*[010]
    + 15*[011] + [100] + 11*[101] + 5*[110] + ...
sage: M = S.minimized()
sage: M.mu[0], M.mu[1], M.left, M.right
(

True
```

property mu

When evaluating a coefficient, this is applied on each letter of a word; the result is a matrix.

This extends *mu* to words over the parent's *alphabet()*.

property right

When evaluating a coefficient, this vector is multiplied from the right to the matrix obtained from *mu* applied on a word.

transposed()

Return the transposed series.

OUTPUT: a *RecognizableSeries*

Each of the matrices in *mu* is transposed. Additionally the vectors *left* and *right* are switched.

EXAMPLES:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
....:         vector([0, 1]), vector([1, 0])).transposed()
sage: S
[1] + 3*[01] + [10] + 5*[11] + 9*[001] + 3*[010]
    + 15*[011] + [100] + 11*[101] + 5*[110] + ...
sage: S.mu[0], S.mu[1], S.left, S.right
(
[3 0]  [ 0  1]
[6 1], [-6  5], (1, 0), (0, 1)
)
sage: T = S.transposed()
sage: T
[1] + [01] + 3*[10] + 5*[11] + [001] + 3*[010]
    + 5*[011] + 9*[100] + 11*[101] + 15*[110] + ...
sage: T.mu[0], T.mu[1], T.left, T.right
(
[3 6]  [ 0 -6]
[0 1], [ 1  5], (0, 1), (1, 0)
)
```

```
>>> from sage.all import *

```

class sage.combinat.recognizable_series.**RecognizableSeriesSpace**(*coefficient_ring*, *indices*, *category*, *minimize_results*)

Bases: `UniqueRepresentation`, `Parent`

The space of recognizable series on the given alphabet and with the given coefficients.

INPUT:

- `coefficient_ring` – a (semi-)ring
- `alphabet` – tuple, list or `TotallyOrderedFiniteSet`. If specified, then the `indices` are the finite words over this `alphabet`. `alphabet` and `indices` cannot be specified at the same time.
- `indices` – a SageMath-parent of finite words over an alphabet. `alphabet` and `indices` cannot be specified at the same time.
- `category` – (default: `None`) the category of this space

EXAMPLES:

We create a recognizable series that counts the number of ones in each word:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec
Space of recognizable series on {0, 1} with coefficients in Integer Ring
sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 1], [0, 1]])),
....:     vector([1, 0]), vector([0, 1]))
[1] + [01] + [10] + 2*[11] + [001] + [010] + 2*[011] + [100] + 2*[101] + 2*[110]␣
↪+ ...
```

```
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> Rec
Space of recognizable series on {0, 1} with coefficients in Integer Ring
>>> Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),␣
↪Matrix([[Integer(1), Integer(1)], [Integer(0), Integer(1)]])),
```

(continues on next page)

(continued from previous page)

```
...     vector([Integer(1), Integer(0)]), vector([Integer(0), Integer(1)]))
[1] + [01] + [10] + 2*[11] + [001] + [010] + 2*[011] + [100] + 2*[101] + 2*[110]␣
↪+ ...
```

All of the following examples create the same space:

```
sage: Rec1 = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec1
Space of recognizable series on {0, 1} with coefficients in Integer Ring
sage: Rec2 = RecognizableSeriesSpace(coefficient_ring=ZZ, alphabet=[0, 1])
sage: Rec2
Space of recognizable series on {0, 1} with coefficients in Integer Ring
sage: Rec3 = RecognizableSeriesSpace(ZZ, indices=Words([0, 1], infinite=False))
sage: Rec3
Space of recognizable series on {0, 1} with coefficients in Integer Ring
```

```
>>> from sage.all import *
>>> Rec1 = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> Rec1
Space of recognizable series on {0, 1} with coefficients in Integer Ring
>>> Rec2 = RecognizableSeriesSpace(coefficient_ring=ZZ, alphabet=[Integer(0),␣
↪Integer(1)])
>>> Rec2
Space of recognizable series on {0, 1} with coefficients in Integer Ring
>>> Rec3 = RecognizableSeriesSpace(ZZ, indices=Words([Integer(0), Integer(1)],␣
↪infinite=False))
>>> Rec3
Space of recognizable series on {0, 1} with coefficients in Integer Ring
```

See also

recognizable series, *RecognizableSeries*.

Element

alias of *RecognizableSeries*

alphabet()

Return the alphabet of this recognizable series space.

OUTPUT: a totally ordered set

EXAMPLES:

```
sage: RecognizableSeriesSpace(ZZ, [0, 1]).alphabet()
{0, 1}
```

```
>>> from sage.all import *
>>> RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)]).alphabet()
{0, 1}
```

coefficient_ring()

Return the coefficients of this recognizable series space.

OUTPUT:

A (semi-)ring

EXAMPLES:

```
sage: RecognizableSeriesSpace(ZZ, [0, 1]).coefficient_ring()
Integer Ring
```

```
>>> from sage.all import *
>>> RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)]).coefficient_ring()
Integer Ring
```

indices()

Return the indices of the recognizable series.

OUTPUT: the set of finite words over the alphabet

EXAMPLES:

```
sage: RecognizableSeriesSpace(ZZ, [0, 1]).indices()
Finite words over {0, 1}
```

```
>>> from sage.all import *
>>> RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)]).indices()
Finite words over {0, 1}
```

property minimize_results

A boolean indicating whether *RecognizableSeries.minimized()* is automatically called after performing operations.

one()

Return the one element of this *RecognizableSeriesSpace*, i.e. the embedding of the one of the coefficient ring into this *RecognizableSeriesSpace*.

EXAMPLES:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: O = Rec.one(); O
[] + ...
sage: O.linear_representation()
((1), Finite family {0: [0], 1: [0]}, (1))
```

```
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> O = Rec.one(); O
[] + ...
>>> O.linear_representation()
((1), Finite family {0: [0], 1: [0]}, (1))
```

one_hadamard()

Return the identity with respect to the *hadamard_product()*, i.e. the coefficient-wise multiplication.

OUTPUT: a *RecognizableSeries*

EXAMPLES:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec.one_hadamard()
[] + [0] + [1] + [00] + [01] + [10]
   + [11] + [000] + [001] + [010] + ...
```

```
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> Rec.one_hadamard()
[] + [0] + [1] + [00] + [01] + [10]
   + [11] + [000] + [001] + [010] + ...
```

some_elements(***kwds*)

Return some elements of this recognizable series space.

See `TestSuite` for a typical use case.

INPUT:

- `kwds` are passed on to the element constructor

OUTPUT: an iterator

EXAMPLES:

```
sage: tuple(RecognizableSeriesSpace(ZZ, [0, 1]).some_elements())
([1] + [01] + [10] + 2*[11] + [001] + [010]
     + 2*[011] + [100] + 2*[101] + 2*[110] + ...,
 [] + [1] + [11] + [111] + [1111] + [11111] + [111111] + ...,
 [] + [0] + [1] + [00] + [10] + [11]
    + [000] - 1*[001] + [100] + [110] + ...,
 2*[] - 1*[1] + 2*[10] - 1*[101]
      + 2*[1010] - 1*[10101] + 2*[101010] + ...,
 [] + [1] + 6*[00] + [11] - 39*[000] + 5*[001] + 6*[100] + [111]
    + 288*[0000] - 33*[0001] + ...,
 -5*[] + ...,
 ...
 210*[] + ...,
 2210*[] - 170*[0] + 170*[1] + ...)
```

```
>>> from sage.all import *
>>> tuple(RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)]).some_
↪elements())
([1] + [01] + [10] + 2*[11] + [001] + [010]
     + 2*[011] + [100] + 2*[101] + 2*[110] + ...,
 [] + [1] + [11] + [111] + [1111] + [11111] + [111111] + ...,
 [] + [0] + [1] + [00] + [10] + [11]
    + [000] - 1*[001] + [100] + [110] + ...,
 2*[] - 1*[1] + 2*[10] - 1*[101]
      + 2*[1010] - 1*[10101] + 2*[101010] + ...,
 [] + [1] + 6*[00] + [11] - 39*[000] + 5*[001] + 6*[100] + [111]
    + 288*[0000] - 33*[0001] + ...,
 -5*[] + ...,
 ...
 210*[] + ...,
 2210*[] - 170*[0] + 170*[1] + ...)
```

sage.combinat.recognizable_series.**minimize_result**(*operation*)

A decorator for operations that enables control of automatic minimization on the result.

INPUT:

- `operation` – a method

OUTPUT: a method with the following additional argument:

- `minimize` – (default: `None`) a boolean or `None`. If `True`, then *`minimized()`* is called after the operation, if `False`, then not. If this argument is `None`, then the default specified by the parent's `minimize_results` is used.

Note

If the result of `operation` is `self`, then minimization is not applied unless `minimize=True` is explicitly set, in particular, independent of the parent's `minimize_results`.

Representations of the symmetric group

Todo

- construct the product of two irreducible representations.
- implement Induction/Restriction of representations.

Warning

This code uses a different convention than in Sagan's book "The Symmetric Group"

class sage.combinat.symmetric_group_representations.**GarsiaProcesiModule**(*SGA*, *shape*)

Bases: `UniqueRepresentation`, `QuotientRing_generic`, *`SymmetricGroupRepresentation`*

A Garsia-Procesi module.

Let λ be a partition of n and R be a commutative ring. The *Garsia-Procesi module* is defined by $R_\lambda := R[x_1, \ldots, x_n]/I_\lambda$, where

$$I_\lambda := \langle e_r(x_{i_1}, \ldots, x_{i_k}) \mid \{i_1, \ldots, i_k\} \subseteq [n] \text{ and } k \geq r > k - d_k(\lambda) \rangle,$$

with e_r being the r-the elementary symmetric function and $d_k(\lambda) = \lambda'_n + \cdots + \lambda'_{n+1-k}$, is the *Tanisaki ideal*.

If we consider $R = \mathbf{Q}$, then the Garsia-Procesi module has the following interpretation. Let $\mathcal{F}_n = GL_n/B$ denote the (complex type A) flag variety. Consider the Springer fiber $F_\lambda \subseteq \mathcal{F}_n$ associated to a nilpotent matrix with Jordan blocks sizes λ. Springer showed that the cohomology ring $H^*(F_\lambda)$ admits a graded S_n-action that agrees with the induced representation of the sign representation of the Young subgroup S_λ. From work of De Concini and Procesi, this S_n-representation is isomorphic to R_λ. Moreover, the graded Frobenius image is known to be a modified Hall-Littlewood polynomial.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 7)
sage: GP421 = SGA.garsia_procesi_module([4, 2, 1])
sage: GP421.dimension()
```

(continues on next page)

(continued from previous page)

```
105
sage: v = GP421.an_element(); v
-gp1 - gp2 - gp3 - gp4 - gp5 - gp6
sage: SGA.an_element() * v
-6*gp1 - 6*gp2 - 6*gp3 - 6*gp4 - 6*gp5 - 5*gp6
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(7))
>>> GP421 = SGA.garsia_procesi_module([Integer(4), Integer(2), Integer(1)])
>>> GP421.dimension()
105
>>> v = GP421.an_element(); v
-gp1 - gp2 - gp3 - gp4 - gp5 - gp6
>>> SGA.an_element() * v
-6*gp1 - 6*gp2 - 6*gp3 - 6*gp4 - 6*gp5 - 5*gp6
```

We verify the result is a modified Hall-Littlewood polynomial by using the Q' Hall-Littlewood polynomials, replacing $q \mapsto q^{-1}$ and multiplying by the smallest power of q so the coefficients are again polynomials:

```
sage: GP421.graded_frobenius_image()
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
 + (q^2+q)*s[6, 1] + s[7]
sage: R.<q> = QQ[]
sage: Sym = SymmetricFunctions(R)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(q).Qp()
sage: mHL = s(Qp[4,2,1]); mHL
s[4, 2, 1] + q*s[4, 3] + q*s[5, 1, 1] + (q^2+q)*s[5, 2]
 + (q^3+q^2)*s[6, 1] + q^4*s[7]
sage: mHL.map_coefficients(lambda c: R(q^4*c(q^-1)))
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
 + (q^2+q)*s[6, 1] + s[7]
```

```
>>> from sage.all import *
>>> GP421.graded_frobenius_image()
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
 + (q^2+q)*s[6, 1] + s[7]
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> Sym = SymmetricFunctions(R)
>>> s = Sym.s()
>>> Qp = Sym.hall_littlewood(q).Qp()
>>> mHL = s(Qp[Integer(4),Integer(2),Integer(1)]); mHL
s[4, 2, 1] + q*s[4, 3] + q*s[5, 1, 1] + (q^2+q)*s[5, 2]
 + (q^3+q^2)*s[6, 1] + q^4*s[7]
>>> mHL.map_coefficients(lambda c: R(q**Integer(4)*c(q**-Integer(1))))
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
 + (q^2+q)*s[6, 1] + s[7]
```

We show that the maximal degree component corresponds to the Yamanouchi words of content λ:

```
sage: B = GP421.graded_decomposition(4).basis()
sage: top_deg = [Word([i+1 for i in b.lift().lift().exponents()[0]]) for b in B]
```

(continues on next page)

(continued from previous page)

```
sage: yamanouchi = [P.to_packed_word() for P in OrderedSetPartitions(range(7), [4,
↪ 2, 1])
....:                if P.to_packed_word().reversal().is_yamanouchi()]
sage: set(top_deg) == set(yamanouchi)
True
```

```
>>> from sage.all import *
>>> B = GP421.graded_decomposition(Integer(4)).basis()
>>> top_deg = [Word([i+Integer(1) for i in b.lift().lift().
↪exponents()[Integer(0)]]) for b in B]
>>> yamanouchi = [P.to_packed_word() for P in␣
↪OrderedSetPartitions(range(Integer(7)), [Integer(4), Integer(2), Integer(1)])
...                if P.to_packed_word().reversal().is_yamanouchi()]
>>> set(top_deg) == set(yamanouchi)
True
```

class Element(*parent*, *rep*, *reduce=True*)

Bases: QuotientRingElement

degree()

Return the degree of self.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP22 = SGA.garsia_procesi_module([2, 2])
sage: for b in GP22.basis():
....:     print(b, b.degree())
gp2*gp3 2
gp1*gp3 2
gp3 1
gp2 1
gp1 1
1 0
sage: v = sum(GP22.basis())
sage: v.degree()
2
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> GP22 = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> for b in GP22.basis():
...     print(b, b.degree())
gp2*gp3 2
gp1*gp3 2
gp3 1
gp2 1
gp1 1
1 0
>>> v = sum(GP22.basis())
>>> v.degree()
2
```

homogeneous_degree()

Return the (homogeneous) degree of `self` if homogeneous otherwise raise an error.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(2), 4)
sage: GP31 = SGA.garsia_procesi_module([3, 1])
sage: for b in GP31.basis():
....:     print(b, b.homogeneous_degree())
gp3 1
gp2 1
gp1 1
1 0
sage: v = sum(GP31.basis()); v
gp1 + gp2 + gp3 + 1
sage: v.homogeneous_degree()
Traceback (most recent call last):
...
ValueError: element is not homogeneous
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(4))
>>> GP31 = SGA.garsia_procesi_module([Integer(3), Integer(1)])
>>> for b in GP31.basis():
...     print(b, b.homogeneous_degree())
gp3 1
gp2 1
gp1 1
1 0
>>> v = sum(GP31.basis()); v
gp1 + gp2 + gp3 + 1
>>> v.homogeneous_degree()
Traceback (most recent call last):
...
ValueError: element is not homogeneous
```

monomial_coefficients(*copy=None*)

Return the monomial coefficients of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP31 = SGA.garsia_procesi_module([3, 1])
sage: v = GP31.an_element(); v
-gp1 - gp2 - gp3
sage: v.monomial_coefficients()
{0: 2, 1: 2, 2: 2, 3: 0}
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> GP31 = SGA.garsia_procesi_module([Integer(3), Integer(1)])
>>> v = GP31.an_element(); v
-gp1 - gp2 - gp3
```

(continues on next page)

(continued from previous page)

```
>>> v.monomial_coefficients()
{0: 2, 1: 2, 2: 2, 3: 0}
```

to_vector(*order=None*)

Return `self` as a (dense) free module vector.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP22 = SGA.garsia_procesi_module([2, 2])
sage: v = GP22.an_element(); v
-gp1 - gp2 - gp3
sage: v.to_vector()
(0, 0, 2, 2, 2, 0)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> GP22 = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> v = GP22.an_element(); v
-gp1 - gp2 - gp3
>>> v.to_vector()
(0, 0, 2, 2, 2, 0)
```

basis()

Return a basis of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
sage: GP.basis()
Family (gp2*gp3, gp1*gp3, gp3, gp2, gp1, 1)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> GP.basis()
Family (gp2*gp3, gp1*gp3, gp3, gp2, gp1, 1)
```

dimension()

Return the dimension of `self`.

The graded Frobenius character of the Garsia-Procesi module R_λ is given by the modified Hall-Littlewood polynomial $\widetilde{H}_{\lambda'}(x;q)$.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(1).Qp()
sage: for la in Partitions(5):
....:     print(SGA.garsia_procesi_module(la).dimension(),
```

(continues on next page)

(continued from previous page)

```
....:           sum(c * StandardTableaux(la).cardinality()
....:               for la, c in s(Qp[la])))
1 1
5 5
10 10
20 20
30 30
60 60
120 120
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> Qp = Sym.hall_littlewood(Integer(1)).Qp()
>>> for la in Partitions(Integer(5)):
...     print(SGA.garsia_procesi_module(la).dimension(),
...           sum(c * StandardTableaux(la).cardinality()
...               for la, c in s(Qp[la])))
1 1
5 5
10 10
20 20
30 30
60 60
120 120
```

get_order()

Return the order of the elements in the basis.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
sage: GP.get_order()
(0, 1, 2, 3, 4, 5)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> GP.get_order()
(0, 1, 2, 3, 4, 5)
```

graded_brauer_character()

Return the graded Brauer character of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(2), 5)
sage: GP311 = SGA.garsia_procesi_module([3, 1, 1])
sage: GP311.graded_brauer_character()
(6*q^3 + 9*q^2 + 4*q + 1, q + 1, q^3 - q^2 - q + 1)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(5))
>>> GP311 = SGA.garsia_procesi_module([Integer(3), Integer(1), Integer(1)])
>>> GP311.graded_brauer_character()
(6*q^3 + 9*q^2 + 4*q + 1, q + 1, q^3 - q^2 - q + 1)
```

graded_character()

Return the graded character of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: GP = SGA.garsia_procesi_module([2, 2, 1])
sage: gchi = GP.graded_character(); gchi
(5*q^4 + 11*q^3 + 9*q^2 + 4*q + 1, -q^4 + q^3 + 3*q^2 + 2*q + 1,
 q^4 - q^3 + q^2 + 1, -q^4 - q^3 + q + 1, -q^4 + q^3 - q + 1,
 q^4 - q^3 - q^2 + 1, q^3 - q^2 - q + 1)
sage: R.<q> = QQ[]
sage: gchi == sum(q^d * D.character()
....:             for d, D in GP.graded_decomposition().items())
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2), Integer(1)])
>>> gchi = GP.graded_character(); gchi
(5*q^4 + 11*q^3 + 9*q^2 + 4*q + 1, -q^4 + q^3 + 3*q^2 + 2*q + 1,
 q^4 - q^3 + q^2 + 1, -q^4 - q^3 + q + 1, -q^4 + q^3 - q + 1,
 q^4 - q^3 - q^2 + 1, q^3 - q^2 - q + 1)
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> gchi == sum(q**d * D.character()
...             for d, D in GP.graded_decomposition().items())
True
```

graded_decomposition(*k=None*)

Return the decomposition of `self` as a direct sum of representations given by a fixed grading.

INPUT:

- `k` – (optional) integer; if given, return the k-th graded part

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(2), 5)
sage: GP32 = SGA.garsia_procesi_module([3, 2])
sage: decomp = GP32.graded_decomposition(); decomp
{0: Subrepresentation with basis {0} of Garsia-Procesi ...,
 1: Subrepresentation with basis {0, 1, 2, 3} of Garsia-Procesi ...,
 2: Subrepresentation with basis {0, 1, 2, 3, 4} of Garsia-Procesi ...}
sage: decomp[2] is GP32.graded_decomposition(2)
True
sage: GP32.graded_decomposition(10)
Subrepresentation with basis {} of Garsia-Procesi module
 of shape [3, 2] over Finite Field of size 2
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(5))
>>> GP32 = SGA.garsia_procesi_module([Integer(3), Integer(2)])
>>> decomp = GP32.graded_decomposition(); decomp
{0: Subrepresentation with basis {0} of Garsia-Procesi ...,
 1: Subrepresentation with basis {0, 1, 2, 3} of Garsia-Procesi ...,
 2: Subrepresentation with basis {0, 1, 2, 3, 4} of Garsia-Procesi ...}
>>> decomp[Integer(2)] is GP32.graded_decomposition(Integer(2))
True
>>> GP32.graded_decomposition(Integer(10))
Subrepresentation with basis {} of Garsia-Procesi module
 of shape [3, 2] over Finite Field of size 2
```

graded_frobenius_image()

Return the graded Frobenius image of `self`.

The graded Frobenius image is the sum of the *sage.combinat.specht_module.SymmetricGroupRepresentation.frobenius_image()* of each graded component, which is known to result in the modified Hall-Littlewood polynomial $\widetilde{H}_\lambda(x;q)$.

EXAMPLES:

We verify that the result is the modified Hall-Littlewood polynomial for $n = 5$:

```
sage: R.<q> = QQ[]
sage: Sym = SymmetricFunctions(R)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(q).Qp()
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: for la in Partitions(5):
....:     f = SGA.garsia_procesi_module(la).graded_frobenius_image()
....:     d = f[la].degree()
....:     assert f.map_coefficients(lambda c: R(c(~q)*q^d)) == s(Qp[la])
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> Sym = SymmetricFunctions(R)
>>> s = Sym.s()
>>> Qp = Sym.hall_littlewood(q).Qp()
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> for la in Partitions(Integer(5)):
...     f = SGA.garsia_procesi_module(la).graded_frobenius_image()
...     d = f[la].degree()
...     assert f.map_coefficients(lambda c: R(c(~q)*q**d)) == s(Qp[la])
```

graded_representation_matrix(*elt*, *q=None*)

Return the matrix corresponding to the left action of the symmetric group (algebra) element `elt` on `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 3)
sage: GP = SGA.garsia_procesi_module([1, 1, 1])
sage: elt = SGA.an_element(); elt
[1, 2, 3] + 2*[1, 3, 2] + [3, 1, 2]
```

(continues on next page)

(continued from previous page)

```
sage: X = GP.graded_representation_matrix(elt); X
[  0   0   0   0   0   0]
[  0 q^2   0   0   0   0]
[  0 q^2   0   0   0   0]
[  0   0   0   q   0   0]
[  0   0   0   q   0   0]
[  0   0   0   0   0   1]
sage: X.parent()
Full MatrixSpace of 6 by 6 dense matrices over
 Univariate Polynomial Ring in q over Finite Field of size 3
sage: R.<q> = GF(3)[]
sage: t = R.quotient([q^2+2*q+1]).gen()
sage: GP.graded_representation_matrix(elt, t)
[       0        0        0        0        0        0]
[       0 qbar + 2        0        0        0        0]
[       0 qbar + 2        0        0        0        0]
[       0        0        0     qbar        0        0]
[       0        0        0     qbar        0        0]
[       0        0        0        0        0        1]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(3))
>>> GP = SGA.garsia_procesi_module([Integer(1), Integer(1), Integer(1)])
>>> elt = SGA.an_element(); elt
[1, 2, 3] + 2*[1, 3, 2] + [3, 1, 2]
>>> X = GP.graded_representation_matrix(elt); X
[  0   0   0   0   0   0]
[  0 q^2   0   0   0   0]
[  0 q^2   0   0   0   0]
[  0   0   0   q   0   0]
[  0   0   0   q   0   0]
[  0   0   0   0   0   1]
>>> X.parent()
Full MatrixSpace of 6 by 6 dense matrices over
 Univariate Polynomial Ring in q over Finite Field of size 3
>>> R = GF(Integer(3))['q']; (q,) = R._first_ngens(1)
>>> t = R.quotient([q**Integer(2)+Integer(2)*q+Integer(1)]).gen()
>>> GP.graded_representation_matrix(elt, t)
[       0        0        0        0        0        0]
[       0 qbar + 2        0        0        0        0]
[       0 qbar + 2        0        0        0        0]
[       0        0        0     qbar        0        0]
[       0        0        0     qbar        0        0]
[       0        0        0        0        0        1]
```

one_basis()

Return the index of the basis element 1.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
```

(continues on next page)

(continued from previous page)

```
sage: GP.one_basis()
5
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> GP.one_basis()
5
```

class sage.combinat.symmetric_group_representations.**SpechtRepresentation**(*parent*, *partition*)

Bases: *SymmetricGroupRepresentation_generic_class*

representation_matrix(*permutation*)

Return the matrix representing the `permutation` in this irreducible representation.

Note

This method caches the results.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.representation_matrix(Permutation([2,1,3,4]))
[ 0 -1  0]
[-1  0  0]
[ 0  0  1]
sage: spc.representation_matrix(Permutation([3,2,1,4]))
[0 0 1]
[0 1 0]
[1 0 0]
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(1)], 'specht')
>>> spc.representation_matrix(Permutation([Integer(2),Integer(1),Integer(3),
↪Integer(4)]))
[ 0 -1  0]
[-1  0  0]
[ 0  0  1]
>>> spc.representation_matrix(Permutation([Integer(3),Integer(2),Integer(1),
↪Integer(4)]))
[0 0 1]
[0 1 0]
[1 0 0]
```

scalar_product(*u*, *v*)

Return `0` if `u+v` is not a permutation, and the signature of the permutation otherwise.

This is the scalar product of a vertex `u` of the underlying Yang-Baxter graph with the vertex `v` in the 'dual' Yang-Baxter graph.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,2], 'specht')
sage: spc.scalar_product((1,0,2,1,0),(0,3,0,3,0))
-1
sage: spc.scalar_product((1,0,2,1,0),(3,0,0,3,0))
0
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], 'specht')
>>> spc.scalar_product((Integer(1),Integer(0),Integer(2),Integer(1),
↪Integer(0)),(Integer(0),Integer(3),Integer(0),Integer(3),Integer(0)))
-1
>>> spc.scalar_product((Integer(1),Integer(0),Integer(2),Integer(1),
↪Integer(0)),(Integer(3),Integer(0),Integer(0),Integer(3),Integer(0)))
0
```

scalar_product_matrix(*permutation=None*)

Return the scalar product matrix corresponding to `permutation`.

The entries are given by the scalar products of `u` and `permutation.action(v)`, where `u` is a vertex in the underlying Yang-Baxter graph and `v` is a vertex in the dual graph.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.scalar_product_matrix()
[ 1  0  0]
[ 0 -1  0]
[ 0  0  1]
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(1)], 'specht')
>>> spc.scalar_product_matrix()
[ 1  0  0]
[ 0 -1  0]
[ 0  0  1]
```

class sage.combinat.symmetric_group_representations.**SpechtRepresentations**(*n*, *ring=None*, *cache_matrices=True*)

Bases: *SymmetricGroupRepresentations_class*

Element

alias of *SpechtRepresentation*

sage.combinat.symmetric_group_representations.**SymmetricGroupRepresentation**(*partition*, *implementation='specht'*, *ring=None*, *cache_matrices=True*)

The irreducible representation of the symmetric group corresponding to `partition`.

INPUT:

- `partition` – a partition of a positive integer

- `implementation` – string (default: `'specht'`); one of:
  - `'seminormal'` – for Young's seminormal representation
  - `'orthogonal'` – for Young's orthogonal representation
  - `'specht'` – for Specht's representation
  - `'unitary'` – for the unitary representation
- `ring` – the ring over which the representation is defined
- `cache_matrices` – boolean (default: `True`); if `True`, then any representation matrices that are computed are cached

EXAMPLES:

Young's orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal"); orth            #␣
↪needs sage.symbolic
Orthogonal representation of the symmetric group corresponding to [2, 1]
sage: all(a*a.transpose() == a.parent().identity_matrix() for a in orth)        #␣
↪needs sage.symbolic
True
```

```
>>> from sage.all import *
>>> orth = SymmetricGroupRepresentation([Integer(2),Integer(1)], "orthogonal");␣
↪orth            # needs sage.symbolic
Orthogonal representation of the symmetric group corresponding to [2, 1]
>>> all(a*a.transpose() == a.parent().identity_matrix() for a in orth)        #␣
↪needs sage.symbolic
True
```

```
sage: # needs sage.symbolic
sage: orth = SymmetricGroupRepresentation([3,2], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [3, 2]
sage: orth([2,1,3,4,5])
[ 1  0  0  0  0]
[ 0  1  0  0  0]
[ 0  0 -1  0  0]
[ 0  0  0  1  0]
[ 0  0  0  0 -1]
sage: orth([1,3,2,4,5])
[          1           0           0           0           0]
[          0        -1/2 1/2*sqrt(3)           0           0]
[          0 1/2*sqrt(3)         1/2           0           0]
[          0           0           0        -1/2 1/2*sqrt(3)]
[          0           0           0 1/2*sqrt(3)         1/2]
sage: orth([1,2,4,3,5])
[       -1/3 2/3*sqrt(2)           0           0           0]
[2/3*sqrt(2)         1/3           0           0           0]
[          0           0           1           0           0]
[          0           0           0           1           0]
[          0           0           0           0          -1]
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> orth = SymmetricGroupRepresentation([Integer(3),Integer(2)], "orthogonal");␣
↪orth
Orthogonal representation of the symmetric group corresponding to [3, 2]
>>> orth([Integer(2),Integer(1),Integer(3),Integer(4),Integer(5)])
[ 1  0  0  0  0]
[ 0  1  0  0  0]
[ 0  0 -1  0  0]
[ 0  0  0  1  0]
[ 0  0  0  0 -1]
>>> orth([Integer(1),Integer(3),Integer(2),Integer(4),Integer(5)])
[          1           0           0           0           0]
[          0        -1/2 1/2*sqrt(3)           0           0]
[          0 1/2*sqrt(3)         1/2           0           0]
[          0           0           0        -1/2 1/2*sqrt(3)]
[          0           0           0 1/2*sqrt(3)         1/2]
>>> orth([Integer(1),Integer(2),Integer(4),Integer(3),Integer(5)])
[       -1/3 2/3*sqrt(2)           0           0           0]
[2/3*sqrt(2)         1/3           0           0           0]
[          0           0           1           0           0]
[          0           0           0           1           0]
[          0           0           0           0          -1]
```

The Specht representation:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc.scalar_product_matrix(Permutation([1,2,3,4,5]))
[ 1  0  0  0  0]
[ 0 -1  0  0  0]
[ 0  0  1  0  0]
[ 0  0  0  1  0]
[-1  0  0  0 -1]
sage: spc.scalar_product_matrix(Permutation([5,4,3,2,1]))
[ 1 -1  0  1  0]

[6 0 0]
[0 1 0]
[0 0 1]
>>> unitary_GF49([Integer(3),Integer(2),Integer(1),Integer(4)])
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
```

(continues on next page)

(continued from previous page)

```
[       0        0        1]
>>> unitary_GF49.verify_representation()
True
```

By default, any representation matrices that are computed are cached:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: spc._cache__representation_matrix
{(([5, 4, 3, 2, 1],), ()): [ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]}
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], "specht")
>>> spc([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
>>> spc._cache__representation_matrix
{(([5, 4, 3, 2, 1],), ()): [ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]}
```

This can be turned off with the keyword `cache_matrices`:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht", cache_matrices=False)
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: hasattr(spc, '_cache__representation_matrix')
False
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], "specht", cache_
↪matrices=False)
>>> spc([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)])
[ 1 -1  0  1  0]
```

(continues on next page)

(continued from previous page)

```
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
>>> hasattr(spc, '_cache__representation_matrix')
False
```

Note

The implementation is based on the paper [Las].

class sage.combinat.symmetric_group_representations.**SymmetricGroupRepresentation_generic_class**(*parent*, *partition*)

Bases: Element

Generic methods for a representation of the symmetric group.

to_character()

Return the character of the representation.

EXAMPLES:

The trivial character:

```
sage: rho = SymmetricGroupRepresentation([3])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, 1, 1]
sage: all(chi(g) == 1 for g in SymmetricGroup(3))
True
```

```
>>> from sage.all import *
>>> rho = SymmetricGroupRepresentation([Integer(3)])
>>> chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
>>> chi.values()
[1, 1, 1]
>>> all(chi(g) == Integer(1) for g in SymmetricGroup(Integer(3)))
True
```

The sign character:

```
sage: rho = SymmetricGroupRepresentation([1,1,1])
sage: chi = rho.to_character(); chi
```

(continues on next page)

(continued from previous page)

```
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, -1, 1]
sage: all(chi(g) == g.sign() for g in SymmetricGroup(3))
True
```

```
>>> from sage.all import *
>>> rho = SymmetricGroupRepresentation([Integer(1),Integer(1),Integer(1)])
>>> chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
>>> chi.values()
[1, -1, 1]
>>> all(chi(g) == g.sign() for g in SymmetricGroup(Integer(3)))
True
```

The defining representation:

```
sage: triv = SymmetricGroupRepresentation([4])
sage: hook = SymmetricGroupRepresentation([3,1])
sage: def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
sage: list(map(def_rep, Permutations(4)))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
sage: [p.to_matrix().trace() for p in Permutations(4)]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
```

```
>>> from sage.all import *
>>> triv = SymmetricGroupRepresentation([Integer(4)])
>>> hook = SymmetricGroupRepresentation([Integer(3),Integer(1)])
>>> def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
>>> list(map(def_rep, Permutations(Integer(4))))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
>>> [p.to_matrix().trace() for p in Permutations(Integer(4))]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
```

verify_representation()

Verify the representation.

This tests that the images of the simple transpositions are involutions and tests that the braid relations hold.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([1,1,1])
sage: spc.verify_representation()
True
sage: spc = SymmetricGroupRepresentation([4,2,1])
sage: spc.verify_representation()
True
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(1),Integer(1),Integer(1)])
>>> spc.verify_representation()
True
```

(continues on next page)

(continued from previous page)

```
>>> spc = SymmetricGroupRepresentation([Integer(4),Integer(2),Integer(1)])
>>> spc.verify_representation()
True
```

sage.combinat.symmetric_group_representations.**SymmetricGroupRepresentations**(*n*, *implementation='specht'*, *ring=None*, *cache_matrices=True*)

Irreducible representations of the symmetric group.

INPUT:

- `n` – positive integer
- `implementation` – string (default: `'specht'`); one of:
  - `'seminormal'` – for Young's seminormal representation
  - `'orthogonal'` – for Young's orthogonal representation
  - `'specht'` – for Specht's representation
  - `'unitary'` – for the unitary representation
- `ring` – the ring over which the representation is defined
- `cache_matrices` – boolean (default: `True`); if `True`, then any representation matrices that are computed are cached

EXAMPLES:

Young's orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentations(3, "orthogonal"); orth                #␣
↪needs sage.symbolic
Orthogonal representations of the symmetric group of order 3! over Symbolic Ring
sage: orth.list()                                                                #␣
↪needs sage.symbolic
[Orthogonal representation of the symmetric group corresponding to [3],
 Orthogonal representation of the symmetric group corresponding to [2, 1],
 Orthogonal representation of the symmetric group corresponding to [1, 1, 1]]
sage: orth([2,1])([1,2,3])                                                       #␣
↪needs sage.symbolic
[1 0]
[0 1]
```

```
>>> from sage.all import *
>>> orth = SymmetricGroupRepresentations(Integer(3), "orthogonal"); orth         ␣
↪     # needs sage.symbolic
Orthogonal representations of the symmetric group of order 3! over Symbolic Ring
>>> orth.list()                                                                  #␣
↪needs sage.symbolic
[Orthogonal representation of the symmetric group corresponding to [3],
 Orthogonal representation of the symmetric group corresponding to [2, 1],
 Orthogonal representation of the symmetric group corresponding to [1, 1, 1]]
>>> orth([Integer(2),Integer(1)])([Integer(1),Integer(2),Integer(3)])            ␣
```

(continues on next page)

(continued from previous page)

```
↪                                                    # needs sage.symbolic
[1 0]
[0 1]
```

Young's seminormal representation.

```
sage: snorm = SymmetricGroupRepresentations(3, "seminormal"); snorm
Seminormal representations of the symmetric group of order 3! over Rational Field
sage: sgn = snorm([1,1,1]); sgn
Seminormal representation of the symmetric group corresponding to [1, 1, 1]
sage: list(map(sgn, Permutations(3)))
[[1], [-1], [-1], [1], [1], [-1]]
```

```
>>> from sage.all import *
>>> snorm = SymmetricGroupRepresentations(Integer(3), "seminormal"); snorm
Seminormal representations of the symmetric group of order 3! over Rational Field
>>> sgn = snorm([Integer(1),Integer(1),Integer(1)]); sgn
Seminormal representation of the symmetric group corresponding to [1, 1, 1]
>>> list(map(sgn, Permutations(Integer(3))))
[[1], [-1], [-1], [1], [1], [-1]]
```

The Specht Representation.

```
sage: spc = SymmetricGroupRepresentations(5, "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring
sage: spc([3,2])([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentations(Integer(5), "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring
>>> spc([Integer(3),Integer(2)])([Integer(5),Integer(4),Integer(3),Integer(2),
↪Integer(1)])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
```

The unitary representation.

```
sage: unitary = SymmetricGroupRepresentations(3, "unitary"); unitary
Unitary representations of the symmetric group of order 3! over Symbolic Ring
sage: unitary_GF49 = SymmetricGroupRepresentations(4, "unitary", ring=GF(7**2));␣
↪unitary_GF49
Unitary representations of the symmetric group of order 4! over Finite Field in␣
↪z2 of size 7^2
sage: unitary_GF49([3,1])([2,1,3,4])
```

(continues on next page)

(continued from previous page)

```
[6 0 0]
[0 1 0]
[0 0 1]
sage: unitary_GF49([3,1])([3,2,1,4])
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
```

```
>>> from sage.all import *
>>> unitary = SymmetricGroupRepresentations(Integer(3), "unitary"); unitary
Unitary representations of the symmetric group of order 3! over Symbolic Ring
>>> unitary_GF49 = SymmetricGroupRepresentations(Integer(4), "unitary",␣
↪ring=GF(Integer(7)**Integer(2))); unitary_GF49
Unitary representations of the symmetric group of order 4! over Finite Field in␣
↪z2 of size 7^2
>>> unitary_GF49([Integer(3),Integer(1)])([Integer(2),Integer(1),Integer(3),
↪Integer(4)])
[6 0 0]
[0 1 0]
[0 0 1]
>>> unitary_GF49([Integer(3),Integer(1)])([Integer(3),Integer(2),Integer(1),
↪Integer(4)])
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
```

Note

The implementation is based on the paper [Las].

AUTHORS:

- Franco Saliola (2009-04-23)

class sage.combinat.symmetric_group_representations.**SymmetricGroupRepresentations_class**(*n*, *ring=None*, *cache_matrices=True*)

Bases: `UniqueRepresentation`, `Parent`

Generic methods for the CombinatorialClass of irreducible representations of the symmetric group.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: sp = SymmetricGroupRepresentations(4, "specht")
sage: sp.cardinality()
5
```

```
>>> from sage.all import *
>>> sp = SymmetricGroupRepresentations(Integer(4), "specht")
>>> sp.cardinality()
5
```

class sage.combinat.symmetric_group_representations.**UnitaryRepresentation**(*parent*, *partition*)

Bases: *SymmetricGroupRepresentation_generic_class*

A unitary representation of the symmetric group.

In characteristic zero, this is the same as the orthogonal representation since they are defined over the reals. In positive characteristic, we are able to construct representations when the field is finite, has square order, and the characteristic does not divide the order of the group. In this case, we construct the representation by first constructing the orthogonal representation ρ and then taking the extended Cholesky decomposition of the unique solution U to the equation $\rho(g)^T U \rho(g) = U$ for all g in G.

representation_matrix(*permutation*)

Return the matrix representing the `permutation` in this irreducible representation.

Note

This method caches the results.

EXAMPLES:

```
sage: unitary_specht = SymmetricGroupRepresentation([3,1], 'unitary',␣
↪ring=GF(7**2))
sage: unitary_specht.representation_matrix(Permutation([2,1,3,4]))
[6 0 0]
[0 1 0]
[0 0 1]
sage: unitary_specht.representation_matrix(Permutation([3,2,1,4]))
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
sage: all(A * A.H == 1 for A in [unitary_specht.representation_matrix(g)
....:                            for g in Permutations(4)])
True
```

```
>>> from sage.all import *
>>> unitary_specht = SymmetricGroupRepresentation([Integer(3),Integer(1)],
↪'unitary', ring=GF(Integer(7)**Integer(2)))
>>> unitary_specht.representation_matrix(Permutation([Integer(2),Integer(1),
↪Integer(3),Integer(4)]))
[6 0 0]
[0 1 0]
[0 0 1]
>>> unitary_specht.representation_matrix(Permutation([Integer(3),Integer(2),
↪Integer(1),Integer(4)]))
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
>>> all(A * A.H == Integer(1) for A in [unitary_specht.representation_
```

(continues on next page)

(continued from previous page)

```
↪matrix(g)
...                                 for g in Permutations(Integer(4))])
True
```

class sage.combinat.symmetric_group_representations.**UnitaryRepresentations**(*n*, *ring=None*, *cache_matrices=True*)

Bases: *SymmetricGroupRepresentations_class*

Element

alias of *UnitaryRepresentation*

class sage.combinat.symmetric_group_representations.**YoungRepresentation_Orthogonal**(*parent*, *partition*)

Bases: *YoungRepresentation_generic*

>>> norm.representation_matrix(p)
[ 1  0]
[ 0 -1]
>>> p = PermutationGroupElement([Integer(1),Integer(3),Integer(2)])
>>> norm.representation_matrix(p)
[-1/2  3/2]
[ 1/2  1/2]
```

representation_matrix_for_simple_transposition(*i*)

Return the matrix representing the transposition that swaps `i` and `i+1`.

EXAMPLES:

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")              #␣
↪needs sage.symbolic
sage: orth.representation_matrix_for_simple_transposition(1)                #␣
↪needs sage.symbolic
[ 1  0]
[ 0 -1]
sage: orth.representation_matrix_for_simple_transposition(2)                #␣
↪needs sage.symbolic
[       -1/2 1/2*sqrt(3)]
[1/2*sqrt(3)         1/2]

sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: norm.representation_matrix_for_simple_transposition(1)
[ 1  0]
[ 0 -1]
sage: norm.representation_matrix_for_simple_transposition(2)
[-1/2  3/2]
[ 1/2  1/2]
```

```
>>> from sage.all import *
>>> orth = SymmetricGroupRepresentation([Integer(2),Integer(1)], "orthogonal
```

(continues on next page)

(continued from previous page)

```
↪")              # needs sage.symbolic
>>> orth.representation_matrix_for_simple_transposition(Integer(1))          ␣
↪     # needs sage.symbolic
[ 1  0]
[ 0 -1]
>>> orth.representation_matrix_for_simple_transposition(Integer(2))          ␣

[-1/2  3/2]
[ 1/2  1/2]
```

class sage.combinat.symmetric_group_representations.**YoungRepresentations_Orthogonal**(*n*, *ring=None*, *cache_matrices=True*)

Bases: *SymmetricGroupRepresentations_class*

Element

alias of *YoungRepresentation_Orthogonal*

class sage.combinat.symmetric_group_representations.**YoungRepresentations_Seminormal**(*n*, *ring=None*, *cache_matrices=True*)

Bases: *SymmetricGroupRepresentations_class*

Element

alias of *YoungRepresentation_Seminormal*

sage.combinat.symmetric_group_representations.**partition_to_vector_of_contents**(*partition*, *reverse=False*)

Return the "vector of contents" associated to `partition`.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_representations import partition_to_
↪vector_of_contents
sage: partition_to_vector_of_contents([3,2])
(0, 1, 2, -1, 0)
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_representations import partition_to_vector_
↪of_contents
```

(continues on next page)

(continued from previous page)

```
>>> partition_to_vector_of_contents([Integer(3),Integer(2)])
(0, 1, 2, -1, 0)
```

Residue sequences of tableaux

A *residue sequence* for a `StandardTableau`, or `StandardTableauTuple`, of size n is an n-tuple $(i_1, i_2, \ldots, i_n)$ of elements of $\mathbf{Z}/e\mathbf{Z}$ for some positive integer $e \geq 1$. Such sequences arise in the representation theory of the symmetric group and the closely related cyclotomic Hecke algebras, and cyclotomic quiver Hecke algebras, where the residue sequences play a similar role to weights in the representations of Lie groups and Lie algebras. These Hecke algebras are semisimple when e is "large enough" and in these cases residue sequences are essentially the same as content sequences (see `sage.combinat.partition.Partition.content()`) and it is not difficult to see that residue sequences are in bijection with the set of standard tableaux. In the non-semisimple case, when e is "small", different standard tableaux can have the same residue sequence. In this case the residue sequences describe how to decompose modules into generalised eigenspaces for the Jucys-Murphy elements for these algebras.

By definition, if t is a `StandardTableau` of size n then the residue sequence of t is the n-tuple $(i_1, \ldots, i_n)$ where $i_m = c - r + e\mathbf{Z}$, if m appears in row r and column c of t. If p is prime then such sequence arise in the representation theory of the symmetric group n characteristic p. More generally, e-residue sequences arise in he representation theory of the Iwahori-Hecke algebra (see `IwahoriHeckeAlgebra`) the symmetric group with Hecke parameter at an e-th root of unity.

More generally, the e-residue sequence of a `StandardTableau` of size n and level l is the n-tuple $(i_1, \ldots, i_n)$ determined by e and a *multicharge* $\kappa = (\kappa_1, \ldots, \kappa_l)$ by setting $i_m = \kappa_k + c - r + e\mathbf{Z}$, if m appears in component k, row r and column c of t. These sequences arise in the representation theory of the cyclotomic Hecke algebras of type A, which are also known as Ariki-Koike algebras.

The residue classes are constructed from standard tableaux:

```
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)

sage: StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,0])

3-residue sequence (0,1,2,0,0) with multicharge (0,0)
>>> StandardTableauTuple([[[Integer(5)]],[[Integer(1),Integer(2)],[Integer(3),
↪Integer(4)]]]).residue_sequence(Integer(3),[Integer(0),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
3-residue sequence (1,2,0,1,0) with multicharge (0,1)
>>> StandardTableauTuple([[[Integer(5)]],[[Integer(1),Integer(2)],[Integer(3),
↪Integer(4)]]]).residue_sequence(Integer(3),[Integer(0),Integer(2)])
3-residue sequence (2,0,1,2,0) with multicharge (0,2)
```

One of the most useful functions of a *ResidueSequence* is that it can return the *StandardTableaux_residue* and *StandardTableaux_residue_shape* that contain all of the tableaux with this residue sequence. Again, these are best accessed via the standard tableaux classes:

```
sage: res = StandardTableau([[1,2],[3,4]]).residue_sequence(2)
sage: res.standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
sage: res.standard_tableaux()[:]
[[[1, 2, 4], [3]],
[[1, 2], [3, 4]],
[[1, 2], [3], [4]],
[[1, 3, 4], [2]],
[[1, 3], [2, 4]],
[[1, 3], [2], [4]]]
sage: res.standard_tableaux(shape=[4])
Standard (4)-tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
sage: res.standard_tableaux(shape=[4])[:]
[]

sage: res=StandardTableauTuple([[[5]],[[1,2],[3,4]]]).residue_sequence(3,[0,0])
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,0) and multicharge (0,0)
sage: res.standard_tableaux(shape=[[1],[2,2]])[:]
[([[5]], [[1, 2], [3, 4]]), ([[4]], [[1, 2], [3, 5]])]
```

```
>>> from sage.all import *
>>> res = StandardTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).residue_
↪sequence(Integer(2))
>>> res.standard_tableaux()
Standard tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
>>> res.standard_tableaux()[:]
[[[1, 2, 4], [3]],
[[1, 2], [3, 4]],
[[1, 2], [3], [4]],
[[1, 3, 4], [2]],
[[1, 3], [2, 4]],
[[1, 3], [2], [4]]]
>>> res.standard_tableaux(shape=[Integer(4)])
Standard (4)-tableaux with 2-residue sequence (0,1,1,0) and multicharge (0)
>>> res.standard_tableaux(shape=[Integer(4)])[:]
[]

>>> res=StandardTableauTuple([[[Integer(5)]],[[Integer(1),Integer(2)],[Integer(3),
↪Integer(4)]]]).residue_sequence(Integer(3),[Integer(0),Integer(0)])
>>> res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,0) and multicharge (0,0)
>>> res.standard_tableaux(shape=[[Integer(1)],[Integer(2),Integer(2)]])[:]
```

(continues on next page)

(continued from previous page)

```
[([[5]], [[1, 2], [3, 4]]), ([[4]], [[1, 2], [3, 5]])]
```

These residue sequences are particularly useful in the graded representation theory of the cyclotomic KLR algebras and the cyclotomic Hecke algebras of type~A; see [DJM1998] and [BK2009].

This module implements the following classes:

- *ResidueSequence*
- *ResidueSequences*

See also

- *Partitions*
- *PartitionTuples*
- *StandardTableaux_residue*
- *StandardTableaux_residue_shape*
- *RowStandardTableauTuples_residue*
- *RowStandardTableauTuples_residue_shape*
- *StandardTableaux*
- *StandardTableauTuples*
- *Tableaux*
- *TableauTuples*

Todo

Strictly speaking this module implements residue sequences of type $A_e^{(1)}$. Residue sequences of other types also need to be implemented.

AUTHORS:

- Andrew Mathas (2016-07-01): Initial version

class sage.combinat.tableau_residues.**ResidueSequence**(*parent*, *residues*, *check*)

Bases: ClonableArray

A residue sequence.

The *residue sequence* of a tableau t (of partition or partition tuple shape) is the sequence $(i_1, i_2, \ldots, i_n)$ where i_k is the residue of l in t, for $k = 1, 2, \ldots, n$, where n is the size of t. Residue sequences are important in the representation theory of the cyclotomic Hecke algebras of type $G(r, 1, n)$, and of the cyclotomic quiver Hecke algebras, because they determine the eigenvalues of the Jucys-Murphy elements upon all modules. More precisely, they index and completely determine the irreducible representations of the (cyclotomic) Gelfand-Tsetlin algebras.

Rather than being called directly, residue sequences are best accessed via the standard tableaux classes *StandardTableau* and *StandardTableauTuple*.

INPUT:

Can be of the form:

- `ResidueSequence(e, res)`,
- `ResidueSequence(e, multicharge, res)`,

where `e` is a positive integer not equal to 1 and `res` is a sequence of integers (the residues).

EXAMPLES:

```
sage: res = StandardTableauTuple([[[1,3],[6]],[[2,7],[4],[5]]]).residue_
↪sequence(3,(0,5))
sage: res
3-residue sequence (0,2,1,1,0,2,0) with multicharge (0,2)
sage: res.quantum_characteristic()
3
sage: res.level()
2
sage: res.size()
7
sage: res.residues()
[0, 2, 1, 1, 0, 2, 0]
sage: res.restrict(2)
3-residue sequence (0,2) with multicharge (0,2)
sage: res.standard_tableaux([[2,1],[1],[2,1]])
Standard (2,1|1|2,1)-tableaux with 3-residue sequence (0,2,1,1,0,2,0) and␣
↪multicharge (0,2)
sage: res.standard_tableaux([[2,2],[3]]).list()
[]
sage: res.standard_tableaux([[2,2],[3]])[:]
[]
sage: res.standard_tableaux()

 ([[1, 3], [2, 7], [4], [5], [6]], []),
 ([[1, 3], [2, 7], [4], [5]], [[6]]),
 ([[1, 3], [2], [4], [5]], [[6, 7]])]
```

The TestSuite fails `_test_pickling` because `__getitem__` does not support slices, so we skip this.

base_ring()

Return the base ring for the residue sequence.

If the *quantum_characteristic()* of the residue sequence `self` is e then the base ring for the sequence is $\mathbf{Z}/e\mathbf{Z}$, or $\mathbf{Z}$ if $e = 0$.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).base_ring()
Ring of integers modulo 3
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),␣
↪[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3)]).base_ring()
Ring of integers modulo 3
```

block()

Return a dictionary β that determines the block associated to the residue sequence `self`.

Two Specht modules for a cyclotomic Hecke algebra of type A belong to the same block, in this sense, if and only if the residue sequences of their standard tableaux have the same block in this sense. The blocks of these algebras are actually indexed by positive roots in the root lattice of an affine special linear group. Instead of than constructing the root lattice, this method simply returns a dictionary β where the keys are residues i and

where the value of the key i is equal to the numbers of nodes in the residue sequence `self` that are equal to i. The dictionary β corresponds to the positive root:

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+,$$

These positive roots also index the blocks of the cyclotomic KLR algebras of type A.

We return a dictionary because when the *quantum_characteristic()* is 0, the Cartan type is A_∞, in which case the simple roots are indexed by the integers, which is infinite.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,0], [0,1,2,0,1,2,0,1,2]).block()
{0: 3, 1: 3, 2: 3}
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), [Integer(0),Integer(0),Integer(0)],␣
↪[Integer(0),Integer(1),Integer(2),Integer(0),Integer(1),Integer(2),
↪Integer(0),Integer(1),Integer(2)]).block()
{0: 3, 1: 3, 2: 3}
```

check()

Raise a `ValueError` if `self` is not a residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).check()
sage: ResidueSequence(3, [0,0,1], [2,0,1,1,2,2,3,3]).check()
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), [Integer(0),Integer(0),Integer(1)],␣
↪[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3)]).check()
>>> ResidueSequence(Integer(3), [Integer(0),Integer(0),Integer(1)],␣
↪[Integer(2),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3)]).check()
```

level()

Return the level of the residue sequence. That is, the level of the corresponding (tuples of) standard tableaux.

The *level* of a residue sequence is the length of its *multicharge()*. This is the same as the level of the *standard_tableaux()* that belong to the residue class of tableaux determined by `self`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).level()
3
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),␣
↪[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3)]).level()
3
```

multicharge()

Return the multicharge for the residue sequence `self`.

The e-residue sequences are associated with a cyclotomic Hecke algebra with Hecke parameter q of *quantum_characteristic()* e and multicharge $(\kappa_1, \ldots, \kappa_l)$. This means that the cyclotomic parameters of the Hecke algebra are $q^{\kappa_1}, \ldots, q^{\kappa_l}$. Equivalently, the Hecke algebra is determined by the dominant weight

$$\sum_{r \in \mathbf{Z}/e\mathbf{Z}} \kappa_r \Lambda_r \in P^+.$$

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).multicharge()
(0, 0, 1)
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),␣
↪[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3)]).multicharge()
(0, 0, 1)
```

negative()

Return the negative of the residue sequence `self`.

That is, if `self` is the residue sequence $(i_1, \ldots, i_n)$ then return $(-i_1, \ldots, -i_n)$. Taking the negative residue sequences is a shadow of tensoring with the sign representation from the cyclotomic Hecke algebras of type A.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,[0,0,1],[0,0,1,1,2,2,3,3]).negative()
3-residue sequence (0,0,2,2,1,1,0,0) with multicharge (0,0,1)
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3),[Integer(0),Integer(0),Integer(1)],[Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),Integer(3),
↪Integer(3)]).negative()
3-residue sequence (0,0,2,2,1,1,0,0) with multicharge (0,0,1)
```

quantum_characteristic()

Return the quantum characteristic of the residue sequence `self`.

The e-residue sequences are associated with a cyclotomic Hecke algebra that has a parameter q of *quantum characteristic* e. This is the smallest positive integer such that $1 + q + \cdots + q^{e-1} = 0$, or $e = 0$ if no such integer exists.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).quantum_characteristic()
3
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),␣
↪[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3)]).quantum_characteristic()
3
```

residues()

Return a list of the residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).residues()
[0, 0, 1, 1, 2, 2, 0, 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(1)),[Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),Integer(3),
↪Integer(3)]).residues()
[0, 0, 1, 1, 2, 2, 0, 0]
```

restrict(m)

Return the subsequence of this sequence of length m.

The residue sequence `self` is of the form $(r_1, \ldots, r_n)$. The function returns the residue sequence $(r_1, \ldots, r_m)$, with the same *quantum_characteristic()* and *multicharge()*.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(7)
3-residue sequence (0,0,1,1,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(6)
3-residue sequence (0,0,1,1,2,2) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]).restrict(4)
3-residue sequence (0,0,1,1) with multicharge (0,0,1)
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(1)),[Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),Integer(3),
↪Integer(3)]).restrict(Integer(7))
3-residue sequence (0,0,1,1,2,2,0) with multicharge (0,0,1)
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(1)),[Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),Integer(3),
↪Integer(3)]).restrict(Integer(6))
```

(continues on next page)

(continued from previous page)

```
3-residue sequence (0,0,1,1,2,2) with multicharge (0,0,1)
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(1)),[Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),Integer(3),
↪Integer(3)]).restrict(Integer(4))
3-residue sequence (0,0,1,1) with multicharge (0,0,1)
```

restrict_row(*cell*, *row*)

Return a residue sequence for the tableau obtained by swapping the row in ending in $cell$ with the row that is row rows above it and which has the same length.

The residue sequence `self` is of the form $(r_1, \ldots, r_n)$. The function returns the residue sequence $(r_1, \ldots, r_m)$, with the same *quantum_characteristic()* and *multicharge()*.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,1,2,2,0,1]).restrict_row((1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (0)
sage: ResidueSequence(3, [1,0], [0,1,2,2,0,1]).restrict_row((1,1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (1,0)
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), [Integer(0),Integer(1),Integer(2),Integer(2),
↪Integer(0),Integer(1)]).restrict_row((Integer(1),Integer(2)),Integer(1))
3-residue sequence (2,0,1,0,1) with multicharge (0)
>>> ResidueSequence(Integer(3), [Integer(1),Integer(0)], [Integer(0),
↪Integer(1),Integer(2),Integer(2),Integer(0),Integer(1)]).restrict_
↪row((Integer(1),Integer(1),Integer(2)),Integer(1))
3-residue sequence (2,0,1,0,1) with multicharge (1,0)
```

row_standard_tableaux(*shape=None*)

Return the residue-class of row standard tableaux that have residue sequence `self`.

INPUT:

- `shape` – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the row standard tableaux with this residue sequence. If the `shape` is given then only tableaux of this shape are returned, otherwise all of the full residue-class of row standard tableaux, or row standard tableaux tuples, is returned. The residue sequence `self` specifies the *multicharge()* of the tableaux which, in turn, determines the *level()* of the tableaux in the residue class.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).row_standard_
↪tableaux([[3],[3],[3]])
Row standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(0)),[Integer(0),
↪Integer(1),Integer(2),Integer(0),Integer(1),Integer(2),Integer(0),
↪Integer(1),Integer(2)]).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(0)),[Integer(0),
↪Integer(1),Integer(2),Integer(0),Integer(1),Integer(2),Integer(0),
↪Integer(1),Integer(2)]).row_standard_tableaux([[Integer(3)],[Integer(3)],
↪[Integer(3)]])
Row standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
```

size()

Return the size of the residue sequence.

This is the size, or length, of the residue sequence, which is the same as the size of the *standard_tableaux()* that belong to the residue class of tableaux determined by `self`.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).size()
8
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),␣
↪[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3)]).size()
8
```

standard_tableaux(*shape=None*)

Return the residue-class of standard tableaux that have residue sequence `self`.

INPUT:

- `shape` – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the standard tableaux with this residue sequence. If the `shape` is given then only tableaux of this shape are returned, otherwise all of the full residue-class of standard tableaux, or standard tableaux tuples, is returned. The residue sequence `self` specifies the *multicharge()* of the tableaux which, in turn, determines the *level()* of the tableaux in the residue class.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge␣
↪(0,0,0)
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).standard_tableaux([[3],
↪[3],[3]])
```

(continues on next page)

(continued from previous page)

```
Standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(0)),[Integer(0),
↪Integer(1),Integer(2),Integer(0),Integer(1),Integer(2),Integer(0),
↪Integer(1),Integer(2)]).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge␣
↪(0,0,0)
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(0)),[Integer(0),
↪Integer(1),Integer(2),Integer(0),Integer(1),Integer(2),Integer(0),
↪Integer(1),Integer(2)]).standard_tableaux([[Integer(3)],[Integer(3)],
↪[Integer(3)]])
Standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and␣
↪multicharge (0,0,0)
```

swap_residues(*i*, *j*)

Return the *new* residue sequence obtained by swapping the residues for `i` and `j`.

INPUT:

- `i`, `j` – two integers between 1 and the length of the residue sequence

If residue sequence `self` is of the form $(r_1, \ldots, r_n)$, and $i < j$, then the residue sequence $(r_1, \ldots, r_j, \ldots, r_i, \ldots, r_m)$, with the same *quantum_characteristic()* and *multicharge()*, is returned.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: res = ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]); res
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ser = res.swap_residues(2,6); ser
3-residue sequence (0,2,1,1,2,0,0,0) with multicharge (0,0,1)
sage: res == ser
False
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> res = ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(1)),
↪[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3)]); res
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
>>> ser = res.swap_residues(Integer(2),Integer(6)); ser
3-residue sequence (0,2,1,1,2,0,0,0) with multicharge (0,0,1)
>>> res == ser
False
```

class sage.combinat.tableau_residues.**ResidueSequences**(*e*, *multicharge=(0,)*)

Bases: `UniqueRepresentation`, `Parent`

A parent class for *ResidueSequence*.

This class exists because *ResidueSequence* needs to have a parent. Apart form being a parent the only useful method that it provides is *cell_residue()*, which is a short-hand for computing the residue of a cell using the *ResidueSequence.quantum_characteristic()* and *ResidueSequence.multicharge()* for the residue class.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(e=0, multicharge=(0,1,2))
0-residue sequences with multicharge (0, 1, 2)
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=0,␣
↪multicharge=(0,1,2))
True
sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=3,␣
↪multicharge=(0,1,2))
False
sage: ResidueSequences(e=0, multicharge=(0,1,2)).element_class
<class 'sage.combinat.tableau_residues.ResidueSequences_with_category.element_
↪class'>
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequences
>>> ResidueSequences(e=Integer(0), multicharge=(Integer(0),Integer(1),Integer(2)))
0-residue sequences with multicharge (0, 1, 2)
>>> ResidueSequences(e=Integer(0), multicharge=(Integer(0),Integer(1),
↪Integer(2))) == ResidueSequences(e=Integer(0), multicharge=(Integer(0),
↪Integer(1),Integer(2)))
True
>>> ResidueSequences(e=Integer(0), multicharge=(Integer(0),Integer(1),
↪Integer(2))) == ResidueSequences(e=Integer(3), multicharge=(Integer(0),
↪Integer(1),Integer(2)))
False
>>> ResidueSequences(e=Integer(0), multicharge=(Integer(0),Integer(1),
↪Integer(2))).element_class
<class 'sage.combinat.tableau_residues.ResidueSequences_with_category.element_
↪class'>
```

Element

alias of *ResidueSequence*

cell_residue(**args*)

Return the residue a cell with respect to the quantum characteristic and the multicharge of the residue sequence.

INPUT:

- `r`, `c` – the row and column indices in level one
- `k`, `r`, `c` – the component, row and column indices in higher levels

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(3).cell_residue(1,1)
0
sage: ResidueSequences(3).cell_residue(2,1)
```

(continues on next page)

(continued from previous page)

```
2
sage: ResidueSequences(3).cell_residue(3,1)
1
sage: ResidueSequences(3).cell_residue(3,2)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,0,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,0)

>>> ResidueSequences(Integer(3),(Integer(0),Integer(1),Integer(2))).cell_
↪residue(Integer(1),Integer(0),Integer(1))
2
```

(continues on next page)

(continued from previous page)

```
>>> ResidueSequences(Integer(3),(Integer(0),Integer(1),Integer(2))).cell_
↪residue(Integer(2),Integer(0),Integer(0))
2
>>> ResidueSequences(Integer(3),(Integer(0),Integer(1),Integer(2))).cell_
↪residue(Integer(2),Integer(1),Integer(0))
1
>>> ResidueSequences(Integer(3),(Integer(0),Integer(1),Integer(2))).cell_
↪residue(Integer(2),Integer(0),Integer(1))
0
```

check_element(*element*)

Check that `element` is a residue sequence with multicharge `self.multicharge()`.

This is weak criteria in that we only require that `element` is a tuple of elements in the underlying base ring of `self`. Such a sequence is always a valid residue sequence, although there may be no tableaux with this residue sequence.

EXAMPLES:

```
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,4,2,2,5,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,0,0) with multicharge (0,0,1)
```

```
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(1)),[Integer(0),
↪Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),Integer(3),
↪Integer(3)]) # indirect doctest
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(1)),[Integer(2),
↪Integer(0),Integer(1),Integer(4),Integer(2),Integer(2),Integer(5),
↪Integer(3)]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,2,0) with multicharge (0,0,1)
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(1)),[Integer(2),
↪Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),Integer(3),
↪Integer(3)]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,0,0) with multicharge (0,0,1)
```

Restricted growth arrays

These combinatorial objects are in bijection with set partitions.

class sage.combinat.restricted_growth.**RestrictedGrowthArrays**(*n*)

Bases: `UniqueRepresentation`, `Parent`

EXAMPLES:

```
sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(3)
```

(continues on next page)

(continued from previous page)

```
sage: R == loads(dumps(R))
True
sage: TestSuite(R).run(skip=['_test_an_element',                              #␣
↪needs sage.libs.flint
....:   '_test_enumerated_set_contains', '_test_some_elements'])
```

```
>>> from sage.all import *
>>> from sage.combinat.restricted_growth import RestrictedGrowthArrays
>>> R = RestrictedGrowthArrays(Integer(3))
>>> R == loads(dumps(R))
True
>>> TestSuite(R).run(skip=['_test_an_element',                              # needs␣
↪sage.libs.flint
...   '_test_enumerated_set_contains', '_test_some_elements'])
```

cardinality()

EXAMPLES:

```
sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(6)
sage: R.cardinality()                                                         #␣
↪needs sage.libs.flint
203
```

```
>>> from sage.all import *
>>> from sage.combinat.restricted_growth import RestrictedGrowthArrays
>>> R = RestrictedGrowthArrays(Integer(6))
>>> R.cardinality()                                                           #␣
↪needs sage.libs.flint
203
```

Ribbon shaped tableaux

class sage.combinat.ribbon_shaped_tableau.**RibbonShapedTableau**(*parent*, *t*)

Bases: *SkewTableau*

A ribbon shaped tableau.

For the purposes of this class, a ribbon shaped tableau is a skew tableau whose shape is a skew partition which:

- has at least one cell in row 1;
- has at least one cell in column 1;
- has exactly one cell in each of q consecutive diagonals, for some nonnegative integer q.

A ribbon is given by a list of the rows from top to bottom.

EXAMPLES:

```
sage: x = RibbonShapedTableau([[None, None, None, 2, 3], [None, 1, 4, 5], [3,␣
↪2]]); x
[[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]
sage: x.pp()
  .   .   .   2   3
```

(continues on next page)

(continued from previous page)

```
  .  1  4  5
  3  2
sage: x.shape()
[5, 4, 2] / [3, 1]
```

```
>>> from sage.all import *
>>> x = RibbonShapedTableau([[None, None, None, Integer(2), Integer(3)], [None,␣
↪Integer(1), Integer(4), Integer(5)], [Integer(3), Integer(2)]]); x
[[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]
>>> x.pp()
  .  .  .  2  3
  .  1  4  5
  3  2
>>> x.shape()
[5, 4, 2] / [3, 1]
```

The entries labeled by `None` correspond to the inner partition. Using `None` is optional; the entries will be shifted accordingly.

```
sage: x = RibbonShapedTableau([[2,3],[1,4,5],[3,2]]); x.pp()
  .  .  .  2  3
  .  1  4  5
  3  2
```

```
>>> from sage.all import *
>>> x = RibbonShapedTableau([[Integer(2),Integer(3)],[Integer(1),Integer(4),
↪Integer(5)],[Integer(3),Integer(2)]]); x.pp()
  .  .  .  2  3
  .  1  4  5
  3  2
```

height()

Return the height of `self`.

The height is given by the number of rows in the outer partition.

EXAMPLES:

```
sage: RibbonShapedTableau([[2,3],[1,4,5]]).height()
2
```

```
>>> from sage.all import *
>>> RibbonShapedTableau([[Integer(2),Integer(3)],[Integer(1),Integer(4),
↪Integer(5)]]).height()
2
```

spin()

Return the spin of `self`.

EXAMPLES:

```
sage: RibbonShapedTableau([[2,3],[1,4,5]]).spin()
1/2
```

```
>>> from sage.all import *
>>> RibbonShapedTableau([[Integer(2),Integer(3)],[Integer(1),Integer(4),
↪Integer(5)]]).spin()
1/2
```

width()

Return the width of the ribbon.

This is given by the length of the longest row in the outer partition.

EXAMPLES:

```
sage: RibbonShapedTableau([[2,3],[1,4,5]]).width()
4
sage: RibbonShapedTableau([]).width()
0
```

```
>>> from sage.all import *
>>> RibbonShapedTableau([[Integer(2),Integer(3)],[Integer(1),Integer(4),
↪Integer(5)]]).width()
4
>>> RibbonShapedTableau([]).width()
0
```

class sage.combinat.ribbon_shaped_tableau.**RibbonShapedTableaux**(*category=None*)

Bases: *SkewTableaux*

The set of all ribbon shaped tableaux.

Element

alias of *RibbonShapedTableau*

from_shape_and_word(*shape*, *word*)

Return the ribbon corresponding to the given ribbon shape and word.

EXAMPLES:

```
sage: RibbonShapedTableaux().from_shape_and_word([1,3],[1,3,3,7])
[[None, None, 1], [3, 3, 7]]
```

```
>>> from sage.all import *
>>> RibbonShapedTableaux().from_shape_and_word([Integer(1),Integer(3)],
↪[Integer(1),Integer(3),Integer(3),Integer(7)])
[[None, None, 1], [3, 3, 7]]
```

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.ribbon_shaped_tableau.**StandardRibbonShapedTableaux**(*category=None*)

Bases: *StandardSkewTableaux*

The set of all standard ribbon shaped tableaux.

INPUT:

- `shape` – (optional) the composition shape of the rows

Element

alias of *RibbonShapedTableau*

from_permutation(*p*)

Return a standard ribbon of size `len(p)` from a permutation `p`. The lengths of each row are given by the distance between the descents of the permutation `p`.

EXAMPLES:

```
sage: import sage.combinat.ribbon_shaped_tableau as rst
sage: [StandardRibbonShapedTableaux().from_permutation(p)
....:  for p in Permutations(3)]
[[[1, 2, 3]],
 [[None, 2], [1, 3]],
 [[1, 3], [2]],
 [[None, 1], [2, 3]],
 [[1, 2], [3]],
 [[1], [2], [3]]]
```

```
>>> from sage.all import *
>>> import sage.combinat.ribbon_shaped_tableau as rst
>>> [StandardRibbonShapedTableaux().from_permutation(p)
...  for p in Permutations(Integer(3))]
[[[1, 2, 3]],
 [[None, 2], [1, 3]],
 [[1, 3], [2]],
 [[None, 1], [2, 3]],
 [[1, 2], [3]],
 [[1], [2], [3]]]
```

from_shape_and_word(*shape*, *word*)

Return the ribbon corresponding to the given ribbon shape and word.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux().from_shape_and_word([2,3],[1,2,3,4,5])
[[None, None, 1, 2], [3, 4, 5]]
```

```
>>> from sage.all import *
>>> StandardRibbonShapedTableaux().from_shape_and_word([Integer(2),
↪Integer(3)],[Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)])
[[None, None, 1, 2], [3, 4, 5]]
```

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.ribbon_shaped_tableau.**StandardRibbonShapedTableaux_shape**(*shape*)

Bases: *StandardRibbonShapedTableaux*

Class of standard ribbon shaped tableaux of ribbon shape `shape`.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux([2,2])
Standard ribbon shaped tableaux of shape [2, 2]
```

(continues on next page)

(continued from previous page)

```
sage: StandardRibbonShapedTableaux([2,2]).first()
[[None, 2, 4], [1, 3]]
sage: StandardRibbonShapedTableaux([2,2]).last()
[[None, 1, 2], [3, 4]]

sage: # needs sage.graphs sage.modules
sage: StandardRibbonShapedTableaux([2,2]).cardinality()
5
sage: StandardRibbonShapedTableaux([2,2]).list()
[[[None, 1, 3], [2, 4]],
 [[None, 1, 2], [3, 4]],
 [[None, 2, 3], [1, 4]],
 [[None, 2, 4], [1, 3]],
 [[None, 1, 4], [2, 3]]]
sage: StandardRibbonShapedTableaux([3,2,2]).cardinality()
155
```

```
>>> from sage.all import *
>>> StandardRibbonShapedTableaux([Integer(2),Integer(2)])
Standard ribbon shaped tableaux of shape [2, 2]
>>> StandardRibbonShapedTableaux([Integer(2),Integer(2)]).first()
[[None, 2, 4], [1, 3]]
>>> StandardRibbonShapedTableaux([Integer(2),Integer(2)]).last()
[[None, 1, 2], [3, 4]]

>>> # needs sage.graphs sage.modules
>>> StandardRibbonShapedTableaux([Integer(2),Integer(2)]).cardinality()
5
>>> StandardRibbonShapedTableaux([Integer(2),Integer(2)]).list()
[[[None, 1, 3], [2, 4]],
 [[None, 1, 2], [3, 4]],
 [[None, 2, 3], [1, 4]],
 [[None, 2, 4], [1, 3]],
 [[None, 1, 4], [2, 3]]]
>>> StandardRibbonShapedTableaux([Integer(3),Integer(2),Integer(2)]).cardinality()
155
```

first()

Return the first standard ribbon of `self`.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux([2,2]).first()
[[None, 2, 4], [1, 3]]
```

```
>>> from sage.all import *
>>> StandardRibbonShapedTableaux([Integer(2),Integer(2)]).first()
[[None, 2, 4], [1, 3]]
```

last()

Return the last standard ribbon of `self`.

EXAMPLES:

```
sage: StandardRibbonShapedTableaux([2,2]).last()
[[None, 1, 2], [3, 4]]
```

```
>>> from sage.all import *
>>> StandardRibbonShapedTableaux([Integer(2),Integer(2)]).last()
[[None, 1, 2], [3, 4]]
```

Ribbon tableaux

class sage.combinat.ribbon_tableau.**MultiSkewTableau**(*parent*, **args*, ***kwds*)

Bases: *CombinatorialElement*

A multi skew tableau which is a tuple of skew tableaux.

EXAMPLES:

```
sage: s = MultiSkewTableau([ [[None,1],[2,3]], [[1,2],[2]] ])
sage: s.size()
6
sage: s.weight()
[2, 3, 1]
sage: s.shape()
[[2, 2] / [1], [2, 1] / []]
```

```
>>> from sage.all import *
>>> s = MultiSkewTableau([ [[None,Integer(1)],[Integer(2),Integer(3)]],␣
↪[[Integer(1),Integer(2)],[Integer(2)]] ])
>>> s.size()
6
>>> s.weight()
[2, 3, 1]
>>> s.shape()
[[2, 2] / [1], [2, 1] / []]
```

inversion_pairs()

Return a list of the inversion pairs of `self`.

EXAMPLES:

```
sage: s = MultiSkewTableau([ [[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]] ])
sage: s.inversion_pairs()
[((0, (0, 0)), (1, (0, 0))),
 ((0, (1, 0)), (1, (0, 1))),
 ((0, (1, 1)), (1, (0, 0))),
 ((0, (1, 1)), (1, (1, 1))),
 ((0, (1, 1)), (2, (0, 0))),
 ((1, (0, 1)), (2, (0, 0))),
 ((1, (1, 1)), (2, (0, 0)))]
```

```
>>> from sage.all import *
>>> s = MultiSkewTableau([ [[Integer(2),Integer(3)],[Integer(5),Integer(5)]],␣
↪[[Integer(1),Integer(1)],[Integer(3),Integer(3)]], [[Integer(2)],
↪[Integer(6)]] ])
```

(continues on next page)

(continued from previous page)

```
>>> s.inversion_pairs()
[((0, (0, 0)), (1, (0, 0))),
 ((0, (1, 0)), (1, (0, 1))),
 ((0, (1, 1)), (1, (0, 0))),
 ((0, (1, 1)), (1, (1, 1))),
 ((0, (1, 1)), (2, (0, 0))),
 ((1, (0, 1)), (2, (0, 0))),
 ((1, (1, 1)), (2, (0, 0)))]
```

inversions()

Return the number of inversion pairs of `self`.

EXAMPLES:

```
sage: t1 = SkewTableau([[1]])
sage: t2 = SkewTableau([[2]])
sage: MultiSkewTableau([t1,t1]).inversions()
0
sage: MultiSkewTableau([t1,t2]).inversions()
0
sage: MultiSkewTableau([t2,t2]).inversions()
0
sage: MultiSkewTableau([t2,t1]).inversions()
1
sage: s = MultiSkewTableau([ [[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]] ])
sage: s.inversions()
7
```

```
>>> from sage.all import *
>>> t1 = SkewTableau([[Integer(1)]])
>>> t2 = SkewTableau([[Integer(2)]])
>>> MultiSkewTableau([t1,t1]).inversions()
0
>>> MultiSkewTableau([t1,t2]).inversions()
0
>>> MultiSkewTableau([t2,t2]).inversions()
0
>>> MultiSkewTableau([t2,t1]).inversions()
1
>>> s = MultiSkewTableau([ [[Integer(2),Integer(3)],[Integer(5),Integer(5)]],␣
↪[[Integer(1),Integer(1)],[Integer(3),Integer(3)]], [[Integer(2)],
↪[Integer(6)]] ])
>>> s.inversions()
7
```

shape()

Return the shape of `self`.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
```

(continues on next page)

(continued from previous page)

```
sage: a.shape()
[[2, 2] / [1], [2, 2] / [1], [2, 2] / [1]]
```

```
>>> from sage.all import *
>>> s = SemistandardSkewTableaux([[Integer(2),Integer(2)],[Integer(1)]]).
↪list()
>>> a = MultiSkewTableau([s[Integer(0)],s[Integer(1)],s[Integer(2)]])
>>> a.shape()
[[2, 2] / [1], [2, 2] / [1], [2, 2] / [1]]
```

size()

Return the size of `self`.

This is the sum of the sizes of the skew tableaux in `self`.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.size()
9
```

```
>>> from sage.all import *
>>> s = SemistandardSkewTableaux([[Integer(2),Integer(2)],[Integer(1)]]).
↪list()
>>> a = MultiSkewTableau([s[Integer(0)],s[Integer(1)],s[Integer(2)]])
>>> a.size()
9
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.weight()
[5, 3, 1]
```

```
>>> from sage.all import *
>>> s = SemistandardSkewTableaux([[Integer(2),Integer(2)],[Integer(1)]]).
↪list()
>>> a = MultiSkewTableau([s[Integer(0)],s[Integer(1)],s[Integer(2)]])
>>> a.weight()
[5, 3, 1]
```

class sage.combinat.ribbon_tableau.**MultiSkewTableaux**(*category=None*)

Bases: `UniqueRepresentation`, `Parent`

Multiskew tableaux.

Element

alias of *MultiSkewTableau*

class sage.combinat.ribbon_tableau.**RibbonTableau**(*parent*, *st*)

Bases: *SkewTableau*

A ribbon tableau.

A ribbon is a connected skew shape which does not contain any 2×2 boxes. A ribbon tableau is a skew tableau whose shape is partitioned into ribbons, each of which is filled with identical entries.

EXAMPLES:

```
sage: rt = RibbonTableau([[None, 1],[2,3]]); rt
[[None, 1], [2, 3]]
sage: rt.inner_shape()
[1]
sage: rt.outer_shape()
[2, 2]

sage: rt = RibbonTableau([[None, None, 0, 0, 0], [None, 0, 0, 2], [1, 0, 1]]); rt.
↪pp()
  .   .   0   0   0
  .   0   0   2
  1   0   1
```

```
>>> from sage.all import *
>>> rt = RibbonTableau([[None, Integer(1)],[Integer(2),Integer(3)]]); rt
[[None, 1], [2, 3]]
>>> rt.inner_shape()
[1]
>>> rt.outer_shape()
[2, 2]

>>> rt = RibbonTableau([[None, None, Integer(0), Integer(0), Integer(0)], [None,␣
↪Integer(0), Integer(0), Integer(2)], [Integer(1), Integer(0), Integer(1)]]); rt.
↪pp()
  .   .   0   0   0
  .   0   0   2
  1   0   1
```

In the previous example, each ribbon is uniquely determined by a nonzero entry. The 0 entries are used to fill in the rest of the skew shape.

Note

Sanity checks are not performed; lists can contain any object.

```
sage: RibbonTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```
>>> from sage.all import *
>>> RibbonTableau(expr=[[Integer(1),Integer(1)],[[Integer(5)],[Integer(3),
↪Integer(4)],[Integer(1),Integer(2)]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

length()

Return the length of the ribbons into a ribbon tableau.

EXAMPLES:

```
sage: RibbonTableau([[None, 1],[2,3]]).length()
1
sage: RibbonTableau([[1,0],[2,0]]).length()
2
```

```
>>> from sage.all import *
>>> RibbonTableau([[None, Integer(1)],[Integer(2),Integer(3)]]).length()
1
>>> RibbonTableau([[Integer(1),Integer(0)],[Integer(2),Integer(0)]]).length()
2
```

to_word()

Return a word obtained from a row reading of `self`.

Warning

Unlike the `to_word` method on skew tableaux (which are a superclass of this), this method does not filter out `None` entries.

EXAMPLES:

```
sage: R = RibbonTableau([[0, 0, 3, 0], [1, 1, 0], [2, 0, 4]])
sage: R.to_word()
word: 2041100030
```

```
>>> from sage.all import *
>>> R = RibbonTableau([[Integer(0), Integer(0), Integer(3), Integer(0)],␣
↪[Integer(1), Integer(1), Integer(0)], [Integer(2), Integer(0), Integer(4)]])
>>> R.to_word()
word: 2041100030
```

class sage.combinat.ribbon_tableau.**RibbonTableaux**

Bases: `UniqueRepresentation`, `Parent`

Ribbon tableaux.

A ribbon tableau is a skew tableau whose skew shape `shape` is tiled by ribbons of length `length`. The weight `weight` is calculated from the labels on the ribbons.

Note

Here we impose the condition that the ribbon tableaux are semistandard.

INPUT(Optional):

- `shape` – skew shape as a list of lists or an object of type SkewPartition
- `length` – integer; `shape` is partitioned into ribbons of length `length`

- `weight` – list of integers; computed from the values of nonzero entries labeling the ribbons

EXAMPLES:

```
sage: RibbonTableaux([[2,1],[]], [1,1,1], 1)
Ribbon tableaux of shape [2, 1] / [] and weight [1, 1, 1] with 1-ribbons

sage: R = RibbonTableaux([[5,4,3],[2,1]], [2,1], 3)
sage: for i in R: i.pp(); print("\n")
  .  .  0  0  0
  .  0  0  2
  1  0  1

  .  .  1  0  0
  .  0  0  0
  1  0  2

  .  .  0  0  0
  .  1  0  1
  2  0  0
```

```
>>> from sage.all import *
>>> RibbonTableaux([[Integer(2),Integer(1)],[]], [Integer(1),Integer(1),
↪Integer(1)], Integer(1))
Ribbon tableaux of shape [2, 1] / [] and weight [1, 1, 1] with 1-ribbons

>>> R = RibbonTableaux([[Integer(5),Integer(4),Integer(3)],[Integer(2),
↪Integer(1)]], [Integer(2),Integer(1)], Integer(3))
>>> for i in R: i.pp(); print("\n")
  .  .  0  0  0
  .  0  0  2
  1  0  1
<BLANKLINE>
  .  .  1  0  0
  .  0  0  0
  1  0  2
<BLANKLINE>
  .  .  0  0  0
  .  1  0  1
  2  0  0
<BLANKLINE>
```

Element

alias of *RibbonTableau*

from_expr(*l*)

Return a *RibbonTableau* from a MuPAD-Combinat expr for a skew tableau. The first list in `expr` is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

```
sage: RibbonTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```
>>> from sage.all import *
>>> RibbonTableaux().from_expr([[Integer(1),Integer(1)],[[Integer(5)],
↪[Integer(3),Integer(4)],[Integer(1),Integer(2)]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.ribbon_tableau.**RibbonTableaux_shape_weight_length**(*shape*, *weight*, *length*)

Bases: *RibbonTableaux*

Ribbon tableaux of a given shape, weight, and length.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: RibbonTableaux([[2,1],[]],[1,1,1],1).cardinality()
2
sage: RibbonTableaux([[2,2],[]],[1,1],2).cardinality()
2
sage: RibbonTableaux([[4,3,3],[]],[2,1,1,1],2).cardinality()
5
```

```
>>> from sage.all import *
>>> RibbonTableaux([[Integer(2),Integer(1)],[]],[Integer(1),Integer(1),
↪Integer(1)],Integer(1)).cardinality()
2
>>> RibbonTableaux([[Integer(2),Integer(2)],[]],[Integer(1),Integer(1)],
↪Integer(2)).cardinality()
2
>>> RibbonTableaux([[Integer(4),Integer(3),Integer(3)],[]],[Integer(2),
↪Integer(1),Integer(1),Integer(1)],Integer(2)).cardinality()
5
```

class sage.combinat.ribbon_tableau.**SemistandardMultiSkewTableaux**(*shape*, *weight*)

Bases: *MultiSkewTableaux*

Semistandard multi skew tableaux.

A multi skew tableau is a k-tuple of skew tableaux of given shape with a specified total weight.

EXAMPLES:

```
sage: S = SemistandardMultiSkewTableaux([ [[2,1],[]], [[2,2],[1]] ], [2,2,2]); S
Semistandard multi skew tableaux of shape [[2, 1] / [], [2, 2] / [1]] and weight␣
↪[2, 2, 2]
sage: S.list()
[[[1, 1], [2]], [[None, 2], [3, 3]]],
 [[1, 2], [2]], [[None, 1], [3, 3]]],
 [[1, 3], [2]], [[None, 2], [1, 3]]],
```

(continues on next page)

(continued from previous page)

```
 [[[1, 3], [2]], [[None, 1], [2, 3]]],
 [[[1, 1], [3]], [[None, 2], [2, 3]]],
 [[[1, 2], [3]], [[None, 2], [1, 3]]],
 [[[1, 2], [3]], [[None, 1], [2, 3]]],
 [[[2, 2], [3]], [[None, 1], [1, 3]]],
 [[[1, 3], [3]], [[None, 1], [2, 2]]],
 [[[2, 3], [3]], [[None, 1], [1, 2]]]]
```

```
>>> from sage.all import *
>>> S = SemistandardMultiSkewTableaux([ [[Integer(2),Integer(1)],[]],␣
↪[[Integer(2),Integer(2)],[Integer(1)]] ], [Integer(2),Integer(2),Integer(2)]); S
Semistandard multi skew tableaux of shape [[2, 1] / [], [2, 2] / [1]] and weight␣
↪[2, 2, 2]
>>> S.list()
[[[[1, 1], [2]], [[None, 2], [3, 3]]],
 [[[1, 2], [2]], [[None, 1], [3, 3]]],
 [[[1, 3], [2]], [[None, 2], [1, 3]]],
 [[[1, 3], [2]], [[None, 1], [2, 3]]],
 [[[1, 1], [3]], [[None, 2], [2, 3]]],
 [[[1, 2], [3]], [[None, 2], [1, 3]]],
 [[[1, 2], [3]], [[None, 1], [2, 3]]],
 [[[2, 2], [3]], [[None, 1], [1, 3]]],
 [[[1, 3], [3]], [[None, 1], [2, 2]]],
 [[[2, 3], [3]], [[None, 1], [1, 2]]]]
```

sage.combinat.ribbon_tableau.**cospin_polynomial**(*part*, *weight*, *length*)

Return the cospin polynomial associated to `part`, `weight`, and `length`.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import cospin_polynomial
sage: cospin_polynomial([6,6,6],[4,2],3)
t^4 + t^3 + 2*t^2 + t + 1
sage: cospin_polynomial([3,3,3,2,1], [3,1], 3)
1
sage: cospin_polynomial([3,3,3,2,1], [2,2], 3)
t + 1
sage: cospin_polynomial([3,3,3,2,1], [2,1,1], 3)
t^2 + 2*t + 2
sage: cospin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
t^3 + 3*t^2 + 5*t + 3
sage: cospin_polynomial([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^2 + 6*t + 2
sage: cospin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^4 + 6*t^3 + 9*t^2 + 5*t + 3
```

```
>>> from sage.all import *
>>> from sage.combinat.ribbon_tableau import cospin_polynomial
>>> cospin_polynomial([Integer(6),Integer(6),Integer(6)],[Integer(4),Integer(2)],
↪Integer(3))
t^4 + t^3 + 2*t^2 + t + 1
>>> cospin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)],␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(3),Integer(1)], Integer(3))
1
>>> cospin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)],␣
↪[Integer(2),Integer(2)], Integer(3))
t + 1
>>> cospin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)],␣
↪[Integer(2),Integer(1),Integer(1)], Integer(3))
t^2 + 2*t + 2
>>> cospin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1)], Integer(3))
t^3 + 3*t^2 + 5*t + 3
>>> cospin_polynomial([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1),
↪Integer(1),Integer(1)], [Integer(2),Integer(2),Integer(1)], Integer(3))
2*t^2 + 6*t + 2
>>> cospin_polynomial([[Integer(6)]*Integer(6), [Integer(3),Integer(3)]],␣
↪[Integer(4),Integer(4),Integer(2)], Integer(3))
3*t^4 + 6*t^3 + 9*t^2 + 5*t + 3
```

sage.combinat.ribbon_tableau.**count_rec**(*nexts*, *current*, *part*, *weight*, *length*)

INPUT:

- `nexts, current, part` – skew partitions
- `weight` – nonnegative integer list
- `length` – integer

sage.combinat.ribbon_tableau.**graph_implementation_rec**(*skp*, *weight*, *length*, *function*)

sage.combinat.ribbon_tableau.**insertion_tableau**(*skp*, *perm*, *evaluation*, *tableau*, *length*)

INPUT:

- `skp` – skew partitions
- `perm, evaluation` – nonnegative integers
- `tableau` – skew tableau
- `length` – integer

sage.combinat.ribbon_tableau.**list_rec**(*nexts*, *current*, *part*, *weight*, *length*)

INPUT:

- `nexts, current, part` – skew partitions
- `weight` – nonnegative integer list
- `length` – integer

sage.combinat.ribbon_tableau.**spin_polynomial**(*part*, *weight*, *length*)

Return the spin polynomial associated to `part`, `weight`, and `length`.

EXAMPLES:

```
sage: # needs sage.symbolic
sage: from sage.combinat.ribbon_tableau import spin_polynomial
sage: spin_polynomial([6,6,6],[4,2],3)
t^6 + t^5 + 2*t^4 + t^3 + t^2
```

(continues on next page)

(continued from previous page)

```
sage: spin_polynomial([6,6,6],[4,1,1],3)
t^6 + 2*t^5 + 3*t^4 + 2*t^3 + t^2
sage: spin_polynomial([3,3,3,2,1], [2,2], 3)
t^(7/2) + t^(5/2)
sage: spin_polynomial([3,3,3,2,1], [2,1,1], 3)
2*t^(7/2) + 2*t^(5/2) + t^(3/2)
sage: spin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
3*t^(7/2) + 5*t^(5/2) + 3*t^(3/2) + sqrt(t)
sage: spin_polynomial([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^(9/2) + 6*t^(7/2) + 2*t^(5/2)
sage: spin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^9 + 5*t^8 + 9*t^7 + 6*t^6 + 3*t^5
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> from sage.combinat.ribbon_tableau import spin_polynomial
>>> spin_polynomial([Integer(6),Integer(6),Integer(6)],[Integer(4),Integer(2)],
↪Integer(3))
t^6 + t^5 + 2*t^4 + t^3 + t^2
>>> spin_polynomial([Integer(6),Integer(6),Integer(6)],[Integer(4),Integer(1),
↪Integer(1)],Integer(3))
t^6 + 2*t^5 + 3*t^4 + 2*t^3 + t^2
>>> spin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)],␣
↪[Integer(2),Integer(2)], Integer(3))
t^(7/2) + t^(5/2)
>>> spin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)],␣
↪[Integer(2),Integer(1),Integer(1)], Integer(3))
2*t^(7/2) + 2*t^(5/2) + t^(3/2)
>>> spin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1)], Integer(3))
3*t^(7/2) + 5*t^(5/2) + 3*t^(3/2) + sqrt(t)
>>> spin_polynomial([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1),
↪Integer(1),Integer(1)], [Integer(2),Integer(2),Integer(1)], Integer(3))
2*t^(9/2) + 6*t^(7/2) + 2*t^(5/2)
>>> spin_polynomial([[Integer(6)]*Integer(6), [Integer(3),Integer(3)]],␣
↪[Integer(4),Integer(4),Integer(2)], Integer(3))
3*t^9 + 5*t^8 + 9*t^7 + 6*t^6 + 3*t^5
```

sage.combinat.ribbon_tableau.**spin_polynomial_square**(*part*, *weight*, *length*)

Return the spin polynomial associated with `part`, `weight`, and `length`, with the substitution $t \to t^2$ made.

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial_square
sage: spin_polynomial_square([6,6,6],[4,2],3)
t^12 + t^10 + 2*t^8 + t^6 + t^4
sage: spin_polynomial_square([6,6,6],[4,1,1],3)
t^12 + 2*t^10 + 3*t^8 + 2*t^6 + t^4
sage: spin_polynomial_square([3,3,3,2,1], [2,2], 3)
t^7 + t^5
sage: spin_polynomial_square([3,3,3,2,1], [2,1,1], 3)
2*t^7 + 2*t^5 + t^3
```

(continues on next page)

(continued from previous page)

```
sage: spin_polynomial_square([3,3,3,2,1], [1,1,1,1], 3)
3*t^7 + 5*t^5 + 3*t^3 + t
sage: spin_polynomial_square([5,4,3,2,1,1,1], [2,2,1], 3)
2*t^9 + 6*t^7 + 2*t^5
sage: spin_polynomial_square([[6]*6, [3,3]], [4,4,2], 3)
3*t^18 + 5*t^16 + 9*t^14 + 6*t^12 + 3*t^10
```

```
>>> from sage.all import *
>>> from sage.combinat.ribbon_tableau import spin_polynomial_square
>>> spin_polynomial_square([Integer(6),Integer(6),Integer(6)],[Integer(4),
↪Integer(2)],Integer(3))
t^12 + t^10 + 2*t^8 + t^6 + t^4
>>> spin_polynomial_square([Integer(6),Integer(6),Integer(6)],[Integer(4),
↪Integer(1),Integer(1)],Integer(3))
t^12 + 2*t^10 + 3*t^8 + 2*t^6 + t^4
>>> spin_polynomial_square([Integer(3),Integer(3),Integer(3),Integer(2),
↪Integer(1)], [Integer(2),Integer(2)], Integer(3))
t^7 + t^5
>>> spin_polynomial_square([Integer(3),Integer(3),Integer(3),Integer(2),
↪Integer(1)], [Integer(2),Integer(1),Integer(1)], Integer(3))
2*t^7 + 2*t^5 + t^3
>>> spin_polynomial_square([Integer(3),Integer(3),Integer(3),Integer(2),
↪Integer(1)], [Integer(1),Integer(1),Integer(1),Integer(1)], Integer(3))
3*t^7 + 5*t^5 + 3*t^3 + t
>>> spin_polynomial_square([Integer(5),Integer(4),Integer(3),Integer(2),
↪Integer(1),Integer(1),Integer(1)], [Integer(2),Integer(2),Integer(1)],␣
↪Integer(3))
2*t^9 + 6*t^7 + 2*t^5
>>> spin_polynomial_square([[Integer(6)]*Integer(6), [Integer(3),Integer(3)]],␣
↪[Integer(4),Integer(4),Integer(2)], Integer(3))
3*t^18 + 5*t^16 + 9*t^14 + 6*t^12 + 3*t^10
```

sage.combinat.ribbon_tableau.**spin_rec**(*t*, *nexts*, *current*, *part*, *weight*, *length*)

Routine used for constructing the spin polynomial.

INPUT:

- `weight` – list of nonnegative integers
- `length` – the length of the ribbons we're tiling with
- `t` – the variable

EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_rec
sage: sp = SkewPartition
sage: t = ZZ['t'].gen()
sage: spin_rec(t, [], [[[], [3, 3]]], sp([[2, 2, 2], []]), [2], 3)
[t^4]
sage: spin_rec(t, [[0], [t^4]], [[[2, 1, 1, 1, 1], [0, 3]], [[2, 2, 2], [3, 0]]],␣
↪sp([[2, 2, 2, 2, 1], []]), [2, 1], 3)
[t^5]
sage: spin_rec(t, [], [[[], [3, 3, 0]]], sp([[3, 3], []]), [2], 3)
```

(continues on next page)

(continued from previous page)

```
[t^2]
sage: spin_rec(t, [[t^4], [t^3], [t^2]], [[[2, 2, 2], [0, 0, 3]], [[3, 2, 1], [0,␣
↪3, 0]], [[3, 3], [3, 0, 0]]], sp([[3, 3, 3], []]), [2, 1], 3)
[t^6 + t^4 + t^2]
sage: spin_rec(t, [[t^5], [t^4], [t^6 + t^4 + t^2]], [[[2, 2, 2, 2, 1], [0, 0,␣
↪3]], [[3, 3, 1, 1, 1], [0, 3, 0]], [[3, 3, 3], [3, 0, 0]]], sp([[3, 3, 3, 2, 1],
↪ []]), [2, 1, 1], 3)
[2*t^7 + 2*t^5 + t^3]
```

```
>>> from sage.all import *
>>> from sage.combinat.ribbon_tableau import spin_rec
>>> sp = SkewPartition
>>> t = ZZ['t'].gen()
>>> spin_rec(t, [], [[[], [Integer(3), Integer(3)]]], sp([[Integer(2), Integer(2),
↪ Integer(2)], []]), [Integer(2)], Integer(3))
[t^4]
>>> spin_rec(t, [[Integer(0)], [t**Integer(4)]], [[[Integer(2), Integer(1),␣
↪Integer(1), Integer(1), Integer(1)], [Integer(0), Integer(3)]], [[Integer(2),␣
↪Integer(2), Integer(2)], [Integer(3), Integer(0)]]], sp([[Integer(2),␣
↪Integer(2), Integer(2), Integer(2), Integer(1)], []]), [Integer(2), Integer(1)],
↪ Integer(3))
[t^5]
>>> spin_rec(t, [], [[[], [Integer(3), Integer(3), Integer(0)]]], sp([[Integer(3),
↪ Integer(3)], []]), [Integer(2)], Integer(3))
[t^2]
>>> spin_rec(t, [[t**Integer(4)], [t**Integer(3)], [t**Integer(2)]],␣
↪[[[Integer(2), Integer(2), Integer(2)], [Integer(0), Integer(0), Integer(3)]],␣
↪[[Integer(3), Integer(2), Integer(1)], [Integer(0), Integer(3), Integer(0)]],␣
↪[[Integer(3), Integer(3)], [Integer(3), Integer(0), Integer(0)]]],␣
↪sp([[Integer(3), Integer(3), Integer(3)], []]), [Integer(2), Integer(1)],␣
↪Integer(3))
[t^6 + t^4 + t^2]
>>> spin_rec(t, [[t**Integer(5)], [t**Integer(4)], [t**Integer(6) + t**Integer(4)␣
↪+ t**Integer(2)]], [[[Integer(2), Integer(2), Integer(2), Integer(2),␣
↪Integer(1)], [Integer(0), Integer(0), Integer(3)]], [[Integer(3), Integer(3),␣
↪Integer(1), Integer(1), Integer(1)], [Integer(0), Integer(3), Integer(0)]],␣
↪[[Integer(3), Integer(3), Integer(3)], [Integer(3), Integer(0), Integer(0)]]],␣
↪sp([[Integer(3), Integer(3), Integer(3), Integer(2), Integer(1)], []]),␣
↪[Integer(2), Integer(1), Integer(1)], Integer(3))
[2*t^7 + 2*t^5 + t^3]
```

Introduction

The Robinson-Schensted-Knuth (RSK) correspondence is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semistandard Young tableaux (P, Q) of identical shape.

The basic operation in the RSK correspondence is a row insertion $P \leftarrow k$ (where P is a given semistandard Young tableau, and k is an integer). Different insertion algorithms have been implemented for the RSK correspondence and can be specified as an argument in the function call.

EXAMPLES:

We can perform RSK and its inverse map on a variety of objects:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: gp = RSK_inverse(p, q); gp
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK(*gp) # RSK of a biword
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
sage: RSK([2,3,2,1,2,3]) # Robinson-Schensted of a word
[[[1, 2, 2, 3], [2], [3]], [[1, 2, 5, 6], [3], [4]]]
sage: RSK([2,3,2,1,2,3], insertion=RSK.rules.EG) # Edelman-Greene
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
sage: m = RSK_inverse(p, q, 'matrix'); m # output as matrix
[0 1]
[1 0]
[0 2]

Insertions currently available

The following insertion algorithms for RSK correspondence are currently available:

- RSK insertion (*RuleRSK*).
- Edelman-Greene insertion (*RuleEG*), an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion).
- Hecke RSK algorithm (*RuleHecke*), defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns).
- Dual RSK insertion (*RuleDualRSK*).
- CoRSK insertion (*RuleCoRSK*), defined in [GR2018v5sol].
- Super RSK insertion (*RuleSuperRSK*), a combination of row and column insertions defined in [Muth2019].
- Star insertion (*RuleStar*), defined in [MPPS2020].

Implementing your own insertion rule

The functions *RSK()* and *RSK_inverse()* are written so that it is easy to implement insertion algorithms you come across in your research.

To implement your own insertion algorithm, you first need to import the base class for a rule:

```
sage: from sage.combinat.rsk import Rule
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import Rule
```

Using the `Rule` class as parent class for your insertion rule, first implement the insertion and the reverse insertion algorithm for *RSK()* and *RSK_inverse()* respectively (as methods `forward_rule` and `backward_rule`). If your insertion algorithm uses the same forward and backward rules as `RuleRSK`, differing only in how an entry is inserted into a row, then this is not necessary, and it suffices to merely implement the `insertion` and `reverse_insertion` methods.

For more information, see *Rule*.

sage.combinat.rsk.**RSK**(*obj1=None*, *obj2=None*, *insertion=<class 'sage.combinat.rsk.RuleRSK'>*, *check_standard=False*, ***options*)

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semistandard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semistandard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i-th step inserts the number k_i into the i-th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i-th row, then k_i is simply appended to the row and the algorithm terminates at this point.

A *generalized permutation* (or *biword*) is a list $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ of pairs such that the letters $j_0, j_1, \ldots, j_{\ell-1}$ are weakly increasing (that is, $j_0 \leq j_1 \leq \cdots \leq j_{\ell-1}$), whereas the letters k_i satisfy $k_i \leq k_{i+1}$ whenever $j_i = j_{i+1}$. The ℓ-tuple $(j_0, j_1, \ldots, j_{\ell-1})$ is called the *top line* of this generalized permutation, whereas the ℓ-tuple $(k_0, k_1, \ldots, k_{\ell-1})$ is called its *bottom line*.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semistandard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p, and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as "Construction A".

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top row to be $(1, 2, \ldots, n)$ where n is the length of w.

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

INPUT:

- `obj1`, `obj2` – can be one of the following:
  - a word in an ordered alphabet (in this case, `obj1` is said word, and `obj2` is `None`)
  - an integer matrix
  - two lists of equal length representing a generalized permutation (namely, the lists $(j_0, j_1, \ldots, j_{\ell-1})$ and $(k_0, k_1, \ldots, k_{\ell-1})$ represent the generalized permutation $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$)
  - any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, `obj1` is said object, and `obj2` is `None`).
- `insertion` – (default: `RSK.rules.RSK`) the following types of insertion are currently supported:
  - `RSK.rules.RSK` (or `'RSK'`) – Robinson-Schensted-Knuth insertion (*RuleRSK*)
  - `RSK.rules.EG` (or `'EG'`) – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)

- `RSK.rules.Hecke` (or `'hecke'`) – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
- `RSK.rules.dualRSK` (or `'dualRSK'`) – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
- `RSK.rules.coRSK` (or `'coRSK'`) – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
- `RSK.rules.superRSK` (or `'super'`) – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
- `RSK.rules.Star` (or `'Star'`) – $\star$-insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)

- `check_standard` – boolean (default: `False`); check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular *Rule* class.

EXAMPLES:

If we only input one row, it is understood that the top row should be $(1, 2, \ldots, n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RSK(Word([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RSK(Word([Integer(2),Integer(3),Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

We can provide a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1),
↪ Integer(1), Integer(2)])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
>>> RSK(Word([Integer(1),Integer(1),Integer(3),Integer(4),Integer(4)]),␣
↪[Integer(1),Integer(4),Integer(2),Integer(1),Integer(3)])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
>>> RSK([Integer(1),Integer(3),Integer(3),Integer(4),Integer(4)],␣
```

(continues on next page)

(continued from previous page)

```
↪Word([Integer(6),Integer(2),Integer(2),Integer(1),Integer(7)]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

We can provide a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK(matrix([[Integer(0),Integer(1)],[Integer(2),Integer(1)]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also provide something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK([[Integer(0),Integer(1)],[Integer(2),Integer(1)]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There is also *RSK_inverse()* which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with *RSK()*, we need to use the python * on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

```
>>> from sage.all import *
>>> RSK_inverse(*RSK([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(2), Integer(1), Integer(1), Integer(2)]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
>>> P,Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(1), Integer(1), Integer(2)])
>>> RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

sage.combinat.rsk.**RSK_inverse**(*p*, *q*, *output='array'*, *insertion=<class 'sage.combinat.rsk.RuleRSK'>*)

Return the generalized permutation corresponding to the pair of tableaux (p, q) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see *RSK()*.

INPUT:

- `p`, `q` – two semistandard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- `output` – (default: `'array'`) if `q` is semistandard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)

  - `'matrix'` – as an integer matrix

  and if `q` is standard, we can also have the output:

  - `'word'` – as a word

  and additionally if `p` is standard, we can also have the output:

  - `'permutation'` – as a permutation

- `insertion` – (default: `RSK.rules.RSK`) the insertion algorithm used in the bijection. Currently the following are supported:
  - `RSK.rules.RSK` (or `'RSK'`) – Robinson-Schensted-Knuth insertion (*RuleRSK*)
  - `RSK.rules.EG` (or `'EG'`) – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)
  - `RSK.rules.Hecke` (or `'hecke'`) – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
  - `RSK.rules.dualRSK` (or `'dualRSK'`) – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
  - `RSK.rules.coRSK` (or `'coRSK'`) – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
  - `RSK.rules.superRSK` (or `'super'`) – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
  - `RSK.rules.Star` (or `'Star'`) – $\star$-insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)

For precise information about constraints on the input and output, see the particular *Rule* class.

Note

In the case of Hecke insertion, the input variable `q` should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both `p` and `q` are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
```

(continues on next page)

(continued from previous page)

```
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

```
>>> from sage.all import *
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],␣
↪[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],␣
↪[Integer(5)]])
>>> RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> RSK_inverse(t1, t2, 'word')
word: 14532
>>> RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
>>> RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
>>> RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
>>> RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
>>> RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(3)]]); q =␣
↪Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3)]])
>>> ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
>>> RSK_inverse(p, q, 'word')
word: 1322
```

In general:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
```

(continues on next page)

(continued from previous page)

```
[0 2]
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]); q =␣
↪Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
>>> RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

Using Hecke insertion:

```
sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

```
>>> from sage.all import *
>>> w = [Integer(5), Integer(4), Integer(3), Integer(1), Integer(4), Integer(2),␣
↪Integer(5), Integer(5)]
>>> pq = RSK(w, insertion=RSK.rules.Hecke)
>>> RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

Note

The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

class sage.combinat.rsk.**Rule**

Bases: `UniqueRepresentation`

Generic base class for an insertion rule for an RSK-type correspondence.

An instance of this class should implement *insertion()* (which can be applied to a letter `j` and a list `r`, and modifies `r` in place by "bumping" `j` into it appropriately; it then returns the bumped-out entry or `None` if no such entry exists) and *reverse_insertion()* (which does the same but for reverse bumping). It may also implement *_backward_format_output()* and *_forward_format_output()* if the RSK correspondence should return something other than (semi)standard tableaux (in the forward direction) and matrices or biwords (in the backward direction). The *to_pairs()* method should also be overridden if the input for the (forward) RSK correspondence is not the usual kind of biwords (i.e., pairs of two n-tuples $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ satisfying $(a_1, b_1) \leq (a_2, b_2) \leq \cdots \leq (a_n, b_n)$ in lexicographic order). Finally, *forward_rule()* and *backward_rule()* have to be overridden if the overall structure of the RSK correspondence differs from that of classical RSK (see, e.g., the case of Hecke insertion, in which a letter bumped into a row may change a different row).

_forward_format_output(*p*, *q*, *check_standard*)

Return final output of the `RSK` correspondence from the output of the corresponding `forward_rule`.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: isinstance(RuleRSK()._forward_format_output([[1, 2, 3, 4, 5]],
....:             [[1, 2, 3, 4, 5]], True)[0], StandardTableau)
True
sage: isinstance(RuleRSK()._forward_format_output([[1, 2, 3, 4, 5]],
....:             [[1, 2, 3, 4, 5]], False)[0], SemistandardTableau)
True
sage: isinstance(RuleRSK()._forward_format_output([[1, 1, 1, 3, 7]],
....:             [[1, 2, 3, 4, 5]], True)[0], SemistandardTableau)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> isinstance(RuleRSK()._forward_format_output([[Integer(1), Integer(2),␣
↪Integer(3), Integer(4), Integer(5)]],
...             [[Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)]],
↪ True)[Integer(0)], StandardTableau)
True
>>> isinstance(RuleRSK()._forward_format_output([[Integer(1), Integer(2),␣
↪Integer(3), Integer(4), Integer(5)]],
...             [[Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)]],
↪ False)[Integer(0)], SemistandardTableau)
True
>>> isinstance(RuleRSK()._forward_format_output([[Integer(1), Integer(1),␣
↪Integer(1), Integer(3), Integer(7)]],
...             [[Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)]],
↪ True)[Integer(0)], SemistandardTableau)
True
```

_backward_format_output(*lower_row*, *upper_row*, *output*, *p_is_standard*, *q_is_standard*)

Return the final output of the `RSK_inverse` correspondence from the output of the corresponding `backward_rule`.

Note

The default implementation of `backward_rule` lists bumped-out entries in the order in which the reverse bumping happens, which is *opposite* to the order of the final output.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: RuleRSK()._backward_format_output([1, 2, 3, 4], None, 'array', False,␣
↪True)
[[1, 2, 3, 4], [4, 3, 2, 1]]
sage: RuleRSK()._backward_format_output([1, 2, 3, 4], None, 'matrix', False,␣
↪True)
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]
[1 0 0 0]
sage: RuleRSK()._backward_format_output([1, 2, 3, 4], None, 'word', False,␣
```

(continues on next page)

(continued from previous page)

```
↪True)
word: 4321
sage: RuleRSK()._backward_format_output([3, 2, 1, 1], [2, 1, 1, 1], 'array',␣
↪False, False)
[[1, 1, 1, 2], [1, 1, 2, 3]]
sage: RuleRSK()._backward_format_output([3, 2, 1, 1], [2, 1, 1, 1], 'matrix',␣
↪False, False)
[2 1 0]
[0 0 1]
sage: RuleRSK()._backward_format_output([1, 2, 3, 4], None, 'word', False,␣
↪False)
Traceback (most recent call last):
...
TypeError: q must be standard to have a word as valid output
sage: RuleRSK()._backward_format_output([1, 2, 3, 4], None, 'random_type',␣
↪False, False)
Traceback (most recent call last):
...
ValueError: invalid output option
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> RuleRSK()._backward_format_output([Integer(1), Integer(2), Integer(3),␣
↪Integer(4)], None, 'array', False, True)
[[1, 2, 3, 4], [4, 3, 2, 1]]
>>> RuleRSK()._backward_format_output([Integer(1), Integer(2), Integer(3),␣
↪Integer(4)], None, 'matrix', False, True)
[0 0 0 1]
[0 0 1 0]

backward_rule(*p*, *q*, *output*)

Return the generalized permutation obtained by applying reverse insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape
- `output` – (default: `'array'`) if `q` is semistandard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)
  - `'matrix'` – as an integer matrix

  and if `q` is standard, we can also have the output:
  - `'word'` – as a word

  and additionally if `p` is standard, we can also have the output:
  - `'permutation'` – as a permutation

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: t1 = Tableau([[1, 3, 4], [2], [3]])
sage: t2 = Tableau([[1, 2, 4], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 1, 1, 3, 7]])
sage: t2 = Tableau([[1, 2, 3, 4, 5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [1, 1, 1, 3, 7]]
sage: t1 = Tableau([[1, 3], [3], [6], [7]])
sage: t2 = Tableau([[1, 4], [2], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [7, 6, 3, 3, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> t1 = Tableau([[Integer(1), Integer(3), Integer(4)], [Integer(2)],␣
↪[Integer(3)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(4)], [Integer(3)],␣
↪[Integer(5)]])
>>> RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
>>> t1 = Tableau([[Integer(1), Integer(1), Integer(1), Integer(3),␣
↪Integer(7)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3), Integer(4),␣
↪Integer(5)]])
>>> RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [1, 1, 1, 3, 7]]
>>> t1 = Tableau([[Integer(1), Integer(3)], [Integer(3)], [Integer(6)],␣
↪[Integer(7)]])
>>> t2 = Tableau([[Integer(1), Integer(4)], [Integer(2)], [Integer(3)],␣
↪[Integer(5)]])
```

(continues on next page)

(continued from previous page)

```
>>> RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [7, 6, 3, 3, 1]]
```

forward_rule(*obj1*, *obj2*, *check_standard=False*, *check=True*)

Return a pair of tableaux obtained by applying forward insertion to the generalized permutation `[obj1, obj2]`.

INPUT:

- `obj1`, `obj2` – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists `obj1` and `obj2` of equal length, to be interpreted as the top row and the bottom row of the biword
  - a matrix `obj1` of nonnegative integers, to be interpreted as the generalized permutation in matrix form (in this case, `obj2` is `None`)
  - a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \ldots, n)$ by default)
  - any object `obj1` which has a method `_rsk_iter()`, as long as this method returns an iterator yielding pairs of numbers, which then are interpreted as top entries and bottom entries in the biword (in this case, `obj2` is `None`)
- `check_standard` – boolean (default: `False`); check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: RuleRSK().forward_rule([3,3,2,4,1], None)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RuleRSK().forward_rule([1, 1, 1, 3, 7], None)
[[[1, 1, 1, 3, 7]], [[1, 2, 3, 4, 5]]]
sage: RuleRSK().forward_rule([7, 6, 3, 3, 1], None)
[[[1, 3], [3], [6], [7]], [[1, 4], [2], [3], [5]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> RuleRSK().forward_rule([Integer(3),Integer(3),Integer(2),Integer(4),
↪Integer(1)], None)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RuleRSK().forward_rule([Integer(1), Integer(1), Integer(1), Integer(3),␣
↪Integer(7)], None)
[[[1, 1, 1, 3, 7]], [[1, 2, 3, 4, 5]]]
>>> RuleRSK().forward_rule([Integer(7), Integer(6), Integer(3), Integer(3),␣
↪Integer(1)], None)
[[[1, 3], [3], [6], [7]], [[1, 4], [2], [3], [5]]]
```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the RSK algorithm, such as two n-tuples `obj1` $= [a_1, a_2, \ldots, a_n]$ and `obj2` $= [b_1, b_2, \ldots, b_n]$ forming a biword (i.e., satisfying $a_1 \leq a_2 \leq \cdots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i \leq b_{i+1}$), or a matrix ("generalized permutation"), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a biword (see the doc of *forward_rule()* for the encodings accepted)
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid biword

EXAMPLES:

```
sage: from sage.combinat.rsk import Rule
sage: list(Rule().to_pairs([1, 2, 2, 2], [2, 1, 1, 2]))
[(1, 2), (2, 1), (2, 1), (2, 2)]
sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: list(Rule().to_pairs(m))
[(1, 2), (2, 1), (3, 2), (3, 2)]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import Rule
>>> list(Rule().to_pairs([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(2), Integer(1), Integer(1), Integer(2)]))
[(1, 2), (2, 1), (2, 1), (2, 2)]
>>> m = Matrix(ZZ, Integer(3), Integer(2), [Integer(0),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(2)]) ; m
[0 1]
[1 0]
[0 2]
>>> list(Rule().to_pairs(m))
[(1, 2), (2, 1), (3, 2), (3, 2)]
```

class sage.combinat.rsk.**RuleCoRSK**

Bases: *RuleRSK*

Rule for coRSK insertion.

CoRSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer a biword, but rather a strict cobiword – i.e., a pair of two lists $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ that satisfy the strict inequalities $(a_1, b_1) \widetilde{<} (a_2, b_2) \widetilde{<} \cdots \widetilde{<} (a_n, b_n)$, where the binary relation $\widetilde{<}$ on pairs of integers is defined by having $(u_1, v_1) \widetilde{<} (u_2, v_2)$ if and only if either $u_1 < u_2$ or ($u_1 = u_2$ and $v_1 > v_2$). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a $\{0, 1\}$-matrix (i.e., a matrix whose entries are 0's and 1's).
- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now Q is row-strict (i.e., its transpose is semistandard) while P is semistandard.

Bumping proceeds in the same way as for RSK insertion.

The RSK and coRSK algorithms agree for permutation matrices.

For more information, see Section A.4 in [Ful1997] (specifically, construction (1d)) or the second solution to Exercise 2.7.12(a) in [GR2018v5sol].

EXAMPLES:

```
sage: RSK([1,2,5,3,1], insertion = RSK.rules.coRSK)
[[[1, 1, 3], [2], [5]], [[1, 2, 3], [4], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion = RSK.rules.coRSK)
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
sage: RSK(Word([3,3,2,4,1]), insertion = RSK.rules.coRSK)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: from sage.combinat.rsk import to_matrix
sage: RSK(to_matrix([1, 1, 3, 3, 4], [3, 2, 2, 1, 3]), insertion = RSK.rules.
↪coRSK)
[[[1, 2, 3], [2], [3]], [[1, 3, 4], [1], [3]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1),Integer(2),Integer(5),Integer(3),Integer(1)], insertion = RSK.
↪rules.coRSK)
[[[1, 1, 3], [2], [5]], [[1, 2, 3], [4], [5]]]
>>> RSK(Word([Integer(2),Integer(3),Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)]), insertion = RSK.rules.coRSK)
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
>>> RSK(Word([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]), insertion␣
↪= RSK.rules.coRSK)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> from sage.combinat.rsk import to_matrix
>>> RSK(to_matrix([Integer(1), Integer(1), Integer(3), Integer(3), Integer(4)],␣
↪[Integer(3), Integer(2), Integer(2), Integer(1), Integer(3)]), insertion = RSK.
↪rules.coRSK)
[[[1, 2, 3], [2], [3]], [[1, 3, 4], [1], [3]]]
```

Using coRSK insertion with a $\{0,1\}$-matrix:

```
sage: RSK(matrix([[0,1],[1,0]]), insertion = RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

```
>>> from sage.all import *
>>> RSK(matrix([[Integer(0),Integer(1)],[Integer(1),Integer(0)]]), insertion =␣
↪RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0,1],[1,0]], insertion = RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

```
>>> from sage.all import *
>>> RSK([[Integer(0),Integer(1)],[Integer(1),Integer(0)]], insertion = RSK.rules.
↪coRSK)
[[[1], [2]], [[1], [2]]]
```

We can also use the inverse correspondence:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 3, 2, 1],
....:             insertion=RSK.rules.coRSK),insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
```

(continues on next page)

(continued from previous page)

```
sage: P,Q = RSK([1, 2, 2, 2], [2, 3, 2, 1],insertion=RSK.rules.coRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
```

```
>>> from sage.all import *
>>> RSK_inverse(*RSK([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(2), Integer(3), Integer(2), Integer(1)],
...          insertion=RSK.rules.coRSK),insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
>>> P,Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(3), Integer(2), Integer(1)],insertion=RSK.rules.coRSK)
>>> RSK_inverse(P, Q, insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
```

When applied to two standard tableaux, backwards coRSK insertion behaves identically to the usual backwards RSK insertion:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.coRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word', insertion=RSK.rules.coRSK)
word: 14532
sage: RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.coRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 5, 4, 2, 3]
```

```
>>> from sage.all import *
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],␣
↪[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],␣
↪[Integer(5)]])
>>> RSK_inverse(t1, t2, insertion=RSK.rules.coRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> RSK_inverse(t1, t2, 'word', insertion=RSK.rules.coRSK)
word: 14532
>>> RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.coRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
```

(continues on next page)

(continued from previous page)

```
[0 1 0 0 0]
>>> RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 5, 3, 2]
>>> RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 3, 2, 5]
>>> RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 2, 5, 4, 3]
>>> RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 5, 4, 2, 3]
```

For coRSK, the first tableau is semistandard while the second tableau is transpose semistandard:

```
sage: p = Tableau([[1,2,2],[5]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q, insertion=RSK.rules.coRSK); ret
[[1, 2, 3, 4], [1, 5, 2, 2]]
sage: RSK_inverse(p, q, 'word', insertion=RSK.rules.coRSK)
word: 1522
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(5)]]); q =␣
↪Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3)]])
>>> ret = RSK_inverse(p, q, insertion=RSK.rules.coRSK); ret
[[1, 2, 3, 4], [1, 5, 2, 2]]
>>> RSK_inverse(p, q, 'word', insertion=RSK.rules.coRSK)
word: 1522
```

backward_rule(*p*, *q*, *output*)

Return the strict cobiword obtained by applying reverse coRSK insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape
- `output` – (default: `'array'`) if `q` is row-strict:
  - `'array'` – as a two-line array (i.e. strict cobiword)
  - `'matrix'` – as a $\{0,1\}$-matrix

  and if `q` is standard, we can have the output:
  - `'word'` – as a word

  and additionally if `p` is standard, we can also have the output:
  - `'permutation'` – as a permutation

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleCoRSK
sage: t1 = Tableau([[1, 1, 2], [2, 3], [4]])
sage: t2 = Tableau([[1, 4, 5], [1, 4], [2]])
sage: RuleCoRSK().backward_rule(t1, t2, 'array')
[[1, 1, 2, 4, 4, 5], [4, 2, 1, 3, 1, 2]]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleCoRSK
>>> t1 = Tableau([[Integer(1), Integer(1), Integer(2)], [Integer(2),␣
↪Integer(3)], [Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(4), Integer(5)], [Integer(1),␣
↪Integer(4)], [Integer(2)]])
>>> RuleCoRSK().backward_rule(t1, t2, 'array')
[[1, 1, 2, 4, 4, 5], [4, 2, 1, 3, 1, 2]]
```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the coRSK algorithm, such as two n-tuples `obj1` $= [a_1, a_2, \ldots, a_n]$ and `obj2` $= [b_1, b_2, \ldots, b_n]$ forming a strict cobiword (i.e., satisfying $a_1 \leq a_2 \leq \cdots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i > b_{i+1}$), or a $\{0,1\}$-matrix ("rook placement"), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a strict cobiword (see the doc of *forward_rule()* for the encodings accepted)
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid strict cobiword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleCoRSK
sage: list(RuleCoRSK().to_pairs([1, 2, 2, 2], [2, 3, 2, 1]))
[(1, 2), (2, 3), (2, 2), (2, 1)]
sage: RuleCoRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])

class sage.combinat.rsk.**RuleDualRSK**

Bases: *Rule*

Rule for dual RSK insertion.

Dual RSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a strict biword (i.e., a pair of two lists $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ that satisfy the strict inequalities $(a_1, b_1) < (a_2, b_2) < \cdots < (a_n, b_n)$ in lexicographic order). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a $\{0, 1\}$-matrix (i.e., a matrix whose entries are 0's and 1's).
- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now P is row-strict (i.e., its transpose is semistandard) while Q is semistandard.
- The main difference is in the way bumping works. Namely, when a number k_i is inserted into the i-th row of P, it bumps out the first integer greater **or equal to** k_i in this row (rather than greater than k_i).

The RSK and dual RSK algorithms agree for permutation matrices.

For more information, see Chapter 7, Section 14 in [Sta-EC2] (where dual RSK is called RSK*) or the third solution to Exercise 2.7.12(a) in [GR2018v5sol].

EXAMPLES:

```
sage: RSK([3,3,2,4,1], insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]), insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [2, 3], [2, 3], [3]], [[1, 2, 8], [3, 6], [4, 7], [5]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)], insertion=RSK.
↪rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
```

(continues on next page)

(continued from previous page)

```
>>> RSK(Word([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]),␣
↪insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
>>> RSK(Word([Integer(2),Integer(3),Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)]), insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [2, 3], [2, 3], [3]], [[1, 2, 8], [3, 6], [4, 7], [5]]]
```

Using dual RSK insertion with a strict biword:

```
sage: RSK([1,1,2,4,4,5],[2,4,1,1,3,2], insertion=RSK.rules.dualRSK)
[[[1, 2], [1, 3], [2, 4]], [[1, 1], [2, 4], [4, 5]]]
sage: RSK([1,1,2,3,3,4,5],[1,3,2,1,3,3,2], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1, 2], [3], [3]], [[1, 1, 3], [2, 4], [3], [5]]]
sage: RSK([1, 2, 2, 2], [2, 1, 2, 4], insertion=RSK.rules.dualRSK)
[[[1, 2, 4], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,1,2,1,7]), insertion=RSK.rules.dualRSK)
[[[1, 2, 7], [1], [6]], [[1, 3, 4], [3], [4]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1),Integer(1),Integer(2),Integer(4),Integer(4),Integer(5)],
↪[Integer(2),Integer(4),Integer(1),Integer(1),Integer(3),Integer(2)],␣
↪insertion=RSK.rules.dualRSK)
[[[1, 2], [1, 3], [2, 4]], [[1, 1], [2, 4], [4, 5]]]
>>> RSK([Integer(1),Integer(1),Integer(2),Integer(3),Integer(3),Integer(4),
↪Integer(5)],[Integer(1),Integer(3),Integer(2),Integer(1),Integer(3),Integer(3),
↪Integer(2)], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1, 2], [3], [3]], [[1, 1, 3], [2, 4], [3], [5]]]
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1),
↪ Integer(2), Integer(4)], insertion=RSK.rules.dualRSK)
[[[1, 2, 4], [2]], [[1, 2, 2], [2]]]
>>> RSK(Word([Integer(1),Integer(1),Integer(3),Integer(4),Integer(4)]),␣
↪[Integer(1),Integer(4),Integer(2),Integer(1),Integer(3)], insertion=RSK.rules.
↪dualRSK)
[[[1, 2, 3], [1], [4]], [[1, 1, 4], [3], [4]]]
>>> RSK([Integer(1),Integer(3),Integer(3),Integer(4),Integer(4)],␣
↪Word([Integer(6),Integer(1),Integer(2),Integer(1),Integer(7)]), insertion=RSK.
↪rules.dualRSK)
[[[1, 2, 7], [1], [6]], [[1, 3, 4], [3], [4]]]
```

Using dual RSK insertion with a $\{0,1\}$-matrix:

```
sage: RSK(matrix([[0,1],[1,1]]), insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK(matrix([[Integer(0),Integer(1)],[Integer(1),Integer(1)]]), insertion=RSK.
↪rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0,1],[1,1]], insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK([[Integer(0),Integer(1)],[Integer(1),Integer(1)]], insertion=RSK.rules.
↪dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]
```

Let us now call the inverse correspondence:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 2, 3],
....:         insertion=RSK.rules.dualRSK),insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 2, 3],insertion=RSK.rules.dualRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
```

```
>>> from sage.all import *
>>> RSK_inverse(*RSK([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(2), Integer(1), Integer(2), Integer(3)],
...          insertion=RSK.rules.dualRSK),insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
>>> P,Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(1), Integer(2), Integer(3)],insertion=RSK.rules.dualRSK)
>>> RSK_inverse(P, Q, insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
```

When applied to two standard tableaux, reverse dual RSK insertion behaves identically to the usual reverse RSK insertion:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word', insertion=RSK.rules.dualRSK)
word: 14532
sage: RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.dualRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 5, 4, 2, 3]
```

```
>>> from sage.all import *
```

(continues on next page)

(continued from previous page)

```
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],␣
↪[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],␣
↪[Integer(5)]])
>>> RSK_inverse(t1, t2, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> RSK_inverse(t1, t2, 'word', insertion=RSK.rules.dualRSK)
word: 14532
>>> RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.dualRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
>>> RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 5, 3, 2]
>>> RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 3, 2, 5]
>>> RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 2, 5, 4, 3]
>>> RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 5, 4, 2, 3]
```

Let us check that forward and backward dual RSK are mutually inverse when the first tableau is merely transpose semistandard:

```
sage: p = Tableau([[1,2,2],[1]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q, insertion=RSK.rules.dualRSK); ret
[[1, 2, 3, 4], [1, 2, 1, 2]]
sage: RSK_inverse(p, q, 'word', insertion=RSK.rules.dualRSK)
word: 1212
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(1)]]); q =␣
↪Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3)]])
>>> ret = RSK_inverse(p, q, insertion=RSK.rules.dualRSK); ret
[[1, 2, 3, 4], [1, 2, 1, 2]]
>>> RSK_inverse(p, q, 'word', insertion=RSK.rules.dualRSK)
word: 1212
```

In general for dual RSK:

```
sage: p = Tableau([[1,1,2],[1]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 3], [1, 1, 1, 2]]
sage: RSK_inverse(p, q, 'matrix', insertion=RSK.rules.dualRSK)
[1 0]
[1 0]
[1 1]
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(1)]]); q =␣
```

(continues on next page)

(continued from previous page)

```
↪Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> RSK_inverse(p, q, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 3], [1, 1, 1, 2]]
>>> RSK_inverse(p, q, 'matrix', insertion=RSK.rules.dualRSK)
[1 0]
[1 0]
[1 1]
```

insertion(*j*, *r*)

Insert the letter `j` from the second row of the biword into the row *r* using dual RSK insertion, if there is bumping to be done.

The row *r* is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleDualRSK
sage: r = [1, 3, 4, 5]
sage: j = RuleDualRSK().insertion(4, r); j
4
sage: r
[1, 3, 4, 5]
sage: r = [1, 2, 3, 6, 7]
sage: j = RuleDualRSK().insertion(4, r); j
6
sage: r
[1, 2, 3, 4, 7]
sage: r = [1, 3]
sage: j = RuleDualRSK().insertion(4, r); j is None
True
sage: r
[1, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleDualRSK
>>> r = [Integer(1), Integer(3), Integer(4), Integer(5)]
>>> j = RuleDualRSK().insertion(Integer(4), r); j
4
>>> r
[1, 3, 4, 5]
>>> r = [Integer(1), Integer(2), Integer(3), Integer(6), Integer(7)]
>>> j = RuleDualRSK().insertion(Integer(4), r); j
6
>>> r
[1, 2, 3, 4, 7]
>>> r = [Integer(1), Integer(3)]
>>> j = RuleDualRSK().insertion(Integer(4), r); j is None
True
>>> r
[1, 3]
```

reverse_insertion(*x*, *row*)

Reverse bump the row `row` of the current insertion tableau with the number `x` using dual RSK insertion.

The row `row` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleDualRSK
sage: r = [1, 2, 4, 6, 7]
sage: x = RuleDualRSK().reverse_insertion(6, r); r
[1, 2, 4, 6, 7]
sage: x
6
sage: r = [1, 2, 4, 5, 7]
sage: x = RuleDualRSK().reverse_insertion(6, r); r
[1, 2, 4, 6, 7]
sage: x
5
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleDualRSK
>>> r = [Integer(1), Integer(2), Integer(4), Integer(6), Integer(7)]
>>> x = RuleDualRSK().reverse_insertion(Integer(6), r); r
[1, 2, 4, 6, 7]
>>> x
6
>>> r = [Integer(1), Integer(2), Integer(4), Integer(5), Integer(7)]
>>> x = RuleDualRSK().reverse_insertion(Integer(6), r); r
[1, 2, 4, 6, 7]
>>> x
5
```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the dual RSK algorithm, such as two n-tuples `obj1` $= [a_1, a_2, \ldots, a_n]$ and `obj2` $= [b_1, b_2, \ldots, b_n]$ forming a strict biword (i.e., satisfying $a_1 \leq a_2 \leq \cdots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i < b_{i+1}$) or a $\{0,1\}$-matrix ("rook placement"), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a strict biword (see the doc of *forward_rule()* for the encodings accepted)
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid strict biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleDualRSK
sage: list(RuleDualRSK().to_pairs([1, 2, 2, 2], [2, 1, 2, 3]))
[(1, 2), (2, 1), (2, 2), (2, 3)]
sage: RuleDualRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])
Traceback (most recent call last):
...
ValueError: invalid strict biword
sage: m = Matrix(ZZ, 3, 2, [0,1,1,1,0,1]) ; m
[0 1]
[1 1]
[0 1]
```

(continues on next page)

(continued from previous page)

```
sage: list(RuleDualRSK().to_pairs(m))
[(1, 2), (2, 1), (2, 2), (3, 2)]
sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: RuleDualRSK().to_pairs(m)
Traceback (most recent call last):
...
ValueError: dual RSK requires a {0, 1}-matrix
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleDualRSK
>>> list(RuleDualRSK().to_pairs([Integer(1), Integer(2), Integer(2),␣
↪Integer(2)], [Integer(2), Integer(1), Integer(2), Integer(3)]))
[(1, 2), (2, 1), (2, 2), (2, 3)]
>>> RuleDualRSK().to_pairs([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(1), Integer(2), Integer(3), Integer(3)])
Traceback (most recent call last):
...
ValueError: invalid strict biword
>>> m = Matrix(ZZ, Integer(3), Integer(2), [Integer(0),Integer(1),Integer(1),
↪Integer(1),Integer(0),Integer(1)]) ; m
[0 1]
[1 1]
[0 1]
>>> list(RuleDualRSK().to_pairs(m))
[(1, 2), (2, 1), (2, 2), (3, 2)]
>>> m = Matrix(ZZ, Integer(3), Integer(2), [Integer(0),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(2)]) ; m
[0 1]
[1 0]
[0 2]
>>> RuleDualRSK().to_pairs(m)
Traceback (most recent call last):
...
ValueError: dual RSK requires a {0, 1}-matrix
```

class sage.combinat.rsk.**RuleEG**

Bases: *Rule*

Rule for Edelman-Greene insertion.

For a reduced word of a permutation (i.e., an element of a type A Coxeter group), one can use Edelman-Greene insertion, an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that (using the notations in the documentation of *RSK()*) if k_i and $k_i + 1$ both exist in row i, we *only* set $k_{i+1} = k_i + 1$ and continue.

EXAMPLES:

Let us reproduce figure 6.4 in [EG1987]:

```
sage: RSK([2,3,2,1,2,3], insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(2),Integer(3),Integer(2),Integer(1),Integer(2),Integer(3)],␣
↪insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

Some more examples:

```
sage: a = [2, 1, 2, 3, 2]
sage: pq = RSK(a, insertion=RSK.rules.EG); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK(RSK_inverse(*pq, insertion=RSK.rules.EG, output='matrix'),
....:     insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK_inverse(*pq, insertion=RSK.rules.EG)
[[1, 2, 3, 4, 5], [2, 1, 2, 3, 2]]
```

```
>>> from sage.all import *
>>> a = [Integer(2), Integer(1), Integer(2), Integer(3), Integer(2)]
>>> pq = RSK(a, insertion=RSK.rules.EG); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
>>> RSK(RSK_inverse(*pq, insertion=RSK.rules.EG, output='matrix'),
...     insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
>>> RSK_inverse(*pq, insertion=RSK.rules.EG)
[[1, 2, 3, 4, 5], [2, 1, 2, 3, 2]]
```

The RSK algorithm (*RSK()*) built using the Edelman-Greene insertion rule `RuleEG` is a bijection from reduced words of permutations/elements of a type A Coxeter group to pairs consisting of an increasing tableau and a standard tableau of the same shape (see [EG1987] Theorem 6.25). The inverse of this bijection is obtained using *RSK_inverse()*. If the optional parameter `output = 'permutation'` is set in *RSK_inverse()*, then the function returns not the reduced word itself but the permutation (of smallest possible size) whose reduced word it is (although the order of the letters is reverse to the usual Sage convention):

```
sage: w = RSK_inverse(*pq, insertion=RSK.rules.EG, output='permutation'); w
[4, 3, 1, 2]
sage: list(reversed(a)) in w.reduced_words()
True
```

```
>>> from sage.all import *
>>> w = RSK_inverse(*pq, insertion=RSK.rules.EG, output='permutation'); w
[4, 3, 1, 2]
>>> list(reversed(a)) in w.reduced_words()
True
```

insertion(j, r)

Insert the letter `j` from the second row of the biword into the row r using Edelman-Greene insertion, if there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleEG
sage: qr, r =  [1,2,3,4,5], [3,3,2,4,8]
```

(continues on next page)

(continued from previous page)

```
sage: j = RuleEG().insertion(9, r)
sage: j is None
True
sage: qr, r = [1,2,3,4,5], [2,3,4,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 4, 5, 8]
sage: j
4
sage: qr, r = [1,2,3,4,5], [2,3,5,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 3, 5, 8]
sage: j
5
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleEG
>>> qr, r =  [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(3),Integer(3),Integer(2),Integer(4),Integer(8)]
>>> j = RuleEG().insertion(Integer(9), r)
>>> j is None
True
>>> qr, r = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(2),Integer(3),Integer(4),Integer(5),Integer(8)]
>>> j = RuleEG().insertion(Integer(3), r); r
[2, 3, 4, 5, 8]
>>> j
4
>>> qr, r = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(2),Integer(3),Integer(5),Integer(5),Integer(8)]
>>> j = RuleEG().insertion(Integer(3), r); r
[2, 3, 3, 5, 8]
>>> j
5
```

reverse_insertion(*x*, *row*)

Reverse bump the row `row` of the current insertion tableau with the number `x`.

The row `row` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleEG
sage: r =  [1,1,1,2,3,3]
sage: x = RuleEG().reverse_insertion(3, r); r
[1, 1, 1, 2, 3, 3]
sage: x
2
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleEG
>>> r =  [Integer(1),Integer(1),Integer(1),Integer(2),Integer(3),Integer(3)]
>>> x = RuleEG().reverse_insertion(Integer(3), r); r
```

(continues on next page)

(continued from previous page)

```
[1, 1, 1, 2, 3, 3]
>>> x
2
```

class sage.combinat.rsk.**RuleHecke**

Bases: *Rule*

Rule for Hecke insertion.

The Hecke RSK algorithm is similar to the classical RSK algorithm, but is defined using the Hecke insertion introduced in [BKSTY06] (but using rows instead of columns). It is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword p has top row $(1, 2, \ldots, n)$ (or, at least, has its top row strictly increasing).

The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$, then the algorithm recursively constructs pairs $(P_0, Q_0), (P_1, Q_1), \ldots, (P_\ell, Q_\ell)$ of tableaux. The construction of P_{t+1} and Q_{t+1} from P_t, Q_t, j_t and k_t proceeds as follows: Set $i = j_t$, $x = k_t$, $P = P_t$ and $Q = Q_t$. We are going to insert x into the increasing tableau P and update the set-valued "recording tableau" Q accordingly. As in the classical RSK algorithm, we first insert x into row 1 of P, then into row 2 of the resulting tableau, and so on, until the construction terminates. The details are different: Suppose we are inserting x into row R of P. If (Case 1) there exists an entry y in row R such that $x < y$, then let y be the minimal such entry. We replace this entry y with x if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting y into the next row of P. If, on the other hand, (Case 2) no such y exists, then we append x to the end of R if the result is an increasing tableau (Subcase 2.1), and otherwise (Subcase 2.2) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with x in P to the shape of Q, and fill it with the one-element set $\{i\}$. In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row R, and add i to the entry of Q in this box (this entry is a set, since Q is set-valued). In either subcase, we terminate the recursion, and set $P_{t+1} = P$ and $Q_{t+1} = Q$.

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set (namely, the set of its entries).

EXAMPLES:

As an example of Hecke insertion, we reproduce Example 2.1 in arXiv 0801.1319v2:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: P,Q = RSK(w, insertion=RSK.rules.Hecke); [P,Q]
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],

>>> wp == w
True
```

backward_rule(*p*, *q*, *output*)

Return the generalized permutation obtained by applying reverse Hecke insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape
- `output` – (default: `'array'`) if `q` is semistandard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)

  and if `q` is standard set-valued, we can have the output:
  - `'word'` – as a word
  - `'list'` – as a list

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: t1 = Tableau([[1, 4], [2], [3]])
sage: t2 = Tableau([[(1, 2), (4,)], [(3,)], [(5,)]])
sage: RuleHecke().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 4], [2, 3]])
sage: t2 = Tableau([[(1, 2), (4,)], [(3,)], [(5,)]])
sage: RuleHecke().backward_rule(t1, t2, 'array')
Traceback (most recent call last):
...
ValueError: p(=[[1, 4], [2, 3]]) and
 q(=[[(1, 2), (4,)], [(3,)], [(5,)]]) must have the same shape
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> t1 = Tableau([[Integer(1), Integer(4)], [Integer(2)], [Integer(3)]])
>>> t2 = Tableau([[(Integer(1), Integer(2)), (Integer(4),)], [(Integer(3),)],␣
↪[(Integer(5),)]])
>>> RuleHecke().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
>>> t1 = Tableau([[Integer(1), Integer(4)], [Integer(2), Integer(3)]])
>>> t2 = Tableau([[(Integer(1), Integer(2)), (Integer(4),)], [(Integer(3),)],␣
↪[(Integer(5),)]])
>>> RuleHecke().backward_rule(t1, t2, 'array')
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: p(=[[1, 4], [2, 3]]) and
 q(=[[(1, 2), (4,)], [(3,)], [(5,)]]) must have the same shape
```

forward_rule(*obj1*, *obj2*, *check_standard=False*)

Return a pair of tableaux obtained by applying Hecke insertion to the generalized permutation `[obj1, obj2]`.

INPUT:

- `obj1`, `obj2` – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists `obj1` and `obj2` of equal length, to be interpreted as the top row and the bottom row of the biword
  - a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \ldots, n)$ by default)
- `check_standard` – boolean (default: `False`); check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: p, q = RuleHecke().forward_rule([3,3,2,4,1], None);p
[[1, 4], [2], [3]]
sage: q
[[(1, 2), (4,)], [(3,)], [(5,)]]
sage: isinstance(p, SemistandardTableau)
True
sage: isinstance(q, Tableau)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> p, q = RuleHecke().forward_rule([Integer(3),Integer(3),Integer(2),
↪Integer(4),Integer(1)], None);p
[[1, 4], [2], [3]]
>>> q
[[(1, 2), (4,)], [(3,)], [(5,)]]
>>> isinstance(p, SemistandardTableau)
True
>>> isinstance(q, Tableau)
True
```

insertion(*j*, *ir*, *r*, *p*)

Insert the letter `j` from the second row of the biword into the row r of the increasing tableau p using Hecke insertion, provided that r is the ir-th row of p, and provided that there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_right
sage: p, q, r =  [], [], [3,3,8,8,8,9]
sage: j, ir = 8, 1
sage: j1 = RuleHecke().insertion(j, ir, r, p)
sage: j1 == r[bisect_right(r, j)]
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> from bisect import bisect_right
>>> p, q, r =  [], [], [Integer(3),Integer(3),Integer(8),Integer(8),
↪Integer(8),Integer(9)]
>>> j, ir = Integer(8), Integer(1)
>>> j1 = RuleHecke().insertion(j, ir, r, p)
>>> j1 == r[bisect_right(r, j)]
True
```

reverse_insertion(*i*, *x*, *row*, *p*)

Reverse bump the row `row` of the current insertion tableau `p` with the number `x`, provided that `row` is the i-th row of p.

The row `row` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_left
sage: r =  [2,3,3,4,8,9]
sage: x, i, p = 9, 1, [1, 2]
sage: x1 = RuleHecke().reverse_insertion(i, x, r, p)
sage: x1 == r[bisect_left(r,x) - 1]
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> from bisect import bisect_left
>>> r =  [Integer(2),Integer(3),Integer(3),Integer(4),Integer(8),Integer(9)]
>>> x, i, p = Integer(9), Integer(1), [Integer(1), Integer(2)]
>>> x1 = RuleHecke().reverse_insertion(i, x, r, p)
>>> x1 == r[bisect_left(r,x) - Integer(1)]
True
```

class sage.combinat.rsk.**RuleRSK**

Bases: *Rule*

Rule for the classical Robinson-Schensted-Knuth insertion.

See *RSK()* for the definition of this operation.

EXAMPLES:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2], insertion=RSK.rules.RSK)
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

(continues on next page)

(continued from previous page)

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q, insertion=RSK.rules.RSK)
[[1, 2, 3, 3], [2, 1, 2, 2]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1),
↪ Integer(1), Integer(2)], insertion=RSK.rules.RSK)
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]); q =␣
↪Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> RSK_inverse(p, q, insertion=RSK.rules.RSK)
[[1, 2, 3, 3], [2, 1, 2, 2]]
```

insertion(j, r)

Insert the letter `j` from the second row of the biword into the row r using classical Schensted insertion, if there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleRSK().insertion(9, r)
sage: j is None
True
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleRSK().insertion(3, r)
sage: j
4
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> qr, r = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(3),Integer(3),Integer(2),Integer(4),Integer(8)]
>>> j = RuleRSK().insertion(Integer(9), r)
>>> j is None
True
>>> qr, r = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(3),Integer(3),Integer(2),Integer(4),Integer(8)]
>>> j = RuleRSK().insertion(Integer(3), r)
>>> j
4
```

reverse_insertion(x, row)

Reverse bump the row `row` of the current insertion tableau with the number `x`.

The row `row` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: r =  [2,3,3,4,8]
```

(continues on next page)

(continued from previous page)

```
sage: x = RuleRSK().reverse_insertion(4, r); r
[2, 3, 4, 4, 8]
sage: x
3
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> r =  [Integer(2),Integer(3),Integer(3),Integer(4),Integer(8)]
>>> x = RuleRSK().reverse_insertion(Integer(4), r); r
[2, 3, 4, 4, 8]
>>> x
3
```

class sage.combinat.rsk.**RuleStar**

Bases: *Rule*

Rule for $\star$-insertion.

The $\star$-insertion is similar to the classical RSK algorithm and is defined in [MPPS2020]. The bottom row of the increasing Hecke biword is a word in the 0-Hecke monoid that is fully commutative. When inserting a letter x into a row R, there are three cases:

- Case 1: If R is empty or $x > \max(R)$, append x to row R and terminate.
- Case 2: Otherwise if x is not in R, locate the smallest y in R with $y > x$. Bump y with x and insert y into the next row.
- Case 3: Otherwise, if x is in R, locate the smallest y in R with $y \leq x$ and interval $[y, x]$ contained in R. Row R remains unchanged and y is to be inserted into the next row.

The $\star$-insertion returns a pair consisting a conjugate of a semistandard tableau and a semistandard tableau. It is a bijection from the collection of all increasing Hecke biwords whose bottom row is a fully commutative word to pairs (P, Q) of tableaux of the same shape such that P is conjugate semistandard, Q is semistandard and the row reading word of P is fully commutative [MPPS2020].

EXAMPLES:

As an example of $\star$-insertion, we reproduce Example 28 in [MPPS2020]:

```
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
sage: ascii_art(p, q)
  1  2  4  1  1  2
  1  4     2  4
  3        4
sage: line1,line2 = RuleStar().backward_rule(p, q)
sage: line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
(4, 2)()(4, 2)(3, 1)

sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[4, 2], [], [4, 2], [3, 1]])
sage: RSK_inverse(*RSK(h,insertion='Star'),insertion='Star',
....:             output='DecreasingHeckeFactorization')
```

(continues on next page)

(continued from previous page)

```
(4, 2)()(4, 2)(3, 1)
sage: p,q = RSK(h, insertion='Star')
sage: ascii_art(p, q)
1  2  4  1  1  2
1  4     2  4
3        4
sage: RSK_inverse(p, q, insertion='Star')
[[1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4]]
sage: f = RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star
↪')
sage: f == h
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> p,q = RuleStar().forward_rule([Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(4),Integer(4)], [Integer(1),Integer(3),Integer(2),Integer(4),Integer(2),
↪Integer(4)])
>>> ascii_art(p, q)
  1  2  4  1  1  2
  1  4     2  4
  3        4
>>> line1,line2 = RuleStar().backward_rule(p, q)
>>> line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
>>> RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
(4, 2)()(4, 2)(3, 1)

>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
>>> h = DecreasingHeckeFactorization([[Integer(4), Integer(2)], [], [Integer(4),␣
↪Integer(2)], [Integer(3), Integer(1)]])
>>> RSK_inverse(*RSK(h,insertion='Star'),insertion='Star',
...             output='DecreasingHeckeFactorization')
(4, 2)()(4, 2)(3, 1)
>>> p,q = RSK(h, insertion='Star')
>>> ascii_art(p, q)
1  2  4  1  1  2
1  4     2  4
3        4
>>> RSK_inverse(p, q, insertion='Star')
[[1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4]]
>>> f = RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
>>> f == h
True
```

Warning

When `output` is set to `'DecreasingHeckeFactorization'`, the inverse of $\star$-insertion of (P, Q) returns a decreasing factorization whose number of factors is the maximum entry of Q:

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
```

```
↪DecreasingHeckeFactorization
sage: h1 = DecreasingHeckeFactorization([[],[3,1],[1]]); h1
()(3, 1)(1)
sage: P,Q = RSK(h1, insertion='Star')
sage: ascii_art(P, Q)
  1  3  1  2
  1     2
sage: h2 = RSK_inverse(P, Q, insertion='Star',
....: output='DecreasingHeckeFactorization'); h2
(3, 1)(1)
>>> from sage.all import *
>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
>>> h1 = DecreasingHeckeFactorization([[],[Integer(3),Integer(1)],
↪[Integer(1)]]); h1
()(3, 1)(1)
>>> P,Q = RSK(h1, insertion='Star')
>>> ascii_art(P, Q)
  1  3  1  2
  1     2
>>> h2 = RSK_inverse(P, Q, insertion='Star',
... output='DecreasingHeckeFactorization'); h2
(3, 1)(1)
```

backward_rule(*p*, *q*, *output='array'*)

Return the increasing Hecke biword obtained by applying reverse $\star$-insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape, where `p` is the conjugate of a semistandard tableau, whose reading word is fully commutative and `q` is a semistandard tableau.
- `output` – (default: `'array'`) if `q` is semistandard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword) that is an increasing Hecke biword
  - `'DecreasingHeckeFactorization'` – as a decreasing factorization in the 0-Hecke monoid

  and if `q` is standard:
  - `'word'` – as a (possibly non-reduced) word in the 0-Hecke monoid

Warning

When output is 'DecreasingHeckeFactorization', the number of factors in the output is the largest number in `obj1`.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
sage: ascii_art(p, q)
  1  2  4  1  1  2
```

(continues on next page)

(continued from previous page)

```
  1  4     2  4
  3        4
sage: line1,line2 = RuleStar().backward_rule(p, q); line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RuleStar().backward_rule(p, q, output = 'DecreasingHeckeFactorization')
(4, 2)()(4, 2)(3, 1)
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> p,q = RuleStar().forward_rule([Integer(1),Integer(1),Integer(2),
↪Integer(2),Integer(4),Integer(4)], [Integer(1),Integer(3),Integer(2),
↪Integer(4),Integer(2),Integer(4)])
>>> ascii_art(p, q)
  1  2  4  1  1  2
  1  4     2  4
  3        4
>>> line1,line2 = RuleStar().backward_rule(p, q); line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
>>> RuleStar().backward_rule(p, q, output = 'DecreasingHeckeFactorization')
(4, 2)()(4, 2)(3, 1)
```

forward_rule(*obj1*, *obj2=None*, *check_braid=True*)

Return a pair of tableaux obtained by applying forward insertion to the increasing Hecke biword `[obj1, obj2]`.

INPUT:

- `obj1`, `obj2` – can be one of the following ways to represent a biword (or, equivalently, an increasing 0-Hecke factorization) that is fully commutative:
  - two lists `obj1` and `obj2` of equal length, to be interpreted as the top row and the bottom row of the biword.
  - a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \ldots, n)$ by default).
  - a DecreasingHeckeFactorization `obj1`, the whose increasing Hecke biword will be interpreted as the bottom row; the top row is understood to be the indices of the factors for each letter in this biword.
- `check_braid` – boolean (default: `True`); indicator to validate that input is associated to a fully commutative word in the 0-Hecke monoid, validation is performed if set to `True`. Otherwise, this validation is ignored.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,3,3], [2,3,3,1,3]); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
sage: p,q = RuleStar().forward_rule([2,3,3,1,3]); p,q
([[1, 3], [2, 3], [2]], [[1, 2], [3, 5], [4]])
sage: p,q = RSK([1,1,2,3,3], [2,3,3,1,3], insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])

sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck␣
↪import DecreasingHeckeFactorization
```

(continues on next page)

(continued from previous page)

```
sage: h = DecreasingHeckeFactorization([[3, 1], [3], [3, 2]])
sage: p,q = RSK(h, insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> p,q = RuleStar().forward_rule([Integer(1),Integer(1),Integer(2),
↪Integer(3),Integer(3)], [Integer(2),Integer(3),Integer(3),Integer(1),
↪Integer(3)]); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
>>> p,q = RuleStar().forward_rule([Integer(2),Integer(3),Integer(3),
↪Integer(1),Integer(3)]); p,q
([[1, 3], [2, 3], [2]], [[1, 2], [3, 5], [4]])
>>> p,q = RSK([Integer(1),Integer(1),Integer(2),Integer(3),Integer(3)],␣
↪[Integer(2),Integer(3),Integer(3),Integer(1),Integer(3)], insertion=RSK.
↪rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])

>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
>>> h = DecreasingHeckeFactorization([[Integer(3), Integer(1)], [Integer(3)],␣
↪[Integer(3), Integer(2)]])
>>> p,q = RSK(h, insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
```

insertion(b, r)

Insert the letter `b` from the second row of the biword into the row `r` using $\star$-insertion defined in [MPPS2020].

The row r is modified in place if bumping occurs and b is not in row r. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().insertion(3, [1,2,4,5])
4
sage: RuleStar().insertion(3, [1,2,3,5])
1
sage: RuleStar().insertion(6, [1,2,3,5]) is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> RuleStar().insertion(Integer(3), [Integer(1),Integer(2),Integer(4),
↪Integer(5)])
4
>>> RuleStar().insertion(Integer(3), [Integer(1),Integer(2),Integer(3),
↪Integer(5)])
1
>>> RuleStar().insertion(Integer(6), [Integer(1),Integer(2),Integer(3),
↪Integer(5)]) is None
True
```

reverse_insertion(*x*, *r*)

Reverse bump the row `r` of the current insertion tableau `p` with number `x`, provided that `r` is the `i`-th row of `p`.

The row `r` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().reverse_insertion(4, [1,2,3,5])
3
sage: RuleStar().reverse_insertion(1, [1,2,3,5])
3
sage: RuleStar().reverse_insertion(5, [1,2,3,5])
5
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> RuleStar().reverse_insertion(Integer(4), [Integer(1),Integer(2),
↪Integer(3),Integer(5)])
3
>>> RuleStar().reverse_insertion(Integer(1), [Integer(1),Integer(2),
↪Integer(3),Integer(5)])
3
>>> RuleStar().reverse_insertion(Integer(5), [Integer(1),Integer(2),
↪Integer(3),Integer(5)])
5
```

class sage.combinat.rsk.**RuleSuperRSK**

Bases: *RuleRSK*

Rule for super RSK insertion.

Super RSK is based on ϵ-insertion, a combination of row and column classical RSK insertion.

Super RSK insertion differs from the classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a restricted super biword (i.e., a pair of two lists $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ that contains entries with even and odd parity and pairs with mixed parity entries do not repeat).
- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now they are semistandard super tableaux.
- The main difference is in the way bumping works. Instead of having only row bumping super RSK uses ϵ-insertion, a combination of classical RSK bumping along the rows and a dual RSK like bumping (i.e. when a number k_i is inserted into the i-th row of P, it bumps out the first integer greater **or equal to** k_i in the column) along the column.

EXAMPLES:

```
sage: RSK([1], [1], insertion='superRSK')
[[[1]], [[1]]]
sage: RSK([1, 2], [1, 3], insertion='superRSK')
[[[1, 3]], [[1, 2]]]
sage: RSK([1, 2, 3], [1, 3, "3p"], insertion='superRSK')
[[[1, 3], [3']], [[1, 2], [3]]]
```

(continues on next page)

(continued from previous page)

```
sage: RSK([1, 3, "3p", "2p"], insertion='superRSK')
[[[1, 3', 3], [2']], [[1', 1, 2'], [2]]]
sage: RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
....:     ["1p", 1, "2p", 2, "3p", "3p", "3p", 3], insertion='superRSK')
[[[1', 2, 3', 3], [1, 3'], [2'], [3']], [[1', 2, 3', 3], [2', 3'], [2], [3]]]
sage: P = SemistandardSuperTableau([[1, '3p', 3], ['2p']])
sage: Q = SemistandardSuperTableau([['1p', 1, '2p'], [2]])
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2], [1, 3, 3', 2']]
```

```
>>> from sage.all import *
>>> RSK([Integer(1)], [Integer(1)], insertion='superRSK')
[[[1]], [[1]]]
>>> RSK([Integer(1), Integer(2)], [Integer(1), Integer(3)], insertion='superRSK')
[[[1, 3]], [[1, 2]]]
>>> RSK([Integer(1), Integer(2), Integer(3)], [Integer(1), Integer(3), "3p"],␣
↪insertion='superRSK')
[[[1, 3], [3']], [[1, 2], [3]]]
>>> RSK([Integer(1), Integer(3), "3p", "2p"], insertion='superRSK')
[[[1, 3', 3], [2']], [[1', 1, 2'], [2]]]
>>> RSK(["1p", "2p", Integer(2), Integer(2), "3p", "3p", Integer(3), Integer(3)],
...     ["1p", Integer(1), "2p", Integer(2), "3p", "3p", "3p", Integer(3)],␣
↪insertion='superRSK')
[[[1', 2, 3', 3], [1, 3'], [2'], [3']], [[1', 2, 3', 3], [2', 3'], [2], [3]]]
>>> P = SemistandardSuperTableau([[Integer(1), '3p', Integer(3)], ['2p']])
>>> Q = SemistandardSuperTableau([['1p', Integer(1), '2p'], [Integer(2)]])
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2], [1, 3, 3', 2']]
```

We apply super RSK on Example 5.1 in [Muth2019]:

```
sage: P,Q = RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
....:           ["3p", 1, 2, 3, "3p", "3p", "2p", "1p"], insertion='superRSK')
sage: (P, Q)
([[1', 2', 3', 3], [1, 2, 3'], [3']], [[1', 2, 2, 3'], [2', 3, 3], [3']])
sage: ascii_art((P, Q))
(  1' 2' 3'  3   1'  2  2 3' )
(   1  2 3'      2'  3  3    )
(  3'         ,  3'          )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]
```

```
>>> from sage.all import *
>>> P,Q = RSK(["1p", "2p", Integer(2), Integer(2), "3p", "3p", Integer(3),␣
↪Integer(3)],
...           ["3p", Integer(1), Integer(2), Integer(3), "3p", "3p", "2p", "1p"],␣
↪insertion='superRSK')
>>> (P, Q)
([[1', 2', 3', 3], [1, 2, 3'], [3']], [[1', 2, 2, 3'], [2', 3, 3], [3']])
>>> ascii_art((P, Q))
(  1' 2' 3'  3   1'  2  2 3' )
(   1  2 3'      2'  3  3    )
```

(continues on next page)

(continued from previous page)

```
(  3'         ,  3'          )
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]
```

Example 6.1 in [Muth2019]:

```
sage: P,Q = RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
....:           ["3p", 1, 2, 3, "3p", "3p", "2p", "1p"], insertion='superRSK')
sage: ascii_art((P, Q))
(  1' 2' 3'  3   1'  2  2 3' )
(   1  2 3'      2'  3  3    )
(  3'         ,  3'          )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]

sage: P,Q = RSK(["1p", 1, "2p", 2, "3p", "3p", "3p", 3],
....:           [3, "2p", 3, 2, "3p", "3p", "1p", 2], insertion='superRSK')
sage: ascii_art((P, Q))
(  1'  2  2 3'   1' 2' 3'  3 )
(  2'  3  3       1  2 3'    )
(  3'         ,  3'          )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2, 3', 3', 3', 3], [3, 2', 3, 2, 3', 3', 1', 2]]
```

```
>>> from sage.all import *
>>> P,Q = RSK(["1p", "2p", Integer(2), Integer(2), "3p", "3p", Integer(3),␣
↪Integer(3)],
...           ["3p", Integer(1), Integer(2), Integer(3), "3p", "3p", "2p", "1p"],␣
↪insertion='superRSK')
>>> ascii_art((P, Q))
(  1' 2' 3'  3   1'  2  2 3' )
(   1  2 3'      2'  3  3    )
(  3'         ,  3'          )
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]

>>> P,Q = RSK(["1p", Integer(1), "2p", Integer(2), "3p", "3p", "3p", Integer(3)],
...           [Integer(3), "2p", Integer(3), Integer(2), "3p", "3p", "1p",␣
↪Integer(2)], insertion='superRSK')
>>> ascii_art((P, Q))
(  1'  2  2 3'   1' 2' 3'  3 )
(  2'  3  3       1  2 3'    )
(  3'         ,  3'          )
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2, 3', 3', 3', 3], [3, 2', 3, 2, 3', 3', 1', 2]]
```

Let us now call the inverse correspondence:

```
sage: P, Q = RSK([1, 2, 2, 2], [2, 1, 2, 3],
....:            insertion=RSK.rules.superRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
```

```
>>> from sage.all import *
>>> P, Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(1), Integer(2), Integer(3)],
...            insertion=RSK.rules.superRSK)
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
```

When applied to two tableaux with only even parity elements, reverse super RSK insertion behaves identically to the usual reverse RSK insertion:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.RSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: t1 = SemistandardSuperTableau([[1, 2, 5], [3], [4]])
sage: t2 = SemistandardSuperTableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.superRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
```

```
>>> from sage.all import *
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],␣
↪[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],␣
↪[Integer(5)]])
>>> RSK_inverse(t1, t2, insertion=RSK.rules.RSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> t1 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(5)],␣
↪[Integer(3)], [Integer(4)]])
>>> t2 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(3)],␣
↪[Integer(4)], [Integer(5)]])
>>> RSK_inverse(t1, t2, insertion=RSK.rules.superRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
```

backward_rule(*p*, *q*, *output='array'*)

Return the restricted super biword obtained by applying reverse super RSK insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape
- `output` – (default: `'array'`) if `q` is row-strict:
  - `'array'` – as a two-line array (i.e. restricted super biword)

  and if `q` is standard, we can have the output:
  - `'word'` – as a word

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: t1 = SemistandardSuperTableau([['1p', '3p', '4p'], [2], [3]])
sage: t2 = SemistandardSuperTableau([[1, 2, 4], [3], [5]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [4', 3, 3', 2, 1']]
```

(continues on next page)

(continued from previous page)

```
sage: t1 = SemistandardSuperTableau([[1, 3], ['3p']])
sage: t2 = SemistandardSuperTableau([[1, 2], [3]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3], [1, 3, 3']]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> t1 = SemistandardSuperTableau([['1p', '3p', '4p'], [Integer(2)],␣
↪[Integer(3)]])
>>> t2 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(4)],␣
↪[Integer(3)], [Integer(5)]])
>>> RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [4', 3, 3', 2, 1']]
>>> t1 = SemistandardSuperTableau([[Integer(1), Integer(3)], ['3p']])
>>> t2 = SemistandardSuperTableau([[Integer(1), Integer(2)], [Integer(3)]])
>>> RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3], [1, 3, 3']]
```

forward_rule(*obj1*, *obj2*, *check_standard=False*, *check=True*)

Return a pair of tableaux obtained by applying forward insertion to the restricted super biword `[obj1, obj2]`.

INPUT:

- `obj1`, `obj2` – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists `obj1` and `obj2` of equal length, to be interpreted as the top row and the bottom row of the biword
  - a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \ldots, n)$ by default)
  - any object `obj1` which has a method `_rsk_iter()`, as long as this method returns an iterator yielding pairs of numbers, which then are interpreted as top entries and bottom entries in the biword (in this case, `obj2` is `None`)
- `check_standard` – boolean (default: `False`); check if either of the resulting tableaux is a standard super tableau, and if so, typecast it as such
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid restricted super biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: p, q = RuleSuperRSK().forward_rule([1, 2], [1, 3]); p
[[1, 3]]
sage: q
[[1, 2]]
sage: isinstance(p, SemistandardSuperTableau)
True
sage: isinstance(q, SemistandardSuperTableau)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> p, q = RuleSuperRSK().forward_rule([Integer(1), Integer(2)], [Integer(1),␣
↪Integer(3)]); p
[[1, 3]]
>>> q
[[1, 2]]
>>> isinstance(p, SemistandardSuperTableau)
True
>>> isinstance(q, SemistandardSuperTableau)
True
```

insertion(*j*, *r*, *epsilon=0*)

Insert the letter `j` from the second row of the biword into the row `r` using dual RSK insertion or classical Schensted insertion depending on the value of `epsilon`, if there is bumping to be done.

The row *r* is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: from bisect import bisect_left, bisect_right
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=0); r
[1, 3, 3, 3, 3]
sage: j
4
sage: y_pos
4
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y_pos
1
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> from bisect import bisect_left, bisect_right
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = Integer(3)
>>> j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=Integer(0)); r
[1, 3, 3, 3, 3]
>>> j
4
>>> y_pos
4
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = Integer(3)
>>> j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=Integer(1)); r
```

(continues on next page)

(continued from previous page)

```
[1, 3, 3, 3, 4]
>>> j
3
>>> y_pos
1
```

reverse_insertion(*x*, *row*, *epsilon=0*)

Reverse bump the row `row` of the current insertion tableau with the number `x` using dual RSK insertion or classical Schensted insertion depending on the value of $epsilon$.

The row `row` is modified in place. The bumped-out entry is returned along with the bumped position.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: from bisect import bisect_left, bisect_right
sage: r = [1, 3, 3, 3, 4]
sage: j = 2
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
[2, 3, 3, 3, 4]
sage: j
1
sage: y
0
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
[3, 3, 3, 3, 4]
sage: j
1
sage: y
0
sage: r = [1, 3, 3, 3, 4]
sage: j = (3)
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y
3
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> from bisect import bisect_left, bisect_right
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = Integer(2)
>>> j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=Integer(0)); r
[2, 3, 3, 3, 4]
>>> j
1
>>> y
0
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
```

(continues on next page)

(continued from previous page)

```
>>> j = Integer(3)
>>> j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=Integer(0)); r
[3, 3, 3, 3, 4]
>>> j
1
>>> y
0
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = (Integer(3))
>>> j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=Integer(1)); r
[1, 3, 3, 3, 4]
>>> j
3
>>> y
3
```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the super RSK algorithm, such as two n-tuples `obj1` $= [a_1, a_2, \ldots, a_n]$ and `obj2` $= [b_1, b_2, \ldots, b_n]$ forming a restricted super biword (i.e., entries with even and odd parity and no repetition of corresponding pairs with mixed parity entries) return the array $[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a restricted super biword (see the doc of *forward_rule()* for the encodings accepted)
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid restricted super biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: list(RuleSuperRSK().to_pairs([2, '1p', 1],[1, 1, '1p']))
[(2, 1), (1', 1), (1, 1')]
sage: list(RuleSuperRSK().to_pairs([1, '1p', '2p']))
[(1', 1), (1, 1'), (2', 2')]
sage: list(RuleSuperRSK().to_pairs([1, 1], ['1p', '1p']))
Traceback (most recent call last):
...
ValueError: invalid restricted superbiword
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> list(RuleSuperRSK().to_pairs([Integer(2), '1p', Integer(1)],[Integer(1),␣
↪Integer(1), '1p']))
[(2, 1), (1', 1), (1, 1')]
>>> list(RuleSuperRSK().to_pairs([Integer(1), '1p', '2p']))
[(1', 1), (1, 1'), (2', 2')]
>>> list(RuleSuperRSK().to_pairs([Integer(1), Integer(1)], ['1p', '1p']))
Traceback (most recent call last):
...
ValueError: invalid restricted superbiword
```

sage.combinat.rsk.**robinson_schensted_knuth**(*obj1=None*, *obj2=None*, *insertion=<class 'sage.combinat.rsk.RuleRSK'>*, *check_standard=False*, ***options*)

alias of *RSK()*.

sage.combinat.rsk.**robinson_schensted_knuth_inverse**(*p*, *q*, *output='array'*, *insertion=<class 'sage.combinat.rsk.RuleRSK'>*)

alias of *RSK_inverse()*.

sage.combinat.rsk.**to_matrix**(*t*, *b*)

Return the integer matrix corresponding to a two-line array.

INPUT:

- `t` – the top row of the array
- `b` – the bottom row of the array

OUTPUT:

An $m \times n$-matrix (where m and n are the maximum entries in t and b respectively) whose (i, j)-th entry, for any i and j, is the number of all positions k satisfying $t_k = i$ and $b_k = j$.

EXAMPLES:

```
sage: from sage.combinat.rsk import to_matrix
sage: to_matrix([1, 1, 3, 3, 4], [2, 3, 1, 1, 3])
[0 1 1]
[0 0 0]
[2 0 0]
[0 0 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import to_matrix
>>> to_matrix([Integer(1), Integer(1), Integer(3), Integer(3), Integer(4)],␣
↪[Integer(2), Integer(3), Integer(1), Integer(1), Integer(3)])
[0 1 1]
[0 0 0]
[2 0 0]
[0 0 1]
```

Rooted (unordered) trees

AUTHORS:

- Florent Hivert (2011): initial version

class sage.combinat.rooted_tree.**LabelledRootedTree**(*parent*, *children*, *label=None*, *check=True*)

Bases: *AbstractLabelledClonableTree*, *RootedTree*

Labelled rooted trees.

A labelled rooted tree is a rooted tree with a label attached at each node.

More formally: The *labelled rooted trees* are an inductive datatype defined as follows: A labelled rooted tree is a multiset of labelled rooted trees, endowed with a label (which can be any object, including `None`). The trees that belong to this multiset are said to be the *children* of the tree. (Notice that the labels of these children may and may not be of the same type as the label of the tree). A labelled rooted tree which has no children (so the only information it carries is its label) is said to be a *leaf*.

Every labelled rooted tree gives rise to an unlabelled rooted tree (*RootedTree*) by forgetting the labels. (This is implemented as a conversion.)

INPUT:

- `children` – list or tuple or more generally any iterable of trees or objects convertible to trees
- `label` – any hashable Sage object (default: `None`)

Note

It is required that all labels are comparable.

EXAMPLES:

```
sage: x = LabelledRootedTree([], label = 3); x
3[]
sage: LabelledRootedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree([[],[[], []]], label = 3)
3[None[], None[None[], None[]]]
```

```
>>> from sage.all import *
>>> x = LabelledRootedTree([], label = Integer(3)); x
3[]
>>> LabelledRootedTree([x, x, x], label = Integer(2))
2[3[], 3[], 3[]]
>>> LabelledRootedTree((x, x, x), label = Integer(2))
2[3[], 3[], 3[]]
>>> LabelledRootedTree([[],[[], []]], label = Integer(3))
3[None[], None[None[], None[]]]
```

Children are reordered using the value of the *sort_key()* method:

```
sage: y = LabelledRootedTree([], label = 5); y
5[]
sage: xyy2 = LabelledRootedTree((x, y, y), label = 2); xyy2
2[3[], 5[], 5[]]
sage: yxy2 = LabelledRootedTree((y, x, y), label = 2); yxy2
2[3[], 5[], 5[]]
sage: xyy2 == yxy2
True
```

```
>>> from sage.all import *
>>> y = LabelledRootedTree([], label = Integer(5)); y
5[]
>>> xyy2 = LabelledRootedTree((x, y, y), label = Integer(2)); xyy2
2[3[], 5[], 5[]]
>>> yxy2 = LabelledRootedTree((y, x, y), label = Integer(2)); yxy2
2[3[], 5[], 5[]]
>>> xyy2 == yxy2
True
```

Converting labelled into unlabelled rooted trees by forgetting the labels, and back (the labels are initialized as None):

```
sage: yxy2crude = RootedTree(yxy2); yxy2crude
[[], [], []]
sage: LabelledRootedTree(yxy2crude)
None[None[], None[], None[]]
```

```
>>> from sage.all import *
>>> yxy2crude = RootedTree(yxy2); yxy2crude
[[], [], []]
>>> LabelledRootedTree(yxy2crude)
None[None[], None[], None[]]
```

sort_key()

Return a tuple of nonnegative integers encoding the labelled rooted tree self.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the labelled rooted tree uniquely, and can be used to sort the labelled rooted trees provided that the labels belong to a type which is totally ordered.

Note

The tree self must be normalized before calling this method (see *normalize()*). This does not matter unless you are inside the clone() context manager, because outside of it every rooted tree is already normalized.

Note

This method overrides *RootedTree.sort_key()* and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of RootedOrderedTree; under some circumstances they could inherit it from another superclass instead of from *RootedTree*, which would cause the method to forget the labelling. See the docstrings of *RootedTree.sort_key()* and *sage.combinat.ordered_tree.OrderedTree.sort_key()*.

EXAMPLES:

```
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.sort_key()
((0, 3),)
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
```

(continues on next page)

(continued from previous page)

```
sage: LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
sage: lb = RootedTrees()([[],[[], []]]).canonical_labelling()
sage: lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```

```
>>> from sage.all import *
>>> LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
>>> x = LRT([], label = Integer(3)); x
3[]
>>> x.sort_key()
((0, 3),)
>>> y = LRT([x, x, x], label = Integer(2)); y
2[3[], 3[], 3[]]
>>> y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
>>> LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
>>> lb = RootedTrees()([[],[[], []]]).canonical_labelling()
>>> lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```

class sage.combinat.rooted_tree.**LabelledRootedTrees**

Bases: UniqueRepresentation, Parent

This is a parent stub to serve as a factory class for labelled rooted trees.

EXAMPLES:

```
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.parent() is LRT
True
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.parent() is LRT
True
```

```
>>> from sage.all import *
>>> LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
>>> x = LRT([], label = Integer(3)); x
3[]
>>> x.parent() is LRT
True
>>> y = LRT([x, x, x], label = Integer(2)); y
2[3[], 3[], 3[]]
>>> y.parent() is LRT
True
```

Todo

Add the possibility to restrict the labels to a fixed set.

class sage.combinat.rooted_tree.**LabelledRootedTrees_all**(*category=None*)

Bases: *LabelledRootedTrees*

Class of all (unordered) labelled rooted trees.

See *LabelledRootedTree* for a definition.

Element

alias of *LabelledRootedTree*

labelled_trees()

Return the set of labelled trees associated to `self`.

EXAMPLES:

```
sage: LabelledRootedTrees().labelled_trees()
Labelled rooted trees
```

```
>>> from sage.all import *
>>> LabelledRootedTrees().labelled_trees()
Labelled rooted trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

EXAMPLES:

```
sage: LabelledRootedTrees().unlabelled_trees()
Rooted trees
```

```
>>> from sage.all import *
>>> LabelledRootedTrees().unlabelled_trees()
Rooted trees
```

class sage.combinat.rooted_tree.**RootedTree**(*parent=None*, *children=[]*, *check=True*)

Bases: *AbstractClonableTree*, NormalizedClonableList

The class for unordered rooted trees.

The *unordered rooted trees* are an inductive datatype defined as follows: An unordered rooted tree is a multiset of unordered rooted trees. The trees that belong to this multiset are said to be the *children* of the tree. The tree that has no children is called a *leaf*.

The *labelled rooted trees* (*LabelledRootedTree*) form a subclass of this class; they carry additional data.

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree.

EXAMPLES:

```
sage: RootedTree([])
[]
sage: RootedTree([[], [[]]])
```

(continues on next page)

(continued from previous page)

```
[[], [[]]]
sage: RootedTree([[[]], []])
[[], [[]]]
sage: O = OrderedTree([[[]], []]); O
[[[]], []]
sage: RootedTree(O)  # this is O with the ordering forgotten
[[], [[]]]
```

```
>>> from sage.all import *
>>> RootedTree([])
[]
>>> RootedTree([[], [[]]])
[[], [[]]]
>>> RootedTree([[[]], []])
[[], [[]]]
>>> O = OrderedTree([[[]], []]); O
[[[]], []]
>>> RootedTree(O)  # this is O with the ordering forgotten
[[], [[]]]
```

One can also enter any small rooted tree ("small" meaning that no vertex has more than 15 children) by using a simple numerical encoding of rooted trees, namely, the *from_hexacode()* function. (This function actually parametrizes ordered trees, and here we make it parametrize unordered trees by forgetting the ordering.)

```
sage: from sage.combinat.abstract_tree import from_hexacode
sage: RT = RootedTrees()
sage: from_hexacode('32001010', RT)
[[[]], [[]], [[]], [[]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.abstract_tree import from_hexacode
>>> RT = RootedTrees()
>>> from_hexacode('32001010', RT)
[[[]], [[]], [[]], [[]]]
```

Note

Unlike an ordered tree, an (unordered) rooted tree is a multiset (rather than a list) of children. That is, two ordered trees which differ from each other by switching the order of children are equal to each other as (unordered) rooted trees. Internally, rooted trees are encoded as `sage.structure.list_clone.NormalizedClonableList` instances, and instead of storing their children as an actual multiset, they store their children as a list which is sorted according to their *sort_key()* value. This is as good as storing them as multisets, since the *sort_key()* values are sortable and distinguish different (unordered) trees. However, if you wish to define a subclass of *RootedTree* which implements rooted trees with extra structure (say, a class of edge-colored rooted trees, or a class of rooted trees with a cyclic order on the list of children), then the inherited *sort_key()* method will no longer distinguish different trees (and, as a consequence, equal trees will be regarded as distinct). Thus, you will have to override the method by one that does distinguish different trees.

graft_list(*other*)

Return the list of trees obtained by grafting `other` on `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, chooses a node of `self`, and adds the root of `other` to the list of children of this node. The root of the resulting tree is the root of `self`. (This can be done for each node of `self`; this method returns the list of all results.)

This is useful for free pre-Lie algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_list(x)
[[[]]]
sage: l = y.graft_list(x); l
[[[], [], []], [[], [[]]], [[], [[]]]]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

```
>>> from sage.all import *
>>> RT = RootedTree
>>> x = RT([])
>>> y = RT([x, x])
>>> x.graft_list(x)
[[[]]]
>>> l = y.graft_list(x); l
[[[], [], []], [[], [[]]], [[], [[]]]]
>>> [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

graft_on_root(*other*)

Return the tree obtained by grafting `other` on the root of `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, and adds the root of `other` to the list of children of `self`. The root of the resulting tree is the root of `self`.

This is useful for free Nap algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_on_root(x)
[[]]
sage: y.graft_on_root(x)
[[], [], []]
sage: x.graft_on_root(y)
[[[], []]]
```

```
>>> from sage.all import *
>>> RT = RootedTree
>>> x = RT([])
>>> y = RT([x, x])
>>> x.graft_on_root(x)
[[]]
```

(continues on next page)

(continued from previous page)

```
>>> y.graft_on_root(x)
[[], [], []]
>>> x.graft_on_root(y)
[[[], []]]
```

is_empty()

Return if `self` is the empty tree.

For rooted trees, this always returns `False`.

> **Note**
>
> This is not the same as `bool(t)`, which returns whether `t` has some child or not.

EXAMPLES:

```
sage: t = RootedTrees(4)([[],[[]]])
sage: t.is_empty()
False
sage: bool(t)
True
sage: t = RootedTrees(1)([])
sage: t.is_empty()
False
sage: bool(t)
False
```

```
>>> from sage.all import *
>>> t = RootedTrees(Integer(4))([[],[[]]])
>>> t.is_empty()
False
>>> bool(t)
True
>>> t = RootedTrees(Integer(1))([])
>>> t.is_empty()
False
>>> bool(t)
False
```

normalize()

Normalize `self`.

This function is at the core of the implementation of rooted (unordered) trees. The underlying structure is provided by ordered rooted trees. Every rooted tree is represented by a normalized element in the set of its planar embeddings.

There should be no need to call `normalize` directly as it is called automatically upon creation and cloning or modification (by `NormalizedClonableList`).

The normalization has a recursive definition. It means first that every sub-tree is itself normalized, and also that sub-trees are sorted. Here the sort is performed according to the values of the *sort_key()* method.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[],[[]]]) == RT([[[]],[]])  # indirect doctest
True
sage: rt1 = RT([[],[[]]])
sage: rt2 = RT([[[]],[]])
sage: rt1 is rt2
False
sage: rt1 == rt2
True
sage: rt1._get_list() == rt2._get_list()
True
```

```
>>> from sage.all import *
>>> RT = RootedTree
>>> RT([[],[[]]]) == RT([[[]],[]])  # indirect doctest
True
>>> rt1 = RT([[],[[]]])
>>> rt2 = RT([[[]],[]])
>>> rt1 is rt2
False
>>> rt1 == rt2
True
>>> rt1._get_list() == rt2._get_list()
True
```

single_graft(*x*, *grafting_function*, *path_prefix=()*)

Graft subtrees of x on `self` using the given function.

Let $x_1, x_2, \ldots, x_p$ be the children of the root of x. For each i, the subtree of x comprising all descendants of x_i is joined by a new edge to the vertex of `self` specified by the i-th path in the grafting function (i.e., by the path `grafting_function[i]`).

The number of vertices of the result is the sum of the numbers of vertices of `self` and x minus one, because the root of x is not used.

This is used to define the product of the Grossman-Larson algebras.

INPUT:

- `x` – a rooted tree
- `grafting_function` – list of paths in `self`
- `path_prefix` – tuple (default: `()`)

The `path_prefix` argument is only used for internal recursion.

EXAMPLES:

```
sage: LT = LabelledRootedTrees()
sage: y = LT([LT([],label='b')], label='a')
sage: x = LT([LT([],label='d')], label='c')
sage: y.single_graft(x,[(0,)])
a[b[d[]]]
sage: t = LT([LT([],label='b'),LT([],label='c')], label='a')
sage: s = LT([LT([],label='d'),LT([],label='e')], label='f')
```

(continues on next page)

(continued from previous page)

```
sage: t.single_graft(s,[(0,),(1,)])
a[b[d[]], c[e[]]]
```

```
>>> from sage.all import *
>>> LT = LabelledRootedTrees()
>>> y = LT([LT([],label='b')], label='a')
>>> x = LT([LT([],label='d')], label='c')
>>> y.single_graft(x,[(Integer(0),)])
a[b[d[]]]
>>> t = LT([LT([],label='b'),LT([],label='c')], label='a')
>>> s = LT([LT([],label='d'),LT([],label='e')], label='f')
>>> t.single_graft(s,[(Integer(0),),(Integer(1),)])
a[b[d[]], c[e[]]]
```

sort_key()

Return a tuple of nonnegative integers encoding the rooted tree `self`.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the rooted tree uniquely, and can be used to sort the rooted trees.

Note

The tree `self` must be normalized before calling this method (see *normalize()*). This does not matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note

By default, this method does not encode any extra structure that `self` might have. If you have a subclass inheriting from *RootedTree* which allows for some extra structure, you need to override *sort_key()* in order to preserve this structure (for example, the *LabelledRootedTree* class does this in *LabelledRootedTree.sort_key()*). See the note in the docstring of *sage.combinat.ordered_tree.OrderedTree.sort_key()* for a pitfall.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[]]).sort_key()
(2, 0, 1, 0)
```

```
>>> from sage.all import *
>>> RT = RootedTree
>>> RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
```

(continues on next page)

(continued from previous page)

```
>>> RT([[[]],[]]).sort_key()
(2, 0, 1, 0)
```

class sage.combinat.rooted_tree.**RootedTrees**

Bases: UniqueRepresentation, Parent

Factory class for rooted trees.

INPUT:

- size – integer (optional)

OUTPUT:

the set of all rooted trees (of the given size size if specified)

EXAMPLES:

```
sage: RootedTrees()
Rooted trees

sage: RootedTrees(2)
Rooted trees with 2 nodes
```

```
>>> from sage.all import *
>>> RootedTrees()
Rooted trees

>>> RootedTrees(Integer(2))
Rooted trees with 2 nodes
```

class sage.combinat.rooted_tree.**RootedTrees_all**

Bases: DisjointUnionEnumeratedSets, *RootedTrees*

Class of all (unordered, unlabelled) rooted trees.

See *RootedTree* for a definition.

Element

alias of *RootedTree*

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```
sage: RootedTrees().labelled_trees()
Labelled rooted trees
```

```
>>> from sage.all import *
>>> RootedTrees().labelled_trees()
Labelled rooted trees
```

As a consequence:

```
sage: lb = RootedTrees()([[],[[], []]]).canonical_labelling()
sage: lb
1[2[], 3[4[], 5[]]]
sage: lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.
↪element_class'>
sage: lb.parent()
Labelled rooted trees
```

```
>>> from sage.all import *
>>> lb = RootedTrees()([[],[[], []]]).canonical_labelling()
>>> lb
1[2[], 3[4[], 5[]]]
>>> lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.
↪element_class'>
>>> lb.parent()
Labelled rooted trees
```

leaf()

Return a leaf tree with `self` as parent.

EXAMPLES:

```
sage: RootedTrees().leaf()
[]
```

```
>>> from sage.all import *
>>> RootedTrees().leaf()
[]
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

EXAMPLES:

```
sage: RootedTrees().unlabelled_trees()
Rooted trees
```

```
>>> from sage.all import *
>>> RootedTrees().unlabelled_trees()
Rooted trees
```

class sage.combinat.rooted_tree.**RootedTrees_size**(n)

Bases: *RootedTrees*

The enumerated set of rooted trees with a given number of nodes.

The number of nodes of a rooted tree is defined recursively: The number of nodes of a rooted tree with a children is a plus the sum of the number of nodes of each of these children.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: RootedTrees(1).cardinality()
1
sage: RootedTrees(3).cardinality()
2
```

```
>>> from sage.all import *
>>> RootedTrees(Integer(1)).cardinality()
1
>>> RootedTrees(Integer(3)).cardinality()
2
```

check_element(*el*, *check=True*)

Check that a given tree actually belongs to `self`.

This just checks the number of vertices.

EXAMPLES:

```
sage: RT3 = RootedTrees(3)
sage: RT3([[],[]])      # indirect doctest
[[], []]
sage: RT3([[],[],[]])   # indirect doctest
Traceback (most recent call last):
...
ValueError: wrong number of nodes
```

```
>>> from sage.all import *
>>> RT3 = RootedTrees(Integer(3))
>>> RT3([[],[]])      # indirect doctest
[[], []]
>>> RT3([[],[],[]])   # indirect doctest
Traceback (most recent call last):
...
ValueError: wrong number of nodes
```

element_class()

sage.combinat.rooted_tree.**number_of_rooted_trees**()

Return the number of rooted trees with n nodes.

Compute the number $a(n)$ of rooted trees with n nodes using the recursive formula ([SL000081]):

$$a(n+1) = \frac{1}{n}\sum_{k=1}^{n}\left(\sum_{d|k} d a(d)\right) a(n-k+1)$$

EXAMPLES:

```
sage: from sage.combinat.rooted_tree import number_of_rooted_trees
sage: [number_of_rooted_trees(i) for i in range(10)]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

```
>>> from sage.all import *
>>> from sage.combinat.rooted_tree import number_of_rooted_trees
```

(continues on next page)

(continued from previous page)

```
>>> [number_of_rooted_trees(i) for i in range(Integer(10))]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

REFERENCES:

Schubert polynomials

See Wikipedia article Schubert_polynomial and SymmetricFunctions.com. Schubert polynomials are representatives of cohomology classes in flag varieties. In n variables, they are indexed by permutations $w \in S_n$. They also form a basis for the coinvariant ring of the S_n action on $\mathbf{Z}[x_1, x_2, \ldots, x_n]$.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: w = [1,2,5,4,3];  # a list representing an element of `S_5`
sage: X(w)
X[1, 2, 5, 4, 3]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> w = [Integer(1),Integer(2),Integer(5),Integer(4),Integer(3)];  # a list␣
↪representing an element of `S_5`
>>> X(w)
X[1, 2, 5, 4, 3]
```

This can be expanded in terms of polynomial variables:

```
sage: X(w).expand()
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2
 + x0*x2^2 + x1*x2^2 + x0^2*x3 + x0*x1*x3 + x1^2*x3
 + x0*x2*x3 + x1*x2*x3 + x2^2*x3
```

```
>>> from sage.all import *
>>> X(w).expand()
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2
 + x0*x2^2 + x1*x2^2 + x0^2*x3 + x0*x1*x3 + x1^2*x3
 + x0*x2*x3 + x1*x2*x3 + x2^2*x3
```

We can also convert back from polynomial variables. For example, the longest permutation is a single term. In S_5, this is the element (in one line notation) $w_0 = 54321$:

```
sage: w0 = [5,4,3,2,1]
sage: R.<x0, x1, x2, x3, x4> = PolynomialRing(ZZ)
sage: Sw0 = X(x0^4*x1^3*x2^2*x3);  Sw0
X[5, 4, 3, 2, 1]
```

```
>>> from sage.all import *
>>> w0 = [Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)]
>>> R = PolynomialRing(ZZ, names=('x0', 'x1', 'x2', 'x3', 'x4',)); (x0, x1, x2, x3,␣
↪x4,) = R._first_ngens(5)
>>> Sw0 = X(x0**Integer(4)*x1**Integer(3)*x2**Integer(2)*x3);  Sw0
X[5, 4, 3, 2, 1]
```

The polynomials also have the property that if the indexing permutation w is multiplied by a simple transposition $s_i = (i, i+1)$ such that the length of w is more than the length of ws_i, then the Schubert polynomial of the permutation ws_i is computed by applying the divided difference operator *divided_difference()* to the polynomial indexed by w. For example, applying the divided difference operator ∂_2 to the Schubert polynomial $\mathfrak{S}_{w_0}$:

```
sage: Sw0.divided_difference(2)
X[5, 3, 4, 2, 1]
```

```
>>> from sage.all import *
>>> Sw0.divided_difference(Integer(2))
X[5, 3, 4, 2, 1]
```

We can also check the properties listed in Wikipedia article Schubert_polynomial:

```
sage: X([1,2,3,4,5])  # the identity in one-line notation
X[1]
sage: X([1,3,2,4,5]).expand()  # the transposition swapping 2 and 3
x0 + x1
sage: X([2,4,5,3,1]).expand()
x0^2*x1^2*x2*x3 + x0^2*x1*x2^2*x3 + x0*x1^2*x2^2*x3

sage: w = [4,5,1,2,3]
sage: s = SymmetricFunctions(QQ).schur()
sage: s[3,3].expand(2)
x0^3*x1^3
sage: X(w).expand()
x0^3*x1^3
```

```
>>> from sage.all import *
>>> X([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)])  # the identity in␣
↪one-line notation
X[1]
>>> X([Integer(1),Integer(3),Integer(2),Integer(4),Integer(5)]).expand()  # the␣
↪transposition swapping 2 and 3
x0 + x1
>>> X([Integer(2),Integer(4),Integer(5),Integer(3),Integer(1)]).expand()
x0^2*x1^2*x2*x3 + x0^2*x1*x2^2*x3 + x0*x1^2*x2^2*x3

>>> w = [Integer(4),Integer(5),Integer(1),Integer(2),Integer(3)]
>>> s = SymmetricFunctions(QQ).schur()
>>> s[Integer(3),Integer(3)].expand(Integer(2))
x0^3*x1^3
>>> X(w).expand()
x0^3*x1^3
```

sage.combinat.schubert_polynomial.**SchubertPolynomialRing**(R)

Return the Schubert polynomial ring over `R` on the X basis.

This is the basis made of the Schubert polynomials.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
```

(continues on next page)

(continued from previous page)

```
sage: TestSuite(X).run()
sage: X(1)
X[1]
sage: X([1,2,3])*X([2,1,3])
X[2, 1]
sage: X([2,1,3])*X([2,1,3])
X[3, 1, 2]
sage: X([2,1,3])+X([3,1,2,4])
X[2, 1] + X[3, 1, 2]
sage: a = X([2,1,3])+X([3,1,2,4])
sage: a^2
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
>>> TestSuite(X).run()
>>> X(Integer(1))
X[1]
>>> X([Integer(1),Integer(2),Integer(3)])*X([Integer(2),Integer(1),Integer(3)])
X[2, 1]
>>> X([Integer(2),Integer(1),Integer(3)])*X([Integer(2),Integer(1),Integer(3)])
X[3, 1, 2]
>>> X([Integer(2),Integer(1),Integer(3)])+X([Integer(3),Integer(1),Integer(2),
↪Integer(4)])
X[2, 1] + X[3, 1, 2]
>>> a = X([Integer(2),Integer(1),Integer(3)])+X([Integer(3),Integer(1),Integer(2),
↪Integer(4)])
>>> a**Integer(2)
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

class sage.combinat.schubert_polynomial.**SchubertPolynomialRing_xbasis**(R)

Bases: *CombinatorialFreeModule*

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X == loads(dumps(X))
True
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X == loads(dumps(X))
True
```

Element

alias of *SchubertPolynomial_class*

one_basis()

Return the index of the unit of this algebra.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X.one()  # indirect doctest
X[1]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X.one()  # indirect doctest
X[1]
```

product_on_basis(*left*, *right*)

EXAMPLES:

```
sage: p1 = Permutation([3,2,1])
sage: p2 = Permutation([2,1,3])
sage: X = SchubertPolynomialRing(QQ)
sage: X.product_on_basis(p1,p2)
X[4, 2, 1, 3]
```

```
>>> from sage.all import *
>>> p1 = Permutation([Integer(3),Integer(2),Integer(1)])
>>> p2 = Permutation([Integer(2),Integer(1),Integer(3)])
>>> X = SchubertPolynomialRing(QQ)
>>> X.product_on_basis(p1,p2)
X[4, 2, 1, 3]
```

some_elements()

Return some elements.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X.some_elements()
[X[1], X[1] + 2*X[2, 1], -X[3, 2, 1] + X[4, 2, 1, 3]]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X.some_elements()
[X[1], X[1] + 2*X[2, 1], -X[3, 2, 1] + X[4, 2, 1, 3]]
```

class sage.combinat.schubert_polynomial.**SchubertPolynomial_class**

Bases: IndexedFreeModuleElement

divided_difference(*i*, *algorithm='sage'*)

Return the `i`-th divided difference operator, applied to `self`.

Here, `i` can be either a permutation or a positive integer.

INPUT:

- `i` – permutation or positive integer
- `algorithm` – (default: `'sage'`) either `'sage'` or `'symmetrica'`; this determines which software is called for the computation

OUTPUT:

The result of applying the `i`-th divided difference operator to `self`.

If i is a positive integer, then the i-th divided difference operator δ_i is the linear operator sending each polynomial $f = f(x_1, x_2, \ldots, x_n)$ (in $n \geq i+1$ variables) to the polynomial

$$\frac{f - f_i}{x_i - x_{i+1}}, \qquad \text{where } f_i = f(x_1, x_2, ..., x_{i-1}, x_{i+1}, x_i, x_{i+1}, ..., x_n).$$

If σ is a permutation in the n-th symmetric group, then the σ-th divided difference operator δ_σ is the composition $\delta_{i_1}\delta_{i_2}\cdots\delta_{i_k}$, where $\sigma = s_{i_1} \circ s_{i_2} \circ \cdots \circ s_{i_k}$ is any reduced expression for σ (the precise choice of reduced expression is immaterial).

Note

The *`expand()`* method results in a polynomial in n variables named `x0, x1, ..., x(n-1)` rather than $x_1, x_2, \ldots, x_n$. The variable named `xi` corresponds to x_{i+1}. Thus, `self.divided_difference(i)` involves the variables `x(i-1)` and `xi` getting switched (in the numerator).

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,1])
sage: a.divided_difference(1)
X[2, 3, 1]
sage: a.divided_difference([3,2,1])
X[1]
sage: a.divided_difference(5)
0
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([Integer(3),Integer(2),Integer(1)])
>>> a.divided_difference(Integer(1))
X[2, 3, 1]
>>> a.divided_difference([Integer(3),Integer(2),Integer(1)])
X[1]
>>> a.divided_difference(Integer(5))
0
```

Any divided difference of 0 is 0:

```
sage: X.zero().divided_difference(2)
0
```

```
>>> from sage.all import *
>>> X.zero().divided_difference(Integer(2))
0
```

This is compatible when a permutation is given as input:

```
sage: a = X([3,2,4,1])
sage: a.divided_difference([2,3,1])
0
```

(continues on next page)

(continued from previous page)

```
sage: a.divided_difference(1).divided_difference(2)
0
```

```
>>> from sage.all import *
>>> a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.divided_difference([Integer(2),Integer(3),Integer(1)])
0
>>> a.divided_difference(Integer(1)).divided_difference(Integer(2))
0
```

```
sage: a = X([4,3,2,1])
sage: a.divided_difference([2,3,1])
X[3, 2, 4, 1]
sage: a.divided_difference(1).divided_difference(2)
X[3, 2, 4, 1]
sage: a.divided_difference([4,1,3,2])
X[1, 4, 2, 3]
sage: b = X([4, 1, 3, 2])
sage: b.divided_difference(1).divided_difference(2)
X[1, 3, 4, 2]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3)
X[1, 3, 2]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3).
↪divided_difference(2)
X[1]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3).
↪divided_difference(3)
0
sage: b.divided_difference(1).divided_difference(2).divided_difference(1)
0
```

```
>>> from sage.all import *
>>> a = X([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> a.divided_difference([Integer(2),Integer(3),Integer(1)])
X[3, 2, 4, 1]
>>> a.divided_difference(Integer(1)).divided_difference(Integer(2))
X[3, 2, 4, 1]
>>> a.divided_difference([Integer(4),Integer(1),Integer(3),Integer(2)])
X[1, 4, 2, 3]
>>> b = X([Integer(4), Integer(1), Integer(3), Integer(2)])
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2))
X[1, 3, 4, 2]
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_
↪difference(Integer(3))
X[1, 3, 2]
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_
↪difference(Integer(3)).divided_difference(Integer(2))
X[1]
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_
↪difference(Integer(3)).divided_difference(Integer(3))
0
```

(continues on next page)

(continued from previous page)

```
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_
↪difference(Integer(1))
0
```

expand()

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: X([2,1,3]).expand()
x0
sage: [X(p).expand() for p in Permutations(3)]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> X([Integer(2),Integer(1),Integer(3)]).expand()
x0
>>> [X(p).expand() for p in Permutations(Integer(3))]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

multiply_variable(i)

Return the Schubert polynomial obtained by multiplying `self` by the variable x_i.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.multiply_variable(0)
X[4, 2, 3, 1]
sage: a.multiply_variable(1)
X[3, 4, 2, 1]
sage: a.multiply_variable(2)
X[3, 2, 5, 1, 4] - X[3, 4, 2, 1] - X[4, 2, 3, 1]
sage: a.multiply_variable(3)
X[3, 2, 4, 5, 1]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.multiply_variable(Integer(0))
X[4, 2, 3, 1]
>>> a.multiply_variable(Integer(1))
X[3, 4, 2, 1]
>>> a.multiply_variable(Integer(2))
X[3, 2, 5, 1, 4] - X[3, 4, 2, 1] - X[4, 2, 3, 1]
>>> a.multiply_variable(Integer(3))
X[3, 2, 4, 5, 1]
```

scalar_product(x)

Return the standard scalar product of `self` and `x`.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.scalar_product(a)
0
sage: b = X([4,3,2,1])
sage: b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
sage: Permutation([1, 3, 4, 6, 2, 5, 7]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
sage: s = SymmetricFunctions(ZZ).schur()
sage: c = s([2,1,1])
sage: b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3
 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3
 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
sage: c.expand(4)
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3
 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3
 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.scalar_product(a)
0
>>> b = X([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
>>> Permutation([Integer(1), Integer(3), Integer(4), Integer(6), Integer(2),␣
↪Integer(5), Integer(7)]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
>>> s = SymmetricFunctions(ZZ).schur()
>>> c = s([Integer(2),Integer(1),Integer(1)])
>>> b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3
 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3
 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
>>> c.expand(Integer(4))
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3
 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3
 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
```

Set partitions

This module defines a class for immutable partitioning of a set. For mutable version see `DisjointSet()`.

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration).
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through *SetPartition*.

- Martin Rubey (2017-10-10): Cleanup, add crossings and nestings, add random generation.

class sage.combinat.set_partition.**AbstractSetPartition**

Bases: ClonableArray

Methods of set partitions which are independent of the base set

base_set()

Return the base set of `self`, which is the union of all parts of `self`.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([[1,2,3,4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([]).base_set()
{}
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1)], [Integer(2),Integer(3)], [Integer(4)]]).base_
↪set()
{1, 2, 3, 4}
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_set()
{1, 2, 3, 4}
>>> SetPartition([]).base_set()
{}
```

base_set_cardinality()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1)], [Integer(2),Integer(3)], [Integer(4)]]).base_
↪set_cardinality()
4
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_set_
↪cardinality()
4
```

coarsenings()

Return a list of coarsenings of `self`.

See also

sage.combinat.set_partition.SetPartition.refinements()

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).coarsenings()
[{{1, 2, 3, 4}}, {{1, 3}, {2, 4}}]
sage: SetPartition([[1],[2,4],[3]]).coarsenings()
[{{1, 2, 3, 4}},
 {{1, 2, 4}, {3}},
 {{1, 3}, {2, 4}},
 {{1}, {2, 3, 4}},
 {{1}, {2, 4}, {3}}]
sage: SetPartition([]).coarsenings()
[{}]
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]).
↪coarsenings()
[{{1, 2, 3, 4}}, {{1, 3}, {2, 4}}]
>>> SetPartition([[Integer(1)],[Integer(2),Integer(4)],[Integer(3)]]).
↪coarsenings()
[{{1, 2, 3, 4}},
 {{1, 2, 4}, {3}},
 {{1, 3}, {2, 4}},
 {{1}, {2, 3, 4}},
 {{1}, {2, 4}, {3}}]
>>> SetPartition([]).coarsenings()
[{}]
```

conjugate()

An involution exchanging singletons and circular adjacencies.

This method implements the definition of the conjugate of a set partition defined in [Cal2005].

INPUT:

- `self` – set partition of an ordered set

OUTPUT: a set partition

EXAMPLES:

```
sage: SetPartition([[1,6,7],[2,8],[3,4,5]]).conjugate()
{{1, 4, 7}, {2, 8}, {3}, {5}, {6}}
sage: all(sp.conjugate().conjugate()==sp for sp in SetPartitions([1,3,5,7]))
True
sage: SetPartition([]).conjugate()
{}
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(6),Integer(7)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(4),Integer(5)]]).conjugate()
```

(continues on next page)

(continued from previous page)

```
{{1, 4, 7}, {2, 8}, {3}, {5}, {6}}
>>> all(sp.conjugate().conjugate()==sp for sp in SetPartitions([Integer(1),
↪Integer(3),Integer(5),Integer(7)]))
True
>>> SetPartition([]).conjugate()
{}
```

inf(*other*)

The product of the set partitions `self` and `other`.

The product of two set partitions B and C is defined as the set partition whose parts are the nonempty intersections between each part of B and each part of C. This product is also the infimum of B and C in the classical set partition lattice (that is, the coarsest set partition which is finer than each of B and C). Consequently, `inf` acts as an alias for this method.

See also

sup()

EXAMPLES:

```
sage: x = SetPartition([ [1,2], [3,5,4] ])
sage: y = SetPartition(( (3,1,2), (5,4) ))
sage: x * y
{{1, 2}, {3}, {4, 5}}

sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[2,4], [3], [1]])
sage: sp1.inf(sp2) == s
True
```

```
>>> from sage.all import *
>>> x = SetPartition([ [Integer(1),Integer(2)], [Integer(3),Integer(5),
↪Integer(4)] ])
>>> y = SetPartition(( (Integer(3),Integer(1),Integer(2)), (Integer(5),
↪Integer(4)) ))
>>> x * y
{{1, 2}, {3}, {4, 5}}

>>> S = SetPartitions(Integer(4))
>>> sp1 = S([[Integer(2),Integer(3),Integer(4)], [Integer(1)]])
>>> sp2 = S([[Integer(1),Integer(3)], [Integer(2),Integer(4)]])
>>> s = S([[Integer(2),Integer(4)], [Integer(3)], [Integer(1)]])
>>> sp1.inf(sp2) == s
True
```

max_block_size()

The maximum block size of the diagram.

EXAMPLES:

```
sage: # needs sage.modules
sage: from sage.combinat.diagram_algebras import PartitionDiagram,␣
↪PartitionDiagrams
sage: pd = PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]])
sage: pd.max_block_size()
3
sage: sorted(d.max_block_size() for d in PartitionDiagrams(2))
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 4]
sage: sorted(sp.max_block_size() for sp in SetPartitions(3))
[1, 2, 2, 2, 3]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> from sage.combinat.diagram_algebras import PartitionDiagram,␣
↪PartitionDiagrams
>>> pd = PartitionDiagram([[Integer(1),-Integer(3),-Integer(5)],[Integer(2),
↪Integer(4)],[Integer(3),-Integer(1),-Integer(2)],[Integer(5)],[-
↪Integer(4)]])
>>> pd.max_block_size()
3
>>> sorted(d.max_block_size() for d in PartitionDiagrams(Integer(2)))
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 4]
>>> sorted(sp.max_block_size() for sp in SetPartitions(Integer(3)))
[1, 2, 2, 2, 3]
```

standard_form()

Return `self` as a list of lists.

When the ground set is totally ordered, the elements of each block are listed in increasing order.

This is not related to standard set partitions (which simply means set partitions of $[n] = \{1, 2, \ldots, n\}$ for some integer n) or standardization (*standardization()*).

EXAMPLES:

```
sage: [x.standard_form() for x in SetPartitions(4, [2,2])]                  #␣
↪needs sage.graphs sage.rings.finite_rings
[[[1, 2], [3, 4]], [[1, 4], [2, 3]], [[1, 3], [2, 4]]]
```

```
>>> from sage.all import *
>>> [x.standard_form() for x in SetPartitions(Integer(4), [Integer(2),
↪Integer(2)])]                  # needs sage.graphs sage.rings.finite_rings
[[[1, 2], [3, 4]], [[1, 4], [2, 3]], [[1, 3], [2, 4]]]
```

sup(*t*)

Return the supremum of `self` and `t` in the classical set partition lattice.

The supremum of two set partitions B and C is obtained as the transitive closure of the relation which relates i to j if and only if i and j are in the same part in at least one of the set partitions B and C.

See also

`__mul__`

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[1,2,3,4]])
sage: sp1.sup(sp2) == s
True
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> sp1 = S([[Integer(2),Integer(3),Integer(4)], [Integer(1)]])
>>> sp2 = S([[Integer(1),Integer(3)], [Integer(2),Integer(4)]])
>>> s = S([[Integer(1),Integer(2),Integer(3),Integer(4)]])
>>> sp1.sup(sp2) == s
True
```

class sage.combinat.set_partition.**SetPartition**(*parent*, *s*, *check=True*)

Bases: *AbstractSetPartition*

A partition of a set.

A set partition p of a set S is a partition of S into subsets called parts and represented as a set of sets. By extension, a set partition of a nonnegative integer n is the set partition of the integers from 1 to n. The number of set partitions of n is called the n-th Bell number.

There is a natural integer partition associated with a set partition, namely the nonincreasing sequence of sizes of all its parts.

There is a classical lattice associated with all set partitions of n. The infimum of two set partitions is the set partition obtained by intersecting all the parts of both set partitions. The supremum is obtained by transitive closure of the relation i related to j if and only if they are in the same part in at least one of the set partitions.

We will use terminology from partitions, in particular the *length* of a set partition $A = \{A_1, \ldots, A_k\}$ is the number of parts of A and is denoted by $|A| := k$. The *size* of A is the cardinality of S. We will also sometimes use the notation $[n] := \{1, 2, \ldots, n\}$.

EXAMPLES:

There are 5 set partitions of the set $\{1, 2, 3\}$:

```
sage: SetPartitions(3).cardinality()                                    #␣
↪needs sage.libs.flint
5
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3)).cardinality()                             ␣
↪     # needs sage.libs.flint
5
```

Here is the list of them:

```
sage: SetPartitions(3).list()                                                 #␣
↪needs sage.graphs
[{{1, 2, 3}}, {{1, 2}, {3}}, {{1, 3}, {2}}, {{1}, {2, 3}}, {{1}, {2}, {3}}]
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3)).list()                                          ␣
↪     # needs sage.graphs
[{{1, 2, 3}}, {{1, 2}, {3}}, {{1, 3}, {2}}, {{1}, {2, 3}}, {{1}, {2}, {3}}]
```

There are 6 set partitions of $\{1, 2, 3, 4\}$ whose underlying partition is $[2, 1, 1]$:

```
sage: SetPartitions(4, [2,1,1]).list()                                        #␣
↪needs sage.graphs sage.rings.finite_rings
[{{1}, {2, 4}, {3}},
 {{1}, {2}, {3, 4}},
 {{1, 4}, {2}, {3}},
 {{1, 3}, {2}, {4}},
 {{1, 2}, {3}, {4}},
 {{1}, {2, 3}, {4}}]
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(4), [Integer(2),Integer(1),Integer(1)]).list()      ␣
↪                                  # needs sage.graphs sage.rings.finite_rings
[{{1}, {2, 4}, {3}},
 {{1}, {2}, {3, 4}},
 {{1, 4}, {2}, {3}},
 {{1, 3}, {2}, {4}},
 {{1, 2}, {3}, {4}},
 {{1}, {2, 3}, {4}}]
```

Since Issue #14140, we can create a set partition directly by *SetPartition*, which creates the base set by taking the union of the parts passed in:

```
sage: s = SetPartition([[1,3],[2,4]]); s
{{1, 3}, {2, 4}}
sage: s.parent()
Set partitions
```

```
>>> from sage.all import *
>>> s = SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]); s
{{1, 3}, {2, 4}}
>>> s.parent()
Set partitions
```

apply_permutation(*p*)

Apply `p` to the underlying set of `self`.

INPUT:

- `p` – a permutation

EXAMPLES:

```
sage: x = SetPartition([[1,2], [3,5,4]])
sage: p = Permutation([2,1,4,5,3])
sage: x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
sage: q = Permutation([3,2,1,5,4])
sage: x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}

sage: m = PerfectMatching([(1,4),(2,6),(3,5)])
sage: m.apply_permutation(Permutation([4,1,5,6,3,2]))
[(1, 2), (3, 5), (4, 6)]
```

```
>>> from sage.all import *
>>> x = SetPartition([[Integer(1),Integer(2)], [Integer(3),Integer(5),
↪Integer(4)]])
>>> p = Permutation([Integer(2),Integer(1),Integer(4),Integer(5),Integer(3)])
>>> x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
>>> q = Permutation([Integer(3),Integer(2),Integer(1),Integer(5),Integer(4)])
>>> x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}

>>> m = PerfectMatching([(Integer(1),Integer(4)),(Integer(2),Integer(6)),
↪(Integer(3),Integer(5))])
>>> m.apply_permutation(Permutation([Integer(4),Integer(1),Integer(5),
↪Integer(6),Integer(3),Integer(2)]))
[(1, 2), (3, 5), (4, 6)]
```

arcs()

Return `self` as a list of arcs.

Assuming that the blocks are sorted, the arcs are the pairs of consecutive elements in the blocks.

EXAMPLES:

```
sage: A = SetPartition([[1],[2,3],[4]])
sage: A.arcs()
[(2, 3)]
sage: B = SetPartition([[1,3,6,7],[2,5],[4]])
sage: B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1)],[Integer(2),Integer(3)],[Integer(4)]])
>>> A.arcs()
[(2, 3)]
>>> B = SetPartition([[Integer(1),Integer(3),Integer(6),Integer(7)],
↪[Integer(2),Integer(5)],[Integer(4)]])
>>> B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]
```

cardinality()

Return the `len` of `self`.

EXAMPLES:

```
sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: len(IncreasingArrays()([1,2,3]))
3
```

```
>>> from sage.all import *
>>> from sage.structure.list_clone_demo import IncreasingArrays
>>> len(IncreasingArrays()([Integer(1),Integer(2),Integer(3)]))
3
```

check()

Check that we are a valid set partition.

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1, 3], [2, 4]])
sage: s.check()
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])
>>> s.check()
```

closers()

Return the maximal elements of the blocks.

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.closers()
[7, 8, 9, 12, 13]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
...[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
...Integer(13)],[Integer(8)],[Integer(12)]])
>>> P.closers()
[7, 8, 9, 12, 13]
```

crossings()

Return the crossing arcs of a set partition on a totally ordered set.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns a list of the pairs of crossing lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.crossings()
[((1, 4), (2, 5)), ((1, 4), (3, 6)), ((2, 5), (3, 6)), ((3, 6), (5, 7))]
```

```
>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
↪Integer(7)],[Integer(3),Integer(6)]])
>>> p.crossings()
[((1, 4), (2, 5)), ((1, 4), (3, 6)), ((2, 5), (3, 6)), ((3, 6), (5, 7))]
```

crossings_iterator()

Return the crossing arcs of a set partition on a totally ordered set.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of crossing lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: next(p.crossings_iterator())
((1, 4), (2, 5))
```

```
>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
↪Integer(7)],[Integer(3),Integer(6)]])
>>> next(p.crossings_iterator())
((1, 4), (2, 5))
```

is_atomic()

Return if `self` is an atomic set partition.

A (standard) set partition A can be split if there exist $j < i$ such that $\max(A_j) < \min(A_i)$ where A is ordered by minimal elements. This means we can write $A = B|C$ for some nonempty set partitions B and C. We call a set partition *atomic* if it cannot be split and is nonempty. Here, the pipe symbol $|$ is as defined in method *pipe()*.

EXAMPLES:

```
sage: SetPartition([[1,3], [2]]).is_atomic()
True
sage: SetPartition([[1,3], [2], [4]]).is_atomic()
False
sage: SetPartition([[1], [2,4], [3]]).is_atomic()
False
sage: SetPartition([[1,2,3,4]]).is_atomic()
True
sage: SetPartition([[1, 4], [2], [3]]).is_atomic()
True
sage: SetPartition([]).is_atomic()
False
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(3)], [Integer(2)]]).is_atomic()
True
>>> SetPartition([[Integer(1),Integer(3)], [Integer(2)], [Integer(4)]]).is_
```

(continues on next page)

(continued from previous page)

```
↪atomic()
False
>>> SetPartition([[Integer(1)], [Integer(2),Integer(4)], [Integer(3)]]).is_
↪atomic()
False
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).is_atomic()
True
>>> SetPartition([[Integer(1), Integer(4)], [Integer(2)], [Integer(3)]]).is_
↪atomic()
True
>>> SetPartition([]).is_atomic()
False
```

is_noncrossing()

Check if `self` is noncrossing.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns `True` if the picture obtained this way has no crossings.

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.is_noncrossing()
False

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_noncrossing()
False
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_noncrossing()
True
```

```
>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
↪Integer(7)],[Integer(3),Integer(6)]])
>>> p.is_noncrossing()
False

>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.is_noncrossing()
False
>>> PerfectMatching([(Integer(1), Integer(4)), (Integer(2), Integer(3)),␣
↪(Integer(5), Integer(6))]).is_noncrossing()
True
```

is_nonnesting()

Return if `self` is nonnesting or not.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns `True` if the picture obtained this way has no nestings.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_nonnesting()
False
sage: PerfectMatching([(1, 3), (2, 5), (4, 6)]).is_nonnesting()
True
```

```
>>> from sage.all import *
>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.is_nonnesting()
False
>>> PerfectMatching([(Integer(1), Integer(3)), (Integer(2), Integer(5)),␣
↪(Integer(4), Integer(6))]).is_nonnesting()
True
```

latex_options()

Return the latex options for use in the `_latex_` function as a dictionary. The default values are set using the global options.

Options can be found in *set_latex_options()*

EXAMPLES:

```
sage: SP = SetPartition([[1,6], [3,5,4]]); SP.latex_options()
{'angle': 0,
 'color': 'black',
 'fill': False,
 'plot': None,
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 1}
```

```
>>> from sage.all import *
>>> SP = SetPartition([[Integer(1),Integer(6)], [Integer(3),Integer(5),
↪Integer(4)]]); SP.latex_options()
{'angle': 0,
 'color': 'black',
 'fill': False,
 'plot': None,
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 1}
```

nestings()

Return the nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the list of the pairs of nesting lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```
sage: m = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: m.nestings()
[((1, 6), (3, 5)), ((2, 7), (3, 5))]

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.nestings()
[((2, 8), (4, 7)), ((2, 8), (5, 6)), ((4, 7), (5, 6))]
```

```
>>> from sage.all import *
>>> m = PerfectMatching([(Integer(1), Integer(6)), (Integer(2), Integer(7)),␣
↪(Integer(3), Integer(5)), (Integer(4), Integer(8))])
>>> m.nestings()
[((1, 6), (3, 5)), ((2, 7), (3, 5))]

>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.nestings()
[((2, 8), (4, 7)), ((2, 8), (5, 6)), ((4, 7), (5, 6))]
```

nestings_iterator()

Iterate over the nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of nesting lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```
sage: n = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: it = n.nestings_iterator()
sage: next(it)
((1, 6), (3, 5))
sage: next(it)
((2, 7), (3, 5))
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

```
>>> from sage.all import *
>>> n = PerfectMatching([(Integer(1), Integer(6)), (Integer(2), Integer(7)),␣
↪(Integer(3), Integer(5)), (Integer(4), Integer(8))])
>>> it = n.nestings_iterator()
>>> next(it)
((1, 6), (3, 5))
```

(continues on next page)

(continued from previous page)

```
>>> next(it)
((2, 7), (3, 5))
>>> next(it)
Traceback (most recent call last):
...
StopIteration
```

number_of_crossings()

Return the number of crossings.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the number the pairs of crossing lines.

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.number_of_crossings()
4

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1
```

```
>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
↪Integer(7)],[Integer(3),Integer(6)]])
>>> p.number_of_crossings()
4

>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.number_of_crossings()
1
```

number_of_nestings()

Return the number of nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the number the pairs of nesting lines.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_nestings()
3
```

```
>>> from sage.all import *
>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.number_of_nestings()
3
```

openers()

Return the minimal elements of the blocks.

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.openers()
[1, 3, 5, 8, 12]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> P.openers()
[1, 3, 5, 8, 12]
```

ordered_set_partition_action(s)

Return the action of an ordered set partition `s` on `self`.

Let $A = \{A_1, A_2, \ldots, A_k\}$ be a set partition of some set S and s be an ordered set partition (i.e., set composition) of a subset of $[k]$. Let $A^{\downarrow}$ denote the standardization of A, and $A_{\{i_1,i_2,\ldots,i_m\}}$ denote the sub-partition $\{A_{i_1}, A_{i_2}, \ldots, A_{i_m}\}$ for any subset $\{i_1, \ldots, i_m\}$ of $\{1, \ldots, k\}$. We define the set partition $s(A)$ by

$$s(A) = A^{\downarrow}_{s_1} | A^{\downarrow}_{s_2} | \cdots | A^{\downarrow}_{s_q}.$$

where $s = (s_1, s_2, \ldots, s_q)$. Here, the pipe symbol | is as defined in method *pipe()*.

This is $s[A]$ in section 2.3 in [LM2011].

INPUT:

- `s` – an ordered set partition with base set a subset of $\{1, \ldots, k\}$

EXAMPLES:

```
sage: A = SetPartition([[1], [2,4], [3]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: A.ordered_set_partition_action(s)
{{1}, {2}, {3, 4}}
sage: s = OrderedSetPartition([[2,3], [1]])
sage: A.ordered_set_partition_action(s)
{{1, 3}, {2}, {4}}
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(4)], [Integer(3)]])
>>> s = OrderedSetPartition([[Integer(1),Integer(3)], [Integer(2)]])
>>> A.ordered_set_partition_action(s)
{{1}, {2}, {3, 4}}
```

(continues on next page)

(continued from previous page)

```
>>> s = OrderedSetPartition([[Integer(2),Integer(3)], [Integer(1)]])
>>> A.ordered_set_partition_action(s)
{{1, 3}, {2}, {4}}
```

We create Figure 1 in [LM2011] (we note that there is a typo in the lower-left corner of the table in the published version of the paper, whereas the arXiv version gives the correct partition):

```
sage: A = SetPartition([[1,3], [2,9], [4,5,8], [7]])
sage: B = SetPartition([[1,3], [2,8], [4,5,6], [7]])
sage: C = SetPartition([[1,5], [2,8], [3,4,6], [7]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: t = OrderedSetPartition([[2], [3,4]])
sage: u = OrderedSetPartition([[1], [2,3,4]])
sage: A.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: A.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 6}, {5}}
sage: A.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 7}, {6}}
sage: B.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: B.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: B.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
sage: C.ordered_set_partition_action(s)
{{1, 4}, {2, 3, 5}, {6, 7}}
sage: C.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: C.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1),Integer(3)], [Integer(2),Integer(9)],␣
↪[Integer(4),Integer(5),Integer(8)], [Integer(7)]])
>>> B = SetPartition([[Integer(1),Integer(3)], [Integer(2),Integer(8)],␣
↪[Integer(4),Integer(5),Integer(6)], [Integer(7)]])
>>> C = SetPartition([[Integer(1),Integer(5)], [Integer(2),Integer(8)],␣
↪[Integer(3),Integer(4),Integer(6)], [Integer(7)]])
>>> s = OrderedSetPartition([[Integer(1),Integer(3)], [Integer(2)]])
>>> t = OrderedSetPartition([[Integer(2)], [Integer(3),Integer(4)]])
>>> u = OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3),
↪Integer(4)]])
>>> A.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
>>> A.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 6}, {5}}
>>> A.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 7}, {6}}
>>> B.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
>>> B.ordered_set_partition_action(t)
```

(continues on next page)

(continued from previous page)

```
{{1, 2}, {3, 4, 5}, {6}}
>>> B.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
>>> C.ordered_set_partition_action(s)
{{1, 4}, {2, 3, 5}, {6, 7}}
>>> C.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
>>> C.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
```

REFERENCES:

- [LM2011]

pipe(*other*)

Return the pipe of the set partitions `self` and `other`.

The pipe of two set partitions is defined as follows:

For any integer k and any subset I of $\mathbf{Z}$, let $I+k$ denote the subset of $\mathbf{Z}$ obtained by adding k to every element of k.

If B and C are set partitions of $[n]$ and $[m]$, respectively, then the pipe of B and C is defined as the set partition

$$\{B_1, B_2, \ldots, B_b, C_1 + n, C_2 + n, \ldots, C_c + n\}$$

of $[n+m]$, where $B = \{B_1, B_2, \ldots, B_b\}$ and $C = \{C_1, C_2, \ldots, C_c\}$. This pipe is denoted by $B|C$.

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).pipe(SetPartition([[1,3],[2]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
sage: SetPartition([]).pipe(SetPartition([[1,2],[3,5],[4]]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3,5],[4]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3]]).pipe(SetPartition([[1]]))
{{1, 2}, {3}, {4}}
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]).
↪pipe(SetPartition([[Integer(1),Integer(3)],[Integer(2)]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
>>> SetPartition([]).pipe(SetPartition([[Integer(1),Integer(2)],[Integer(3),
↪Integer(5)],[Integer(4)]]))
{{1, 2}, {3, 5}, {4}}
>>> SetPartition([[Integer(1),Integer(2)],[Integer(3),Integer(5)],
↪[Integer(4)]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
>>> SetPartition([[Integer(1),Integer(2)],[Integer(3)]]).
↪pipe(SetPartition([[Integer(1)]]))
{{1, 2}, {3}, {4}}
```

plot(*angle=None*, *color='black'*, *base_set_dict=None*)

Return a plot of `self`.

INPUT:

- `angle` – (default: $\pi/4$) the angle at which the arcs take off (if angle is negative, the arcs are drawn below the horizontal line)
- `color` – (default: `'black'`) color of the arcs
- `base_set_dict` – (optional) dictionary with keys elements of *base_set()* and values as integer or float

EXAMPLES:

```
sage: p = SetPartition([[1,10,11],[2,3,7],[4,5,6],[8,9]])
sage: p.plot()                                                              #␣
↪needs sage.plot sage.symbolic

refinements()

Return a list of refinements of `self`.

See also

sage.combinat.set_partition.AbstractSetPartition.coarsenings()

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).refinements()                                 #␣
↪needs sage.graphs sage.libs.flint

↪needs sage.graphs sage.libs.flint
[{}]
```

restriction(*I*)

Return the restriction of `self` to a subset `I` (which is given as a set or list or any other iterable).

EXAMPLES:

```
sage: A = SetPartition([[1], [2,3]])
sage: A.restriction([1,2])
{{1}, {2}}
sage: A.restriction([2,3])
{{2, 3}}
sage: A.restriction([])
{}
sage: A.restriction([4])
{}
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(3)]])
>>> A.restriction([Integer(1),Integer(2)])
{{1}, {2}}
>>> A.restriction([Integer(2),Integer(3)])
{{2, 3}}
>>> A.restriction([])
{}
>>> A.restriction([Integer(4)])
{}
```

set_latex_options(***kwargs*)

Set the latex options for use in the _latex_ function.

- `tikz_scale` – (default: 1) scale for use with tikz package
- `plot` – (default: `None`) `None` returns the set notation, `linear` returns a linear plot, `cyclic` returns a cyclic plot

- `color` – (default: `'black'`) the arc colors
- `fill` – boolean (default: `False`); if `True` then fills `color`, else you can pass in a color to alter the fill color - *only works with cyclic plot*
- `show_labels` – boolean (default: `True`); if `True` shows labels (*only works with plots*)
- `radius` – (default: `'1cm'`) radius of circle for cyclic plot - *only works with cyclic plot*
- `angle` – (default: 0) angle for linear plot

EXAMPLES:

```
sage: SP = SetPartition([[1,6], [3,5,4]])
sage: SP.set_latex_options(tikz_scale=2,plot='linear',fill=True,color='blue',
↪angle=45)
sage: SP.set_latex_options(plot='cyclic')
sage: SP.latex_options()
{'angle': 45,
 'color': 'blue',
 'fill': True,
 'plot': 'cyclic',
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 2}
```

```
>>> from sage.all import *
>>> SP = SetPartition([[Integer(1),Integer(6)], [Integer(3),Integer(5),
↪Integer(4)]])
>>> SP.set_latex_options(tikz_scale=Integer(2),plot='linear',fill=True,color=
↪'blue',angle=Integer(45))
>>> SP.set_latex_options(plot='cyclic')
>>> SP.latex_options()
{'angle': 45,
 'color': 'blue',
 'fill': True,
 'plot': 'cyclic',
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 2}
```

shape()

Return the integer partition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(5))
```

(continues on next page)

(continued from previous page)

```
>>> x = S([[Integer(1),Integer(2)], [Integer(3),Integer(5),Integer(4)]])
>>> x.shape()
[3, 2]
>>> y = S([[Integer(2)], [Integer(3),Integer(1)], [Integer(5),Integer(4)]])
>>> y.shape()
[2, 2, 1]
```

shape_partition()

alias of *shape()*.

size()

Return the cardinality of the base set of `self`.

This is an alias for *base_set_cardinality()*.

standardization()

Return the standardization of `self`.

Given a set partition $A = \{A_1, \ldots, A_n\}$ of an ordered set S, the standardization of A is the set partition of $\{1, 2, \ldots, |S|\}$ obtained by replacing the elements of the parts of A by the integers $1, 2, \ldots, |S|$ in such a way that their relative order is preserved (i. e., the smallest element in the whole set partition is replaced by 1, the next-smallest by 2, and so on).

EXAMPLES:

```
sage: SetPartition([[4], [1, 3]]).standardization()
{{1, 2}, {3}}
sage: SetPartition([[4], [6, 3]]).standardization()
{{1, 3}, {2}}
sage: SetPartition([]).standardization()
{}
sage: SetPartition([('c','b'),('d','f'),('e','a')]).standardization()
{{1, 5}, {2, 3}, {4, 6}}
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(4)], [Integer(1), Integer(3)]]).standardization()
{{1, 2}, {3}}
>>> SetPartition([[Integer(4)], [Integer(6), Integer(3)]]).standardization()
{{1, 3}, {2}}
>>> SetPartition([]).standardization()
{}
>>> SetPartition([('c','b'),('d','f'),('e','a')]).standardization()
{{1, 5}, {2, 3}, {4, 6}}
```

strict_coarsenings()

Return all strict coarsenings of `self`.

Strict coarsening is the binary relation on set partitions defined as the transitive-and-reflexive closure of the relation $\prec$ defined as follows: For two set partitions A and B, we have $A \prec B$ if there exist parts A_i, A_j of A such that $\max(A_i) < \min(A_j)$ and $B = A \setminus \{A_i, A_j\} \cup \{A_i \cup A_j\}$.

EXAMPLES:

```
sage: A = SetPartition([[1],[2,3],[4]])
sage: A.strict_coarsenings()
```

(continues on next page)

(continued from previous page)

```
[{{1}, {2, 3}, {4}}, {{1, 2, 3}, {4}}, {{1, 4}, {2, 3}},
 {{1}, {2, 3, 4}}, {{1, 2, 3, 4}}]
sage: SetPartition([[1],[2,4],[3]]).strict_coarsenings()
[{{1}, {2, 4}, {3}}, {{1, 2, 4}, {3}}, {{1, 3}, {2, 4}}]
sage: SetPartition([]).strict_coarsenings()
[{}]
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1)],[Integer(2),Integer(3)],[Integer(4)]])
>>> A.strict_coarsenings()
[{{1}, {2, 3}, {4}}, {{1, 2, 3}, {4}}, {{1, 4}, {2, 3}},
 {{1}, {2, 3, 4}}, {{1, 2, 3, 4}}]
>>> SetPartition([[Integer(1)],[Integer(2),Integer(4)],[Integer(3)]]).strict_
↪coarsenings()
[{{1}, {2, 4}, {3}}, {{1, 2, 4}, {3}}, {{1, 3}, {2, 4}}]
>>> SetPartition([]).strict_coarsenings()
[{}]
```

to_partition()

alias of *shape()*.

to_permutation()

Convert a set partition of $\{1, ..., n\}$ to a permutation by considering the blocks of the partition as cycles.

The cycles are such that the number of excedences is maximised, that is, each cycle is of the form $(a_1, a_2, ..., a_k)$ with $a_1 < a_2 < ... < a_k$.

EXAMPLES:

```
sage: s = SetPartition([[1,3],[2,4]])
sage: s.to_permutation()
[3, 4, 1, 2]
```

```
>>> from sage.all import *
>>> s = SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> s.to_permutation()
[3, 4, 1, 2]
```

to_restricted_growth_word(*bijection='blocks'*)

Convert a set partition of $\{1, ..., n\}$ to a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before.

INPUT:

- `bijection` – (default: `blocks`) defines the map from set partitions to restricted growth functions. These are currently:
  - `blocks`: *to_restricted_growth_word_blocks()*.
  - `intertwining`: *to_restricted_growth_word_intertwining()*.

OUTPUT: a restricted growth word

See also

SetPartitions.from_restricted_growth_word()

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word()
[0, 1, 2, 0, 2, 2, 3, 1, 2]

sage: P.to_restricted_growth_word("intertwining")
[0, 1, 2, 2, 1, 0, 3, 3, 2]

sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.to_restricted_growth_word()
[0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 2, 4, 2]

sage: P.to_restricted_growth_word("intertwining")
[0, 0, 1, 1, 2, 0, 1, 3, 3, 3, 0, 4, 1]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_restricted_growth_word()
[0, 1, 2, 0, 2, 2, 3, 1, 2]

>>> P.to_restricted_growth_word("intertwining")
[0, 1, 2, 2, 1, 0, 3, 3, 2]

>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> P.to_restricted_growth_word()
[0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 2, 4, 2]

>>> P.to_restricted_growth_word("intertwining")
[0, 0, 1, 1, 2, 0, 1, 3, 3, 3, 0, 4, 1]
```

to_restricted_growth_word_blocks()

Convert a set partition of $\{1, ..., n\}$ to a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before.

The word is obtained by sorting the blocks by their minimal element and setting the letters at the positions of the elements in the i-th block to i.

OUTPUT: a restricted growth word

See also

to_restricted_growth_word() SetPartitions.from_restricted_growth_word()

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word_blocks()
[0, 1, 2, 0, 2, 2, 3, 1, 2]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_restricted_growth_word_blocks()
[0, 1, 2, 0, 2, 2, 3, 1, 2]
```

to_restricted_growth_word_intertwining()

Convert a set partition of $\{1, ..., n\}$ to a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before.

The i-th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at i, with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

OUTPUT: a restricted growth word

See also

to_restricted_growth_word() SetPartitions.from_restricted_growth_word()

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word_intertwining()
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_restricted_growth_word_intertwining()
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

to_rook_placement(*bijection='arcs'*)

Return a set of pairs defining a placement of non-attacking rooks on a triangular board.

The cells of the board corresponding to a set partition of $\{1, ..., n\}$ are the pairs (i, j) with $0 < i < j < n+1$.

INPUT:

- `bijection` – (default: `arcs`) defines the bijection from set partitions to rook placements. These are currently:
  - `arcs`: *arcs()*
  - `gamma`: *to_rook_placement_gamma()*
  - `rho`: *to_rook_placement_rho()*
  - `psi`: *to_rook_placement_psi()*

See also

SetPartitions.from_rook_placement()

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.to_rook_placement()
[(1, 2), (2, 4), (4, 7), (3, 9), (5, 6), (6, 10), (10, 11), (11, 13)]
sage: P.to_rook_placement("gamma")
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
sage: P.to_rook_placement("rho")
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
sage: P.to_rook_placement("psi")
[(1, 2), (2, 6), (3, 4), (5, 9), (6, 7), (7, 10), (9, 11), (11, 13)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> P.to_rook_placement()
[(1, 2), (2, 4), (4, 7), (3, 9), (5, 6), (6, 10), (10, 11), (11, 13)]
>>> P.to_rook_placement("gamma")
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
>>> P.to_rook_placement("rho")
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
>>> P.to_rook_placement("psi")
[(1, 2), (2, 6), (3, 4), (5, 9), (6, 7), (7, 10), (9, 11), (11, 13)]
```

to_rook_placement_gamma()

Return the rook diagram obtained by placing rooks according to Wachs and White's bijection gamma.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i-th column from the right and the j-th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the left column. If $n+1-i$ is an opener, column i remains empty. Otherwise, we place a rook into column i, such that the number of cells below the rook, which are not yet attacked by another rook, equals the index of the block to which $n+1-i$ belongs.

OUTPUT: list of coordinates

See also

- *to_rook_placement()*
- *SetPartitions.from_rook_placement()*
- *SetPartitions.from_rook_placement_gamma()*

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_gamma()
[(1, 3), (2, 7), (4, 5), (5, 6), (6, 9)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_rook_placement_gamma()
[(1, 3), (2, 7), (4, 5), (5, 6), (6, 9)]
```

Figure 5 in [WW1991]:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: r = P.to_rook_placement_gamma(); r
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> r = P.to_rook_placement_gamma(); r
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

to_rook_placement_psi()

Return the rook diagram obtained by placing rooks according to Yip's bijection psi.

OUTPUT: list of coordinates

See also

- *to_rook_placement()*
- *SetPartitions.from_rook_placement()*
- *SetPartitions.from_rook_placement_psi()*

EXAMPLES:

Example 36 (arXiv version: Example 4.5) in [Yip2018]:

```
sage: P = SetPartition([[1, 5], [2], [3, 8, 9], [4], [6, 7]])
sage: P.to_rook_placement_psi()
[(1, 7), (3, 8), (4, 5), (7, 9)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1), Integer(5)], [Integer(2)], [Integer(3),␣
↪Integer(8), Integer(9)], [Integer(4)], [Integer(6), Integer(7)]])
>>> P.to_rook_placement_psi()
[(1, 7), (3, 8), (4, 5), (7, 9)]
```

Note that the columns corresponding to the minimal elements of the blocks remain empty.

to_rook_placement_rho()

Return the rook diagram obtained by placing rooks according to Wachs and White's bijection rho.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i-th column from the right and the j-th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the top row. The columns corresponding to the closers of the set partition remain empty. Let rs_j be the number of closers which are larger than j and whose block is before the block of j.

We then place a rook into row j, such that the number of cells to the left of the rook, which are not yet attacked by another rook and are not in a column corresponding to a closer, equals rs_j, unless there are not enough cells in this row available, in which case the row remains empty.

One can show that the precisely those rows which correspond to openers of the set partition remain empty.

OUTPUT: list of coordinates

See also

- *to_rook_placement()*
- *SetPartitions.from_rook_placement()*
- *SetPartitions.from_rook_placement_rho()*

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_rho()
[(1, 5), (2, 6), (3, 4), (5, 9), (6, 8)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_rook_placement_rho()
[(1, 5), (2, 6), (3, 4), (5, 9), (6, 8)]
```

Figure 6 in [WW1991]:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: r = P.to_rook_placement_rho(); r
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]

sage: sorted(P.closers() + [i for i, _ in r]) == list(range(1,14))
True
sage: sorted(P.openers() + [j for _, j in r]) == list(range(1,14))
True
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> r = P.to_rook_placement_rho(); r
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]

>>> sorted(P.closers() + [i for i, _ in r]) == list(range(Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(14)))
True
>>> sorted(P.openers() + [j for _, j in r]) == list(range(Integer(1),
↪Integer(14)))
True
```

class sage.combinat.set_partition.**SetPartitions**

Bases: UniqueRepresentation, Parent

An (unordered) partition of a set S is a set of pairwise disjoint nonempty subsets with union S, and is represented by a sorted list of such subsets.

`SetPartitions(s)` returns the class of all set partitions of the set `s`, which can be given as a set or a string; if a string, each character is considered an element.

`SetPartitions(n)`, where `n` is an integer, returns the class of all set partitions of the set $\{1, 2, \ldots, n\}$.

You may specify a second argument k. If k is an integer, *SetPartitions* returns the class of set partitions into k parts; if it is an integer partition, *SetPartitions* returns the class of set partitions whose block sizes correspond to that integer partition.

The Bell number B_n, named in honor of Eric Temple Bell, is the number of different partitions of a set with n elements.

EXAMPLES:

```
sage: S = [1,2,3,4]
sage: SetPartitions(S, 2)
Set partitions of {1, 2, 3, 4} with 2 parts
sage: SetPartitions([1,2,3,4], [3,1]).list()                                #␣
↪needs sage.graphs sage.rings.finite_rings
[{{1}, {2, 3, 4}}, {{1, 2, 3}, {4}}, {{1, 2, 4}, {3}}, {{1, 3, 4}, {2}}]
sage: SetPartitions(7, [3,3,1]).cardinality()                               #␣
↪needs sage.libs.flint
70
```

```
>>> from sage.all import *
>>> S = [Integer(1),Integer(2),Integer(3),Integer(4)]
>>> SetPartitions(S, Integer(2))
Set partitions of {1, 2, 3, 4} with 2 parts
>>> SetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)], [Integer(3),
↪Integer(1)]).list()                                    # needs sage.graphs sage.
↪rings.finite_rings
[{{1}, {2, 3, 4}}, {{1, 2, 3}, {4}}, {{1, 2, 4}, {3}}, {{1, 3, 4}, {2}}]
>>> SetPartitions(Integer(7), [Integer(3),Integer(3),Integer(1)]).cardinality()  ␣
↪                                  # needs sage.libs.flint
70
```

In strings, repeated letters are not considered distinct as of Issue #14140:

```
sage: SetPartitions('abcde').cardinality()                                  #␣
↪needs sage.libs.flint
52
sage: SetPartitions('aabcd').cardinality()                                  #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.libs.flint
15
```

```
>>> from sage.all import *
>>> SetPartitions('abcde').cardinality()                                    #␣
↪needs sage.libs.flint
52
>>> SetPartitions('aabcd').cardinality()                                    #␣
↪needs sage.libs.flint
15
```

If the number of parts exceeds the length of the set, an empty iterator is returned (Issue #37643):

```
sage: SetPartitions(range(3), 4).list()
[]
sage: SetPartitions('abcd', 6).list()
[]
```

```
>>> from sage.all import *
>>> SetPartitions(range(Integer(3)), Integer(4)).list()
[]
>>> SetPartitions('abcd', Integer(6)).list()
[]
```

Element

alias of *SetPartition*

from_arcs(*arcs*, *n*)

Return the coarsest set partition of $\{1, \ldots, n\}$ such that any two elements connected by an arc are in the same block.

INPUT:

- `n` – integer specifying the size of the set partition to be produced
- `arcs` – list of pairs specifying which elements are in the same block

See also

- *from_rook_placement()*
- *SetPartition.to_rook_placement()*
- *SetPartition.arcs()*

EXAMPLES:

```
sage: SetPartitions().from_arcs([(2,3)], 5)
{{1}, {2, 3}, {4}, {5}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_arcs([(Integer(2),Integer(3))], Integer(5))
{{1}, {2, 3}, {4}, {5}}
```

from_restricted_growth_word(*w*, *bijection='blocks'*)

Convert a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, ..., n\}$.

INPUT:

- `w` – a restricted growth word
- `bijection` – (default: `blocks`) defines the map from restricted growth functions to set partitions. These are currently:
  - `blocks`: .
  - `intertwining`: *from_restricted_growth_word_intertwining()*.

OUTPUT: a set partition

See also

SetPartition.to_restricted_growth_word()

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word([0, 1, 2, 0, 2, 2, 3, 1, 2])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

sage: SetPartitions().from_restricted_growth_word([0, 0, 1, 0, 2, 2, 0, 3, 1,␣
↪2, 2, 4, 2])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}

sage: SetPartitions().from_restricted_growth_word([0, 0, 1, 0, 2, 2, 0, 3, 1,␣
↪2, 2, 4, 2], "intertwining")
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_restricted_growth_word([Integer(0), Integer(1),␣
↪Integer(2), Integer(0), Integer(2), Integer(2), Integer(3), Integer(1),␣
↪Integer(2)])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

>>> SetPartitions().from_restricted_growth_word([Integer(0), Integer(0),␣
↪Integer(1), Integer(0), Integer(2), Integer(2), Integer(0), Integer(3),␣
↪Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}

>>> SetPartitions().from_restricted_growth_word([Integer(0), Integer(0),␣
↪Integer(1), Integer(0), Integer(2), Integer(2), Integer(0), Integer(3),␣
↪Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)], "intertwining")
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

from_restricted_growth_word_blocks(*w*)

Convert a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, ..., n\}$.

`w[i]` is the index of the block containing `i+1` when sorting the blocks by their minimal element.

INPUT:

- `w` – a restricted growth word

OUTPUT: a set partition

See also

from_restricted_growth_word() SetPartition.to_restricted_growth_word()

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word_blocks([0, 0, 1, 0, 2, 2, 0,
↪ 3, 1, 2, 2, 4, 2])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_restricted_growth_word_blocks([Integer(0),␣
↪Integer(0), Integer(1), Integer(0), Integer(2), Integer(2), Integer(0),␣
↪Integer(3), Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_restricted_growth_word_intertwining(*w*)

Convert a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, ..., n\}$.

The i-th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at i, with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

INPUT:

- `w` – a restricted growth word

OUTPUT: a set partition

See also

from_restricted_growth_word() SetPartition.to_restricted_growth_word()

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word_intertwining([0, 0, 1, 0, 2,
↪ 2, 0, 3, 1, 2, 2, 4, 2])
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_restricted_growth_word_intertwining([Integer(0),␣
↪Integer(0), Integer(1), Integer(0), Integer(2), Integer(2), Integer(0),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(3), Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)])
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

from_rook_placement(*rooks*, *bijection='arcs'*, *n=None*)

Convert a rook placement of the triangular grid to a set partition of $\{1, ..., n\}$.

If `n` is not given, it is first checked whether it can be determined from the parent, otherwise it is the maximal occurring integer in the set of rooks.

INPUT:

- `rooks` – list of pairs (i, j) satisfying $0 < i < j < n + 1$
- `bijection` – (default: `arcs`) defines the map from rook placements to set partitions. These are currently:
  - `arcs`: *from_arcs()*.
  - `gamma`: *from_rook_placement_gamma()*.
  - `rho`: *from_rook_placement_rho()*.
  - `psi`: *from_rook_placement_psi()*.
- `n` – (optional) the size of the ground set

See also

SetPartition.to_rook_placement()

EXAMPLES:

```
sage: SetPartitions(9).from_rook_placement([[1,4],[2,8],[3,5],[5,6],[6,9]])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

sage: SetPartitions(13).from_rook_placement([[12,13],[10,12],[8,9],[7,11],[5,
↪8],[4,6],[3,5],[1,4]], "gamma")
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(9)).from_rook_placement([[Integer(1),Integer(4)],
↪[Integer(2),Integer(8)],[Integer(3),Integer(5)],[Integer(5),Integer(6)],
↪[Integer(6),Integer(9)]])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

>>> SetPartitions(Integer(13)).from_rook_placement([[Integer(12),Integer(13)],
↪[Integer(10),Integer(12)],[Integer(8),Integer(9)],[Integer(7),Integer(11)],
↪[Integer(5),Integer(8)],[Integer(4),Integer(6)],[Integer(3),Integer(5)],
↪[Integer(1),Integer(4)]], "gamma")
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_rook_placement_gamma(*rooks*, *n*)

Return the set partition of $\{1, ..., n\}$ corresponding to the given rook placement by applying Wachs and White's bijection gamma.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i-th column from the right and the j-th row from the top.

INPUT:

- `n` – integer specifying the size of the set partition to be produced
- `rooks` – list of pairs (i, j) such that $0 < i < j < n + 1$

OUTPUT: a set partition

See also

- *from_rook_placement()*
- *SetPartition.to_rook_placement()*
- *SetPartition.to_rook_placement_gamma()*

EXAMPLES:

Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12,␣
↪13)]
```

```
>>> from sage.all import *
>>> r = [(Integer(1), Integer(4)), (Integer(3), Integer(5)), (Integer(4),␣
↪Integer(6)), (Integer(5), Integer(8)), (Integer(7), Integer(11)),␣
↪(Integer(8), Integer(9)), (Integer(10), Integer(12)), (Integer(12),␣
↪Integer(13))]
```

Note that the rook $(1, 4)$, translated into Wachs and White's convention, is a rook in row 4 from the top and column 13 from the left. The corresponding set partition is:

```
sage: SetPartitions().from_rook_placement_gamma(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_rook_placement_gamma(r, Integer(13))
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_rook_placement_psi(*rooks*, *n*)

Return the set partition of $\{1, ..., n\}$ corresponding to the given rook placement by applying Yip's bijection psi.

INPUT:

- `n` – integer specifying the size of the set partition to be produced
- `rooks` – list of pairs (i, j) such that $0 < i < j < n + 1$

OUTPUT: a set partition

See also

- *from_rook_placement()*
- *SetPartition.to_rook_placement()*
- *SetPartition.to_rook_placement_psi()*

EXAMPLES:

Example 36 (arXiv version: Example 4.5) in [Yip2018] concerns the following rook placement:

```
sage: r = [(4,5), (1,7), (3, 8), (7,9)]
sage: SetPartitions().from_rook_placement_psi(r, 9)
{{1, 5}, {2}, {3, 8, 9}, {4}, {6, 7}}
```

```
>>> from sage.all import *
>>> r = [(Integer(4),Integer(5)), (Integer(1),Integer(7)), (Integer(3),␣
↪Integer(8)), (Integer(7),Integer(9))]
>>> SetPartitions().from_rook_placement_psi(r, Integer(9))
{{1, 5}, {2}, {3, 8, 9}, {4}, {6, 7}}
```

from_rook_placement_rho(*rooks*, *n*)

Return the set partition of $\{1, ..., n\}$ corresponding to the given rook placement by applying Wachs and White's bijection rho.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i-th column from the right and the j-th row from the top.

INPUT:

- `n` – integer specifying the size of the set partition to be produced
- `rooks` – list of pairs (i, j) such that $0 < i < j < n + 1$

OUTPUT: a set partition

See also

- *from_rook_placement()*
- *SetPartition.to_rook_placement()*
- *SetPartition.to_rook_placement_rho()*

EXAMPLES:

Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11,␣
↪13)]
```

```
>>> from sage.all import *
>>> r = [(Integer(1), Integer(2)), (Integer(2), Integer(6)), (Integer(3),␣
↪Integer(4)), (Integer(4), Integer(10)), (Integer(5), Integer(9)),␣
```

(continues on next page)

(continued from previous page)

```
↪(Integer(6), Integer(7)), (Integer(10), Integer(11)), (Integer(11),␣
↪Integer(13))]
```

Note that the rook $(1, 2)$, translated into Wachs and White's convention, is a rook in row 2 from the top and column 13 from the left. The corresponding set partition is:

```
sage: SetPartitions().from_rook_placement_rho(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_rook_placement_rho(r, Integer(13))
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

is_less_than(s, t)

Check if $s < t$ in the refinement ordering on set partitions.

This means that s is a refinement of t and satisfies $s \neq t$.

A set partition s is said to be a refinement of a set partition t of the same set if and only if each part of s is a subset of a part of t.

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1,3],[2,4]])
sage: t = S([[1],[2],[3],[4]])
sage: S.is_less_than(t, s)
True
sage: S.is_less_than(s, t)
False
sage: S.is_less_than(s, s)
False
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> t = S([[Integer(1)],[Integer(2)],[Integer(3)],[Integer(4)]])
>>> S.is_less_than(t, s)
True
>>> S.is_less_than(s, t)
False
>>> S.is_less_than(s, s)
False
```

is_strict_refinement(s, t)

Return `True` if `s` is a strict refinement of `t` and satisfies $s \neq t$.

A set partition s is said to be a strict refinement of a set partition t of the same set if and only if one can obtain t from s by repeatedly combining pairs of parts whose convex hulls don't intersect (i. e., whenever we are combining two parts, the maximum of each of them should be smaller than the minimum of the other).

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1],[2],[3],[4]])
sage: t = S([[1,3],[2,4]])
sage: u = S([[1,2,3,4]])
sage: S.is_strict_refinement(s, t)
True
sage: S.is_strict_refinement(t, u)
False
sage: A = SetPartition([[1,3],[2,4]])
sage: B = SetPartition([[1,2,3,4]])
sage: S.is_strict_refinement(s, A)
True
sage: S.is_strict_refinement(t, B)
False
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1)],[Integer(2)],[Integer(3)],[Integer(4)]])
>>> t = S([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> u = S([[Integer(1),Integer(2),Integer(3),Integer(4)]])
>>> S.is_strict_refinement(s, t)
True
>>> S.is_strict_refinement(t, u)
False
>>> A = SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> B = SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]])
>>> S.is_strict_refinement(s, A)
True
>>> S.is_strict_refinement(t, B)
False
```

lt(*s*, *t*)

alias of *is_less_than()*.

class sage.combinat.set_partition.**SetPartitions_all**

Bases: *SetPartitions*

All set partitions.

subset(*size=None*, ***kwargs*)

Return the subset of set partitions of a given size and additional keyword arguments.

EXAMPLES:

```
sage: P = SetPartitions()
sage: P.subset(4)
Set partitions of {1, 2, 3, 4}
```

```
>>> from sage.all import *
>>> P = SetPartitions()
>>> P.subset(Integer(4))
Set partitions of {1, 2, 3, 4}
```

class sage.combinat.set_partition.**SetPartitions_set**(*s*)

Bases: *SetPartitions*

Set partitions of a fixed set S.

base_set()

Return the base set of `self`.

EXAMPLES:

```
sage: SetPartitions(3).base_set()
{1, 2, 3}

sage: sorted(SetPartitions(["a", "b", "c"]).base_set())
['a', 'b', 'c']
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3)).base_set()
{1, 2, 3}

>>> sorted(SetPartitions(["a", "b", "c"]).base_set())
['a', 'b', 'c']
```

base_set_cardinality()

Return the cardinality of the base set of `self`.

EXAMPLES:

```
sage: SetPartitions(3).base_set_cardinality()
3
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3)).base_set_cardinality()
3
```

cardinality()

Return the number of set partitions of the set S.

The cardinality is given by the n-th Bell number where n is the number of elements in the set S.

EXAMPLES:

```
sage: # needs sage.libs.flint
sage: SetPartitions([1,2,3,4]).cardinality()
15
sage: SetPartitions(3).cardinality()
5
sage: SetPartitions(3,2).cardinality()
3
sage: SetPartitions([]).cardinality()
1
```

```
>>> from sage.all import *
>>> # needs sage.libs.flint
>>> SetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)]).cardinality()
```

(continues on next page)

(continued from previous page)

```
15
>>> SetPartitions(Integer(3)).cardinality()
5
>>> SetPartitions(Integer(3),Integer(2)).cardinality()
3
>>> SetPartitions([]).cardinality()
1
```

random_element()

Return a random set partition.

This is a very naive implementation of Knuths outline in F3B, 7.2.1.5.

EXAMPLES:

```
sage: S = SetPartitions(10)
sage: s = S.random_element()                                                #␣
↪needs sage.symbolic
sage: s.parent() is S                                                       #␣
↪needs sage.symbolic
True
sage: assert s in S, s                                                      #␣
↪needs sage.symbolic

sage: S = SetPartitions(["a", "b", "c"])
sage: s = S.random_element()                                                #␣
↪needs sage.symbolic
sage: s.parent() is S                                                       #␣
↪needs sage.symbolic
True
sage: assert s in S, s                                                      #␣
↪needs sage.symbolic
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(10))
>>> s = S.random_element()                                                  #␣
↪needs sage.symbolic
>>> s.parent() is S                                                         #␣
↪needs sage.symbolic
True
>>> assert s in S, s                                                        #␣
↪needs sage.symbolic

>>> S = SetPartitions(["a", "b", "c"])
>>> s = S.random_element()                                                  #␣
↪needs sage.symbolic
>>> s.parent() is S                                                         #␣
↪needs sage.symbolic
True
>>> assert s in S, s                                                        #␣
↪needs sage.symbolic
```

class sage.combinat.set_partition.**SetPartitions_setn**(s, k)

Bases: *SetPartitions_set*

Set partitions with a given number of blocks.

cardinality()

The Stirling number of the second kind is the number of partitions of a set of size n into k blocks.

EXAMPLES:

```
sage: SetPartitions(5, 3).cardinality()
25
sage: stirling_number2(5,3)
25
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(5), Integer(3)).cardinality()
25
>>> stirling_number2(Integer(5),Integer(3))
25
```

number_of_blocks()

Return the number of blocks of the set partitions in `self`.

EXAMPLES:

```
sage: SetPartitions(5, 3).number_of_blocks()
3
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(5), Integer(3)).number_of_blocks()
3
```

random_element()

Return a random set partition of `self`.

See https://mathoverflow.net/questions/141999.

EXAMPLES:

```
sage: S = SetPartitions(10, 4)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s

sage: S = SetPartitions(["a", "b", "c"], 2)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(10), Integer(4))
>>> s = S.random_element()
>>> s.parent() is S
```

(continues on next page)

(continued from previous page)

```
True
>>> assert s in S, s

>>> S = SetPartitions(["a", "b", "c"], Integer(2))
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s
```

class sage.combinat.set_partition.**SetPartitions_setparts**(*s*, *parts*)

Bases: *SetPartitions_set*

Set partitions with fixed partition sizes corresponding to an integer partition λ.

cardinality()

Return the cardinality of `self`.

This algorithm counts for each block of the partition the number of ways to fill it using values from the set. Then, for each distinct value v of block size, we divide the result by the number of ways to arrange the blocks of size v in the set partition.

For example, if we want to count the number of set partitions of size 13 having [3,3,3,2,2] as underlying partition we compute the number of ways to fill each block of the partition, which is $\binom{13}{3}\binom{10}{3}\binom{7}{3}\binom{4}{2}\binom{2}{2}$ and as we have three blocks of size 3 and two blocks of size 2, we divide the result by 3!2! which gives us 600600.

EXAMPLES:

```
sage: SetPartitions(3, [2,1]).cardinality()
3
sage: SetPartitions(13, Partition([3,3,3,2,2])).cardinality()
600600
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3), [Integer(2),Integer(1)]).cardinality()
3
>>> SetPartitions(Integer(13), Partition([Integer(3),Integer(3),Integer(3),
↪Integer(2),Integer(2)])).cardinality()
600600
```

random_element()

Return a random set partition of `self`.

ALGORITHM:

Based on the cardinality method. For each block size k_i, we choose a uniformly random subset $X_i \subseteq S_i$ of size k_i of the elements S_i that have not yet been selected. Thus, we define $S_{i+1} = S_i \setminus X_i$ with $S_i = S$ being the defining set. This is not yet proven to be uniformly distributed, but numerical tests show this is likely uniform.

EXAMPLES:

```
sage: S = SetPartitions(10, [4,3,2,1])
sage: s = S.random_element()
sage: s.parent() is S
True
```

(continues on next page)

(continued from previous page)

```
sage: assert s in S, s

sage: S = SetPartitions(["a", "b", "c", "d"], [2,2])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(10), [Integer(4),Integer(3),Integer(2),
↪Integer(1)])
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s

>>> S = SetPartitions(["a", "b", "c", "d"], [Integer(2),Integer(2)])
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s
```

shape()

Return the partition of block sizes of the set partitions in `self`.

EXAMPLES:

```
sage: SetPartitions(5, [2,2,1]).shape()
[2, 2, 1]
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(5), [Integer(2),Integer(2),Integer(1)]).shape()
[2, 2, 1]
```

sage.combinat.set_partition.**cyclic_permutations_of_set_partition**(*set_part*)

Return all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition
sage: cyclic_permutations_of_set_partition([[1,2,3,4],[5,6,7]])
[[(1, 2, 3, 4), (5, 6, 7)],
 [(1, 2, 4, 3), (5, 6, 7)],
 [(1, 3, 2, 4), (5, 6, 7)],
 [(1, 3, 4, 2), (5, 6, 7)],
 [(1, 4, 2, 3), (5, 6, 7)],
 [(1, 4, 3, 2), (5, 6, 7)],
 [(1, 2, 3, 4), (5, 7, 6)],
 [(1, 2, 4, 3), (5, 7, 6)],
```

(continues on next page)

(continued from previous page)

```
 [(1, 3, 2, 4), (5, 7, 6)],
 [(1, 3, 4, 2), (5, 7, 6)],
 [(1, 4, 2, 3), (5, 7, 6)],
 [(1, 4, 3, 2), (5, 7, 6)]]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition import cyclic_permutations_of_set_partition
>>> cyclic_permutations_of_set_partition([[Integer(1),Integer(2),Integer(3),
↪Integer(4)],[Integer(5),Integer(6),Integer(7)]])
[[(1, 2, 3, 4), (5, 6, 7)],
 [(1, 2, 4, 3), (5, 6, 7)],
 [(1, 3, 2, 4), (5, 6, 7)],
 [(1, 3, 4, 2), (5, 6, 7)],
 [(1, 4, 2, 3), (5, 6, 7)],
 [(1, 4, 3, 2), (5, 6, 7)],
 [(1, 2, 3, 4), (5, 7, 6)],
 [(1, 2, 4, 3), (5, 7, 6)],
 [(1, 3, 2, 4), (5, 7, 6)],
 [(1, 3, 4, 2), (5, 7, 6)],
 [(1, 4, 2, 3), (5, 7, 6)],
 [(1, 4, 3, 2), (5, 7, 6)]]
```

sage.combinat.set_partition.**cyclic_permutations_of_set_partition_iterator**(*set_part*)

Iterate over all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_
↪partition_iterator
sage: list(cyclic_permutations_of_set_partition_iterator([[1,2,3,4],[5,6,7]]))
[[(1, 2, 3, 4), (5, 6, 7)],
 [(1, 2, 4, 3), (5, 6, 7)],
 [(1, 3, 2, 4), (5, 6, 7)],
 [(1, 3, 4, 2), (5, 6, 7)],
 [(1, 4, 2, 3), (5, 6, 7)],
 [(1, 4, 3, 2), (5, 6, 7)],
 [(1, 2, 3, 4), (5, 7, 6)],
 [(1, 2, 4, 3), (5, 7, 6)],
 [(1, 3, 2, 4), (5, 7, 6)],
 [(1, 3, 4, 2), (5, 7, 6)],
 [(1, 4, 2, 3), (5, 7, 6)],
 [(1, 4, 3, 2), (5, 7, 6)]]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition import cyclic_permutations_of_set_partition_
↪iterator
>>> list(cyclic_permutations_of_set_partition_iterator([[Integer(1),Integer(2),
↪Integer(3),Integer(4)],[Integer(5),Integer(6),Integer(7)]]))
[[(1, 2, 3, 4), (5, 6, 7)],
```

(continues on next page)

(continued from previous page)

```
 [(1, 2, 4, 3), (5, 6, 7)],
 [(1, 3, 2, 4), (5, 6, 7)],
 [(1, 3, 4, 2), (5, 6, 7)],
 [(1, 4, 2, 3), (5, 6, 7)],
 [(1, 4, 3, 2), (5, 6, 7)],
 [(1, 2, 3, 4), (5, 7, 6)],
 [(1, 2, 4, 3), (5, 7, 6)],
 [(1, 3, 2, 4), (5, 7, 6)],
 [(1, 3, 4, 2), (5, 7, 6)],
 [(1, 4, 2, 3), (5, 7, 6)],
 [(1, 4, 3, 2), (5, 7, 6)]]
```

Shard intersection order

This file builds a combinatorial version of the shard intersection order of type A (in the classification of finite Coxeter groups). This is a lattice on the set of permutations, closely related to noncrossing partitions and the weak order.

For technical reasons, the elements of the posets are not permutations, but can be easily converted from and to permutations:

```
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

```
>>> from sage.all import *
>>> from sage.combinat.shard_order import ShardPosetElement
>>> p0 = Permutation([Integer(1),Integer(3),Integer(4),Integer(2)])
>>> e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
>>> Permutation(list(e0)) == p0
True
```

See also

A general implementation for all finite Coxeter groups is available as `shard_poset()`

class sage.combinat.shard_order.**ShardPosetElement**(*p*)

Bases: `tuple`

An element of the shard poset.

This is basically a permutation with extra stored arguments:

- `p` – the permutation itself as a tuple
- `runs` – the decreasing runs as a tuple of tuples
- `run_indices` – list; `integer -> index of the run`
- `dpg` – the transitive closure of the shard preorder graph
- `spg` – the transitive reduction of the shard preorder graph

These elements can easily be converted from and to permutations:

```
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

```
>>> from sage.all import *
>>> from sage.combinat.shard_order import ShardPosetElement
>>> p0 = Permutation([Integer(1),Integer(3),Integer(4),Integer(2)])
>>> e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
>>> Permutation(list(e0)) == p0
True
```

sage.combinat.shard_order.**shard_poset**(n)

Return the shard intersection order on permutations of size n.

This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the descending runs and their relative positions.

The shard intersection order is given by the implication (or refinement) order on the set of pre-orders defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension n. The shard poset is given by the inclusion of these cones.

See also

shard_preorder_graph()

EXAMPLES:

```
sage: P = posets.ShardPoset(4); P  # indirect doctest
Finite poset containing 24 elements
sage: P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
sage: P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
sage: P.is_self_dual()
False
```

```
>>> from sage.all import *
>>> P = posets.ShardPoset(Integer(4)); P  # indirect doctest
Finite poset containing 24 elements
>>> P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
>>> P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
```

(continues on next page)

(continued from previous page)

```
>>> P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
>>> P.is_self_dual()
False
```

sage.combinat.shard_order.**shard_preorder_graph**(*runs*)

Return the preorder attached to a tuple of decreasing runs.

This is a directed graph, whose vertices correspond to the runs.

There is an edge from a run R to a run S if R is before S in the list of runs and the two intervals defined by the initial and final indices of R and S overlap.

This only depends on the initial and final indices of the runs. For this reason, this input can also be given in that shorten way.

INPUT:

- `runs` – either
  - a tuple of tuples, the runs of a permutation, or
  - a tuple of pairs (i, j), each one standing for a run from i to j

OUTPUT: a directed graph, with vertices labelled by integers

EXAMPLES:

```
sage: from sage.combinat.shard_order import shard_preorder_graph
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
sage: def cut(lr):
....:     return tuple((r[0], r[-1]) for r in lr)
sage: shard_preorder_graph(cut(s.decreasing_runs()))
Digraph on 5 vertices
sage: s = Permutation([9,4,3,2,8,6,5,1,7])
sage: P = shard_preorder_graph(s.decreasing_runs())
sage: P.is_isomorphic(digraphs.TransitiveTournament(3))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.shard_order import shard_preorder_graph
>>> s = Permutation([Integer(2),Integer(8),Integer(3),Integer(9),Integer(6),
↪Integer(4),Integer(5),Integer(1),Integer(7)])
>>> def cut(lr):
...     return tuple((r[Integer(0)], r[-Integer(1)]) for r in lr)
>>> shard_preorder_graph(cut(s.decreasing_runs()))
Digraph on 5 vertices
>>> s = Permutation([Integer(9),Integer(4),Integer(3),Integer(2),Integer(8),
↪Integer(6),Integer(5),Integer(1),Integer(7)])
>>> P = shard_preorder_graph(s.decreasing_runs())
>>> P.is_isomorphic(digraphs.TransitiveTournament(Integer(3)))
True
```

Shifted primed tableaux

AUTHORS:

- Kirill Paramonov (2017-08-18): initial implementation
- Chaman Agrawal (2019-08-12): add parameter to allow primed diagonal entry

class sage.combinat.shifted_primed_tableau.**CrystalElementShiftedPrimedTableau**(*parent*, *T*, *skew=None*, *check=True*, *preprocessed=False*)

Bases: *ShiftedPrimedTableau*

Class for elements of `crystals.ShiftedPrimedTableaux`.

e(*ind*)

Compute the action of the crystal operator e_i on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

- `ind` – an element in the index set of the crystal

OUTPUT: primed tableau or `None`

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,'2p','3p'], [2,'3p',3,3],[3,4]])
sage: t.pp()
1  1  1  2' 3'
   2  3' 3  3
      3  4
sage: s = t.e(2)
sage: s.pp()
1  1  1  2' 3'
   2  2  3  3
      3  4
sage: t == s.f(2)
True

sage: SPT = ShiftedPrimedTableaux([2,1])
sage: t = SPT([[2,'3p'],[3]])
sage: t.e(-1).pp()
1  3'
   3
sage: t.e(1).pp()
1  3'
   3
sage: t.e(2).pp()
2  2
   3

sage: r = SPT([[2, 2],[3]])
sage: r.e(-1).pp()
1  2
```

(continues on next page)

f(*ind*)

Compute the action of the crystal operator f_i on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

- `ind` – element in the index set of the crystal

OUTPUT: primed tableau or `None`

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,1,'3p'],[2,2,2,'3p'],[3,3]])
sage: t.pp()
1  1  1  1  3'
   2  2  2  3'
      3  3
sage: s = t.f(2)
sage: s is None
True

sage: t = SPT([[1,1,1,'2p','3p'],[2,2,3,3],[3,4]])
sage: t.pp()
1  1  1  2' 3'
   2  2  3  3
      3  4
sage: s = t.f(2)
sage: s.pp()
1  1  1  2' 3'
   2  3' 3  3
      3  4

sage: SPT = ShiftedPrimedTableaux([2,1])
sage: t = SPT([[1,1],[2]])
sage: t.f(-1).pp()
1  2'
```

↪is None
True
```

is_highest_weight(*index_set=None*)

Return whether `self` is a highest weight element of the crystal.

An element is highest weight if it vanishes under all crystal operators e_i.

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([(1, 1, 1, 1, 1), (2, 2, 2, "3p"), (3, 3)])
sage: t.is_highest_weight()
True

sage: SPT = ShiftedPrimedTableaux([5,4])
sage: s = SPT([(1, 1, 1, 1, 1), (2, 2, "3p", 3)])
sage: s.is_highest_weight(index_set=[1])
True
```

```
>>> from sage.all import *
>>> SPT = ShiftedPrimedTableaux([Integer(5),Integer(4),Integer(2)])
>>> t = SPT([(Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)),␣
↪(Integer(2), Integer(2), Integer(2), "3p"), (Integer(3), Integer(3))])
>>> t.is_highest_weight()
True

>>> SPT = ShiftedPrimedTableaux([Integer(5),Integer(4)])
>>> s = SPT([(Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)),␣
↪(Integer(2), Integer(2), "3p", Integer(3))])
>>> s.is_highest_weight(index_set=[Integer(1)])
True
```

reading_word()

Return the reading word of `self`.

The reading word of a shifted primed tableau is constructed as follows:

1. List all primed entries in the tableau, column by column, in decreasing order within each column, moving from the rightmost column to the left, and with all the primes removed (i.e. all entries are increased by half a unit).
2. Then list all unprimed entries, row by row, in increasing order within each row, moving from the bottommost row to the top.

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([4,2])
sage: t = SPT([[1,'2p',2,2],[2,'3p']])
sage: t.reading_word()
[3, 2, 2, 1, 2, 2]
```

```
>>> from sage.all import *
>>> SPT = ShiftedPrimedTableaux([Integer(4),Integer(2)])
>>> t = SPT([[Integer(1),'2p',Integer(2),Integer(2)],[Integer(2),'3p']])
>>> t.reading_word()
[3, 2, 2, 1, 2, 2]
```

weight()

Return the weight of `self`.

The weight of a shifted primed tableau is defined to be the vector with i-th component equal to the number of entries i and i' in the tableau.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.weight()
(1, 4, 1)
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1),'2p',Integer(2),Integer(2)],
↪[Integer(2),'3p']])
>>> t.weight()
(1, 4, 1)
```

class sage.combinat.shifted_primed_tableau.**PrimedEntry**(*entry=None*, *double=None*)

Bases: SageObject

The class of entries in shifted primed tableaux.

An entry in a shifted primed tableau is an element in the alphabet $\{1' < 1 < 2' < 2 < \cdots < n' < n\}$. The difference between two elements i and $i-1$ counts as a whole unit, whereas the difference between i and i' counts as half a unit. Internally, we represent an unprimed element x as $2x$ and the primed elements as the corresponding odd integer that respects the total order.

INPUT:

- `entry` – half integer or string of an integer possibly ending in `p` or `'`
- `double` – the doubled value

decrease_half()

Decrease `self` by half a unit.

decrease_one()

Decrease `self` by one unit.

increase_half()

Increase `self` by half a unit.

increase_one()

Increase `self` by one unit.

integer()

Return the corresponding integer i for primed entries of the form i or i'.

is_primed()

Check if `self` is a primed element.

is_unprimed()

Check if `self` is an unprimed element.

primed()

Prime `self` if it is an unprimed element.

unprimed()

Unprime `self` if it is a primed element.

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableau**(*parent*, *T*, *skew=None*, *check=True*, *preprocessed=False*)

Bases: `ClonableArray`

A shifted primed tableau.

A primed tableau is a tableau of shifted shape in the alphabet $X' = \{1' < 1 < 2' < 2 < \cdots < n' < n\}$ such that

1. the entries are weakly increasing along rows and columns;
2. a row cannot have two repeated primed elements, and a column cannot have two repeated non-primed elements;

Skew shape of the shifted primed tableaux is specified either with an optional argument `skew` or with `None` entries.

Primed entries in the main diagonal can be allowed with the optional boolean parameter `primed_diagonal``(default: ``False`).

EXAMPLES:

```
sage: T = ShiftedPrimedTableaux([4,2])
sage: T([[1,"2'","3'",3],[2,"3'"]])[1]
(2, 3')
sage: t = ShiftedPrimedTableau([[1,"2p",2.5,3],[2,2.5]])
sage: t[1]
(2, 3')
sage: ShiftedPrimedTableau([["2p",2,3],["2p","3p"],[2]], skew=[2,1])
[(None, None, 2', 2, 3), (None, 2', 3'), (2,)]
sage: ShiftedPrimedTableau([[None,None,"2p"],[None,"2p"]])
[(None, None, 2'), (None, 2')]
sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: T([[1,"2'","3'",3],["2'","3'"]])[1] # With primed diagonal entry
(2', 3')
```

```
>>> from sage.all import *
>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2)])
>>> T([[Integer(1),"2'","3'",Integer(3)],[Integer(2),"3'"]])[Integer(1)]
(2, 3')
>>> t = ShiftedPrimedTableau([[Integer(1),"2p",RealNumber('2.5'),Integer(3)],
↪[Integer(2),RealNumber('2.5')]])
>>> t[Integer(1)]
(2, 3')
```

(continues on next page)

(continued from previous page)

```
>>> ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p","3p"],[Integer(2)]],␣
↪skew=[Integer(2),Integer(1)])
[(None, None, 2', 2, 3), (None, 2', 3'), (2,)]
>>> ShiftedPrimedTableau([[None,None,"2p"],[None,"2p"]])
[(None, None, 2'), (None, 2')]
>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2)], primed_diagonal=True)
>>> T([[Integer(1),"2'","3'",Integer(3)],["2'","3'"]])[Integer(1)] # With primed␣
↪diagonal entry
(2', 3')
```

check()

Check that `self` is a valid primed tableau.

EXAMPLES:

```
sage: T = ShiftedPrimedTableaux([4,2])
sage: t = T([[1,'2p',2,2],[2,'3p']])
sage: t.check()
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"],[2]],skew=[2,1])
sage: s.check()
sage: t = T([['1p','2p',2,2],[2,'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '2p', 2, 2], [2, '3p']] is not an element of
 Shifted Primed Tableaux of shape [4, 2]

sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: t = T([['1p','2p',2,2],[2,'3p']])  # primed_diagonal allowed
sage: t.check()
sage: t = T([['1p','1p',2,2],[2,'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '1p', 2, 2], [2, '3p']] is not an element of
 Shifted Primed Tableaux of shape [4, 2] and maximum entry 6
```

```
>>> from sage.all import *
>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2)])
>>> t = T([[Integer(1),'2p',Integer(2),Integer(2)],[Integer(2),'3p']])
>>> t.check()
>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"],
↪[Integer(2)]],skew=[Integer(2),Integer(1)])
>>> s.check()
>>> t = T([['1p','2p',Integer(2),Integer(2)],[Integer(2),'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '2p', 2, 2], [2, '3p']] is not an element of
 Shifted Primed Tableaux of shape [4, 2]

>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2)], primed_diagonal=True)
>>> t = T([['1p','2p',Integer(2),Integer(2)],[Integer(2),'3p']])  # primed_
↪diagonal allowed
>>> t.check()
```

(continues on next page)

(continued from previous page)

```
>>> t = T([['1p','1p',Integer(2),Integer(2)],[Integer(2),'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '1p', 2, 2], [2, '3p']] is not an element of
 Shifted Primed Tableaux of shape [4, 2] and maximum entry 6
```

is_standard()

Return `True` if the entries of `self` are in bijection with positive primed integers $1', 1, 2', \ldots, n$.

EXAMPLES:

```
sage: ShiftedPrimedTableau([["1'", 1, "2'"], [2, "3'"]],
....:                      primed_diagonal=True).is_standard()
True
sage: ShiftedPrimedTableau([["1'", 1, 2], ["2'", "3'"]],
....:                      primed_diagonal=True).is_standard()
True
sage: ShiftedPrimedTableau([["1'", 1, 1], ["2'", 2]],
....:                      primed_diagonal=True).is_standard()
False
sage: ShiftedPrimedTableau([[1, "2'"], [2]]).is_standard()
False
sage: s = ShiftedPrimedTableau([[None, None,"1p","2p",2],[None,"1"]])
sage: s.is_standard()
True
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableau([["1'", Integer(1), "2'"], [Integer(2), "3'"]],
...                      primed_diagonal=True).is_standard()
True
>>> ShiftedPrimedTableau([["1'", Integer(1), Integer(2)], ["2'", "3'"]],
...                      primed_diagonal=True).is_standard()
True
>>> ShiftedPrimedTableau([["1'", Integer(1), Integer(1)], ["2'", Integer(2)]],
...                      primed_diagonal=True).is_standard()
False
>>> ShiftedPrimedTableau([[Integer(1), "2'"], [Integer(2)]]).is_standard()
False
>>> s = ShiftedPrimedTableau([[None, None,"1p","2p",Integer(2)],[None,"1"]])
>>> s.is_standard()
True
```

max_entry()

Return the minimum unprimed letter $x > y$ for all y in `self`.

EXAMPLES:

```
sage: Tab = ShiftedPrimedTableau([(1,1,'2p','3p'),(2,2)])
sage: Tab.max_entry()
3
```

```
>>> from sage.all import *
>>> Tab = ShiftedPrimedTableau([(Integer(1),Integer(1),'2p','3p'),(Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2))])
>>> Tab.max_entry()
3
```

pp()

Pretty print `self`.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.pp()
1  2' 2  2
   2  3'
sage: t = ShiftedPrimedTableau([[10,'11p',11,11],[11,'12']])
sage: t.pp()
10  11' 11  11
    11  12
sage: s = ShiftedPrimedTableau([['2p',2,3],['2p']],skew=[2,1])
sage: s.pp()
 .  .  2' 2  3
    .  2'
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1),'2p',Integer(2),Integer(2)],
↪[Integer(2),'3p']])
>>> t.pp()
1  2' 2  2
   2  3'
>>> t = ShiftedPrimedTableau([[Integer(10),'11p',Integer(11),Integer(11)],
↪[Integer(11),'12']])
>>> t.pp()
10  11' 11  11
    11  12
>>> s = ShiftedPrimedTableau([['2p',Integer(2),Integer(3)],['2p']],
↪skew=[Integer(2),Integer(1)])
>>> s.pp()
 .  .  2' 2  3
    .  2'
```

restrict(*n*)

Return the restriction of the shifted tableau to all the numbers less than or equal to `n`.

> **Note**
>
> If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method *restriction_outer_shape()* is preferred. Similarly if only the skew shape is needed, use *restriction_shape()*.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.restrict(2).pp()
1  2' 2  2
   2

sage: t.restrict("2p").pp()
1  2'

sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"]], skew=[2,1])
sage: s.restrict(2).pp()
.  .  2' 2
   .  2'
sage: s.restrict(1.5).pp()
.  .  2'
   .  2'
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1),'2p',Integer(2),Integer(2)],
↪[Integer(2),'3p']])
>>> t.restrict(Integer(2)).pp()
1  2' 2  2
   2

>>> t.restrict("2p").pp()
1  2'

>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"]],␣
↪skew=[Integer(2),Integer(1)])
>>> s.restrict(Integer(2)).pp()
.  .  2' 2
   .  2'
>>> s.restrict(RealNumber('1.5')).pp()
.  .  2'
   .  2'
```

restriction_outer_shape(n)

Return the outer shape of the restriction of the shifted tableau `self` to n.

If T is a (skew) shifted tableau and n is a half-integer, then the restriction of T to n is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the outer shape of the restriction. For the restriction itself, use *restrict()*.

EXAMPLES:

```
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"]], skew=[2,1])
sage: s.pp()
.  .  2' 2  3
   .  2'
sage: s.restriction_outer_shape(2)
[4, 2]
sage: s.restriction_outer_shape("2p")
[3, 2]
```

```
>>> from sage.all import *
>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"]],␣
↪skew=[Integer(2),Integer(1)])
>>> s.pp()
.  .  2' 2  3
   .  2'
>>> s.restriction_outer_shape(Integer(2))
[4, 2]
>>> s.restriction_outer_shape("2p")
[3, 2]
```

restriction_shape(*n*)

Return the skew shape of the restriction of the skew tableau `self` to `n`.

If T is a shifted tableau and n is a half-integer, then the restriction of T to n is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the skew shape of the restriction. For the restriction itself, use *restrict()*.

EXAMPLES:

```
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"]], skew=[2,1])
sage: s.pp()
 .  .  2' 2  3
    .  2'

sage: s.restriction_shape(2)
[4, 2] / [2, 1]
```

```
>>> from sage.all import *
>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"]],␣
↪skew=[Integer(2),Integer(1)])
>>> s.pp()
 .  .  2' 2  3
    .  2'

>>> s.restriction_shape(Integer(2))
[4, 2] / [2, 1]
```

shape()

Return the shape of the underlying partition of `self`.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.shape()
[4, 2]
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"]],skew=[2,1])
sage: s.shape()
[5, 2] / [2, 1]
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1),'2p',Integer(2),Integer(2)],
↪[Integer(2),'3p']])
```

(continues on next page)

(continued from previous page)

```
>>> t.shape()
[4, 2]
>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"]],
↪skew=[Integer(2),Integer(1)])
>>> s.shape()
[5, 2] / [2, 1]
```

to_chain()

Return the chain of partitions corresponding to the (skew) shifted tableau `self`, interlaced by one of the colours `1` is the added cell is on the diagonal, `2` if an ordinary entry is added and `3` if a primed entry is added.

EXAMPLES:

```
sage: s = ShiftedPrimedTableau([(1, 2, 3.5, 5, 6.5), (3, 5.5)])
sage: s.pp()
 1  2  4' 5  7'
    3  6'

sage: s.to_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]

sage: s = ShiftedPrimedTableau([(1, 3.5), (2.5,), (6,)], skew=[2,1])
sage: s.pp()
 .  .  1  4'
    .  3'
       6

sage: s.to_chain()
[[2, 1], 2, [3, 1], 0, [3, 1], 3, [3, 2], 3, [4, 2], 0, [4, 2], 1, [4, 2, 1]]
```

```
>>> from sage.all import *
>>> s = ShiftedPrimedTableau([(Integer(1), Integer(2), RealNumber('3.5'),␣
↪Integer(5), RealNumber('6.5')), (Integer(3), RealNumber('5.5'))])
>>> s.pp()
 1  2  4' 5  7'
    3  6'

>>> s.to_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]

>>> s = ShiftedPrimedTableau([(Integer(1), RealNumber('3.5')), (RealNumber('2.
↪5'),), (Integer(6),)], skew=[Integer(2),Integer(1)])
>>> s.pp()
 .  .  1  4'
    .  3'
       6

>>> s.to_chain()
[[2, 1], 2, [3, 1], 0, [3, 1], 3, [3, 2], 3, [4, 2], 0, [4, 2], 1, [4, 2, 1]]
```

weight()

Return the weight of `self`.

The weight of a shifted primed tableau is defined to be the vector with i-th component equal to the number of entries i and i' in the tableau.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([['2p',2,2],[2,'3p']], skew=[1])
sage: t.weight()
(0, 4, 1)
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([['2p',Integer(2),Integer(2)],[Integer(2),'3p']],
↪ skew=[Integer(1)])
>>> t.weight()
(0, 4, 1)
```

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux**(*skew=None*, *primed_diagonal=False*)

Bases: `UniqueRepresentation`, `Parent`

Return the combinatorial class of shifted primed tableaux subject to the constraints given by the arguments.

A primed tableau is a tableau of shifted shape on the alphabet $X' = \{1' < 1 < 2' < 2 < \cdots < n' < n\}$ such that

1. the entries are weakly increasing along rows and columns
2. a row cannot have two repeated primed entries, and a column cannot have two repeated non-primed entries

INPUT:

Valid optional keywords:

- `shape` – the (outer skew) shape of tableaux
- `weight` – the weight of tableaux
- `max_entry` – the maximum entry of tableaux
- `skew` – the inner skew shape of tableaux
- `primed_diagonal` – allow primed entries in main diagonal of tableaux

The weight of a tableau is defined to be the vector with i-th component equal to the number of entries i and i' in the tableau. The sum of the coordinates in the weight vector must be equal to the number of entries in the partition.

The `shape` and `skew` must be strictly decreasing partitions. The `primed_diagonal` is a boolean (default: `False`).

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2]); SPT
Shifted Primed Tableaux of weight (1, 2, 2) and shape [3, 2]
sage: SPT.list()
[[(1, 2, 2), (3, 3)],
 [(1, 2', 3'), (2, 3)],
 [(1, 2', 3'), (2, 3')],
 [(1, 2', 2), (3, 3)]]
sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2],
....:                             primed_diagonal=True); SPT
Shifted Primed Tableaux of weight (1, 2, 2) and shape [3, 2]
```

(continues on next page)

(continued from previous page)

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_all**(*skew=None*, *primed_diagonal=False*)

Bases: *ShiftedPrimedTableaux*

The class of all shifted primed tableaux.

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_shape**(*shape*, *max_entry=None*, *skew=None*, *primed_diagonal=False*)

Bases: *ShiftedPrimedTableaux*

Shifted primed tableaux of a fixed shape.

Shifted primed tableaux admit a type A_n classical crystal structure with highest weights corresponding to a given shape.

The list of module generators consists of all elements of the crystal with nonincreasing weight entries.

The crystal is constructed following operations described in [HPS2017] and [AO2018].

The optional `primed_diagonal` allows primed entries in the main diagonal of all the Shifted primed tableaux of a fixed shape. If the `max_entry` is `None` then `max_entry` is set to the total number of entries in the tableau if `primed_diagonal` is `True`.

EXAMPLES:

```
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4).cardinality()
384
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableaux([Integer(4),Integer(3),Integer(1)], max_
↪entry=Integer(4))
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
>>> ShiftedPrimedTableaux([Integer(4),Integer(3),Integer(1)], max_
```

(continues on next page)

(continued from previous page)

```
↪entry=Integer(4)).cardinality()
384
```

We compute some of the crystal structure:

```
sage: SPTC = crystals.ShiftedPrimedTableaux([3,2], 3)
sage: T = SPTC.module_generators[-1]
sage: T
[(1, 1, 2'), (2, 3')]
sage: T.f(2)
[(1, 1, 3'), (2, 3')]
sage: len(SPTC.module_generators)
7
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
24
```

```
>>> from sage.all import *
>>> SPTC = crystals.ShiftedPrimedTableaux([Integer(3),Integer(2)], Integer(3))
>>> T = SPTC.module_generators[-Integer(1)]
>>> T
[(1, 1, 2'), (2, 3')]
>>> T.f(Integer(2))
[(1, 1, 3'), (2, 3')]
>>> len(SPTC.module_generators)
7
>>> SPTC[Integer(0)]
[(1, 1, 1), (2, 2)]
>>> SPTC.cardinality()
24
```

We compare this implementation with the $q(n)$-crystal on (tensor products) of letters:

```
sage: tableau_crystal = crystals.ShiftedPrimedTableaux([4,1], 3)
sage: tableau_digraph = tableau_crystal.digraph()
sage: c = crystals.Letters(['Q', 3])
sage: tensor_crystal = tensor([c]*5)
sage: u = tensor_crystal(c(1), c(1), c(1), c(2), c(1))
sage: subcrystal = tensor_crystal.subcrystal(generators=[u],
....:                                        index_set=[1,2,-1])
sage: tensor_digraph = subcrystal.digraph()
sage: tensor_digraph.is_isomorphic(tableau_digraph, edge_labels=True)
True
```

```
>>> from sage.all import *
>>> tableau_crystal = crystals.ShiftedPrimedTableaux([Integer(4),Integer(1)],␣
↪Integer(3))
>>> tableau_digraph = tableau_crystal.digraph()
>>> c = crystals.Letters(['Q', Integer(3)])
>>> tensor_crystal = tensor([c]*Integer(5))
>>> u = tensor_crystal(c(Integer(1)), c(Integer(1)), c(Integer(1)), c(Integer(2)),
```

(continues on next page)

(continued from previous page)

```
↪ c(Integer(1)))
>>> subcrystal = tensor_crystal.subcrystal(generators=[u],
...                                         index_set=[Integer(1),Integer(2),-
↪Integer(1)])
>>> tensor_digraph = subcrystal.digraph()
>>> tensor_digraph.is_isomorphic(tableau_digraph, edge_labels=True)
True
```

If we allow primed entries in the main diagonal:

```
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4,
....:                       primed_diagonal=True)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4,
....:                       primed_diagonal=True).cardinality()
3072
sage: SPTC = ShiftedPrimedTableaux([3,2], max_entry=3,
....:                              primed_diagonal=True)
sage: T = SPTC[-1]
sage: T
[(1', 2', 2), (3', 3)]
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
96
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableaux([Integer(4),Integer(3),Integer(1)], max_
↪entry=Integer(4),
...                       primed_diagonal=True)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
>>> ShiftedPrimedTableaux([Integer(4),Integer(3),Integer(1)], max_
↪entry=Integer(4),
...                       primed_diagonal=True).cardinality()
3072
>>> SPTC = ShiftedPrimedTableaux([Integer(3),Integer(2)], max_entry=Integer(3),
...                              primed_diagonal=True)
>>> T = SPTC[-Integer(1)]
>>> T
[(1', 2', 2), (3', 3)]
>>> SPTC[Integer(0)]
[(1, 1, 1), (2, 2)]
>>> SPTC.cardinality()
96
```

module_generators()

Return the generators of `self` as a crystal.

shape()

Return the shape of the shifted tableaux `self`.

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_weight**(*weight*, *skew=None*, *primed_diagonal=False*)

Bases: *ShiftedPrimedTableaux*

Shifted primed tableaux of fixed weight.

EXAMPLES:

```
sage: ShiftedPrimedTableaux(weight=(2,3,1))
Shifted Primed Tableaux of weight (2, 3, 1)
sage: ShiftedPrimedTableaux(weight=(2,3,1)).cardinality()
17
sage: SPT = ShiftedPrimedTableaux(weight=(2,3,1), primed_diagonal=True)
sage: SPT.cardinality()
64
sage: T = ShiftedPrimedTableaux(weight=(3,2), primed_diagonal=True)
sage: T[:5]
[[(1, 1, 1, 2, 2)],
 [(1, 1, 1, 2', 2)],
 [(1', 1, 1, 2, 2)],
 [(1', 1, 1, 2', 2)],
 [(1, 1, 1, 2), (2,)]]
sage: T.cardinality()
16
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1)))
Shifted Primed Tableaux of weight (2, 3, 1)
>>> ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1))).cardinality()
17
>>> SPT = ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1)), primed_
↪diagonal=True)
>>> SPT.cardinality()
64
>>> T = ShiftedPrimedTableaux(weight=(Integer(3),Integer(2)), primed_
↪diagonal=True)
>>> T[:Integer(5)]
[[(1, 1, 1, 2, 2)],
 [(1, 1, 1, 2', 2)],
 [(1', 1, 1, 2, 2)],
 [(1', 1, 1, 2', 2)],
 [(1, 1, 1, 2), (2,)]]
>>> T.cardinality()
16
```

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_weight_shape**(*weight*, *shape*, *skew=None*, *primed_diagonal=False*)

Bases: *ShiftedPrimedTableaux*

Shifted primed tableaux of the fixed weight and shape.

EXAMPLES:

```
sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2))
Shifted Primed Tableaux of weight (2, 3, 2) and shape [4, 2, 1]
sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2)).cardinality()
4
sage: T = ShiftedPrimedTableaux([4,2,1], weight=(2,3,2),
....:                           primed_diagonal=True)
sage: T[:6]
[[(1, 1, 2, 2), (2, 3'), (3,)],
 [(1, 1, 2, 2), (2, 3'), (3',)],
 [(1, 1, 2, 2), (2', 3'), (3,)],
 [(1, 1, 2, 2), (2', 3'), (3',)],
 [(1, 1, 2', 3), (2, 2), (3,)],
 [(1, 1, 2', 3), (2, 2), (3',)]]
sage: T.cardinality()
32
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableaux([Integer(4),Integer(2),Integer(1)], weight=(Integer(2),
↪Integer(3),Integer(2)))
Shifted Primed Tableaux of weight (2, 3, 2) and shape [4, 2, 1]
>>> ShiftedPrimedTableaux([Integer(4),Integer(2),Integer(1)], weight=(Integer(2),
↪Integer(3),Integer(2))).cardinality()
4
>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2),Integer(1)],␣
↪weight=(Integer(2),Integer(3),Integer(2)),
...                           primed_diagonal=True)
>>> T[:Integer(6)]
[[(1, 1, 2, 2), (2, 3'), (3,)],
 [(1, 1, 2, 2), (2, 3'), (3',)],
 [(1, 1, 2, 2), (2', 3'), (3,)],
 [(1, 1, 2, 2), (2', 3'), (3',)],
 [(1, 1, 2', 3), (2, 2), (3,)],
 [(1, 1, 2', 3), (2, 2), (3',)]]
>>> T.cardinality()
32
```

Shuffle product of iterables

The shuffle product of two sequences of lengths m and n is a sum over the $\binom{m+n}{n}$ ways of interleaving the two sequences.

That could be defined inductively by:

$$(a_n)_{n\geqslant 0} \sqcup\!\sqcup (b_m)_{m\geqslant 0} = a_0 \cdot ((a_n)_{n\geqslant 1} \sqcup\!\sqcup (b_m)_{m\geqslant 0}) + b_0 \cdot ((a_n)_{n\geqslant 0} \sqcup\!\sqcup (b_m)_{m\geqslant 1})$$

with (a_n) and (b_m) two non-empty sequences and if one of them is empty then the product is equals to the other.

The shuffle product has been introduced by S. Eilenberg and S. Mac Lane in 1953 [EilLan53].

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct([1,2], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'],
 ['a', 1, 2, 'b', 'c'],
```

(continues on next page)

(continued from previous page)

```
 [1, 'a', 2, 'b', 'c'],
 ['a', 'b', 1, 2, 'c'],
 ['a', 1, 'b', 2, 'c'],
 [1, 'a', 'b', 2, 'c'],
 ['a', 'b', 'c', 1, 2],
 ['a', 'b', 1, 'c', 2],
 ['a', 1, 'b', 'c', 2],
 [1, 'a', 'b', 'c', 2]]
```

```
>>> from sage.all import *
>>> from sage.combinat.shuffle import ShuffleProduct
>>> list(ShuffleProduct([Integer(1),Integer(2)], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'],
 ['a', 1, 2, 'b', 'c'],
 [1, 'a', 2, 'b', 'c'],
 ['a', 'b', 1, 2, 'c'],
 ['a', 1, 'b', 2, 'c'],
 [1, 'a', 'b', 2, 'c'],
 ['a', 'b', 'c', 1, 2],
 ['a', 'b', 1, 'c', 2],
 ['a', 1, 'b', 'c', 2],
 [1, 'a', 'b', 'c', 2]]
```

class sage.combinat.shuffle.**SetShuffleProduct**(*l1*, *l2*, *element_constructor=None*)

Bases: *ShuffleProduct_abstract*

The union of all possible shuffle products of two sets of iterables.

EXAMPLES:

```
sage: from sage.combinat.shuffle import SetShuffleProduct
sage: sorted(SetShuffleProduct({(1,), (2,3)}, {(4,5), (6,)}))
[[1, 4, 5],
 [1, 6],
 [2, 3, 4, 5],
 [2, 3, 6],
 [2, 4, 3, 5],
 [2, 4, 5, 3],
 [2, 6, 3],
 [4, 1, 5],
 [4, 2, 3, 5],
 [4, 2, 5, 3],
 [4, 5, 1],
 [4, 5, 2, 3],
 [6, 1],
 [6, 2, 3]]
```

```
>>> from sage.all import *
>>> from sage.combinat.shuffle import SetShuffleProduct
```

(continues on next page)

(continued from previous page)

```
>>> sorted(SetShuffleProduct({(Integer(1),), (Integer(2),Integer(3))},
↪{(Integer(4),Integer(5)), (Integer(6),)}))

```

cardinality()

The cardinality is defined by the sum of the cardinality of all shuffles. That means by a sum of binomials.

class sage.combinat.shuffle.**ShuffleProduct**(*l1*, *l2*, *element_constructor=None*)

Bases: *ShuffleProduct_abstract*

Shuffle product of two iterables.

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct("abc", "de", element_constructor="".join))
['abcde',
 'adbce',
 'dabce',
 'abdce',
 'adebc',
 'daebc',
 'deabc',
 'adbec',
 'dabec',
 'abdec']
sage: list(ShuffleProduct("", "de", element_constructor="".join))
['de']
```

```
>>> from sage.all import *
>>> from sage.combinat.shuffle import ShuffleProduct
>>> list(ShuffleProduct("abc", "de", element_constructor="".join))
['abcde',
 'adbce',
 'dabce',
 'abdce',
 'adebc',
 'daebc',
 'deabc',
 'adbec',
```

(continues on next page)

(continued from previous page)

```
 'dabec',
 'abdec']
>>> list(ShuffleProduct("", "de", element_constructor="".join))
['de']
```

cardinality()

Return the number of shuffles of l_1 and l_2, respectively of lengths m and n, which is $\binom{m+n}{n}$.

class sage.combinat.shuffle.**ShuffleProduct_abstract**(*l1*, *l2*, *element_constructor=None*)

Bases: Parent

Abstract base class for shuffle products.

class sage.combinat.shuffle.**ShuffleProduct_overlapping**(*w1*, *w2*, *element_constructor=None*, *add=<built-in function add>*)

Bases: *ShuffleProduct_abstract*

The overlapping shuffle product of the two words `w1` and `w2`.

If u and v are two words whose letters belong to an additive monoid or to another kind of alphabet on which addition is well-defined, then the *overlapping shuffle product* of u and v is a certain multiset of words defined as follows: Let a and b be the lengths of u and v, respectively. Let A be the set $\{(0,1),(0,2),\cdots,(0,a)\}$, and let B be the set $\{(1,1),(1,2),\cdots,(1,b)\}$. Notice that the sets A and B are disjoint. We can make A and B into posets by setting $(k,i) \leq (k,j)$ for all $k \in \{0,1\}$ and $i \leq j$. Then, $A \cup B$ becomes a poset by disjoint union (we don't set $(0,i) \leq (1,i)$). Let p be the map from $A \cup B$ to the set of all letters which sends every $(0,i)$ to the i-th letter of u, and every $(1,j)$ to the j-th letter of v. For every nonnegative integer c and every surjective map $f : A \cup B \to \{1,2,\cdots,c\}$ for which both restrictions $f\mid_A$ and $f\mid_B$ are strictly increasing, let $w(f)$ be the length-c word such that for every $1 \leq k \leq c$, the k-th letter of $w(f)$ equals $\sum_{j \in f^{-1}(k)} p(j)$ (this sum always has either one or two addends). The overlapping shuffle product of u and v is then the multiset of all $w(f)$ with c ranging over all nonnegative integers and f ranging over the surjective maps $f : A \cup B \to \{1,2,\cdots,c\}$ for which both restrictions $f\mid_A$ and $f\mid_B$ are strictly increasing.

If one restricts c to a particular fixed nonnegative integer, then the multiset is instead called the *overlapping shuffle product with precisely `a + b - c` overlaps*. This is nonempty only if $\max\{a,b\} \leq c \leq a+b$.

If $c = a+b$, then the overlapping shuffle product with precisely $a+b-c$ overlaps is plainly the shuffle product (*ShuffleProduct_w1w2*).

INPUT:

- `w1`, `w2` – iterables
- `element_constructor` – (default: the parent of `w1`) the function used to construct the output
- `add` – (default: `+`) the addition function

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct_overlapping
sage: w, u = [[2, 9], [9, 1]]
sage: S = ShuffleProduct_overlapping(w, u)
sage: sorted(S)
[[2, 9, 1, 9],
 [2, 9, 9, 1],
 [2, 9, 9, 1],
 [2, 9, 10],
 [2, 18, 1],
```

 [{2, 3}, {1, 2, 4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2}, {3, 4, 5, 6}],
 [{1, 2, 3}, {3, 4, 5, 6}]]
```

class sage.combinat.shuffle.**ShuffleProduct_overlapping_r**(*w1*, *w2*, *r*, *element_constructor=None*, *add=<built-in function add>*)

Bases: *ShuffleProduct_abstract*

The overlapping shuffle product of the two words `w1` and `w2` with precisely `r` overlaps.

See *ShuffleProduct_overlapping* for a definition.

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct_overlapping_r
sage: w, u = map(Words(range(20)), [[2, 9], [9, 1]])
sage: S = ShuffleProduct_overlapping_r(w,u,1)
sage: list(S)
[word: 11,9,1,
 word: 2,18,1,
 word: 11,1,9,
 word: 2,9,10,
 word: 939,
 word: 9,2,10]
```

```
>>> from sage.all import *
>>> from sage.combinat.shuffle import ShuffleProduct_overlapping_r
>>> w, u = map(Words(range(Integer(20))), [[Integer(2), Integer(9)], [Integer(9),␣
↪Integer(1)]])
>>> S = ShuffleProduct_overlapping_r(w,u,Integer(1))
>>> list(S)
[word: 11,9,1,
 word: 2,18,1,
 word: 11,1,9,
 word: 2,9,10,
 word: 939,
 word: 9,2,10]
```

Sidon sets and their generalizations, Sidon g-sets

AUTHORS:

- Martin Raum (07-25-2011)

sage.combinat.sidon_sets.**sidon_sets**(*N*, *g=1*)

Return the set of all Sidon-g sets that have elements less than or equal to N.

A Sidon-g set is a set of positive integers $A \subset [1, N]$ such that any integer M can be obtain at most g times as

sums of unordered pairs of elements of A (the two elements are not necessary distinct):

$$\#\{(a_i, a_j) | a_i, a_j \in A, a_i + a_j = M, a_i \leq a_j\} \leq g$$

INPUT:

- `N` – positive integer
- `g` – positive integer (default: 1)

OUTPUT: a Sage set with categories whose element are also set of integers

EXAMPLES:

```
sage: S = sidon_sets(3, 2)
sage: sorted(S, key=str)
[{1, 2, 3}, {1, 2}, {1, 3}, {1}, {2, 3}, {2}, {3}, {}]
sage: S.cardinality()
8
sage: S.category()
Category of finite enumerated sets
sage: sid = S.an_element()
sage: sid
{2}
sage: sid.category()
Category of finite enumerated sets
```

```
>>> from sage.all import *
>>> S = sidon_sets(Integer(3), Integer(2))
>>> sorted(S, key=str)
[{1, 2, 3}, {1, 2}, {1, 3}, {1}, {2, 3}, {2}, {3}, {}]
>>> S.cardinality()
8
>>> S.category()
Category of finite enumerated sets
>>> sid = S.an_element()
>>> sid
{2}
>>> sid.category()
Category of finite enumerated sets
```

`sage.combinat.sidon_sets.`**`sidon_sets_rec`**`(g=1)`

Return the set of all Sidon-g sets that have elements less than or equal to N without checking the arguments. This internal function should not be call directly by user.

Signed compositions

`class` `sage.combinat.composition_signed.`**`SignedCompositions`**`(n)`

Bases: *`Compositions_n`*

The class of signed compositions of n.

EXAMPLES:

```
sage: SC3 = SignedCompositions(3); SC3
Signed compositions of 3
```

(continues on next page)

(continued from previous page)

```
sage: SC3.cardinality()
18
sage: len(SC3.list())
18
sage: SC3.first()
[1, 1, 1]
sage: SC3.last()
[-3]
sage: SC3.random_element() # random
[1, -1, 1]
sage: SC3.list()
[[1, 1, 1],
 [1, 1, -1],
 [1, -1, 1],
 [1, -1, -1],
 [-1, 1, 1],
 [-1, 1, -1],
 [-1, -1, 1],
 [-1, -1, -1],
 [1, 2],
 [1, -2],
 [-1, 2],
 [-1, -2],
 [2, 1],
 [2, -1],
 [-2, 1],
 [-2, -1],
 [3],
 [-3]]
```

```
>>> from sage.all import *
>>> SC3 = SignedCompositions(Integer(3)); SC3
Signed compositions of 3
>>> SC3.cardinality()
18
>>> len(SC3.list())
18
>>> SC3.first()
[1, 1, 1]
>>> SC3.last()
[-3]
>>> SC3.random_element() # random
[1, -1, 1]
>>> SC3.list()
[[1, 1, 1],
 [1, 1, -1],
 [1, -1, 1],
 [1, -1, -1],
 [-1, 1, 1],
 [-1, 1, -1],
 [-1, -1, 1],
 [-1, -1, -1],
```

(continues on next page)

(continued from previous page)

```
[1, 2],
[1, -2],
[-1, 2],
[-1, -2],
[2, 1],
[2, -1],
[-2, 1],
[-2, -1],
[3],
[-3]]
```

cardinality()

Return the number of elements in `self`.

The number of signed compositions of n is equal to

$$\sum_{i=1}^{n+1} \binom{n-1}{i-1} 2^i$$

EXAMPLES:

```
sage: SC4 = SignedCompositions(4)
sage: SC4.cardinality() == len(SC4.list())
True
sage: SignedCompositions(3).cardinality()
18
```

```
>>> from sage.all import *
>>> SC4 = SignedCompositions(Integer(4))
>>> SC4.cardinality() == len(SC4.list())
True
>>> SignedCompositions(Integer(3)).cardinality()
18
```

Similarity class types of matrices with entries in a finite field

The notion of a matrix conjugacy class type was introduced by J. A. Green in [Green55], in the context of computing the irreducible characters of finite general linear groups. The class types are equivalence classes of similarity classes of square matrices with entries in a finite field which, roughly speaking, have the same qualitative properties.

For example, all similarity classes of the same class type have centralizers of the same cardinality and the same degrees of elementary divisors. Qualitative properties of similarity classes such as semisimplicity and regularity descend to class types.

The most important feature of similarity class types is that, for any n, the number of similarity class types of $n \times n$ matrices is independent of q. This makes it possible to perform many combinatorial calculations treating q as a formal variable.

In order to define similarity class types, recall that similarity classes of $n \times n$ matrices with entries in $\mathbf{F}_q$ correspond to functions

$$c : \mathrm{Irr}\mathbf{F}_{q[t]} \to \Lambda$$

such that

$$\sum_{f \in \mathrm{Irr}\mathbf{F}_{q[t]}} |c(f)| \deg f = n,$$

where we denote the set of irreducible monic polynomials in $\mathbf{F}_{q[t]}$ by $\mathrm{Irr}\mathbf{F}_{q[t]}$, the set of all partitions by Λ, and the size of $\lambda \in \Lambda$ by $|\lambda|$.

Similarity classes indexed by functions c_1 and c_2 as above are said to be of the same type if there exists a degree-preserving self-bijection σ of $\mathrm{Irr}\mathbf{F}_{q[t]}$ such that $c_2 = c_1 \circ \sigma$. Thus, the type of c remembers only the degrees of the polynomials (and not the polynomials themselves) for which c takes a certain value λ. Replacing each irreducible polynomial of degree d for which c takes a non-trivial value λ by the pair (d, λ), we obtain a multiset of such pairs. Clearly, c_1 and c_2 have the same type if and only if these multisets are equal. Thus a similarity class type may be viewed as a multiset of pairs of the form (d, λ).

For 2×2 matrices there are four types:

```
sage: for tau in SimilarityClassTypes(2):
....:     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

```
>>> from sage.all import *
>>> for tau in SimilarityClassTypes(Integer(2)):
...     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

These four types correspond to the regular split semisimple matrices, the non-semisimple matrices, the central matrices and the irreducible matrices respectively.

For any matrix A in a given similarity class type, it is possible to calculate the number elements in the similarity class of A, the dimension of the algebra of matrices in $M_n(A)$ that commute with A, and the cardinality of the subgroup of $GL_n(\mathbf{F}_q)$ that commute with A. For each similarity class type, it is also possible to compute the number of classes of that type (and hence, the total number of matrices of that type). All these calculations treat the cardinality q of the finite field as a formal variable:

```
sage: M = SimilarityClassType([[1, [1]], [1, [1]]])
sage: M.class_card()
q^2 + q
sage: M.centralizer_algebra_dim()
2
sage: M.centralizer_group_card()
q^2 - 2*q + 1
sage: M.number_of_classes()
1/2*q^2 - 1/2*q
sage: M.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

```
>>> from sage.all import *
>>> M = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1), [Integer(1)]]])
>>> M.class_card()
q^2 + q
>>> M.centralizer_algebra_dim()
2
>>> M.centralizer_group_card()
```

(continues on next page)

(continued from previous page)

```
q^2 - 2*q + 1
>>> M.number_of_classes()
1/2*q^2 - 1/2*q
>>> M.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

We now describe two applications of similarity class types.

We say that an $n \times n$ matrix has rational canonical form type λ for some partition λ of n if the diagonal blocks in the rational canonical form have sizes given by the parts of λ. Thus the matrices with rational canonical type (n) are the regular ones, while the matrices with rational canonical type (1^n) are the central ones.

Using similarity class types, it becomes easy to get a formula for the number of matrices with a given rational canonical type:

```
sage: def matrices_with_rcf(la):
....:     return sum([tau.number_of_matrices() for tau in filter(lambda tau:tau.
↪rcf()==la, SimilarityClassTypes(la.size()))])
sage: matrices_with_rcf(Partition([2,1]))
q^6 + q^5 + q^4 - q^3 - q^2 - q
```

```
>>> from sage.all import *
>>> def matrices_with_rcf(la):
...     return sum([tau.number_of_matrices() for tau in filter(lambda tau:tau.
↪rcf()==la, SimilarityClassTypes(la.size()))])
>>> matrices_with_rcf(Partition([Integer(2),Integer(1)]))
q^6 + q^5 + q^4 - q^3 - q^2 - q
```

Similarity class types can also be used to calculate the number of simultaneous similarity classes of k-tuples of $n \times n$ matrices with entries in $\mathbf{F}_q$ by using Burnside's lemma:

```
sage: from sage.combinat.similarity_class_type import order_of_general_linear_group,␣
↪centralizer_algebra_dim
sage: q = ZZ['q'].gen()
sage: def simultaneous_similarity_classes(n, k):
....:     return SimilarityClassTypes(n).sum(lambda la: q**(k*centralizer_algebra_
↪dim(la)), invertible = True)/order_of_general_linear_group(n)
sage: simultaneous_similarity_classes(3, 2)
q^10 + q^8 + 2*q^7 + 2*q^6 + 2*q^5 + q^4
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import order_of_general_linear_group,␣
↪centralizer_algebra_dim
>>> q = ZZ['q'].gen()
>>> def simultaneous_similarity_classes(n, k):
...     return SimilarityClassTypes(n).sum(lambda la: q**(k*centralizer_algebra_
↪dim(la)), invertible = True)/order_of_general_linear_group(n)
>>> simultaneous_similarity_classes(Integer(3), Integer(2))
q^10 + q^8 + 2*q^7 + 2*q^6 + 2*q^5 + q^4
```

Similarity class types can be used to compute the coefficients of generating functions coming from the cycle index type techniques of Kung and Stong (see Morrison [Morrison06]).

They can also be used to compute the number of invariant subspaces for a matrix over a finite field of any given dimension.

For this we use the elegant recursive formula of Ramaré [R17] (see also [PR22]).

Along with the results of [PSS13], similarity class types can be used to calculate the number of similarity classes of matrices of order n with entries in a principal ideal local ring of length two with residue field of cardinality q with centralizer of any given cardinality up to $n = 4$. Among these, the classes which are selftranspose can also be counted:

```
sage: from sage.combinat.similarity_class_type import matrix_centralizer_
↪cardinalities_length_two
sage: list(matrix_centralizer_cardinalities_length_two(3))
[(q^6 - 3*q^5 + 3*q^4 - q^3, 1/6*q^6 - 1/2*q^5 + 1/3*q^4),
(q^6 - 2*q^5 + q^4, q^5 - q^4),
(q^8 - 3*q^7 + 3*q^6 - q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^10 - 2*q^9 + 2*q^7 - q^6, q^4 - q^3),
(q^8 - q^7 - q^6 + q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^6 - q^5 - q^4 + q^3, 1/2*q^6 - 1/2*q^5),
(q^6 - q^5, q^4),
(q^10 - 2*q^9 + q^8, q^3),
(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^8 - q^7, q^3 + q^2),
(q^12 - 3*q^11 + 3*q^10 - q^9, 1/6*q^4 - 1/2*q^3 + 1/3*q^2),
(q^12 - 2*q^11 + q^10, q^3 - q^2),
(q^14 - 2*q^13 + 2*q^11 - q^10, q^3 - q^2),
(q^12 - q^11 - q^10 + q^9, 1/2*q^4 - 1/2*q^3),
(q^12 - q^11, q^2),
(q^14 - 2*q^13 + q^12, q^2),
(q^18 - q^17 - q^16 + q^14 + q^13 - q^12, q^2),
(q^12 - q^9, 1/3*q^4 - 1/3*q^2),
(q^6 - q^3, 1/3*q^6 - 1/3*q^4)]
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import matrix_centralizer_cardinalities_
↪length_two
>>> list(matrix_centralizer_cardinalities_length_two(Integer(3)))
[(q^6 - 3*q^5 + 3*q^4 - q^3, 1/6*q^6 - 1/2*q^5 + 1/3*q^4),
(q^6 - 2*q^5 + q^4, q^5 - q^4),
(q^8 - 3*q^7 + 3*q^6 - q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^10 - 2*q^9 + 2*q^7 - q^6, q^4 - q^3),
(q^8 - q^7 - q^6 + q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^6 - q^5 - q^4 + q^3, 1/2*q^6 - 1/2*q^5),
(q^6 - q^5, q^4),
(q^10 - 2*q^9 + q^8, q^3),
(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^8 - q^7, q^3 + q^2),
(q^12 - 3*q^11 + 3*q^10 - q^9, 1/6*q^4 - 1/2*q^3 + 1/3*q^2),
(q^12 - 2*q^11 + q^10, q^3 - q^2),
(q^14 - 2*q^13 + 2*q^11 - q^10, q^3 - q^2),
(q^12 - q^11 - q^10 + q^9, 1/2*q^4 - 1/2*q^3),
(q^12 - q^11, q^2),
(q^14 - 2*q^13 + q^12, q^2),
(q^18 - q^17 - q^16 + q^14 + q^13 - q^12, q^2),
(q^12 - q^9, 1/3*q^4 - 1/3*q^2),
(q^6 - q^3, 1/3*q^6 - 1/3*q^4)]
```

class sage.combinat.similarity_class_type.**PrimarySimilarityClassType**(*parent*, *deg*, *par*)

Bases: Element

A primary similarity class type is a pair consisting of a partition and a positive integer.

For a partition λ and a positive integer d, the primary similarity class type (d, λ) represents similarity classes of square matrices of order $|\lambda| \cdot d$ with entries in a finite field of order q which correspond to the $\mathbf{F}_{q[t]}$-module

$$\frac{\mathbf{F}_{q[t]}}{p(t)^{\lambda_1}} \oplus \frac{\mathbf{F}_{q[t]}}{p(t)^{\lambda_2}} \oplus \cdots$$

for some irreducible polynomial $p(t)$ of degree d.

centralizer_algebra_dim()

Return the dimension of the algebra of matrices which commute with a matrix of type self.

For a partition (d, λ) this dimension is given by $d(\lambda_1 + 3\lambda_2 + 5\lambda_3 + \cdots)$.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.centralizer_algebra_dim()
28
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),␣
↪Integer(1)])
>>> PT.centralizer_algebra_dim()
28
```

centralizer_group_card(*q=None*)

Return the cardinality of the centralizer group of a matrix of type self in a field of order q.

INPUT:

- q – integer or an indeterminate

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(1, [])
sage: PT.centralizer_group_card()
1
sage: PT = PrimarySimilarityClassType(2, [1, 1])
sage: PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(1), [])
>>> PT.centralizer_group_card()
1
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(1), Integer(1)])
>>> PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2
```

degree()

Return degree of `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.degree()
2
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),␣
↪Integer(1)])
>>> PT.degree()
2
```

invariant_subspace_generating_function(*q=None*, *t=None*)

Return the invariant subspace generating function of `self`.

INPUT:

- `q` – (optional) an integer or an inderminate
- `t` – (optional) an indeterminate

EXAMPLES:

```
sage: PrimarySimilarityClassType(1, [2, 2]).invariant_subspace_generating_
↪function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

```
>>> from sage.all import *
>>> PrimarySimilarityClassType(Integer(1), [Integer(2), Integer(2)]).
↪invariant_subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

partition()

Return partition corresponding to `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.partition()
[3, 2, 1]
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),␣
↪Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> PT.partition()
[3, 2, 1]
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.size()
12
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),␣
↪Integer(1)])
>>> PT.size()
12
```

statistic(*func*, *q=None*)

Return $n_\lambda(q^d)$ where n_λ is the value returned by `func` upon input λ, if `self` is (d, λ).

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 1])
sage: q = ZZ['q'].gen()
sage: PT.statistic(lambda la:q**la.size(), q = q)
q^8
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(1)])
>>> q = ZZ['q'].gen()
>>> PT.statistic(lambda la:q**la.size(), q = q)
q^8
```

class sage.combinat.similarity_class_type.**PrimarySimilarityClassTypes**(*n*, *min*)

Bases: `UniqueRepresentation`, `Parent`

All primary similarity class types of size `n` whose degree is greater than that of `min` or whose degree is that of `min` and whose partition is less than of `min` in lexicographic order.

A primary similarity class type of size n is a pair (λ, d) consisting of a partition λ and a positive integer d such that $|\lambda|d = n$.

INPUT:

- `n` – positive integer
- `min` – a primary matrix type of size `n`

EXAMPLES:

If `min` is not specified, then the class of all primary similarity class types of size `n` is created:

```
sage: PTC = PrimarySimilarityClassTypes(2)
sage: for PT in PTC:
....:     print(PT)
```

(continues on next page)

(continued from previous page)

```
[1, [2]]
[1, [1, 1]]
[2, [1]]
```

```
>>> from sage.all import *
>>> PTC = PrimarySimilarityClassTypes(Integer(2))
>>> for PT in PTC:
...     print(PT)
[1, [2]]
[1, [1, 1]]
[2, [1]]
```

If `min` is specified, then the class consists of only those primary similarity class types whose degree is greater than that of `min` or whose degree is that of `min` and whose partition is less than of `min` in lexicographic order:

```
sage: PTC = PrimarySimilarityClassTypes(2, min = PrimarySimilarityClassType(1, [1,
↪ 1]))
sage: for PT in PTC:
....:     print(PT)
[1, [1, 1]]
[2, [1]]
```

```
>>> from sage.all import *
>>> PTC = PrimarySimilarityClassTypes(Integer(2), min =␣
↪PrimarySimilarityClassType(Integer(1), [Integer(1), Integer(1)]))
>>> for PT in PTC:
...     print(PT)
[1, [1, 1]]
[2, [1]]
```

Element

alias of *PrimarySimilarityClassType*

size()

Return size of elements of `self`.

The size of a primary similarity class type (d, λ) is $d|\lambda|$.

EXAMPLES:

```
sage: PTC = PrimarySimilarityClassTypes(2)
sage: PTC.size()
2
```

```
>>> from sage.all import *
>>> PTC = PrimarySimilarityClassTypes(Integer(2))
>>> PTC.size()
2
```

class sage.combinat.similarity_class_type.**SimilarityClassType**(*parent*, *tau*)

Bases: *CombinatorialElement*

A similarity class type.

A matrix type is a multiset of primary similarity class types.

INPUT:

- `tau` – list of primary similarity class types or a square matrix over a finite field

EXAMPLES:

```
sage: tau1 = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]]); tau1
[[2, [2, 1]], [3, [3, 2, 1]]]

sage: SimilarityClassType(Matrix(GF(2), [[1,1],[0,1]]))
[[1, [2]]]
```

```
>>> from sage.all import *
>>> tau1 = SimilarityClassType([[Integer(3), [Integer(3), Integer(2),␣
↪Integer(1)]], [Integer(2), [Integer(2), Integer(1)]]]); tau1
[[2, [2, 1]], [3, [3, 2, 1]]]

>>> SimilarityClassType(Matrix(GF(Integer(2)), [[Integer(1),Integer(1)],
↪[Integer(0),Integer(1)]]))
[[1, [2]]]
```

as_partition_dictionary()

Return a dictionary whose keys are the partitions of types occurring in `self` and the value at the key λ is the partition formed by sorting the degrees of primary types with partition λ.

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.as_partition_dictionary()
{[1]: [1, 1]}
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.as_partition_dictionary()
{[1]: [1, 1]}
```

centralizer_algebra_dim()

Return the dimension of the algebra of matrices which commute with a matrix of type `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_algebra_dim()
2
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.centralizer_algebra_dim()
2
```

centralizer_group_card(*q=None*)

Return the cardinality of the group of matrices in $GL_n(\mathbf{F}_q)$ which commute with a matrix of type `self`.

INPUT:

- `q` – integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_group_card()
q^2 - 2*q + 1
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.centralizer_group_card()
q^2 - 2*q + 1
```

class_card(*q=None*)

Return the number of matrices in each similarity class of type `self`.

INPUT:

- `q` – integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1, 1, 1, 1]]])
sage: tau.class_card()
1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.class_card()
q^2 + q
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1), Integer(1),␣
↪Integer(1), Integer(1)]]])
>>> tau.class_card()
1
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.class_card()
q^2 + q
```

invariant_subspace_generating_function(*q=None*, *t=None*)

Return the invariant subspace generating function of `self`.

The invariant subspace generating function is the function is the polynomial

$$\sum_{j \geq 0} a_j(q) t^j,$$

where $a_j(q)$ denotes the number of j-dimensional invariant subspaces of dimensiona j for any matrix with the similarity class type `self` with entries in a field of order q.

EXAMPLES:

```
sage: SimilarityClassType([[1, [2, 2]]]).invariant_subspace_generating_
↪function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
sage: A = Matrix(GF(2),[(0, 1, 0, 0), (0, 1, 1, 1), (1, 0, 1, 0), (1, 1, 0,␣
↪0)])
sage: SimilarityClassType(A).invariant_subspace_generating_function()
t^4 + 1
```

```
>>> from sage.all import *
>>> SimilarityClassType([[Integer(1), [Integer(2), Integer(2)]]]).invariant_
↪subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
>>> A = Matrix(GF(Integer(2)),[(Integer(0), Integer(1), Integer(0),␣
↪Integer(0)), (Integer(0), Integer(1), Integer(1), Integer(1)), (Integer(1),␣
↪Integer(0), Integer(1), Integer(0)), (Integer(1), Integer(1), Integer(0),␣
↪Integer(0))])
>>> SimilarityClassType(A).invariant_subspace_generating_function()
t^4 + 1
```

is_regular()

Return `True` if every primary type in `self` has partition with one part.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1]], [1, [3]]])
sage: tau.is_regular()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [3]]])
sage: tau.is_regular()
False
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(2), [Integer(1)]], [Integer(1),␣
↪[Integer(3)]]])
>>> tau.is_regular()
True
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1)]],␣
↪[Integer(1), [Integer(3)]]])
>>> tau.is_regular()
False
```

is_semisimple()

Return `True` if every primary similarity class type in `self` has all parts equal to `1`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [1]]])
sage: tau.is_semisimple()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [2]]])
sage: tau.is_semisimple()
False
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1)]],␣
↪[Integer(1), [Integer(1)]]])
>>> tau.is_semisimple()
True
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1)]],␣
↪[Integer(1), [Integer(2)]]])
>>> tau.is_semisimple()
False
```

number_of_classes(*invertible=False*, *q=None*)

Return the number of similarity classes of matrices of type `self`.

INPUT:

- `invertible` – boolean; return number of invertible classes if set to `True`
- `q` – integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_classes()
1/2*q^2 - 1/2*q
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.number_of_classes()
1/2*q^2 - 1/2*q
```

number_of_matrices(*invertible=False*, *q=None*)

Return the number of matrices of type `self`.

INPUT:

- `invertible` – a boolean; return the number of invertible matrices if set

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]]])
sage: tau.number_of_matrices()
q
sage: tau.number_of_matrices(invertible = True)
q - 1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]]])
>>> tau.number_of_matrices()
q
>>> tau.number_of_matrices(invertible = True)
q - 1
```

(continues on next page)

(continued from previous page)

```
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

rcf()

Return the partition corresponding to the rational canonical form of a matrix of type `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1, 1, 1]], [1, [3, 2]]])
sage: tau.rcf()
[5, 4, 2]
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1),␣
↪Integer(1)]], [Integer(1), [Integer(3), Integer(2)]]])
>>> tau.rcf()
[5, 4, 2]
```

size()

Return the sum of the sizes of the primary parts of `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.size()
24
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(3), [Integer(3), Integer(2),␣
↪Integer(1)]], [Integer(2), [Integer(2), Integer(1)]]])
>>> tau.size()
24
```

statistic(*func*, *q=None*)

Return.

$$\prod_{(d,\lambda)\in\tau} n_\lambda(q^d)$$

where $n_\lambda(q)$ is the value returned by `func` on the input λ.

INPUT:

- `func` – a function that takes a partition to a polynomial in `q`
- `q` – integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [2, 1]], [2, [1, 1]]])
sage: from sage.combinat.similarity_class_type import fq
sage: tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()]))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
```

(continues on next page)

(continued from previous page)

```
sage: q = ZZ['q'].gen()
sage: tau.statistic(lambda la: q**la.size(), q = q)
q^8
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(2), Integer(1)]], [Integer(2), [Integer(1), Integer(1)]]])
>>> from sage.combinat.similarity_class_type import fq
>>> tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()]))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
>>> q = ZZ['q'].gen()
>>> tau.statistic(lambda la: q**la.size(), q = q)
q^8
```

class sage.combinat.similarity_class_type.**SimilarityClassTypes**(*n*, *min*)

Bases: UniqueRepresentation, Parent

Class of all similarity class types of size n with all primary matrix types greater than or equal to the primary matrix type min.

A similarity class type is a multiset of primary matrix types.

INPUT:

- n – nonnegative integer
- min – a primary similarity class type

EXAMPLES:

If min is not specified, then the class of all matrix types of size n is constructed:

```
sage: M = SimilarityClassTypes(2)
sage: for tau in M:
....:     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

```
>>> from sage.all import *
>>> M = SimilarityClassTypes(Integer(2))
>>> for tau in M:
...     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

If min is specified, then the class consists of only those similarity class types which are multisets of primary matrix types which either have size greater than that of min, or if they have size equal to that of min, then they occur after min in the iterator for PrimarySimilarityClassTypes(n), where n is the size of min:

```
sage: M = SimilarityClassTypes(2, min = [1, [1, 1]])
sage: for tau in M:
```

(continues on next page)

(continued from previous page)

```
....:     print(tau)
[[1, [1, 1]]]
[[2, [1]]]
```

```
>>> from sage.all import *
>>> M = SimilarityClassTypes(Integer(2), min = [Integer(1), [Integer(1),␣
↪Integer(1)]])
>>> for tau in M:
...     print(tau)
[[1, [1, 1]]]
[[2, [1]]]
```

Element

alias of *SimilarityClassType*

size()

Return size of `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.parent().size()
24
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(3), [Integer(3), Integer(2),␣
↪Integer(1)]], [Integer(2), [Integer(2), Integer(1)]]])
>>> tau.parent().size()
24
```

sum(*stat*, *sumover='matrices'*, *invertible=False*, *q=None*)

Return the sum of a local statistic over all types.

Given a set of functions $n_\lambda(q)$ (these could be polynomials or rational functions in q, for each similarity class type τ define

$$n_\tau(q) = \prod_{(d,\lambda)\in\tau} n_\lambda(q^d).$$

This function returns

$$\sum n_{\tau(g)}(q)$$

where $\tau(g)$ denotes the type of a matrix g, and the sum is over all $n \times n$ matrices if `sumover` is set to `'matrices'`, is over all $n \times n$ similarity classes if `sumover` is set to `'classes'`, and over all $n \times n$ types if `sumover` is set to `'types'`. If `invertible` is set to `True`, then the sum is only over invertible matrices or classes.

INPUT:

- `stat` – a function which takes partitions and returns a function of `q`
- `sumover` – can be one of the following:
  - `'matrices'`
  - `'classes'`

- 'types'

- q – integer or an indeterminate

OUTPUT: a function of q

EXAMPLES:

```
sage: M = SimilarityClassTypes(2)
sage: M.sum(lambda la:1)
q^4
sage: M.sum(lambda la:1, invertible = True)
q^4 - q^3 - q^2 + q
sage: M.sum(lambda la:1, sumover = "classes")
q^2 + q
sage: M.sum(lambda la:1, sumover = "classes", invertible = True)
q^2 - 1
```

```
>>> from sage.all import *
>>> M = SimilarityClassTypes(Integer(2))
>>> M.sum(lambda la:Integer(1))
q^4
>>> M.sum(lambda la:Integer(1), invertible = True)
q^4 - q^3 - q^2 + q
>>> M.sum(lambda la:Integer(1), sumover = "classes")
q^2 + q
>>> M.sum(lambda la:Integer(1), sumover = "classes", invertible = True)
q^2 - 1
```

Burside's lemma can be used to calculate the number of similarity classes of matrices:

```
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim,
↪ order_of_general_linear_group
sage: q = ZZ['q'].gen()
sage: M.sum(lambda la:q**centralizer_algebra_dim(la), invertible = True)/
↪order_of_general_linear_group(2)
q^2 + q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import centralizer_algebra_dim,␣
↪order_of_general_linear_group
>>> q = ZZ['q'].gen()
>>> M.sum(lambda la:q**centralizer_algebra_dim(la), invertible = True)/order_
↪of_general_linear_group(Integer(2))
q^2 + q
```

sage.combinat.similarity_class_type.**centralizer_algebra_dim**()

Return the dimension of the centralizer algebra in $M_n(\mathbf{F}_q)$ of a nilpotent matrix whose Jordan blocks are given by la.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim
sage: centralizer_algebra_dim(Partition([2, 1]))
5
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import centralizer_algebra_dim
>>> centralizer_algebra_dim(Partition([Integer(2), Integer(1)]))
5
```

Note

If it is a list, `la` is expected to be sorted in decreasing order.

sage.combinat.similarity_class_type.**centralizer_group_cardinality**(*q=None*)

Return the cardinality of the centralizer group in $GL_n(\mathbf{F}_q)$ of a nilpotent matrix whose Jordan blocks are given by `la`.

INPUT:

- `lambda` – a partition
- `q` – an integer or an indeterminate

OUTPUT: a polynomial function of `q`

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import centralizer_group_
↪cardinality
sage: q = ZZ['q'].gen()
sage: centralizer_group_cardinality(Partition([2, 1]))
q^5 - 2*q^4 + q^3
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import centralizer_group_cardinality
>>> q = ZZ['q'].gen()
>>> centralizer_group_cardinality(Partition([Integer(2), Integer(1)]))
q^5 - 2*q^4 + q^3
```

sage.combinat.similarity_class_type.**dictionary_from_generator**(*gen*)

Given a generator for a list of pairs (c, f), construct a dictionary whose keys are the distinct values for c and whose value at c is the sum of f over all pairs of the form (c', f) such that $c = c'$.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import dictionary_from_generator
sage: dictionary_from_generator(((x // 2, x) for x in range(10)))
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import dictionary_from_generator
>>> dictionary_from_generator(((x // Integer(2), x) for x in range(Integer(10))))
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

It also works with lists:

```
sage: dictionary_from_generator([(x // 2, x) for x in range(10)])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

```
sage: from sage.all import *
sage: dictionary_from_generator([(x // Integer(2), x) for x in range(Integer(10))])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

```
>>> from sage.all import *
>>> dictionary_from_generator([(x // Integer(2), x) for x in range(Integer(10))])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

Note

Since the generator is first converted to a list, memory usage could be high.

sage.combinat.similarity_class_type.**ext_orbit_centralizers**(*input_data*, *q=None*, *selftranspose=False*)

Generate pairs consisting of centralizer cardinalities of orbits in $\mathrm{Ext}^1(M, M)$ for the action of $\mathrm{Aut}(M, M)$, where M is the $\mathbf{F}_{q[t]}$-module constructed from `input` and their frequencies.

INPUT:

- `input_data` – input for *input_parsing()*
- `q` – (default: q) an integer or an indeterminate
- `selftranspose` – boolean (default: `False`); stating if we only want selftranspose type

sage.combinat.similarity_class_type.**ext_orbits**(*input_data*, *q=None*, *selftranspose=False*)

Return the number of orbits in $\mathrm{Ext}^1(M, M)$ for the action of $\mathrm{Aut}(M, M)$, where M is the $\mathbf{F}_{q[t]}$-module constructed from `input_data`.

INPUT:

- `input_data` – input for *input_parsing()*
- `q` – (default: q) an integer or an indeterminate
- `selftranspose` – boolean (default: `False`); stating if we only want selftranspose type

sage.combinat.similarity_class_type.**fq**(*q=None*)

Return $(1 - q^{-1})(1 - q^{-2}) \cdots (1 - q^{-n})$.

INPUT:

- `n` – nonnegative integer
- `q` – integer or an indeterminate

OUTPUT: a rational function in `q`

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import fq
sage: fq(0)
1
sage: fq(3)
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import fq
>>> fq(Integer(0))
1
>>> fq(Integer(3))
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6
```

sage.combinat.similarity_class_type.**input_parsing**(*data*)

Recognize and return the intended type of `input`.

sage.combinat.similarity_class_type.**invariant_subspace_generating_function**(*la*, *q=None*, *t=None*)

Return the invariant subspace generating function of a nilpotent matrix with Jordan block sizes given by `la`.

INPUT:

- `la` – a partition
- `q` – (optional) an integer or an inderminate
- `t` – (optional) an indeterminate

OUTPUT: a polynomial in `t` whose coefficients are polynomials in `q`

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import invariant_subspace_
↪generating_function
sage: invariant_subspace_generating_function([2,2])
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import invariant_subspace_generating_
↪function
>>> invariant_subspace_generating_function([Integer(2),Integer(2)])
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

sage.combinat.similarity_class_type.**matrix_centralizer_cardinalities**(*n*, *q=None*, *invertible=False*)

Generate pairs consisting of centralizer cardinalities of matrices over a finite field and their frequencies.

sage.combinat.similarity_class_type.**matrix_centralizer_cardinalities_length_two**(*n*, *q=None*, *selftranspose=False*, *invertible=False*)

Generate pairs consisting of centralizer cardinalities of matrices over a principal ideal local ring of length two with residue field of order `q` and their frequencies.

INPUT:

- `n` – the order
- `q` – (default: q) an integer or an indeterminate
- `selftranspose` – boolean (default: `False`); stating if we only want selftranspose type
- `invertible` – boolean (default: `False`); stating if we only want invertible type

sage.combinat.similarity_class_type.**matrix_similarity_classes**(*n*, *q=None*, *invertible=False*)

Return the number of matrix similarity classes over a finite field of order `q`.

sage.combinat.similarity_class_type.**matrix_similarity_classes_length_two**(*n*, *q=None*, *selftranspose=False*, *invertible=False*)

Return the number of similarity classes of matrices of order `n` with entries in a principal ideal local ring of length two.

INPUT:

- `n` – the order
- `q` – (default: q) an integer or an indeterminate
- `selftranspose` – boolean (default: `False`); stating if we only want selftranspose type
- `invertible` – boolean (default: `False`); stating if we only want invertible type

EXAMPLES:

We can generate Table 6 of [PSS13]:

```
sage: from sage.combinat.similarity_class_type import matrix_similarity_classes_
↪length_two
sage: matrix_similarity_classes_length_two(2)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, invertible = True)
q^4 - q
sage: matrix_similarity_classes_length_two(3)
q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
sage: matrix_similarity_classes_length_two(3, invertible = true)
q^6 - q^3 + 2*q^2 - 2*q
sage: matrix_similarity_classes_length_two(4)
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
sage: matrix_similarity_classes_length_two(4, invertible = True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import matrix_similarity_classes_
↪length_two
>>> matrix_similarity_classes_length_two(Integer(2))
q^4 + q^3 + q^2
>>> matrix_similarity_classes_length_two(Integer(2), invertible = True)
q^4 - q
>>> matrix_similarity_classes_length_two(Integer(3))
q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
>>> matrix_similarity_classes_length_two(Integer(3), invertible = true)
q^6 - q^3 + 2*q^2 - 2*q
>>> matrix_similarity_classes_length_two(Integer(4))
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
>>> matrix_similarity_classes_length_two(Integer(4), invertible = True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q
```

And also Table 7:

```
sage: matrix_similarity_classes_length_two(2, selftranspose = True)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, selftranspose = True, invertible =␣
↪True)
q^4 - q
sage: matrix_similarity_classes_length_two(3, selftranspose = True)
```

(continues on next page)

(continued from previous page)

```
q^6 + q^5 + 2*q^4 + q^3
sage: matrix_similarity_classes_length_two(3, selftranspose = True, invertible =␣
↪True)
q^6 - q^3
sage: matrix_similarity_classes_length_two(4, selftranspose = True)
q^8 + q^7 + 3*q^6 + 3*q^5 + 3*q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(4, selftranspose = True, invertible =␣
↪True)
q^8 + q^6 - q^5 - q
```

```
>>> from sage.all import *
>>> matrix_similarity_classes_length_two(Integer(2), selftranspose = True)
q^4 + q^3 + q^2
>>> matrix_similarity_classes_length_two(Integer(2), selftranspose = True,␣
↪invertible = True)
q^4 - q
>>> matrix_similarity_classes_length_two(Integer(3), selftranspose = True)
q^6 + q^5 + 2*q^4 + q^3
>>> matrix_similarity_classes_length_two(Integer(3), selftranspose = True,␣
↪invertible = True)
q^6 - q^3
>>> matrix_similarity_classes_length_two(Integer(4), selftranspose = True)
q^8 + q^7 + 3*q^6 + 3*q^5 + 3*q^4 + q^3 + q^2
>>> matrix_similarity_classes_length_two(Integer(4), selftranspose = True,␣
↪invertible = True)
q^8 + q^6 - q^5 - q
```

sage.combinat.similarity_class_type.**order_of_general_linear_group**(*q=None*)

Return the cardinality of the group of $n \times n$ invertible matrices with entries in a field of order q.

INPUT:

- n – nonnegative integer
- q – integer or an indeterminate

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import order_of_general_linear_
↪group
sage: order_of_general_linear_group(0)
1
sage: order_of_general_linear_group(2)
q^4 - q^3 - q^2 + q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import order_of_general_linear_group
>>> order_of_general_linear_group(Integer(0))
1
>>> order_of_general_linear_group(Integer(2))
q^4 - q^3 - q^2 + q
```

sage.combinat.similarity_class_type.**primitives**(*invertible=False*, *q=None*)

Return the number of similarity classes of simple matrices of order n with entries in a finite field of order q. This

is the same as the number of irreducible polynomials of degree d.

If `invertible` is `True`, then only the number of similarity classes of invertible matrices is returned.

Note

All primitive classes are invertible unless `n` is 1.

INPUT:

- `n` – positive integer
- `invertible` – boolean; if set, only number of nonzero classes is returned
- `q` – integer or an indeterminate

OUTPUT: a rational function of the variable `q`

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import primitives
sage: primitives(1)
q
sage: primitives(1, invertible = True)
q - 1
sage: primitives(4)
1/4*q^4 - 1/4*q^2
sage: primitives(4, invertible = True)
1/4*q^4 - 1/4*q^2
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import primitives
>>> primitives(Integer(1))
q
>>> primitives(Integer(1), invertible = True)
q - 1
>>> primitives(Integer(4))
1/4*q^4 - 1/4*q^2
>>> primitives(Integer(4), invertible = True)
1/4*q^4 - 1/4*q^2
```

Six vertex model

class sage.combinat.six_vertex_model.**SixVertexConfiguration**

Bases: `ClonableArray`

A configuration in the six vertex model.

check()

Check if `self` is a valid 6 vertex configuration.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M[0].check()
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> M[Integer(0)].check()
```

energy(*epsilon*)

Return the energy of the configuration.

The energy of a configuration ν is defined as

$$E(\nu) = n_0\epsilon_0 + n_1\epsilon_1 + \cdots + n_5\epsilon_5$$

where n_i is the number of vertices of type i and ϵ_i is the i-th energy constant.

Note

We number our configurations as:

0. LR
1. LU
2. LD
3. UD
4. UR
5. RD

which differs from Wikipedia article Ice-type_model.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: nu = M[2]; nu
    ^    ^    ^
    |    |    |
--> # -> # <- # <--
    ^    |    ^
    |    V    |
--> # <- # -> # <--
    |    ^    |
    V    |    V
--> # -> # <- # <--
    |    |    |
    V    V    V
sage: nu.energy([1,2,1,2,1,2])
15
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> nu = M[Integer(2)]; nu
    ^    ^    ^
    |    |    |
--> # -> # <- # <--
    ^    |    ^
```

(continues on next page)

(continued from previous page)

```
    |    V    |
--> # <- # -> # <--
    |    ^    |
    V    |    V
--> # -> # <- # <--
    |    |    |
    V    V    V
>>> nu.energy([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1),
↪Integer(2)])
15
```

A KDP energy:

```
sage: nu.energy([1,1,0,1,0,1])
7
```

```
>>> from sage.all import *
>>> nu.energy([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1)])
7
```

A Rys F energy:

```
sage: nu.energy([0,1,1,0,1,1])
4
```

```
>>> from sage.all import *
>>> nu.energy([Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(1)])
4
```

The zero field assumption:

```
sage: nu.energy([1,2,3,1,3,2])
15
```

```
>>> from sage.all import *
>>> nu.energy([Integer(1),Integer(2),Integer(3),Integer(1),Integer(3),
↪Integer(2)])
15
```

plot(*color='sign'*)

Return a plot of `self`.

INPUT:

- `color` – can be any of the following:
  - `4` – use 4 colors: black, red, blue, and green with each corresponding to up, right, down, and left respectively
  - `2` – use 2 colors: red for horizontal, blue for vertical arrows
  - `'sign'` – use red for right and down arrows, blue for left and up arrows

- a list of 4 colors for each direction
- a function which takes a direction and a boolean corresponding to the sign

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: print(M[0].plot().description())                                      #␣
↪needs sage.plot
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
Arrow from (1.0,1.0) to (1.0,2.0)
Arrow from (2.0,0.0) to (1.0,0.0)
Arrow from (2.0,1.0) to (1.0,1.0)
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(2), boundary_conditions='ice')
>>> print(M[Integer(0)].plot().description())                               ␣
↪     # needs sage.plot
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
Arrow from (1.0,1.0) to (1.0,2.0)
Arrow from (2.0,0.0) to (1.0,0.0)
Arrow from (2.0,1.0) to (1.0,1.0)
```

to_signed_matrix()

Return the signed matrix of `self`.

The signed matrix corresponding to a six vertex configuration is given by 0 if there is a cross flow, a 1 if the outward arrows are vertical and -1 if the outward arrows are horizontal.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: [x.to_signed_matrix() for x in M]                                     #␣
↪needs sage.modules
[
[1 0 0]  [1 0 0]  [ 0  1  0]  [0 1 0]  [0 1 0]  [0 0 1]  [0 0 1]
[0 1 0]  [0 0 1]  [ 1 -1  1]  [1 0 0]  [0 0 1]  [1 0 0]  [0 1 0]
[0 0 1], [0 1 0], [ 0  1  0], [0 0 1], [1 0 0], [0 1 0], [1 0 0]
]
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> [x.to_signed_matrix() for x in M]                                    #␣
↪needs sage.modules
[
[1 0 0]  [1 0 0]  [ 0  1  0]  [0 1 0]  [0 1 0]  [0 0 1]  [0 0 1]
[0 1 0]  [0 0 1]  [ 1 -1  1]  [1 0 0]  [0 0 1]  [1 0 0]  [0 1 0]
[0 0 1], [0 1 0], [ 0  1  0], [0 0 1], [1 0 0], [0 1 0], [1 0 0]
]
```

class sage.combinat.six_vertex_model.**SixVertexModel**(*n*, *m*, *boundary_conditions*)

Bases: UniqueRepresentation, Parent

The six vertex model.

We model a configuration by indicating which configuration by the following six configurations which are determined by the two outgoing arrows in the Up, Right, Down, Left directions:

1. LR:

```
    |
    V
<-- # -->
    ^
    |
```

2. LU:

```
    ^
    |
<-- # <--
    ^
    |
```

3. LD:

```
    |
    V
<-- # <--
    |
    V
```

4. UD:

```
    ^
    |
--> # <--
    |
    V
```

5. UR:

```
    ^
    |
--> # -->
```

(continues on next page)

(continued from previous page)

```
    ^
    |
```

6. RD:

```
    |
    V
--> # -->
    |
    V
```

INPUT:

- `n` – the number of rows
- `m` – (optional) the number of columns, if not specified, then the number of columns is the number of rows
- `boundary_conditions` – (optional) a quadruple of tuples whose entries are either:
  - `True` for an inward arrow,
  - `False` for an outward arrow, or
  - `None` for no boundary condition.

  There are also the following predefined boundary conditions:
  - `'ice'` – the top and bottom boundary conditions are outward and the left and right boundary conditions are inward; this gives the square ice model. Also called domain wall boundary conditions.
  - `'domain wall'` – same as `'ice'`.
  - `'alternating'` – the boundary conditions alternate between inward and outward.
  - `'free'` – there are no boundary conditions.

EXAMPLES:

Here are the six types of vertices that can be created:

```
sage: M = SixVertexModel(1)
sage: list(M)
[
    |           ^           |           ^           ^           |
    V           |           V           |           |           V
<-- # -->   <-- # <--   <-- # <--   --> # <--   --> # -->   --> # -->
    ^           ^           |           |           ^           |
    |     ,     |     ,     V     ,     V     ,     |     ,     V
]
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(1))
>>> list(M)
[
    |           ^           |           ^           ^           |
    V           |           V           |           |           V
<-- # -->   <-- # <--   <-- # <--   --> # <--   --> # -->   --> # -->
    ^           ^           |           |           ^           |
```

(continues on next page)

(continued from previous page)

```
    |    ,     |    ,     V    ,     V    ,     |    ,     V
]
```

When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```
sage: M = SixVertexModel(1, boundary_conditions='ice')
sage: len(M)
1
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: len(M)
42
sage: all(len(SixVertexModel(n, boundary_conditions='ice'))                    #␣
↪needs sage.modules
....:     == AlternatingSignMatrices(n).cardinality() for n in range(1, 7))
True
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(1), boundary_conditions='ice')
>>> len(M)
1
>>> M = SixVertexModel(Integer(4), boundary_conditions='ice')
>>> len(M)
42
>>> all(len(SixVertexModel(n, boundary_conditions='ice'))                      #␣
↪needs sage.modules
...      == AlternatingSignMatrices(n).cardinality() for n in range(Integer(1),␣
↪Integer(7)))
True
```

An example with a specified non-standard boundary condition and non-rectangular shape:

```
sage: M = SixVertexModel(2, 1, [[None], [True,True], [None], [None,None]])
sage: list(M)
[
    ^          ^          |          ^
    |          |          V          |
<-- # <--  <-- # <--  <-- # <--  --> # <--
    ^          ^          |          |
    |          |          V          V
<-- # <--  --> # <--  <-- # <--  <-- # <--
    ^          |          |          |
    |    ,     V    ,     V    ,     V
]
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(2), Integer(1), [[None], [True,True], [None],␣
↪[None,None]])
>>> list(M)
[
    ^          ^          |          ^
    |          |          V          |
```

(continues on next page)

(continued from previous page)

```
<-- # <--  <-- # <--  <-- # <--  --> # <--
    ^          ^          |          |
    |          |          V          V
<-- # <--  --> # <--  <-- # <--  <-- # <--
    ^          |          |          |
    |    ,     V    ,     V    ,     V
]
```

REFERENCES:

- Wikipedia article Vertex_model
- Wikipedia article Ice-type_model

Element

alias of *SixVertexConfiguration*

boundary_conditions()

Return the boundary conditions of `self`.

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(2), boundary_conditions='ice')
>>> M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

partition_function(*beta*, *epsilon*)

Return the partition function of `self`.

The partition function of a 6 vertex model is defined by:

$$Z = \sum_{\nu} e^{-\beta E(\nu)}$$

where we sum over all configurations and E is the energy function. The constant β is known as the *inverse temperature* and is equal to $1/k_B T$ where k_B is Boltzmann's constant and T is the system's temperature.

INPUT:

- `beta` – the inverse temperature constant β
- `epsilon` – the energy constants, see *energy()*

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M.partition_function(2, [1,2,1,2,1,2])                                #␣
↪needs sage.symbolic
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> M.partition_function(Integer(2), [Integer(1),Integer(2),Integer(1),
↪Integer(2),Integer(1),Integer(2)])                                    # needs␣
↪sage.symbolic
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```

class sage.combinat.six_vertex_model.**SquareIceModel**(*n*)

Bases: *SixVertexModel*

The square ice model.

The square ice model is a 6 vertex model on an $n \times n$ grid with the boundary conditions that the top and bottom boundaries are pointing outward and the left and right boundaries are pointing inward. These boundary conditions are also called domain wall boundary conditions.

Configurations of the 6 vertex model with domain wall boundary conditions are in bijection with alternating sign matrices.

class Element

Bases: *SixVertexConfiguration*

An element in the square ice model.

to_alternating_sign_matrix()

Return an alternating sign matrix of `self`.

See also

to_signed_matrix()

EXAMPLES:

```
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: M[6].to_alternating_sign_matrix()                                #␣
↪needs sage.modules
[1 0 0 0]
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]
sage: M[7].to_alternating_sign_matrix()                                #␣
↪needs sage.modules
[ 0  1  0  0]
[ 1 -1  1  0]
[ 0  1 -1  1]
[ 0  0  1  0]
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(4), boundary_conditions='ice')
>>> M[Integer(6)].to_alternating_sign_matrix()                          ␣
↪     # needs sage.modules
```

(continues on next page)

(continued from previous page)

```

[ 0  1  0  0]
[ 1 -1  1  0]
[ 0  1 -1  1]
[ 0  0  1  0]
```

from_alternating_sign_matrix(*asm*)

Return a configuration from the alternating sign matrix `asm`.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
↪needs sage.modules
sage: M.from_alternating_sign_matrix(asm)
↪needs sage.modules

```

Skew partitions

A skew partition `skp` of size n is a pair of partitions $[p_1, p_2]$ where p_1 is a partition of the integer n_1, p_2 is a partition of the integer n_2, p_2 is an inner partition of p_1, and $n = n_1 - n_2$. We say that p_1 and p_2 are respectively the *inner* and *outer* partitions of `skp`.

A skew partition can be depicted by a diagram made of rows of cells, in the same way as a partition. Only the cells of the outer partition p_1 which are not in the inner partition p_2 appear in the picture. For example, this is the diagram of the skew partition [[5,4,3,1],[3,3,1]].

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).diagram())
   **
   *
 **
*
```

```
>>> from sage.all import *
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).diagram())
   **
   *
 **
*
```

A skew partition can be *connected*, which can easily be described in graphic terms: for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge. This is the diagram of the connected skew partition `[[5,4,3,1],[3,1]]`:

```
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
   **
 ***
***
*
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

```
>>> from sage.all import *
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]]).diagram())
   **
 ***
***
*
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]]).is_connected()
True
```

The first example of a skew partition is not a connected one.

Applying a reflection with respect to the main diagonal yields the diagram of the *conjugate skew partition*, here `[[4,3,3,2,1],[3,3,2]]`:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).conjugate()
[4, 3, 3, 2, 1] / [3, 2, 2]
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).conjugate().diagram())
```

(continues on next page)

(continued from previous page)

```
   *
  *
  *
**
*
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).conjugate()
[4, 3, 3, 2, 1] / [3, 2, 2]
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).conjugate().diagram())
   *
  *
  *
**
*
```

The *outer corners* of a skew partition are the corners of its outer partition. The *inner corners* are the internal corners of the outer partition when the inner partition is taken off. Shown below are the coordinates of the inner and outer corners.

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).outer_corners()
[(0, 4), (1, 3), (2, 2), (3, 0)]
sage: SkewPartition([[5,4,3,1],[3,3,1]]).inner_corners()
[(0, 3), (2, 1), (3, 0)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).outer_corners()
[(0, 4), (1, 3), (2, 2), (3, 0)]
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).inner_corners()
[(0, 3), (2, 1), (3, 0)]
```

EXAMPLES:

There are 9 skew partitions of size 3, with no empty row nor empty column:

```
sage: SkewPartitions(3).cardinality()
9
sage: SkewPartitions(3).list()
[[3] / [],
 [2, 1] / [],
 [3, 1] / [1],
 [2, 2] / [1],
 [3, 2] / [2],
 [1, 1, 1] / [],
 [2, 2, 1] / [1, 1],
 [2, 1, 1] / [1],
 [3, 2, 1] / [2, 1]]
```

```
>>> from sage.all import *
>>> SkewPartitions(Integer(3)).cardinality()
9
>>> SkewPartitions(Integer(3)).list()
[[3] / [],
 [2, 1] / [],
 [3, 1] / [1],
 [2, 2] / [1],
 [3, 2] / [2],
 [1, 1, 1] / [],
 [2, 2, 1] / [1, 1],
 [2, 1, 1] / [1],
 [3, 2, 1] / [2, 1]]
```

There are 4 connected skew partitions of size 3:

```
sage: SkewPartitions(3, overlap=1).cardinality()
4
sage: SkewPartitions(3, overlap=1).list()
[[3] / [], [2, 1] / [], [2, 2] / [1], [1, 1, 1] / []]
```

```
>>> from sage.all import *
>>> SkewPartitions(Integer(3), overlap=Integer(1)).cardinality()
4
>>> SkewPartitions(Integer(3), overlap=Integer(1)).list()
[[3] / [], [2, 1] / [], [2, 2] / [1], [1, 1, 1] / []]
```

This is the conjugate of the skew partition `[[4,3,1], [2]]`

```
sage: SkewPartition([[4,3,1], [2]]).conjugate()
[3, 2, 2, 1] / [1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)], [Integer(2)]]).conjugate()
[3, 2, 2, 1] / [1, 1]
```

Geometrically, we just applied a reflection with respect to the main diagonal on the diagram of the partition. Of course, this operation is an involution:

```
sage: SkewPartition([[4,3,1],[2]]).conjugate().conjugate()
[4, 3, 1] / [2]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]]).conjugate().
↪conjugate()
[4, 3, 1] / [2]
```

The *jacobi_trudi()* method computes the Jacobi-Trudi matrix. See [Mac1995] for a definition and discussion.

```
sage: SkewPartition([[4,3,1],[2]]).jacobi_trudi()                              #␣
↪needs sage.modules
[h[2]  h[]    0]
```

(continues on next page)

(continued from previous page)

```
[h[5] h[3]  h[]]
[h[6] h[4] h[1]]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]]).jacobi_trudi()  ␣
↪                                # needs sage.modules
[h[2]  h[]    0]
[h[5] h[3]  h[]]
[h[6] h[4] h[1]]
```

This example shows how to compute the corners of a skew partition.

```
sage: SkewPartition([[4,3,1],[2]]).inner_corners()
[(0, 2), (1, 0)]
sage: SkewPartition([[4,3,1],[2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]]).inner_corners()
[(0, 2), (1, 0)]
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

class sage.combinat.skew_partition.**SkewPartition**(*parent*, *skp*)

Bases: *CombinatorialElement*

A skew partition.

A skew partition of shape λ/μ is the Young diagram from the partition λ and removing the partition μ from the upper-left corner in English convention.

cell_poset(*orientation='SE'*)

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to `'SE'`). Concretely, `orientation` has to be specified to one of the strings `'NW'`, `'NE'`, `'SW'`, and `'SE'`, standing for "northwest", "northeast", "southwest" and "southeast", respectively. If `orientation` is `'SE'`, then the order relation of the poset is such that a cell u is greater or equal to a cell v in the poset if and only if u lies weakly southeast of v (this means that u can be reached from v by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of `self`, written as tuples of zero-based coordinates (so that $(3, 7)$ stands for the 8-th cell of the 4-th row, etc.).

EXAMPLES:

```
sage: # needs sage.graphs
sage: p = SkewPartition([[3,3,1], [2,1]])
sage: Q = p.cell_poset(); Q
Finite poset containing 4 elements
sage: sorted(Q)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: sorted(Q.minimal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(Q.upper_covers((1, 1)))
[(1, 2)]
sage: sorted(Q.upper_covers((0, 2)))
[(1, 2)]

sage: # needs sage.graphs
sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 4 elements
sage: sorted(P)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: sorted(P.maximal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]

sage: # needs sage.graphs
sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 4 elements
sage: sorted(R)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: R.upper_covers((2, 0))
[(1, 1)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1]
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> p = SkewPartition([[Integer(3),Integer(3),Integer(1)], [Integer(2),
↪Integer(1)]])
>>> Q = p.cell_poset(); Q
Finite poset containing 4 elements
>>> sorted(Q)
[(0, 2), (1, 1), (1, 2), (2, 0)]
>>> sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
>>> sorted(Q.minimal_elements())
```

(continues on next page)

(continued from previous page)

```
[(0, 2), (1, 1), (2, 0)]
>>> sorted(Q.upper_covers((Integer(1), Integer(1))))
[(1, 2)]
>>> sorted(Q.upper_covers((Integer(0), Integer(2))))
[(1, 2)]

>>> # needs sage.graphs
>>> P = p.cell_poset(orientation="NW"); P
Finite poset containing 4 elements
>>> sorted(P)
[(0, 2), (1, 1), (1, 2), (2, 0)]
>>> sorted(P.minimal_elements())
[(1, 2), (2, 0)]
>>> sorted(P.maximal_elements())
[(0, 2), (1, 1), (2, 0)]
>>> sorted(P.upper_covers((Integer(1), Integer(2))))
[(0, 2), (1, 1)]

>>> # needs sage.graphs
>>> R = p.cell_poset(orientation="NE"); R
Finite poset containing 4 elements
>>> sorted(R)
[(0, 2), (1, 1), (1, 2), (2, 0)]
>>> R.maximal_elements()
[(0, 2)]
>>> R.minimal_elements()
[(2, 0)]
>>> R.upper_covers((Integer(2), Integer(0)))
[(1, 1)]
>>> sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1]
```

cells()

Return the coordinates of the cells of `self`. Coordinates are given as `(row-index, column-index)` and are 0 based.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[4, 3, 1], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[2], []]).cells()
[(0, 0), (0, 1)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], [Integer(2)]]).
↪cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
>>> SkewPartition([[Integer(2)], []]).cells()
```

(continues on next page)

(continued from previous page)

```
[(0, 0), (0, 1)]
```

column_lengths()

Return the column lengths of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).column_lengths()
[1, 2, 1]
sage: SkewPartition([[5,2,2,2],[2,1]]).column_lengths()
[2, 3, 1, 1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).column_lengths()
[1, 2, 1]
>>> SkewPartition([[Integer(5),Integer(2),Integer(2),Integer(2)],[Integer(2),
↪Integer(1)]]).column_lengths()
[2, 3, 1, 1, 1]
```

columns_intersection_set()

Return the set of cells in the columns of the outer shape of `self` which columns intersect the skew diagram of `self`.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([ (0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.columns_intersection_set() == cells
True
```

```
>>> from sage.all import *
>>> skp = SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]])
>>> cells = Set([ (Integer(0),Integer(0)), (Integer(0), Integer(1)),␣
↪(Integer(0),Integer(2)), (Integer(1), Integer(0)), (Integer(1), Integer(1)),
↪ (Integer(2), Integer(0))])
>>> skp.columns_intersection_set() == cells
True
```

conjugate()

Return the conjugate of the skew partition skp.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2]]).conjugate()
[3, 2, 1] / [1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2)]]).
↪conjugate()
[3, 2, 1] / [1, 1]
```

diagram()

alias of *ferrers_diagram()*.

ferrers_diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
   **
   *
 **
*
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
   **
 ***
***
*
sage: SkewPartitions.options(diagram_str='#', convention='French')
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
#
###
 ###
   ##
sage: SkewPartitions.options._reset()
```

```
>>> from sage.all import *
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],
↪[Integer(3),Integer(3),Integer(1)]]).ferrers_diagram())
   **
   *
 **
*
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],
↪[Integer(3),Integer(1)]]).diagram())
   **
 ***
***
*
>>> SkewPartitions.options(diagram_str='#', convention='French')
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],
↪[Integer(3),Integer(1)]]).diagram())
#
###
 ###
   ##
>>> SkewPartitions.options._reset()
```

frobenius_rank()

Return the Frobenius rank of the skew partition `self`.

The Frobenius rank of a skew partition λ/μ can be defined in various ways. The quickest one is probably the following: Writing λ as $(\lambda_1, \lambda_2, \cdots, \lambda_N)$, and writing μ as $(\mu_1, \mu_2, \cdots, \mu_N)$, we define the Frobenius rank

of λ/μ to be the number of all $1 \leq i \leq N$ such that

$$\lambda_i - i \notin \{\mu_1 - 1, \mu_2 - 2, \cdots, \mu_N - N\}.$$

In other words, the Frobenius rank of λ/μ is the number of rows in the Jacobi-Trudi matrix of λ/μ which don't contain h_0. Further definitions have been considered in [Sta2002] (where Frobenius rank is just being called rank).

If μ is the empty shape, then the Frobenius rank of λ/μ is just the usual Frobenius rank of the partition λ (see *frobenius_rank()*).

EXAMPLES:

```
sage: SkewPartition([[8,8,7,4], [4,1,1]]).frobenius_rank()
4
sage: SkewPartition([[2,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1,1]]).frobenius_rank()
2
sage: SkewPartition([[5,4,3,2], [2,1,1]]).frobenius_rank()
3
sage: SkewPartition([[4,2,1], [3,1,1]]).frobenius_rank()
2
sage: SkewPartition([[4,2,1], [3,2,1]]).frobenius_rank()
1
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(8),Integer(8),Integer(7),Integer(4)], [Integer(4),
↪Integer(1),Integer(1)]]).frobenius_rank()
4
>>> SkewPartition([[Integer(2),Integer(1)], [Integer(1)]]).frobenius_rank()
2
>>> SkewPartition([[Integer(2),Integer(1),Integer(1)], [Integer(1)]]).
↪frobenius_rank()
2
>>> SkewPartition([[Integer(2),Integer(1),Integer(1)], [Integer(1),
↪Integer(1)]]).frobenius_rank()
2
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(2)], [Integer(2),
↪Integer(1),Integer(1)]]).frobenius_rank()
3
>>> SkewPartition([[Integer(4),Integer(2),Integer(1)], [Integer(3),Integer(1),
↪Integer(1)]]).frobenius_rank()
2
>>> SkewPartition([[Integer(4),Integer(2),Integer(1)], [Integer(3),Integer(2),
↪Integer(1)]]).frobenius_rank()
1
```

If the inner shape is empty, then the Frobenius rank of the skew partition is just the standard Frobenius rank of the partition:

```
sage: all( SkewPartition([lam, Partition([])]).frobenius_rank()
....:      == lam.frobenius_rank() for i in range(6)
```

(continues on next page)

(continued from previous page)

```
....:       for lam in Partitions(i) )
True
```

```
>>> from sage.all import *
>>> all( SkewPartition([lam, Partition([])]).frobenius_rank()
...       == lam.frobenius_rank() for i in range(Integer(6))
...       for lam in Partitions(i) )
True
```

If the inner and outer shapes are equal, then the Frobenius rank is zero:

```
sage: all( SkewPartition([lam, lam]).frobenius_rank() == 0
....:       for i in range(6) for lam in Partitions(i) )
True
```

```
>>> from sage.all import *
>>> all( SkewPartition([lam, lam]).frobenius_rank() == Integer(0)
...       for i in range(Integer(6)) for lam in Partitions(i) )
True
```

inner()

Return the inner partition of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).inner()
[1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).inner()
[1, 1]
```

inner_corners()

Return a list of the inner corners of `self`.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).inner_corners()
[(0, 2), (1, 0)]
sage: SkewPartition([[4, 3, 1], []]).inner_corners()
[(0, 0)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], [Integer(2)]]).inner_
↪corners()
[(0, 2), (1, 0)]
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], []]).inner_corners()
[(0, 0)]
```

is_connected()

Return `True` if `self` is a connected skew partition.

A skew partition is said to be *connected* if for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge.

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).is_connected()
False
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).is_connected()
False
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]]).is_connected()
True
```

is_overlap(*n*)

Return `True` if the overlap of `self` is at most `n`.

See also

overlap()

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,1]]).is_overlap(1)
True
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]]).is_overlap(Integer(1))
True
```

is_ribbon()

Return `True` if and only if `self` is a ribbon.

This means that if it has exactly one cell in each of q consecutive diagonals for some nonnegative integer q.

EXAMPLES:

```
sage: P = SkewPartition([[4,4,3,3],[3,2,2]])
sage: P.pp()
   *
  **
  *
***
sage: P.is_ribbon()
True

sage: P = SkewPartition([[4,3,3],[1,1]])
sage: P.pp()
```

(continues on next page)

(continued from previous page)

```
 ***
 **
***
sage: P.is_ribbon()
False

sage: P = SkewPartition([[4,4,3,2],[3,2,2]])
sage: P.pp()
   *
  **
  *
**
sage: P.is_ribbon()
False

sage: P = SkewPartition([[4,4,3,3],[4,2,2,1]])
sage: P.pp()

  **
  *
 **
sage: P.is_ribbon()
True

sage: P = SkewPartition([[4,4,3,3],[4,2,2]])
sage: P.pp()

  **
  *
***
sage: P.is_ribbon()
True

sage: SkewPartition([[2,2,1],[2,2,1]]).is_ribbon()
True
```

```
>>> from sage.all import *
>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(3)],
↪[Integer(3),Integer(2),Integer(2)]])
>>> P.pp()
   *
  **
  *
***
>>> P.is_ribbon()
True

>>> P = SkewPartition([[Integer(4),Integer(3),Integer(3)],[Integer(1),
↪Integer(1)]])
>>> P.pp()
 ***
 **
```

(continues on next page)

(continued from previous page)

```
***
>>> P.is_ribbon()
False

>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(2)],
↪[Integer(3),Integer(2),Integer(2)]])
>>> P.pp()
   *
  **
  *
**
>>> P.is_ribbon()
False

>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(3)],
↪[Integer(4),Integer(2),Integer(2),Integer(1)]])
>>> P.pp()
<BLANKLINE>
  **
  *
 **
>>> P.is_ribbon()
True

>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(3)],
↪[Integer(4),Integer(2),Integer(2)]])
>>> P.pp()
<BLANKLINE>
  **
  *
***
>>> P.is_ribbon()
True

>>> SkewPartition([[Integer(2),Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).is_ribbon()
True
```

jacobi_trudi()

Return the Jacobi-Trudi matrix of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).jacobi_trudi()                    #␣
↪needs sage.modules
[h[1]    0    0]
[h[3] h[1]    0]
[h[5] h[3] h[1]]
sage: SkewPartition([[4,3,2],[2,1]]).jacobi_trudi()                    #␣
↪needs sage.modules
[h[2]  h[]    0]
[h[4] h[2]  h[]]
[h[6] h[4] h[2]]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).jacobi_trudi()                          # needs sage.modules
[h[1]    0    0]
[h[3] h[1]    0]
[h[5] h[3] h[1]]
>>> SkewPartition([[Integer(4),Integer(3),Integer(2)],[Integer(2),
↪Integer(1)]]).jacobi_trudi()                          # needs sage.modules
[h[2]  h[]    0]
[h[4] h[2]  h[]]
[h[6] h[4] h[2]]
```

k_conjugate(k)

Return the k-conjugate of the skew partition.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(3)
[2, 1, 1, 1, 1] / [2, 1]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(4)
[2, 2, 1, 1] / [2, 1]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(5)
[3, 2, 1] / [2, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).k_conjugate(Integer(3))
[2, 1, 1, 1, 1] / [2, 1]
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).k_conjugate(Integer(4))
[2, 2, 1, 1] / [2, 1]
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).k_conjugate(Integer(5))
[3, 2, 1] / [2, 1]
```

outer()

Return the outer partition of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).outer()
[3, 2, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).outer()
[3, 2, 1]
```

outer_corners()

Return a list of the outer corners of `self`.

These are corners that are contained inside of the shape. For the corners which are outside of the shape, use *outside_corners()*.

Warning

In the case that `self` is an honest (rather than skew) partition, these are the *corners()* of the outer partition. In the language of [Sag2001] these would be the "inner corners" of the outer partition.

See also

- *sage.combinat.skew_partition.SkewPartition.outside_corners()*
- *sage.combinat.partition.Partition.outside_corners()*

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], [Integer(2)]]).outer_
↪corners()
[(0, 3), (1, 2), (2, 0)]
```

outside_corners()

Return the outside corners of `self`.

The outside corners are corners which are outside of the shape. This should not be confused with *outer_corners()* which consists of corners inside the shape. It returns a result analogous to the `.outside_corners()` method on (non-skew) `Partitions`.

See also

- *sage.combinat.skew_partition.SkewPartition.outer_corners()*
- *sage.combinat.partition.Partition.outside_corners()*

EXAMPLES:

```
sage: mu = SkewPartition([[3,2,1],[2,1]])
sage: mu.pp()
  *
 *
*
sage: mu.outside_corners()
[(0, 3), (1, 2), (2, 1), (3, 0)]
```

```
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]])
>>> mu.pp()
  *
 *
```

(continues on next page)

(continued from previous page)

```
*
>>> mu.outside_corners()
[(0, 3), (1, 2), (2, 1), (3, 0)]
```

overlap()

Return the overlap of `self`.

The overlap of two consecutive rows in a skew partition is the number of pairs of cells (one in each row) that share a common edge. This number can be positive, zero, or negative.

The overlap of a skew partition is the minimum of the overlap of the consecutive rows, or infinity in the case of at most one row. If the overlap is positive, then the skew partition is called *connected*.

EXAMPLES:

```
sage: SkewPartition([[],[]]).overlap()
+Infinity
sage: SkewPartition([[1],[]]).overlap()
+Infinity
sage: SkewPartition([[10],[]]).overlap()
+Infinity
sage: SkewPartition([[10],[2]]).overlap()
+Infinity
sage: SkewPartition([[10,1],[2]]).overlap()
-1
sage: SkewPartition([[10,10],[1]]).overlap()
9
```

```
>>> from sage.all import *
>>> SkewPartition([[],[]]).overlap()
+Infinity
>>> SkewPartition([[Integer(1)],[]]).overlap()
+Infinity
>>> SkewPartition([[Integer(10)],[]]).overlap()
+Infinity
>>> SkewPartition([[Integer(10)],[Integer(2)]]).overlap()
+Infinity
>>> SkewPartition([[Integer(10),Integer(1)],[Integer(2)]]).overlap()
-1
>>> SkewPartition([[Integer(10),Integer(10)],[Integer(1)]]).overlap()
9
```

pieri_macdonald_coeffs()

Computation of the coefficients which appear in the Pieri formula for Macdonald polynomials given in his book (Chapter 6.6 formula 6.24(ii))

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).pieri_macdonald_coeffs()
1
sage: SkewPartition([[3,2,1],[2,2]]).pieri_macdonald_coeffs()
(q^2*t^3 - q^2*t - t^2 + 1)/(q^2*t^3 - q*t^2 - q*t + 1)
sage: SkewPartition([[3,2,1],[2,2,1]]).pieri_macdonald_coeffs()
(q^6*t^8 - q^6*t^6 - q^4*t^7 - q^5*t^5 + q^4*t^5 - q^3*t^6 + q^5*t^3 + 2*q^
```

(continues on next page)

(continued from previous page)

```
↪3*t^4 + q*t^5 - q^3*t^2 + q^2*t^3 - q*t^3 - q^2*t - t^2 + 1)/(q^6*t^8 - q^
↪5*t^7 - q^5*t^6 - q^4*t^6 + q^3*t^5 + 2*q^3*t^4 + q^3*t^3 - q^2*t^2 - q*t^2␣

↪- q*t + 1)
>>> SkewPartition([[Integer(3),Integer(3),Integer(2),Integer(2)],[Integer(3),
↪Integer(2),Integer(2),Integer(1)]]).pieri_macdonald_coeffs()
(q^5*t^6 - q^5*t^5 + q^4*t^6 - q^4*t^5 - q^4*t^3 + q^4*t^2 - q^3*t^3 - q^2*t^
↪4 + q^3*t^2 + q^2*t^3 - q*t^4 + q*t^3 + q*t - q + t - 1)/(q^5*t^6 - q^4*t^5␣
↪- q^3*t^4 - q^3*t^3 + q^2*t^3 + q^2*t^2 + q*t - 1)
```

pp()

Pretty-print `self`.

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).pp()
   **
   *
 **
*
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).pp()
   **
   *
 **
*
```

quotient(k)

The quotient map extended to skew partitions.

EXAMPLES:

```
sage: SkewPartition([[3, 3, 2, 1], [2, 1]]).quotient(2)
[[3] / [], [] / []]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3), Integer(3), Integer(2), Integer(1)],␣
↪[Integer(2), Integer(1)]]).quotient(Integer(2))
[[3] / [], [] / []]
```

row_lengths()

Return the row lengths of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).row_lengths()
[2, 1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).row_lengths()
[2, 1, 1]
```

rows_intersection_set()

Return the set of cells in the rows of the outer shape of `self` which rows intersect the skew diagram of `self`.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([ (0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.rows_intersection_set() == cells
True
```

```
>>> from sage.all import *
>>> skp = SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]])
>>> cells = Set([ (Integer(0),Integer(0)), (Integer(0), Integer(1)),␣
↪(Integer(0),Integer(2)), (Integer(1), Integer(0)), (Integer(1), Integer(1)),
↪ (Integer(2), Integer(0))])
>>> skp.rows_intersection_set() == cells
True
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).size()
4
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).size()
4
```

specht_module(*base_ring=None*)

Return the Specht module corresponding to `self`.

EXAMPLES:

```
sage: mu = SkewPartition([[3,2,1], [2]])
sage: SM = mu.specht_module(QQ)                                                 #␣
↪needs sage.modules
sage: s = SymmetricFunctions(QQ).s()                                            #␣
↪needs sage.modules
sage: s(SM.frobenius_image())                                                   #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(3),Integer(2),Integer(1)], [Integer(2)]])
>>> SM = mu.specht_module(QQ)                                                   #␣
↪needs sage.modules
>>> s = SymmetricFunctions(QQ).s()                                              #␣
↪needs sage.modules
>>> s(SM.frobenius_image())                                                     #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

We verify that the Frobenius image is the corresponding skew Schur function:

```
sage: s[3,2,1].skew_by(s[2])                                                    #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```
>>> from sage.all import *
>>> s[Integer(3),Integer(2),Integer(1)].skew_by(s[Integer(2)])                  ␣
↪                                  # needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```
sage: mu = SkewPartition([[4,2,1], [2,1]])
sage: SM = mu.specht_module(QQ)                                                 #␣
↪needs sage.modules
sage: s(SM.frobenius_image())                                                   #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
sage: s(mu)                                                                     #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
```

```
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(4),Integer(2),Integer(1)], [Integer(2),
↪Integer(1)]])
>>> SM = mu.specht_module(QQ)                                                   #␣
↪needs sage.modules
>>> s(SM.frobenius_image())                                                     #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
>>> s(mu)                                                                       #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
```

specht_module_dimension(*base_ring=None*)

Return the dimension of the Specht module corresponding to `self`.

This is equal to the number of standard (skew) tableaux of shape `self`.

EXAMPLES:

```
sage: mu = SkewPartition([[3,2,1], [2]])
sage: mu.specht_module_dimension()                                          #␣
↪needs sage.modules
8
sage: mu.specht_module_dimension(GF(2))                                     #␣
↪needs sage.modules sage.rings.finite_rings
8
```

```
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(3),Integer(2),Integer(1)], [Integer(2)]])
>>> mu.specht_module_dimension()                                            #␣
↪needs sage.modules
8
>>> mu.specht_module_dimension(GF(Integer(2)))                                ␣
↪     # needs sage.modules sage.rings.finite_rings
8
```

to_dag(*format='string'*)

Return a directed acyclic graph corresponding to the skew partition `self`.

The directed acyclic graph corresponding to a skew partition p is the digraph whose vertices are the cells of p, and whose edges go from each cell to its lower and right neighbors (in English notation).

INPUT:

- `format` – either `'string'` or `'tuple'` (default: `'string'`); determines whether the vertices of the resulting dag will be strings or 2-tuples of coordinates

EXAMPLES:

```
sage: # needs sage.graphs
sage: dag = SkewPartition([[3, 3, 1], [1, 1]]).to_dag()
sage: dag.edges(sort=True)
[('0,1', '0,2', None),
('0,1', '1,1', None),
('0,2', '1,2', None),
('1,1', '1,2', None)]
sage: dag.vertices(sort=True)
['0,1', '0,2', '1,1', '1,2', '2,0']
sage: dag = SkewPartition([[3, 2, 1], [1, 1]]).to_dag(format='tuple')
sage: dag.edges(sort=True)
[((0, 1), (0, 2), None), ((0, 1), (1, 1), None)]
sage: dag.vertices(sort=True)
[(0, 1), (0, 2), (1, 1), (2, 0)]
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> dag = SkewPartition([[Integer(3), Integer(3), Integer(1)], [Integer(1),␣
↪Integer(1)]]).to_dag()
```

(continues on next page)

(continued from previous page)

```
>>> dag.edges(sort=True)
[('0,1', '0,2', None),
('0,1', '1,1', None),
('0,2', '1,2', None),
('1,1', '1,2', None)]
>>> dag.vertices(sort=True)
['0,1', '0,2', '1,1', '1,2', '2,0']
>>> dag = SkewPartition([[Integer(3), Integer(2), Integer(1)], [Integer(1),␣
↪Integer(1)]]).to_dag(format='tuple')
>>> dag.edges(sort=True)
[((0, 1), (0, 2), None), ((0, 1), (1, 1), None)]
>>> dag.vertices(sort=True)
[(0, 1), (0, 2), (1, 1), (2, 0)]
```

to_list()

Return `self` as a list of lists.

EXAMPLES:

```
sage: s = SkewPartition([[4,3,1],[2]])
sage: s.to_list()
[[4, 3, 1], [2]]
sage: type(s.to_list())
<class 'list'>
```

```
>>> from sage.all import *
>>> s = SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]])
>>> s.to_list()
[[4, 3, 1], [2]]
>>> type(s.to_list())
<class 'list'>
```

class sage.combinat.skew_partition.**SkewPartitions**(*is_infinite=False*)

Bases: `UniqueRepresentation`, `Parent`

Skew partitions.

Warning

The iterator of this class only yields skew partitions which are reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column.

EXAMPLES:

```
sage: SkewPartitions(4)
Skew partitions of 4
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(row_lengths=[2,1,2])
Skew partitions with row lengths [2, 1, 2]
sage: SkewPartitions(4, overlap=2)
Skew partitions of 4 with a minimum overlap of 2
```

(continues on next page)

(continued from previous page)

```
sage: SkewPartitions(4, overlap=2).list()
[[4] / [], [2, 2] / []]
```

```
>>> from sage.all import *
>>> SkewPartitions(Integer(4))
Skew partitions of 4
>>> SkewPartitions(Integer(4)).cardinality()
28
>>> SkewPartitions(row_lengths=[Integer(2),Integer(1),Integer(2)])
Skew partitions with row lengths [2, 1, 2]
>>> SkewPartitions(Integer(4), overlap=Integer(2))
Skew partitions of 4 with a minimum overlap of 2
>>> SkewPartitions(Integer(4), overlap=Integer(2)).list()
[[4] / [], [2, 2] / []]
```

Element

alias of *SkewPartition*

from_row_and_column_length(*rowL*, *colL*)

Construct a partition from its row lengths and column lengths.

INPUT:

- `rowL` – a composition or a list of positive integers
- `colL` – a composition or a list of positive integers

OUTPUT:

- If it exists the unique skew-partitions with row lengths `rowL` and column lengths `colL`.
- Raise a `ValueError` if `rowL` and `colL` are not compatible.

EXAMPLES:

```
sage: S = SkewPartitions()
sage: print(S.from_row_and_column_length([3,1,2,2],[2,3,1,1,1]).diagram())
  ***
 *
**
**
sage: S.from_row_and_column_length([],[])
[] / []
sage: S.from_row_and_column_length([1],[1])
[1] / []
sage: S.from_row_and_column_length([2,1],[2,1])
[2, 1] / []
sage: S.from_row_and_column_length([1,2],[1,2])
[2, 2] / [1]
sage: S.from_row_and_column_length([1,2],[1,3])
Traceback (most recent call last):
...
ValueError: sum mismatch: [1, 2] and [1, 3]
sage: S.from_row_and_column_length([3,2,1,2],[2,3,1,1,1])
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: incompatible row and column length : [3, 2, 1, 2] and [2, 3, 1, 1,
↪ 1]
```

```
>>> from sage.all import *
>>> S = SkewPartitions()
>>> print(S.from_row_and_column_length([Integer(3),Integer(1),Integer(2),
↪Integer(2)],[Integer(2),Integer(3),Integer(1),Integer(1),Integer(1)]).
↪diagram())
  ***
 *
**
**
>>> S.from_row_and_column_length([],[])
[] / []
>>> S.from_row_and_column_length([Integer(1)],[Integer(1)])
[1] / []
>>> S.from_row_and_column_length([Integer(2),Integer(1)],[Integer(2),
↪Integer(1)])
[2, 1] / []
>>> S.from_row_and_column_length([Integer(1),Integer(2)],[Integer(1),
↪Integer(2)])
[2, 2] / [1]
>>> S.from_row_and_column_length([Integer(1),Integer(2)],[Integer(1),
↪Integer(3)])
Traceback (most recent call last):
...
ValueError: sum mismatch: [1, 2] and [1, 3]
>>> S.from_row_and_column_length([Integer(3),Integer(2),Integer(1),
↪Integer(2)],[Integer(2),Integer(3),Integer(1),Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: incompatible row and column length : [3, 2, 1, 2] and [2, 3, 1, 1,
↪ 1]
```

Warning

If some rows and columns have length zero, there is no way to retrieve unambiguously the skew partition. We therefore raise a `ValueError`. For examples here are two skew partitions with the same row and column lengths:

```
sage: skp1 = SkewPartition([[2,2],[2,2]])
sage: skp2 = SkewPartition([[2,1],[2,1]])
sage: skp1.row_lengths(), skp1.column_lengths()
([0, 0], [0, 0])
sage: skp2.row_lengths(), skp2.column_lengths()
([0, 0], [0, 0])
sage: SkewPartitions().from_row_and_column_length([0,0], [0,0])
Traceback (most recent call last):
...
ValueError: row and column length must be positive
```

```
>>> from sage.all import *
>>> skp1 = SkewPartition([[Integer(2),Integer(2)],[Integer(2),Integer(2)]])
>>> skp2 = SkewPartition([[Integer(2),Integer(1)],[Integer(2),Integer(1)]])
>>> skp1.row_lengths(), skp1.column_lengths()
([0, 0], [0, 0])
>>> skp2.row_lengths(), skp2.column_lengths()
([0, 0], [0, 0])
>>> SkewPartitions().from_row_and_column_length([Integer(0),Integer(0)],␣
↪[Integer(0),Integer(0)])
Traceback (most recent call last):
...
ValueError: row and column length must be positive
```

options = Current options for SkewPartitions - convention: English - diagram_str: * - display: quotient - latex: young_diagram - latex_diagram_str: \ast - latex_marking_str: X

class sage.combinat.skew_partition.**SkewPartitions_all**

Bases: *SkewPartitions*

Class of all skew partitions.

class sage.combinat.skew_partition.**SkewPartitions_n**(*n*, *overlap*)

Bases: *SkewPartitions*

The set of skew partitions of `n` with overlap at least `overlap` and no empty row.

INPUT:

- `n` – nonnegative integer
- `overlap` – integer (default: 0)

Caveat: this set is stable under conjugation only for `overlap` equal to 0 or 1. What exactly happens for negative overlaps is not yet well specified and subject to change (we may want to introduce vertical overlap constraints as well).

Todo

As is, this set is essentially the composition of `Compositions(n)` (which give the row lengths) and `SkewPartition(n, row_lengths=...)`, and one would want to "inherit" list and cardinality from this composition.

cardinality()

Return the number of skew partitions of the integer n (with given overlap, if specified; and with no empty rows before the last row).

EXAMPLES:

```
sage: SkewPartitions(0).cardinality()
1
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(5).cardinality()
```

(continues on next page)

(continued from previous page)

```
87
sage: SkewPartitions(4, overlap=1).cardinality()
9
sage: SkewPartitions(5, overlap=1).cardinality()
20
sage: s = SkewPartitions(5, overlap=-1)
sage: s.cardinality() == len(s.list())
True
```

```
>>> from sage.all import *
>>> SkewPartitions(Integer(0)).cardinality()
1
>>> SkewPartitions(Integer(4)).cardinality()
28
>>> SkewPartitions(Integer(5)).cardinality()
87
>>> SkewPartitions(Integer(4), overlap=Integer(1)).cardinality()
9
>>> SkewPartitions(Integer(5), overlap=Integer(1)).cardinality()
20
>>> s = SkewPartitions(Integer(5), overlap=-Integer(1))
>>> s.cardinality() == len(s.list())
True
```

class sage.combinat.skew_partition.**SkewPartitions_rowlengths**(*co*, *overlap*)

Bases: *SkewPartitions*

All skew partitions with given row lengths.

sage.combinat.skew_partition.**row_lengths_aux**(*skp*)

EXAMPLES:

```
sage: from sage.combinat.skew_partition import row_lengths_aux
sage: row_lengths_aux([[5,4,3,1],[3,3,1]])
[2, 1, 2]
sage: row_lengths_aux([[5,4,3,1],[3,1]])
[2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.skew_partition import row_lengths_aux
>>> row_lengths_aux([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]])
[2, 1, 2]
>>> row_lengths_aux([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]])
[2, 3]
```

Skew tableaux

AUTHORS:

- Mike Hansen: Initial version
- Travis Scrimshaw, Arthur Lubovsky (2013-02-11): Factored out CombinatorialClass

- Trevor K. Karn (2022-08-03): added `backward_slide`
- Joseph McDonough (2025-04-09): added `add_entry` and `anti_restrict`

class sage.combinat.skew_tableau.**SemistandardSkewTableaux**(*category=None*)

Bases: *SkewTableaux*

Semistandard skew tableaux.

This class can be initialized with several optional variables: the size of the skew tableaux (as a nameless integer variable), their shape (as a nameless skew partition variable), their weight (*weight()*, as a nameless second variable after either the size or the shape) and their maximum entry (as an optional keyword variable called `max_entry`, unless the weight has been specified). If neither the weight nor the maximum entry is specified, the maximum entry defaults to the size of the tableau.

Note that "maximum entry" does not literally mean the highest entry; instead it is just an upper bound that no entry is allowed to surpass.

EXAMPLES:

The (infinite) class of all semistandard skew tableaux:

```
sage: SemistandardSkewTableaux()
Semistandard skew tableaux
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux()
Semistandard skew tableaux
```

The (still infinite) class of all semistandard skew tableaux with maximum entry 2:

```
sage: SemistandardSkewTableaux(max_entry=2)
Semistandard skew tableaux with maximum entry 2
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(max_entry=Integer(2))
Semistandard skew tableaux with maximum entry 2
```

The class of all semistandard skew tableaux of given size 3 and maximum entry 3:

```
sage: SemistandardSkewTableaux(3)
Semistandard skew tableaux of size 3 and maximum entry 3
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(3))
Semistandard skew tableaux of size 3 and maximum entry 3
```

To set a different maximum entry:

```
sage: SemistandardSkewTableaux(3, max_entry = 7)
Semistandard skew tableaux of size 3 and maximum entry 7
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(3), max_entry = Integer(7))
Semistandard skew tableaux of size 3 and maximum entry 7
```

Specifying a shape:

```
sage: SemistandardSkewTableaux([[2,1],[]])
Semistandard skew tableaux of shape [2, 1] / [] and maximum entry 3
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[]])
Semistandard skew tableaux of shape [2, 1] / [] and maximum entry 3
```

Specifying both a shape and a maximum entry:

```
sage: S = SemistandardSkewTableaux([[2,1],[1]], max_entry = 3); S
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
sage: S.list()
[[[None, 1], [1]],
 [[None, 2], [1]],
 [[None, 1], [2]],
 [[None, 3], [1]],
 [[None, 1], [3]],
 [[None, 2], [2]],
 [[None, 3], [2]],
 [[None, 2], [3]],
 [[None, 3], [3]]]

sage: for n in range(5):
....:     print("{} {}".format(n, len(SemistandardSkewTableaux([[2,2,1],[1]], max_
↪entry = n))))
0 0
1 0
2 1
3 9
4 35
```

```
>>> from sage.all import *
>>> S = SemistandardSkewTableaux([[Integer(2),Integer(1)],[Integer(1)]], max_
↪entry = Integer(3)); S
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
>>> S.list()
[[[None, 1], [1]],
 [[None, 2], [1]],
 [[None, 1], [2]],
 [[None, 3], [1]],
 [[None, 1], [3]],
 [[None, 2], [2]],
 [[None, 3], [2]],
 [[None, 2], [3]],
 [[None, 3], [3]]]

>>> for n in range(Integer(5)):
...     print("{} {}".format(n, len(SemistandardSkewTableaux([[Integer(2),
↪Integer(2),Integer(1)],[Integer(1)]], max_entry = n))))
0 0
1 0
2 1
```

(continues on next page)

(continued from previous page)

```
3 9
4 35
```

Specifying a shape and a weight:

```
sage: SemistandardSkewTableaux([[2,1],[]],[2,1])
Semistandard skew tableaux of shape [2, 1] / [] and weight [2, 1]
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[]],[Integer(2),Integer(1)])
Semistandard skew tableaux of shape [2, 1] / [] and weight [2, 1]
```

(the maximum entry is redundant in this case and thus is ignored).

Specifying a size and a weight:

```
sage: SemistandardSkewTableaux(3, [2,1])
Semistandard skew tableaux of size 3 and weight [2, 1]
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(3), [Integer(2),Integer(1)])
Semistandard skew tableaux of size 3 and weight [2, 1]
```

Warning

If the shape is not specified, the iterator of this class yields only skew tableaux whose shape is reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column. (Otherwise it would go on indefinitely.)

Warning

This class acts as a factory. The resulting classes are mainly useful for iteration. Do not rely on their containment tests, as they are not correct, e. g.:

```
sage: SkewTableau([[None]]) in SemistandardSkewTableaux(2)
True
```

```
>>> from sage.all import *
>>> SkewTableau([[None]]) in SemistandardSkewTableaux(Integer(2))
True
```

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_all**(*max_entry*)

Bases: *SemistandardSkewTableaux*

Class of all semistandard skew tableaux, possibly with a given maximum entry.

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_shape**(*p*, *max_entry*)

Bases: *SemistandardSkewTableaux*

Class of semistandard skew tableaux of a fixed skew shape λ/μ with a given max entry.

A semistandard skew tableau with max entry i is required to have all its entries less or equal to i. It is not required to actually contain an entry i.

INPUT:

- `p` – a skew partition
- `max_entry` – the max entry; defaults to the size of `p`

Warning

Input is not checked; please use *SemistandardSkewTableaux* to ensure the options are properly parsed.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux([[2,1],[]]).cardinality()
8
sage: SemistandardSkewTableaux([[2,1],[]], max_entry=2).cardinality()
2
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[]]).cardinality()
8
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[]], max_
↪entry=Integer(2)).cardinality()
2
```

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_shape_weight**(*p*, *mu*)

Bases: *SemistandardSkewTableaux*

Class of semistandard skew tableaux of a fixed skew shape λ/ν and weight μ.

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_size**(*n*, *max_entry*)

Bases: *SemistandardSkewTableaux*

Class of all semistandard skew tableaux of a fixed size n, possibly with a given maximum entry.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2).cardinality()
8
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(2)).cardinality()
8
```

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_size_weight**(*n*, *mu*)

Bases: *SemistandardSkewTableaux*

Class of semistandard tableaux of a fixed size n and weight μ.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2,[1,1]).cardinality()
4
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(2),[Integer(1),Integer(1)]).cardinality()
4
```

class sage.combinat.skew_tableau.**SkewTableau**(*parent*, *st*)

Bases: ClonableList

A skew tableau.

Note that Sage by default uses the English convention for partitions and tableaux. To change this, see *Tableaux.options()*.

EXAMPLES:

```
sage: st = SkewTableau([[None, 1],[2,3]]); st
[[None, 1], [2, 3]]
sage: st.inner_shape()
[1]
sage: st.outer_shape()
[2, 2]
```

```
>>> from sage.all import *
>>> st = SkewTableau([[None, Integer(1)],[Integer(2),Integer(3)]]); st
[[None, 1], [2, 3]]
>>> st.inner_shape()
[1]
>>> st.outer_shape()
[2, 2]
```

The `expr` form of a skew tableau consists of the inner partition followed by a list of the entries in each row from bottom to top:

```
sage: SkewTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```
>>> from sage.all import *
>>> SkewTableau(expr=[[Integer(1),Integer(1)],[[Integer(5)],[Integer(3),
↪Integer(4)],[Integer(1),Integer(2)]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

The `chain` form of a skew tableau consists of a list of partitions $\lambda_1, \lambda_2, \ldots,$, such that all cells in λ_{i+1} that are not in λ_i have entry i:

```
sage: SkewTableau(chain=[[2], [2, 1], [3, 1], [4, 3, 2, 1]])
[[None, None, 2, 3], [1, 3, 3], [3, 3], [3]]
```

```
>>> from sage.all import *
>>> SkewTableau(chain=[[Integer(2)], [Integer(2), Integer(1)], [Integer(3),␣
↪Integer(1)], [Integer(4), Integer(3), Integer(2), Integer(1)]])
[[None, None, 2, 3], [1, 3, 3], [3, 3], [3]]
```

add_entry(*cell*, *m*)

Return the result of setting the entry in cell `cell` equal to `m` in the skew tableau `self`. If the cell is already part of `self`, it replaces the current entry. Otherwise, it attempts to add the cell to the skew tableau.

INPUT:

- `cell` – a pair of nonnegative integers
- `m` – a nonnegative integer

OUTPUT:

The skew tableau `self` with entry in cell `cell` set to `m`. This overwrites an existing entry if `cell` already belongs to `self`, otherwise it adds the cell to the shape.

Note

Both coordinates of `cell` are interpreted as starting at 0. So, `cell == (0, 0)` corresponds to the northwesternmost cell

EXAMPLES:

```
sage: S = SkewTableau([[None, None,1],[1,2,5]]); S.pp()
.  .  1
1  2  5
sage: T = S.add_entry([0,1],1); T.pp()
.  1  1
1  2  5
sage: U = T.add_entry([2,0],3); U.pp()
.  1  1
1  2  5
3
sage: U.add_entry([1,3],4)
Traceback (most recent call last):
...
IndexError: (1, 3) is not an addable cell of the tableau
sage: U.add_entry([0,3],4).pp()
.  1  1  4
1  2  5
3
```

```
>>> from sage.all import *
>>> S = SkewTableau([[None, None,Integer(1)],[Integer(1),Integer(2),
↪Integer(5)]]); S.pp()
.  .  1
1  2  5
>>> T = S.add_entry([Integer(0),Integer(1)],Integer(1)); T.pp()
.  1  1
1  2  5
>>> U = T.add_entry([Integer(2),Integer(0)],Integer(3)); U.pp()
.  1  1
1  2  5
3
>>> U.add_entry([Integer(1),Integer(3)],Integer(4))
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
IndexError: (1, 3) is not an addable cell of the tableau
>>> U.add_entry([Integer(0),Integer(3)],Integer(4)).pp()
.  1  1  4
1  2  5
3
```

anti_restrict(*n*)

Return the skew tableau formed by removing all of the cells from `self` that are filled with a number at most `n`.

INPUT:

- `n` – a nonnegative integer

OUTPUT:

The skew tableau `self` with all entries less than or equal to `n` removed.

EXAMPLES:

```
sage: S = SkewTableau([[None,1,2,3],[4,5,6]])
sage: S.anti_restrict(2)
[[None, None, None, 3], [4, 5, 6]]
sage: S.anti_restrict(1).anti_restrict(2) == S.anti_restrict(2)
True
```

```
>>> from sage.all import *
>>> S = SkewTableau([[None,Integer(1),Integer(2),Integer(3)],[Integer(4),
↪Integer(5),Integer(6)]])
>>> S.anti_restrict(Integer(2))
[[None, None, None, 3], [4, 5, 6]]
>>> S.anti_restrict(Integer(1)).anti_restrict(Integer(2)) == S.anti_
↪restrict(Integer(2))
True
```

backward_slide(*corner=None*)

Apply a backward jeu de taquin slide on the specified outside `corner` of `self`.

Backward jeu de taquin slides are defined in Section 3.7 of [Sag2001].

Warning

The *sage.combinat.skew_partition.SkewPartition.inner_corners()* and *sage.combinat.skew_partition.SkewPartition.outer_corners()* are the *sage.combinat.partition.Partition.corners()* of the inner and outer partitions of the skew shape. They are different from the inner/outer corners defined in [Sag2001].

The "inner corners" of [Sag2001] may be found by calling *sage.combinat.skew_partition.SkewPartition.outer_corners()*. The "outer corners" of [Sag2001] may be found by calling `self.outer_shape().outside_corners()`.

EXAMPLES:

```
sage: T = SkewTableaux()([[2, 2], [4, 4], [5]])
sage: Tableaux.options.display='array'
sage: Q = T.backward_slide(); Q
. 2 2
4 4
5
sage: Q.backward_slide((1, 2))
. 2 2
. 4 4
5
sage: Q.reverse_slide((1, 2)) == Q.backward_slide((1, 2))
True

sage: T = SkewTableaux()([[1, 3],[3],[5]]); T
1 3
3
5
sage: T.reverse_slide((1,1))
. 1
3 3
5
```

```
>>> from sage.all import *
>>> T = SkewTableaux()([[Integer(2), Integer(2)], [Integer(4), Integer(4)],␣
↪[Integer(5)]])
>>> Tableaux.options.display='array'
>>> Q = T.backward_slide(); Q
. 2 2
4 4
5
>>> Q.backward_slide((Integer(1), Integer(2)))
. 2 2
. 4 4
5
>>> Q.reverse_slide((Integer(1), Integer(2))) == Q.backward_slide((Integer(1),
↪ Integer(2)))
True

>>> T = SkewTableaux()([[Integer(1), Integer(3)],[Integer(3)],[Integer(5)]]);␣
↪T
1 3
3
5
>>> T.reverse_slide((Integer(1),Integer(1)))
. 1
3 3
5
```

bender_knuth_involution(*k*, *rows=None*, *check=True*)

Return the image of `self` under the k-th Bender–Knuth involution, assuming `self` is a skew semistandard tableau.

Let T be a tableau, then a *lower free `k` in `T`* means a cell of T which is filled with the integer k and whose

direct lower neighbor is not filled with the integer $k+1$ (in particular, this lower neighbor might not exist at all). Let an *upper free `k + 1` in `T`* mean a cell of T which is filled with the integer $k+1$ and whose direct upper neighbor is not filled with the integer k (in particular, this neighbor might not exist at all). It is clear that for any row r of T, the lower free k's and the upper free $k+1$'s in r together form a contiguous interval or r.

The *`k`-th Bender–Knuth switch at row `i`* changes the entries of the cells in this interval in such a way that if it used to have a entries of k and b entries of $k+1$, it will now have b entries of k and a entries of $k+1$. For fixed k, the k-th Bender–Knuth switches for different i commute. The composition of the k-th Bender–Knuth switches for all rows is called the *`k`-th Bender–Knuth involution*. This is used to show that the Schur functions defined by semistandard (skew) tableaux are symmetric functions.

INPUT:

- `k` – integer
- `rows` – (default: `None`) when set to `None`, the method computes the k-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the k-th Bender–Knuth switches at row i over all i in `rows`. When set to an integer i, the method computes the k-th Bender–Knuth switch at row i. Note the indexing of the rows starts with 1.
- `check` – (default: `True`) check to make sure `self` is semistandard; set to `False` to avoid this check

OUTPUT:

The image of `self` under either the k-th Bender–Knuth involution, the k-th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```
sage: t = SkewTableau([[None,None,None,4,4,5,6,7],[None,2,4,6,7,7,7],

>>> t.bender_knuth_involution(Integer(666)) == t
True
>>> t.bender_knuth_involution(Integer(4), Integer(2)) == t
True
>>> t.bender_knuth_involution(Integer(4), Integer(3))
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
```

The Bender–Knuth involution is an involution:

```
sage: t = SkewTableau([[None,3,4,4],[None,6,10],[7,7,11],[18]])
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k)
....:     == t for k in range(1,4))
True
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(3),Integer(4),Integer(4)],[None,Integer(6),
↪Integer(10)],[Integer(7),Integer(7),Integer(11)],[Integer(18)]])
>>> all(t.bender_knuth_involution(k).bender_knuth_involution(k)
...     == t for k in range(Integer(1),Integer(4)))
True
```

The same for the single switches:

```
sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j)
....:     == t for k in range(1,5) for j in range(1, 5))
True
```

```
>>> from sage.all import *
>>> all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j)
...     == t for k in range(Integer(1),Integer(5)) for j in range(Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(5)))
True
```

Locality of the Bender–Knuth involutions:

```
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l)
....:     == t.bender_knuth_involution(l).bender_knuth_involution(k)
....:     for k in range(1,5) for l in range(1,5) if abs(k - l) > 1)
True
```

```
>>> from sage.all import *
>>> all(t.bender_knuth_involution(k).bender_knuth_involution(l)
...     == t.bender_knuth_involution(l).bender_knuth_involution(k)
...     for k in range(Integer(1),Integer(5)) for l in range(Integer(1),
↪Integer(5)) if abs(k - l) > Integer(1))
True
```

cells()

Return the cells in `self`.

EXAMPLES:

```
sage: s = SkewTableau([[None,1,2],[3],[6]])
sage: s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3)],[Integer(6)]])
>>> s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]
```

cells_by_content(*c*)

Return the coordinates of the cells in `self` with content `c`.

EXAMPLES:

```
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.cells_by_content(0)
[(1, 1)]
sage: s.cells_by_content(1)
[(0, 1), (1, 2)]
sage: s.cells_by_content(2)
[(0, 2)]
sage: s.cells_by_content(-1)
[(1, 0)]
sage: s.cells_by_content(-2)
[(2, 0)]
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3),Integer(4),
↪Integer(5)],[Integer(6)]])
>>> s.cells_by_content(Integer(0))
[(1, 1)]
>>> s.cells_by_content(Integer(1))
[(0, 1), (1, 2)]
>>> s.cells_by_content(Integer(2))
[(0, 2)]
>>> s.cells_by_content(-Integer(1))
[(1, 0)]
>>> s.cells_by_content(-Integer(2))
[(2, 0)]
```

cells_containing(*i*)

Return the list of cells in which the letter `i` appears in the tableau `self`. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates (a, b), where both rows and columns are counted from 0 (so $a = 0$ means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```
sage: t = SkewTableau([[None,None,3],[None,3,5],[4,5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(2)
[]

sage: t = SkewTableau([[None,None,None,None],[None,4,5],[None,5,6],[None,9],
↪[None]])
sage: t.cells_containing(2)
[]
sage: t.cells_containing(4)
[(1, 1)]
sage: t.cells_containing(5)
[(2, 1), (1, 2)]

sage: SkewTableau([]).cells_containing(3)
[]

sage: SkewTableau([[None,None],[None]]).cells_containing(3)
[]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,None,Integer(3)],[None,Integer(3),Integer(5)],
↪[Integer(4),Integer(5)]])
>>> t.cells_containing(Integer(5))
[(2, 1), (1, 2)]
>>> t.cells_containing(Integer(4))
[(2, 0)]
```

(continues on next page)

(continued from previous page)

```
>>> t.cells_containing(Integer(2))
[]

>>> t = SkewTableau([[None,None,None,None],[None,Integer(4),Integer(5)],[None,
↪Integer(5),Integer(6)],[None,Integer(9)],[None]])
>>> t.cells_containing(Integer(2))
[]
>>> t.cells_containing(Integer(4))
[(1, 1)]
>>> t.cells_containing(Integer(5))
[(2, 1), (1, 2)]

>>> SkewTableau([]).cells_containing(Integer(3))
[]

>>> SkewTableau([[None,None],[None]]).cells_containing(Integer(3))
[]
```

check()

Check that `self` is a valid skew tableau. This is currently far too liberal, and only checks some trivial things.

EXAMPLES:

```
sage: t = SkewTableau([[None,1,1],[2]])
sage: t.check()

sage: t = SkewTableau([[None, None, 1], [2, 4], [], [3, 4, 5]])
Traceback (most recent call last):
...
TypeError: a skew tableau cannot have an empty list for a row

sage: s = SkewTableau([[1, None, None],[2, None],[3]])
Traceback (most recent call last):
...
TypeError: not a valid skew tableau
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(1),Integer(1)],[Integer(2)]])
>>> t.check()

>>> t = SkewTableau([[None, None, Integer(1)], [Integer(2), Integer(4)], [],␣
↪[Integer(3), Integer(4), Integer(5)]])
Traceback (most recent call last):
...
TypeError: a skew tableau cannot have an empty list for a row

>>> s = SkewTableau([[Integer(1), None, None],[Integer(2), None],
↪[Integer(3)]])
Traceback (most recent call last):
...
TypeError: not a valid skew tableau
```

column_stabilizer()

Return the `PermutationGroup()` corresponding to the column stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```
sage: # needs sage.groups
sage: cs = SkewTableau([[None,2,3],[1,5],[4]]).column_stabilizer()
sage: cs.order() == factorial(2) * factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> cs = SkewTableau([[None,Integer(2),Integer(3)],[Integer(1),Integer(5)],
↪[Integer(4)]]).column_stabilizer()
>>> cs.order() == factorial(Integer(2)) * factorial(Integer(2))
True
>>> PermutationGroupElement([(Integer(1),Integer(3),Integer(2)),(Integer(4),
↪Integer(5))]) in cs
False
>>> PermutationGroupElement([(Integer(1),Integer(4))]) in cs
True
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2,3]]).conjugate()
[[None, 2], [1, 3]]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]]).conjugate()
[[None, 2], [1, 3]]
```

entries_by_content(*c*)

Return the entries in `self` with content `c`.

EXAMPLES:

```
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.entries_by_content(0)
[4]
sage: s.entries_by_content(1)
[1, 5]
sage: s.entries_by_content(2)
[2]
sage: s.entries_by_content(-1)
[3]
```

(continues on next page)

(continued from previous page)

```
sage: s.entries_by_content(-2)
[6]
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3),Integer(4),
↪Integer(5)],[Integer(6)]])
>>> s.entries_by_content(Integer(0))
[4]
>>> s.entries_by_content(Integer(1))
[1, 5]
>>> s.entries_by_content(Integer(2))
[2]
>>> s.entries_by_content(-Integer(1))
[3]
>>> s.entries_by_content(-Integer(2))
[6]
```

evaluation()

alias of *weight()*.

filling()

Return a list of the non-empty entries in `self`.

EXAMPLES:

```
sage: t = SkewTableau([[None,1],[2,3]])
sage: t.filling()
[[1], [2, 3]]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> t.filling()
[[1], [2, 3]]
```

inner_shape()

Return the inner shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).inner_shape()
[1, 1]
sage: SkewTableau([[1,2],[3,4],[7]]).inner_shape()
[]
sage: SkewTableau([[None,None,None,2,3],[None,1],[None],[2]]).inner_shape()
[3, 1, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1),Integer(2)],[None,Integer(3)],
↪[Integer(4)]]).inner_shape()
[1, 1]
>>> SkewTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)],
↪[Integer(7)]]).inner_shape()
```

(continues on next page)

(continued from previous page)

```
[]
>>> SkewTableau([[None,None,None,Integer(2),Integer(3)],[None,Integer(1)],
↪[None],[Integer(2)]]).inner_shape()
[3, 1, 1]
```

inner_size()

Return the size of the inner shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).inner_size()
2
sage: SkewTableau([[None, 2], [1, 3]]).inner_size()
1
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],␣
↪[Integer(1)]]).inner_size()
2
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).inner_size()
1
```

is_k_tableau(k)

Check whether `self` is a valid skew weak k-tableau.

EXAMPLES:

```
sage: t = SkewTableau([[None,2,3],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None,1,3],[2,2],[3]])
sage: t.is_k_tableau(3)
False
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(2),Integer(3)],[Integer(2),Integer(3)],
↪[Integer(3)]])
>>> t.is_k_tableau(Integer(3))
True
>>> t = SkewTableau([[None,Integer(1),Integer(3)],[Integer(2),Integer(2)],
↪[Integer(3)]])
>>> t.is_k_tableau(Integer(3))
False
```

is_ribbon()

Return `True` if and only if the shape of `self` is a ribbon.

This means that it has exactly one cell in each of q consecutive diagonals for some nonnegative integer q.

EXAMPLES:

```
sage: S = SkewTableau([[None, None, 1, 2],[None, None, 3],[1, 3, 4]])
sage: S.pp()
```

(continues on next page)

(continued from previous page)

```
  .  .  1  2
  .  .  3
  1  3  4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, 1, 1, 2],[None, 2, 3],[1, 3, 4]])
sage: S.pp()
  .  1  1  2
  .  2  3
  1  3  4
sage: S.is_ribbon()
False

sage: S = SkewTableau([[None, None, 1, 2],[None, None, 3],[1]])
sage: S.pp()
  .  .  1  2
  .  .  3
  1
sage: S.is_ribbon()
False

sage: S = SkewTableau([[None, None, None, None],[None, None, 3],[1, 2, 4]])
sage: S.pp()
  .  .  .  .
  .  .  3
  1  2  4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, None, None, None],[None, None, 3],[None, 2, 4]])
sage: S.pp()
  .  .  .  .
  .  .  3
  .  2  4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, None],[None]])
sage: S.pp()
  .  .
  .
sage: S.is_ribbon()
True
```

```
>>> from sage.all import *
>>> S = SkewTableau([[None, None, Integer(1), Integer(2)],[None, None,␣
↪Integer(3)],[Integer(1), Integer(3), Integer(4)]])
>>> S.pp()
  .  .  1  2
  .  .  3
  1  3  4
```

(continues on next page)

(continued from previous page)

```
>>> S.is_ribbon()
True

>>> S = SkewTableau([[None, Integer(1), Integer(1), Integer(2)],[None,␣
↪Integer(2), Integer(3)],[Integer(1), Integer(3), Integer(4)]])
>>> S.pp()
  .  1  1  2
  .  2  3
  1  3  4
>>> S.is_ribbon()
False

>>> S = SkewTableau([[None, None, Integer(1), Integer(2)],[None, None,␣
↪Integer(3)],[Integer(1)]])
>>> S.pp()
  .  .  1  2
  .  .  3
  1
>>> S.is_ribbon()
False

>>> S = SkewTableau([[None, None, None, None],[None, None, Integer(3)],
↪[Integer(1), Integer(2), Integer(4)]])
>>> S.pp()
  .  .  .  .
  .  .  3
  1  2  4
>>> S.is_ribbon()
True

>>> S = SkewTableau([[None, None, None, None],[None, None, Integer(3)],[None,␣
↪Integer(2), Integer(4)]])
>>> S.pp()
  .  .  .  .
  .  .  3
  .  2  4
>>> S.is_ribbon()
True

>>> S = SkewTableau([[None, None],[None]])
>>> S.pp()
  .  .
  .
>>> S.is_ribbon()
True
```

is_semistandard()

Return `True` if `self` is a semistandard skew tableau and `False` otherwise.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 2], [1, 3]]).is_semistandard()
```

(continues on next page)

(continued from previous page)

```
True
sage: SkewTableau([[None, 2], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 3], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 3, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [1, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2, 3], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [None, None, 4]]).is_semistandard()
False
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2), Integer(2)], [Integer(1), Integer(3)]]).
↪is_semistandard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(2), Integer(4)]]).is_
↪semistandard()
True
>>> SkewTableau([[None, Integer(3)], [Integer(2), Integer(4)]]).is_
↪semistandard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(2)]]).is_
↪semistandard()
False
>>> SkewTableau([[None, Integer(2), Integer(3)]]).is_semistandard()
True
>>> SkewTableau([[None, Integer(3), Integer(2)]]).is_semistandard()
False
>>> SkewTableau([[None, Integer(2), Integer(3)], [Integer(1), Integer(4)]]).
↪is_semistandard()
True
>>> SkewTableau([[None, Integer(2), Integer(3)], [Integer(1), Integer(2)]]).
↪is_semistandard()
False
>>> SkewTableau([[None, Integer(2), Integer(3)], [None, None, Integer(4)]]).
↪is_semistandard()
False
```

is_standard()

Return `True` if `self` is a standard skew tableau and `False` otherwise.

EXAMPLES:

```
sage: SkewTableau([[None, 2], [1, 3]]).is_standard()
True
```

(continues on next page)

(continued from previous page)

```
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 3], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).is_standard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(2), Integer(4)]]).is_standard()
False
>>> SkewTableau([[None, Integer(3)], [Integer(2), Integer(4)]]).is_standard()
False
>>> SkewTableau([[None, Integer(2)], [Integer(2), Integer(4)]]).is_standard()
False
```

outer_shape()

Return the outer shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).outer_shape()
[3, 2, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1),Integer(2)],[None,Integer(3)],
↪[Integer(4)]]).outer_shape()
[3, 2, 1]
```

outer_size()

Return the size of the outer shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).outer_size()
6
sage: SkewTableau([[None, 2], [1, 3]]).outer_size()
4
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],␣
↪[Integer(1)]]).outer_size()
6
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).outer_size()
4
```

pp()

Return a pretty print string of the tableau.

EXAMPLES:

```
sage: SkewTableau([[None,2,3],[None,4],[5]]).pp()
  .  2  3
  .  4
  5
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(2),Integer(3)],[None,Integer(4)],
↪[Integer(5)]]).pp()
  .  2  3
  .  4
  5
```

rectify(*algorithm=None*)

Return a *StandardTableau*, *SemistandardTableau*, or just *Tableau* formed by applying the jeu de taquin process to `self`.

See page 15 of [Ful1997].

INPUT:

- `algorithm` – (optional) if set to `'jdt'`, rectifies by jeu de taquin; if set to `'schensted'`, rectifies by Schensted insertion of the reading word. Otherwise, guesses which will be faster.

EXAMPLES:

```
sage: S = SkewTableau([[None,1],[2,3]])
sage: S.rectify()
[[1, 3], [2]]
sage: T = SkewTableau([[None, None, None, 4],[None,None,1,6],[None,None,5],[2,
↪3]])
sage: T.rectify()
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='jdt')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='schensted')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='spaghetti')
Traceback (most recent call last):
...
ValueError: algorithm must be 'jdt', 'schensted', or None
```

```
>>> from sage.all import *
>>> S = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> S.rectify()
[[1, 3], [2]]
>>> T = SkewTableau([[None, None, None, Integer(4)],[None,None,Integer(1),
↪Integer(6)],[None,None,Integer(5)],[Integer(2),Integer(3)]])
>>> T.rectify()
[[1, 3, 4, 6], [2, 5]]
>>> T.rectify(algorithm='jdt')
[[1, 3, 4, 6], [2, 5]]
>>> T.rectify(algorithm='schensted')
[[1, 3, 4, 6], [2, 5]]
>>> T.rectify(algorithm='spaghetti')
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: algorithm must be 'jdt', 'schensted', or None
```

restrict(n)

Return the restriction of the (semi)standard skew tableau to all the numbers less than or equal to `n`.

> **Note**
>
> If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method *restriction_outer_shape()* is preferred. Similarly if only the skew shape is needed, use *restriction_shape()*.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).restrict(2)
[[None, 1], [2]]
sage: SkewTableau([[None,1],[2],[3]]).restrict(1)
[[None, 1]]
sage: SkewTableau([[None,1],[1],[2]]).restrict(1)
[[None, 1], [1]]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).
↪restrict(Integer(2))
[[None, 1], [2]]
>>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).
↪restrict(Integer(1))
[[None, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).
↪restrict(Integer(1))
[[None, 1], [1]]
```

restriction_outer_shape(n)

Return the outer shape of the restriction of the semistandard skew tableau `self` to n.

If T is a semistandard skew tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the outer shape of the restriction. For the restriction itself, use *restrict()*.

EXAMPLES:

```
sage: SkewTableau([[None,None],[2,3],[3,4]]).restriction_outer_shape(3)
[2, 2, 1]
sage: SkewTableau([[None,2],[None],[4],[5]]).restriction_outer_shape(2)
[2, 1]
sage: T = SkewTableau([[None,None,3,5],[None,4,4],[17]])
sage: T.restriction_outer_shape(0)
[2, 1]
sage: T.restriction_outer_shape(2)
[2, 1]
```

(continues on next page)

(continued from previous page)

```
sage: T.restriction_outer_shape(3)
[3, 1]
sage: T.restriction_outer_shape(4)
[3, 3]
sage: T.restriction_outer_shape(19)
[4, 3, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,None],[Integer(2),Integer(3)],[Integer(3),
↪Integer(4)]]).restriction_outer_shape(Integer(3))
[2, 2, 1]
>>> SkewTableau([[None,Integer(2)],[None],[Integer(4)],[Integer(5)]]).
↪restriction_outer_shape(Integer(2))
[2, 1]
>>> T = SkewTableau([[None,None,Integer(3),Integer(5)],[None,Integer(4),
↪Integer(4)],[Integer(17)]])
>>> T.restriction_outer_shape(Integer(0))
[2, 1]
>>> T.restriction_outer_shape(Integer(2))
[2, 1]
>>> T.restriction_outer_shape(Integer(3))
[3, 1]
>>> T.restriction_outer_shape(Integer(4))
[3, 3]
>>> T.restriction_outer_shape(Integer(19))
[4, 3, 1]
```

restriction_shape(*n*)

Return the skew shape of the restriction of the semistandard skew tableau `self` to `n`.

If T is a semistandard skew tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the skew shape of the restriction. For the restriction itself, use *restrict()*.

EXAMPLES:

```
sage: SkewTableau([[None,None],[2,3],[3,4]]).restriction_shape(3)
[2, 2, 1] / [2]
sage: SkewTableau([[None,2],[None],[4],[5]]).restriction_shape(2)
[2, 1] / [1, 1]
sage: T = SkewTableau([[None,None,3,5],[None,4,4],[17]])
sage: T.restriction_shape(0)
[2, 1] / [2, 1]
sage: T.restriction_shape(2)
[2, 1] / [2, 1]
sage: T.restriction_shape(3)
[3, 1] / [2, 1]
sage: T.restriction_shape(4)
[3, 3] / [2, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,None],[Integer(2),Integer(3)],[Integer(3),
```

(continues on next page)

(continued from previous page)

```
↪Integer(4)]]).restriction_shape(Integer(3))
[2, 2, 1] / [2]
>>> SkewTableau([[None,Integer(2)],[None],[Integer(4)],[Integer(5)]]).
↪restriction_shape(Integer(2))
[2, 1] / [1, 1]
>>> T = SkewTableau([[None,None,Integer(3),Integer(5)],[None,Integer(4),
↪Integer(4)],[Integer(17)]])
>>> T.restriction_shape(Integer(0))
[2, 1] / [2, 1]
>>> T.restriction_shape(Integer(2))
[2, 1] / [2, 1]
>>> T.restriction_shape(Integer(3))
[3, 1] / [2, 1]
>>> T.restriction_shape(Integer(4))
[3, 3] / [2, 1]
```

reverse_slide(*corner=None*)

alias of *backward_slide()*.

row_stabilizer()

Return the PermutationGroup() corresponding to the row stabilizer of self.

This assumes that every integer from 1 to the size of self appears exactly once in self.

EXAMPLES:

```
sage: # needs sage.groups
sage: rs = SkewTableau([[None,1,2,3],[4,5]]).row_stabilizer()
sage: rs.order() == factorial(3) * factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs = SkewTableau([[None,1,2],[3]]).row_stabilizer()
sage: PermutationGroupElement([(1,2),(3,)]) in rs
True
sage: rs.one().domain()
[1, 2, 3]
sage: rs = SkewTableau([[None,None,1],[None,2],[3]]).row_stabilizer()
sage: rs.order()
1
sage: rs = SkewTableau([[None,None,2,4,5],[1,3]]).row_stabilizer()
sage: rs.order()
12
sage: rs = SkewTableau([]).row_stabilizer()
sage: rs.order()
1
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> rs = SkewTableau([[None,Integer(1),Integer(2),Integer(3)],[Integer(4),
↪Integer(5)]]).row_stabilizer()
```

(continues on next page)

(continued from previous page)

```
>>> rs.order() == factorial(Integer(3)) * factorial(Integer(2))
True
>>> PermutationGroupElement([(Integer(1),Integer(3),Integer(2)),(Integer(4),
↪Integer(5))]) in rs
True
>>> PermutationGroupElement([(Integer(1),Integer(4))]) in rs
False
>>> rs = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3)]]).row_
↪stabilizer()
>>> PermutationGroupElement([(Integer(1),Integer(2)),(Integer(3),)]) in rs
True
>>> rs.one().domain()
[1, 2, 3]
>>> rs = SkewTableau([[None,None,Integer(1)],[None,Integer(2)],[Integer(3)]]).
↪row_stabilizer()
>>> rs.order()
1
>>> rs = SkewTableau([[None,None,Integer(2),Integer(4),Integer(5)],
↪[Integer(1),Integer(3)]]).row_stabilizer()
>>> rs.order()
12
>>> rs = SkewTableau([]).row_stabilizer()
>>> rs.order()
1
```

shape()

Return the shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).shape()
[3, 2, 1] / [1, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1),Integer(2)],[None,Integer(3)],
↪[Integer(4)]]).shape()
[3, 2, 1] / [1, 1]
```

shuffle(*t2*)

Shuffle the standard tableaux `self` and `t2`.

Let `t1 = self`. The shape of `t2` must extend the shape of `t1`, that is, `self.outer_shape() == t2.inner_shape()`. Then this function computes the pair of tableaux `(t2_new, t1_new)` obtained by using jeu de taquin slides to move the boxes of `t2` behind the boxes of `self`.

The entries of `t2_new` are obtained by performing successive inwards jeu de taquin slides on `t2` in the order indicated by the entries of `t1`, from largest to smallest. The entries of `t1` then slide outwards one by one and land in the squares vacated successively by `t2`, forming `t1_new`.

Note

Equivalently, the entries of `t1_new` are obtained by performing outer jeu de taquin slides on `t1` in the order indicated by the entries of `t2`, from smallest to largest. In this case the entries of `t2` slide backwards

and fill the squares successively vacated by `t1` and so form `t2_new`. (This is not how the algorithm is implemented.)

INPUT:

- `self`, `t2` – a pair of standard SkewTableaux with `self.outer_shape() == t2.inner_shape()`

OUTPUT:

- `t2_new, t1_new` – a pair of standard *SkewTableaux* with `t2_new.outer_shape() == t1_new.inner_shape()`

EXAMPLES:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: (t2_new, t1_new) = t1.shuffle(t2)
sage: t1_new
[[None, None, None, 2], [None, None, 1], [None, 3, 4]]
sage: t2_new
[[None, 2, 3], [1, 4], [5]]
sage: t1_new.outer_shape() == t2.outer_shape()
True
sage: t2_new.inner_shape() == t1.inner_shape()
True
```

```
>>> from sage.all import *
>>> t1 = SkewTableau([[None, Integer(1), Integer(2)], [Integer(3),␣
↪Integer(4)]])
>>> t2 = SkewTableau([[None, None, None, Integer(3)], [None, None,␣
↪Integer(4)], [Integer(1), Integer(2), Integer(5)]])
>>> (t2_new, t1_new) = t1.shuffle(t2)
>>> t1_new
[[None, None, None, 2], [None, None, 1], [None, 3, 4]]
>>> t2_new
[[None, 2, 3], [1, 4], [5]]
>>> t1_new.outer_shape() == t2.outer_shape()
True
>>> t2_new.inner_shape() == t1.inner_shape()
True
```

Shuffling is an involution:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: sh = lambda x,y : x.shuffle(y)
sage: (t1, t2) == sh(*sh(t1, t2))
True
```

```
>>> from sage.all import *
>>> t1 = SkewTableau([[None, Integer(1), Integer(2)], [Integer(3),␣
↪Integer(4)]])
>>> t2 = SkewTableau([[None, None, None, Integer(3)], [None, None,␣
↪Integer(4)], [Integer(1), Integer(2), Integer(5)]])
```

(continues on next page)

(continued from previous page)

```
>>> sh = lambda x,y : x.shuffle(y)
>>> (t1, t2) == sh(*sh(t1, t2))
True
```

Both tableaux must be standard:

```
sage: t1 = SkewTableau([[None, 1, 2], [2, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 6]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
```

```
>>> from sage.all import *
>>> t1 = SkewTableau([[None, Integer(1), Integer(2)], [Integer(2),␣
↪Integer(4)]])
>>> t2 = SkewTableau([[None, None, None, Integer(3)], [None, None,␣
↪Integer(4)], [Integer(1), Integer(2), Integer(5)]])
>>> t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
>>> t1 = SkewTableau([[None, Integer(1), Integer(2)], [Integer(3),␣
↪Integer(4)]])
>>> t2 = SkewTableau([[None, None, None, Integer(3)], [None, None,␣
↪Integer(4)], [Integer(1), Integer(2), Integer(6)]])
>>> t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
```

The shapes (not just the nonempty cells) must be adjacent:

```
sage: t1 = SkewTableau([[None, None, None], [1]])
sage: t2 = SkewTableau([[None], [None], [1]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the shapes must be adjacent
```

```
>>> from sage.all import *
>>> t1 = SkewTableau([[None, None, None], [Integer(1)]])
>>> t2 = SkewTableau([[None], [None], [Integer(1)]])
>>> t1.shuffle(t2)
Traceback (most recent call last):
...
```

(continues on next page)

(continued from previous page)

```
ValueError: the shapes must be adjacent
```

size()

Return the number of cells in `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).size()
4
sage: SkewTableau([[None, 2], [1, 3]]).size()
3
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],␣
↪[Integer(1)]]).size()
4
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).size()
3
```

slide(*corner=None*, *return_vacated=False*)

Apply a jeu de taquin slide to `self` on the specified inner corner and return the resulting tableau.

If no corner is given, the topmost inner corner is chosen.

The optional parameter `return_vacated=True` causes the output to be the pair `(t, (i, j))` where `t` is the new tableau and `(i, j)` are the coordinates of the vacated square.

See [Ful1997] p12-13.

EXAMPLES:

```
sage: st = SkewTableau([[None, None, None, None, 2], [None, None, None, None,␣
↪6], [None, 2, 4, 4], [2, 3, 6], [5, 5]])
sage: st.slide((2, 0))
[[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3,␣
↪5, 6], [5]]
sage: st2 = SkewTableau([[None, None, 3], [None, 2, 4], [1, 5]])
sage: st2.slide((1, 0), True)
([[None, None, 3], [1, 2, 4], [5]], (2, 1))
```

```
>>> from sage.all import *
>>> st = SkewTableau([[None, None, None, None, Integer(2)], [None, None, None,
↪ None, Integer(6)], [None, Integer(2), Integer(4), Integer(4)], [Integer(2),
↪ Integer(3), Integer(6)], [Integer(5), Integer(5)]])
>>> st.slide((Integer(2), Integer(0)))
[[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3,␣
↪5, 6], [5]]
>>> st2 = SkewTableau([[None, None, Integer(3)], [None, Integer(2),␣
↪Integer(4)], [Integer(1), Integer(5)]])
>>> st2.slide((Integer(1), Integer(0)), True)
([[None, None, 3], [1, 2, 4], [5]], (2, 1))
```

standardization(*check=True*)

Return the standardization of `self`, assuming `self` is a semistandard skew tableau.

The standardization of a semistandard skew tableau T is the standard skew tableau $\mathrm{st}(T)$ of the same shape as T whose reversed reading word is the standardization of the reversed reading word of T.

The standardization of a word w can be formed by replacing all 1's in w by $1, 2, \ldots, k_1$ from left to right, all 2's in w by $k_1+1, k_1+2, \ldots, k_2$, and repeating for all letters that appear in w. See also *sage.combinat.words.finite_word.FiniteWord_class.standard_permutation()*.

INPUT:

- `check` – (default: `True`) check to make sure `self` is semistandard; set to `False` to avoid this check

EXAMPLES:

```
sage: t = SkewTableau([[None,None,3,4,7,19],[None,4,4,8],[None,5,16,17],
↪[None],[2],[3]])
sage: t.standardization()
[[None, None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1],␣
↪[2]]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,None,Integer(3),Integer(4),Integer(7),Integer(19)],
↪[None,Integer(4),Integer(4),Integer(8)],[None,Integer(5),Integer(16),
↪Integer(17)],[None],[Integer(2)],[Integer(3)]])
>>> t.standardization()
[[None, None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1],␣
↪[2]]
```

Standard skew tableaux are fixed under standardization:

```
sage: p = Partition([4,3,3,2])
sage: q = Partitions(3).random_element()                                    #␣
↪needs sage.libs.flint
sage: all(t == t.standardization()                                          #␣
↪needs sage.libs.flint
....:     for t in StandardSkewTableaux([p, q]))
True
```

```
>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(3),Integer(3),Integer(2)])
>>> q = Partitions(Integer(3)).random_element()                                ␣
↪     # needs sage.libs.flint
>>> all(t == t.standardization()                                            #␣
↪needs sage.libs.flint
...     for t in StandardSkewTableaux([p, q]))
True
```

The reading word of the standardization is the standardization of the reading word:

```
sage: t = SkewTableau([[None,3,4,4],[None,6,10],[7,7,11],[18]])
sage: t.to_word().standard_permutation() == t.standardization().to_
↪permutation()
True
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(3),Integer(4),Integer(4)],[None,Integer(6),
```

(continues on next page)

(continued from previous page)

```
↪Integer(10)],[Integer(7),Integer(7),Integer(11)],[Integer(18)]])
>>> t.to_word().standard_permutation() == t.standardization().to_permutation()
True
```

to_chain(*max_entry=None*)

Return the chain of partitions corresponding to the (semi)standard skew tableau `self`.

The optional keyword parameter `max_entry` can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer `n`, then the chain is constructed from the positions of the letters $1, 2, \ldots, n$ in the tableau.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=2)
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=3)
[[1], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=1)
[[1], [2, 1]]
sage: SkewTableau([[None,None,2],[None,3],[None,5]]).to_chain(max_entry=6)
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
sage: SkewTableau([]).to_chain()
[[]]
sage: SkewTableau([]).to_chain(max_entry=1)
[[], []]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_
↪entry=Integer(2))
[[1], [2, 1], [2, 1, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_
↪entry=Integer(3))
[[1], [2, 1], [2, 1, 1], [2, 1, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_
↪entry=Integer(1))
[[1], [2, 1]]
>>> SkewTableau([[None,None,Integer(2)],[None,Integer(3)],[None,Integer(5)]]).
↪to_chain(max_entry=Integer(6))
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
>>> SkewTableau([]).to_chain()
[[]]
>>> SkewTableau([]).to_chain(max_entry=Integer(1))
[[], []]
```

to_expr()

The first list in a result corresponds to the inner partition of the skew shape. The second list is a list of the rows in the skew tableau read from the bottom up.

Provided for compatibility with MuPAD-Combinat. In MuPAD-Combinat, if `t` is a skew tableau, then to_expr gives the same result as `expr(t)` would give in MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableau([[None,1,1,3],[None,2,2],[1]]).to_expr()
[[1, 1], [[1], [2, 2], [1, 1, 3]]]
sage: SkewTableau([]).to_expr()
[[], []]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1),Integer(1),Integer(3)],[None,Integer(2),
↪Integer(2)],[Integer(1)]]).to_expr()
[[1, 1], [[1], [2, 2], [1, 1, 3]]]
>>> SkewTableau([]).to_expr()
[[], []]
```

to_list()

Return a (mutable) list representation of `self`.

EXAMPLES:

```
sage: stlist = [[None, None, 3], [None, 1, 3], [2, 2]]
sage: st = SkewTableau(stlist)
sage: st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]
sage: st.to_list() == stlist
True
```

```
>>> from sage.all import *
>>> stlist = [[None, None, Integer(3)], [None, Integer(1), Integer(3)],␣
↪[Integer(2), Integer(2)]]
>>> st = SkewTableau(stlist)
>>> st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]
>>> st.to_list() == stlist
True
```

to_permutation()

Return a permutation with the entries of `self` obtained by reading `self` row by row, from the bottommost to the topmost row, with each row being read from left to right, in English convention. See *to_word_by_row()*.

EXAMPLES:

```
sage: SkewTableau([[None,2],[3,4],[None],[1]]).to_permutation()
[1, 3, 4, 2]
sage: SkewTableau([[None,2],[None,4],[1],[3]]).to_permutation()
[3, 1, 4, 2]
sage: SkewTableau([[None]]).to_permutation()
[]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(2)],[Integer(3),Integer(4)],[None],
↪[Integer(1)]]).to_permutation()
[1, 3, 4, 2]
>>> SkewTableau([[None,Integer(2)],[None,Integer(4)],[Integer(1)],
↪[Integer(3)]]).to_permutation()
[3, 1, 4, 2]
>>> SkewTableau([[None]]).to_permutation()
[]
```

to_ribbon(*check_input=True*)

Return `self` as a ribbon-shaped tableau (*RibbonShapedTableau*), provided that the shape of `self` is a ribbon.

INPUT:

- `check_input` – boolean (default: `True`); whether or not to check that `self` indeed has ribbon shape

EXAMPLES:

```
sage: SkewTableau([[None,1],[2,3]]).to_ribbon()
[[None, 1], [2, 3]]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]]).to_ribbon()
[[None, 1], [2, 3]]
```

to_tableau()

Return a tableau with the same filling. This only works if the inner shape of the skew tableau has size zero.

EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]).to_tableau()
[[1, 2], [3, 4]]
```

```
>>> from sage.all import *
>>> SkewTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).to_
↪tableau()
[[1, 2], [3, 4]]
```

to_word()

alias of *to_word_by_row()*.

to_word_by_column()

Return the word obtained from a column reading of the skew tableau.

This is the word obtained by concatenating the columns from the rightmost one (in English notation) to the leftmost one.

EXAMPLES:

```
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.pp()
  .  1
  2  3
```

(continues on next page)

(continued from previous page)

```
sage: s.to_word_by_column()
word: 132
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> s.pp()
  .  1
  2  3
>>> s.to_word_by_column()
word: 132
```

```
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
.  2  4
.  3
1
sage: s.to_word_by_column()
word: 4231
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],␣
↪[Integer(1)]])
>>> s.pp()
.  2  4
.  3
1
>>> s.to_word_by_column()
word: 4231
```

to_word_by_row()

Return a word obtained from a row reading of `self`.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

```
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.pp()
  .  1
  2  3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
  .  2  4
  .  3
  1
sage: s.to_word_by_row()
word: 1324
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> s.pp()
  .  1
  2  3
>>> s.to_word_by_row()
word: 231
>>> s = SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],␣
↪[Integer(1)]])
>>> s.pp()
  .  2  4
  .  3
  1
>>> s.to_word_by_row()
word: 1324
```

weight()

Return the weight (aka evaluation) of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau T is the sequence $(a_1, a_2, a_3, \ldots)$, where a_k is the number of entries of T equal to k. This sequence contains only finitely many nonzero entries.

The weight of a skew tableau T is the same as the weight of the reading word of T, for any reading order.

evaluation() is a synonym for this method.

EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]

sage: SkewTableau([[None,2],[None,4],[None,5],[None]]).weight()
[0, 1, 0, 1, 1]

sage: SkewTableau([]).weight()
[]

sage: SkewTableau([[None,None,None],[None]]).weight()
[]

sage: SkewTableau([[None,3,4],[None,6,7],[4,8],[5,13],[6],[7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).weight()
[1, 1, 1, 1]

>>> SkewTableau([[None,Integer(2)],[None,Integer(4)],[None,Integer(5)],
↪[None]]).weight()
[0, 1, 0, 1, 1]

>>> SkewTableau([]).weight()
[]
```

(continues on next page)

(continued from previous page)

```
>>> SkewTableau([[None,None,None],[None]]).weight()
[]

>>> SkewTableau([[None,Integer(3),Integer(4)],[None,Integer(6),Integer(7)],
↪[Integer(4),Integer(8)],[Integer(5),Integer(13)],[Integer(6)],
↪[Integer(7)]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

class sage.combinat.skew_tableau.**SkewTableaux**(*category=None*)

Bases: UniqueRepresentation, Parent

Class of all skew tableaux.

Element

alias of *SkewTableau*

from_chain(*chain*)

Return the tableau corresponding to the chain of partitions.

EXAMPLES:

```
sage: SkewTableaux().from_chain([[1,1],[2,1],[3,1],[3,2],[3,3],[3,3,1]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```
>>> from sage.all import *
>>> SkewTableaux().from_chain([[Integer(1),Integer(1)],[Integer(2),
↪Integer(1)],[Integer(3),Integer(1)],[Integer(3),Integer(2)],[Integer(3),
↪Integer(3)],[Integer(3),Integer(3),Integer(1)]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_expr(*expr*)

Return a *SkewTableau* from a MuPAD-Combinat expr for a skew tableau.

The first list in `expr` is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```
>>> from sage.all import *
>>> SkewTableaux().from_expr([[Integer(1),Integer(1)],[[Integer(5)],
↪[Integer(3),Integer(4)],[Integer(1),Integer(2)]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_shape_and_word(*shape*, *word*)

Return the skew tableau corresponding to the skew partition `shape` and the word `word` obtained from the row reading.

EXAMPLES:

```
sage: t = SkewTableau([[None, 1, 3], [None, 2], [4]])
sage: shape = t.shape()
sage: word  = t.to_word()
sage: SkewTableaux().from_shape_and_word(shape, word)
[[None, 1, 3], [None, 2], [4]]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None, Integer(1), Integer(3)], [None, Integer(2)],␣
↪[Integer(4)]])
>>> shape = t.shape()
>>> word  = t.to_word()
>>> SkewTableaux().from_shape_and_word(shape, word)
[[None, 1, 3], [None, 2], [4]]
```

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.skew_tableau.**StandardSkewTableaux**(*category=None*)

Bases: *SkewTableaux*

Standard skew tableaux.

EXAMPLES:

```
sage: S = StandardSkewTableaux(); S
Standard skew tableaux
sage: S.cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> S = StandardSkewTableaux(); S
Standard skew tableaux
>>> S.cardinality()
+Infinity
```

```
sage: S = StandardSkewTableaux(2); S
Standard skew tableaux of size 2
sage: S.cardinality()                                                    #␣
↪needs sage.modules
4
```

```
>>> from sage.all import *
>>> S = StandardSkewTableaux(Integer(2)); S
Standard skew tableaux of size 2
>>> S.cardinality()                                                      #␣
↪needs sage.modules
4
```

```
sage: # needs sage.graphs sage.modules
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).list()
[[[None, 2, 3], [None, 4], [1]],
 [[None, 1, 2], [None, 3], [4]],
```

(continues on next page)

(continued from previous page)

```
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 2, 4], [None, 3], [1]]]
```

```
>>> from sage.all import *
>>> # needs sage.graphs sage.modules
>>> StandardSkewTableaux([[Integer(3), Integer(2), Integer(1)], [Integer(1),␣
↪Integer(1)]]).list()
[[[None, 2, 3], [None, 4], [1]],
 [[None, 1, 2], [None, 3], [4]],
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 2, 4], [None, 3], [1]]]
```

class sage.combinat.skew_tableau.**StandardSkewTableaux_all**

Bases: *StandardSkewTableaux*

Class of all standard skew tableaux.

class sage.combinat.skew_tableau.**StandardSkewTableaux_shape**(*skp*)

Bases: *StandardSkewTableaux*

Standard skew tableaux of a fixed skew shape λ/μ.

cardinality()

Return the number of standard skew tableaux with shape of the skew partition `skp`. This uses a formula due to Aitken (see Cor. 7.16.3 of [Sta-EC2]).

EXAMPLES:

```
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).cardinality()                #␣
↪needs sage.modules
8
```

```
>>> from sage.all import *
>>> StandardSkewTableaux([[Integer(3), Integer(2), Integer(1)], [Integer(1),␣
↪Integer(1)]]).cardinality()                # needs sage.modules
8
```

class sage.combinat.skew_tableau.**StandardSkewTableaux_size**(*n*)

Bases: *StandardSkewTableaux*

Standard skew tableaux of a fixed size n.

cardinality()

EXAMPLES:

```
sage: # needs sage.modules
sage: StandardSkewTableaux(1).cardinality()
1
sage: StandardSkewTableaux(2).cardinality()
4
sage: StandardSkewTableaux(3).cardinality()
24
sage: StandardSkewTableaux(4).cardinality()
194
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> StandardSkewTableaux(Integer(1)).cardinality()
1
>>> StandardSkewTableaux(Integer(2)).cardinality()
4
>>> StandardSkewTableaux(Integer(3)).cardinality()
24
>>> StandardSkewTableaux(Integer(4)).cardinality()
194
```

Specht modules

Todo

Integrate this with the implementations in `sage.modules.with_basis.representation`.

AUTHORS:

- Travis Scrimshaw (2023-1-22): initial version
- Travis Scrimshaw (2023-11-23): added simple modules based on code from Sacha Goldman

class sage.combinat.specht_module.**MaximalSpechtSubmodule**(*specht_module*)

Bases: *SymmetricGroupRepresentation*, SubmoduleWithBasis

The maximal submodule U^λ of the Specht module S^λ.

ALGORITHM:

We construct U^λ as the intersection $S \cap S^\perp$, where $S^\perp$ is the orthogonal complement of the Specht module S inside of the tabloid module T (with respect to the natural bilinear form on T).

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,2])
sage: U = SM.maximal_submodule()
sage: u = U.an_element(); u
2*U[0] + 2*U[1]
sage: [p * u for p in list(SGA.basis())[:4]]
[2*U[0] + 2*U[1], 2*U[2] + 2*U[3], 2*U[0] + 2*U[1], 2*U[2] + 2*U[3]]
sage: sum(SGA.basis()) * u
0
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> U = SM.maximal_submodule()
>>> u = U.an_element(); u
2*U[0] + 2*U[1]
>>> [p * u for p in list(SGA.basis())[:Integer(4)]]
[2*U[0] + 2*U[1], 2*U[2] + 2*U[3], 2*U[0] + 2*U[1], 2*U[2] + 2*U[3]]
>>> sum(SGA.basis()) * u
0
```

Element

alias of *Element*

class sage.combinat.specht_module.**SimpleModule**(*specht_module*)

Bases: *SymmetricGroupRepresentation*, QuotientModuleWithBasis

The simple S_n-module associated with a partition λ.

The simple module D^λ is the quotient of the Specht module S^λ by its *maximal submodule* U^λ.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,1,1])
sage: D = SM.simple_module()
sage: v = D.an_element(); v
2*D[[[1, 3, 5], [2], [4]]] + 2*D[[[1, 4, 5], [2], [3]]]
sage: SGA.an_element() * v
2*D[[[1, 2, 4], [3], [5]]] + 2*D[[[1, 2, 5], [3], [4]]] + 2*D[[[1, 3, 4], [2],␣
↪[5]]] + D[[[1, 4, 5], [2], [3]]]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(1),Integer(1)])
>>> D = SM.simple_module()
>>> v = D.an_element(); v
2*D[[[1, 3, 5], [2], [4]]] + 2*D[[[1, 4, 5], [2], [3]]]
>>> SGA.an_element() * v
2*D[[[1, 2, 4], [3], [5]]] + 2*D[[[1, 2, 5], [3], [4]]] + 2*D[[[1, 3, 4], [2],␣
↪[5]]] + D[[[1, 4, 5], [2], [3]]]
```

We give an example on how to construct the decomposition matrix (the Specht modules are a complete set of irreducible projective modules) and the Cartan matrix of a symmetric group algebra:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: BM = matrix(SGA.simple_module(la).brauer_character()
....:             for la in Partitions(4, regular=3))
sage: SBT = matrix(SGA.specht_module(la).brauer_character()
....:              for la in Partitions(4))
sage: D = SBT * ~BM; D
[1 0 0 0]
[0 1 0 0]
[1 0 1 0]
```

(continues on next page)

(continued from previous page)

```
[0 0 0 1]
[0 0 1 0]
sage: D.transpose() * D
[2 0 1 0]
[0 1 0 0]
[1 0 2 0]
[0 0 0 1]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> BM = matrix(SGA.simple_module(la).brauer_character()
...              for la in Partitions(Integer(4), regular=Integer(3)))
>>> SBT = matrix(SGA.specht_module(la).brauer_character()
...               for la in Partitions(Integer(4)))
>>> D = SBT * ~BM; D
[1 0 0 0]
[0 1 0 0]
[1 0 1 0]
[0 0 0 1]
[0 0 1 0]
>>> D.transpose() * D
[2 0 1 0]
[0 1 0 0]
[1 0 2 0]
[0 0 0 1]
```

We verify this against the direct computation (up to reindexing the rows and columns):

```
sage: SGA.cartan_invariants_matrix()  # long time
[1 0 0 0]
[0 1 0 0]
[0 0 2 1]
[0 0 1 2]
```

```
>>> from sage.all import *
>>> SGA.cartan_invariants_matrix()  # long time
[1 0 0 0]
[0 1 0 0]
[0 0 2 1]
[0 0 1 2]
```

Element

alias of *Element*

class sage.combinat.specht_module.**SpechtModule**(*SGA*, *D*)

Bases: *SymmetricGroupRepresentation*, SubmoduleWithBasis

A Specht module.

Let S_n be the symmetric group on n letters and R be a commutative ring. The *Specht module* S^D for a diagram D is an S_n-module defined as follows. Let

$$R(D) := \sum_{w \in R_D} w, \qquad C(D) := \sum_{w \in C_D} (-1)^w w,$$

where R_D (resp. C_D) is the row (resp. column) stabilizer of D. Then, we construct the Specht module S^D as the left ideal

$$S^D = R[S_n]C(D)R(D),$$

where $R[S_n]$ is the group algebra of S_n over R.

INPUT:

- `SGA` – a symmetric group algebra
- `D` – a diagram

EXAMPLES:

We begin by constructing all irreducible Specht modules for the symmetric group S_4 and show that they give a full set of irreducible representations both by having distinct Frobenius characters and the sum of the square of their dimensions is equal to $4!$:

```
sage: SP = [la.specht_module(QQ) for la in Partitions(4)]
sage: s = SymmetricFunctions(QQ).s()
sage: [s(S.frobenius_image()) for S in SP]
[s[4], s[3, 1], s[2, 2], s[2, 1, 1], s[1, 1, 1, 1]]
sage: sum(S.dimension()^2 for S in SP)
24
```

```
>>> from sage.all import *
>>> SP = [la.specht_module(QQ) for la in Partitions(Integer(4))]
>>> s = SymmetricFunctions(QQ).s()
>>> [s(S.frobenius_image()) for S in SP]
[s[4], s[3, 1], s[2, 2], s[2, 1, 1], s[1, 1, 1, 1]]
>>> sum(S.dimension()**Integer(2) for S in SP)
24
```

Next, we compute the Specht module for a more general diagram for S_5 and compute its irreducible decomposition by using its Frobenius character:

```
sage: D = [(0,0), (0,1), (1,1), (1,2), (0,3)]
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module(D)
sage: SM.dimension()
9
sage: s(SM.frobenius_image())
s[3, 2] + s[4, 1]
```

```
>>> from sage.all import *
>>> D = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(1),
↪Integer(1)), (Integer(1),Integer(2)), (Integer(0),Integer(3))]
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module(D)
>>> SM.dimension()
9
>>> s(SM.frobenius_image())
s[3, 2] + s[4, 1]
```

This carries a natural (left) action of the symmetric group (algebra):

```
sage: S5 = SGA.group()
sage: v = SM.an_element(); v
2*S[0] + 2*S[1] + 3*S[2]
sage: S5([2,1,5,3,4]) * v
3*S[0] + 2*S[1] + 2*S[2]
sage: x = SGA.an_element(); x
[1, 2, 3, 4, 5] + 2*[1, 2, 3, 5, 4] + 3*[1, 2, 4, 3, 5] + [5, 1, 2, 3, 4]
sage: x * v
15*S[0] + 14*S[1] + 16*S[2] - 7*S[5] + 2*S[6] + 2*S[7]
```

```
>>> from sage.all import *
>>> S5 = SGA.group()
>>> v = SM.an_element(); v
2*S[0] + 2*S[1] + 3*S[2]
>>> S5([Integer(2),Integer(1),Integer(5),Integer(3),Integer(4)]) * v
3*S[0] + 2*S[1] + 2*S[2]
>>> x = SGA.an_element(); x
[1, 2, 3, 4, 5] + 2*[1, 2, 3, 5, 4] + 3*[1, 2, 4, 3, 5] + [5, 1, 2, 3, 4]
>>> x * v
15*S[0] + 14*S[1] + 16*S[2] - 7*S[5] + 2*S[6] + 2*S[7]
```

See also

SpechtRepresentation for an implementation of the representation by matrices.

class Element

Bases: IndexedFreeModuleElement

class sage.combinat.specht_module.**SpechtModuleTableauxBasis**(*ambient*)

Bases: *SpechtModule*

A Specht module of a partition in the classical standard tableau basis.

This is constructed as a S_n-submodule of the *TabloidModule* (also referred to as the standard module).

See also

- *SpechtModule* for the generic diagram implementation constructed as a left ideal of the group algebra
- *SpechtRepresentation* for an implementation of the representation by matrices.

bilinear_form(*u*, *v*)

Return the natural bilinear form of `self` applied to `u` and `v`.

The natural bilinear form is given by the pullback of the natural bilinear form on the tabloid module (where the tabloid basis is an orthonormal basis).

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([2,2,1])
sage: u = SM.an_element(); u
```

(continues on next page)

(continued from previous page)

```
3*S[[1, 2], [3, 5], [4]] + 2*S[[1, 3], [2, 5], [4]] + 2*S[[1, 4], [2, 5], [3]]
sage: v = sum(SM.basis())
sage: SM.bilinear_form(u, v)
140
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(2),Integer(2),Integer(1)])
>>> u = SM.an_element(); u
3*S[[1, 2], [3, 5], [4]] + 2*S[[1, 3], [2, 5], [4]] + 2*S[[1, 4], [2, 5], [3]]
>>> v = sum(SM.basis())
>>> SM.bilinear_form(u, v)
140
```

gram_matrix()

Return the Gram matrix of the natural bilinear form of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([2,2,1])
sage: M = SM.gram_matrix(); M
[12  4 -4 -4  4]
[ 4 12  4  4  4]
[-4  4 12  4  4]
[-4  4  4 12  4]
[ 4  4  4  4 12]
sage: M.det() != 0
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(2),Integer(2),Integer(1)])
>>> M = SM.gram_matrix(); M
[12  4 -4 -4  4]
[ 4 12  4  4  4]
[-4  4 12  4  4]
[-4  4  4 12  4]
[ 4  4  4  4 12]
>>> M.det() != Integer(0)
True
```

intrinsic_arrangement(*base_ring=None*)

Return the intrinsic arrangement of `self`.

Consider the Specht module S^λ with λ a (integer) partition of n (i.e., S^λ is an S_n-module). The *intrinsic arrangement* of S^λ is the central hyperplane arrangement in S^λ given by the hyperplanes H_α, indexed by a set partition α of $\{1, \ldots, n\}$ of size λ, defined by

$$H_\alpha := \bigoplus_{\tau \in T_\alpha} (S^\lambda)^\tau,$$

where T_α is some set of generating transpositions of the Young subgroup S_α and V^τ denotes the τ-invariant subspace of V. (These hyperplanes do not depend on the choice of T_α.)

This was introduced in [TVY2020] as a generalization of the braid arrangement, which is the case when $\lambda = (n-1, 1)$ (equivalently, for the irreducible representation of S_n given by the type A_{n-1} root system).

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: SM = SGA.specht_module([2, 1, 1])
sage: A = SM.intrinsic_arrangement()
sage: A.hyperplanes()
(Hyperplane T0 - T1 - 3*T2 + 0,
 Hyperplane T0 - T1 + T2 + 0,
 Hyperplane T0 + 3*T1 + T2 + 0,
 Hyperplane 3*T0 + T1 - T2 + 0)
sage: A.is_free()
False
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> SM = SGA.specht_module([Integer(2), Integer(1), Integer(1)])
>>> A = SM.intrinsic_arrangement()
>>> A.hyperplanes()
(Hyperplane T0 - T1 - 3*T2 + 0,
 Hyperplane T0 - T1 + T2 + 0,
 Hyperplane T0 + 3*T1 + T2 + 0,
 Hyperplane 3*T0 + T1 - T2 + 0)
>>> A.is_free()
False
```

We reproduce Example 3 of [TVY2020]:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: for la in Partitions(5):
....:     SM = SGA.specht_module(la)
....:     A = SM.intrinsic_arrangement()
....:     print(la, A.characteristic_polynomial())
[5] 1
[4, 1] x^4 - 10*x^3 + 35*x^2 - 50*x + 24
[3, 2] x^5 - 15*x^4 + 90*x^3 - 260*x^2 + 350*x - 166
[3, 1, 1] x^6 - 10*x^5 + 45*x^4 - 115*x^3 + 175*x^2 - 147*x + 51
[2, 2, 1] x^5 - 10*x^4 + 45*x^3 - 105*x^2 + 120*x - 51
[2, 1, 1, 1] x^4 - 5*x^3 + 10*x^2 - 10*x + 4
[1, 1, 1, 1, 1] 1

sage: A = SGA.specht_module([4, 1]).intrinsic_arrangement()
sage: A.characteristic_polynomial().factor()
(x - 4) * (x - 3) * (x - 2) * (x - 1)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> for la in Partitions(Integer(5)):
...     SM = SGA.specht_module(la)
...     A = SM.intrinsic_arrangement()
...     print(la, A.characteristic_polynomial())
[5] 1
```

(continues on next page)

(continued from previous page)

```
[4, 1] x^4 - 10*x^3 + 35*x^2 - 50*x + 24
[3, 2] x^5 - 15*x^4 + 90*x^3 - 260*x^2 + 350*x - 166
[3, 1, 1] x^6 - 10*x^5 + 45*x^4 - 115*x^3 + 175*x^2 - 147*x + 51
[2, 2, 1] x^5 - 10*x^4 + 45*x^3 - 105*x^2 + 120*x - 51
[2, 1, 1, 1] x^4 - 5*x^3 + 10*x^2 - 10*x + 4
[1, 1, 1, 1, 1] 1

>>> A = SGA.specht_module([Integer(4), Integer(1)]).intrinsic_arrangement()
>>> A.characteristic_polynomial().factor()
(x - 4) * (x - 3) * (x - 2) * (x - 1)
```

lift()

The lift (embedding) map from `self` to the ambient space.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([3, 1, 1])
sage: SM.lift
Generic morphism:
  From: Specht module of [3, 1, 1] over Rational Field
  To:   Tabloid module of [3, 1, 1] over Rational Field
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(3), Integer(1), Integer(1)])
>>> SM.lift
Generic morphism:
  From: Specht module of [3, 1, 1] over Rational Field
  To:   Tabloid module of [3, 1, 1] over Rational Field
```

maximal_submodule()

Return the maximal submodule of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,2])
sage: U = SM.maximal_submodule()
sage: U.dimension()
4
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> U = SM.maximal_submodule()
>>> U.dimension()
4
```

retract()

The retract map from the ambient space.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: X = SGA.tabloid_module([2,2,1])
sage: Y = X.specht_module()
sage: Y.retract
Generic morphism:
  From: Tabloid module of [2, 2, 1] over Rational Field
  To:   Specht module of [2, 2, 1] over Rational Field
sage: all(Y.retract(u.lift()) == u for u in Y.basis())
True

sage: Y.retract(X.zero())
0
sage: Y.retract(sum(X.basis()))
Traceback (most recent call last):
...
ValueError: ... is not in the image
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> X = SGA.tabloid_module([Integer(2),Integer(2),Integer(1)])
>>> Y = X.specht_module()
>>> Y.retract
Generic morphism:
  From: Tabloid module of [2, 2, 1] over Rational Field
  To:   Specht module of [2, 2, 1] over Rational Field
>>> all(Y.retract(u.lift()) == u for u in Y.basis())
True

>>> Y.retract(X.zero())
0
>>> Y.retract(sum(X.basis()))
Traceback (most recent call last):
...
ValueError: ... is not in the image
```

simple_module()

Return the simple (or irreducible) S_n-submodule of `self`.

See also

SimpleModule

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,2])
sage: L = SM.simple_module()
sage: L.dimension()
1

sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([3,2])
```

(continues on next page)

(continued from previous page)

```
sage: SM.simple_module() is SM
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> L = SM.simple_module()
>>> L.dimension()
1

>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> SM.simple_module() is SM
True
```

class sage.combinat.specht_module.**SymmetricGroupRepresentation**(*SGA*)

Bases: Representation_abstract

Mixin class for symmetric group (algebra) representations.

frobenius_image()

Return the Frobenius image of `self`.

The Frobenius map is defined as the map to symmetric functions

$$F(\chi) = \frac{1}{n!} \sum_{w \in S_n} \chi(w) p_{\rho(w)},$$

where χ is the character of the S_n-module `self`, p_λ is the powersum symmetric function basis element indexed by λ, and $\rho(w)$ is the cycle type of w as a partition. Specifically, this map takes irreducible representations indexed by λ to the Schur function s_λ.

EXAMPLES:

```
sage: SM = Partition([2,2,1]).specht_module(QQ)
sage: SM.frobenius_image()
s[2, 2, 1]
sage: SM = Partition([4,1]).specht_module(CyclotomicField(5))
sage: SM.frobenius_image()
s[4, 1]
```

```
>>> from sage.all import *
>>> SM = Partition([Integer(2),Integer(2),Integer(1)]).specht_module(QQ)
>>> SM.frobenius_image()
s[2, 2, 1]
>>> SM = Partition([Integer(4),Integer(1)]).specht_
↪module(CyclotomicField(Integer(5)))
>>> SM.frobenius_image()
s[4, 1]
```

We verify the regular representation:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (3,3), (4,4)])
```

(continues on next page)

(continued from previous page)

```
sage: F = D.specht_module(QQ).frobenius_image(); F
s[1, 1, 1, 1, 1] + 4*s[2, 1, 1, 1] + 5*s[2, 2, 1]
 + 6*s[3, 1, 1] + 5*s[3, 2] + 4*s[4, 1] + s[5]
sage: s = SymmetricFunctions(QQ).s()
sage: F == sum(StandardTableaux(la).cardinality() * s[la]
....:          for la in Partitions(5))
True
sage: all(s[la] == la.specht_module(QQ).frobenius_image()
....:     for n in range(1, 5) for la in Partitions(n))
True

sage: D = Diagram([(0,0), (1,1), (1,2), (2,3), (2,4)])
sage: SM = D.specht_module(QQ)
sage: SM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(2)), (Integer(3),Integer(3)), (Integer(4),Integer(4))])
>>> F = D.specht_module(QQ).frobenius_image(); F
s[1, 1, 1, 1, 1] + 4*s[2, 1, 1, 1] + 5*s[2, 2, 1]
 + 6*s[3, 1, 1] + 5*s[3, 2] + 4*s[4, 1] + s[5]
>>> s = SymmetricFunctions(QQ).s()
>>> F == sum(StandardTableaux(la).cardinality() * s[la]
...          for la in Partitions(Integer(5)))
True
>>> all(s[la] == la.specht_module(QQ).frobenius_image()
...     for n in range(Integer(1), Integer(5)) for la in Partitions(n))
True

>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(1),Integer(2)), (Integer(2),Integer(3)), (Integer(2),Integer(4))])
>>> SM = D.specht_module(QQ)
>>> SM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

An example using the tabloid module:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2, 2, 1])
sage: TM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> TM = SGA.tabloid_module([Integer(2), Integer(2), Integer(1)])
>>> TM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

class sage.combinat.specht_module.**TabloidModule**(*SGA*, *shape*)

Bases: *SymmetricGroupRepresentation*, *CombinatorialFreeModule*

The vector space of all tabloids of a fixed shape with the natural symmetric group action.

A *tabloid* is an *OrderedSetPartition* whose underlying set is $\{1, \ldots, n\}$. The symmetric group acts by permuting the entries of the set. Hence, this is a representation of the symmetric group defined over any field. This is a left representation, so the permutation applied to the entries depends on the multiplication convention of the defining symmetric group algebra.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: TM = SGA.tabloid_module([2, 2, 1])
sage: TM.dimension()
30
sage: TM.brauer_character()
(30, 6, 2, 0, 0)
sage: IM = TM.invariant_module()
sage: IM.dimension()
1
sage: IM.basis()[0].lift() == sum(TM.basis())
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> TM = SGA.tabloid_module([Integer(2), Integer(2), Integer(1)])
>>> TM.dimension()
30
>>> TM.brauer_character()
(30, 6, 2, 0, 0)
>>> IM = TM.invariant_module()
>>> IM.dimension()
1
>>> IM.basis()[Integer(0)].lift() == sum(TM.basis())
True
```

class Element

Bases: IndexedFreeModuleElement

bilinear_form(*u*, *v*)

Return the natural bilinear form of `self` applied to `u` and `v`.

The natural bilinear form is given by defining the tabloid basis to be orthonormal.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2,2,1])
sage: u = TM.an_element(); u
2*T[{1, 2}, {3, 4}, {5}] + 2*T[{1, 2}, {3, 5}, {4}] + 3*T[{1, 2}, {4, 5}, {3}]
sage: v = sum(TM.basis())
sage: TM.bilinear_form(u, v)
7
sage: TM.bilinear_form(u, TM.zero())
0
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> TM = SGA.tabloid_module([Integer(2),Integer(2),Integer(1)])
>>> u = TM.an_element(); u
2*T[{1, 2}, {3, 4}, {5}] + 2*T[{1, 2}, {3, 5}, {4}] + 3*T[{1, 2}, {4, 5}, {3}]
>>> v = sum(TM.basis())
>>> TM.bilinear_form(u, v)
7
>>> TM.bilinear_form(u, TM.zero())
0
```

specht_module()

Return the Specht submodule of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2,2,1])
sage: TM.specht_module() is SGA.specht_module([2,2,1])
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> TM = SGA.tabloid_module([Integer(2),Integer(2),Integer(1)])
>>> TM.specht_module() is SGA.specht_module([Integer(2),Integer(2),
↪Integer(1)])
True
```

sage.combinat.specht_module.**polytabloid**(T)

Compute the polytabloid element associated to a tableau `T`.

For a tableau T, the polytabloid associated to T is

$$e_T = \sum_{\sigma \in C_T} (-1)^\sigma \{\sigma T\},$$

where $\{\}$ is the row-equivalence class, i.e. a tabloid, and C_T is the column stabilizer of T. The sum takes place in the module spanned by tabloids $\{T\}$.

OUTPUT:

A `dict` whose keys are tabloids represented by tuples of frozensets and whose values are the coefficient.

EXAMPLES:

```
sage: from sage.combinat.specht_module import polytabloid
sage: T = StandardTableau([[1,3,4],[2,5]])
sage: polytabloid(T)
{(frozenset({1, 3, 4}), frozenset({2, 5})): 1,
 (frozenset({1, 4, 5}), frozenset({2, 3})): -1,
 (frozenset({2, 3, 4}), frozenset({1, 5})): -1,
 (frozenset({2, 4, 5}), frozenset({1, 3})): 1}
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import polytabloid
```

(continues on next page)

(continued from previous page)

```
>>> T = StandardTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(5)]])
>>> polytabloid(T)
{(frozenset({1, 3, 4}), frozenset({2, 5})): 1,
 (frozenset({1, 4, 5}), frozenset({2, 3})): -1,
 (frozenset({2, 3, 4}), frozenset({1, 5})): -1,
 (frozenset({2, 4, 5}), frozenset({1, 3})): 1}
```

sage.combinat.specht_module.**simple_module_rank**(*la*, *base_ring*)

Return the rank of the simple S_n-module corresponding to the partition `la` of size n over `base_ring`.

EXAMPLES:

```
sage: from sage.combinat.specht_module import simple_module_rank
sage: simple_module_rank([3,2,1,1], GF(3))
13
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import simple_module_rank
>>> simple_module_rank([Integer(3),Integer(2),Integer(1),Integer(1)],␣
↪GF(Integer(3)))
13
```

sage.combinat.specht_module.**specht_module_rank**(*D*, *base_ring=None*)

Return the rank of the Specht module of diagram `D`.

EXAMPLES:

```
sage: from sage.combinat.specht_module import specht_module_rank
sage: specht_module_rank([(0,0), (1,1), (2,2)])
6
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import specht_module_rank
>>> specht_module_rank([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(2))])
6
```

sage.combinat.specht_module.**specht_module_spanning_set**(*D*, *SGA=None*)

Return a spanning set of the Specht module of diagram `D`.

INPUT:

- `D` – list of cells `(r,c)` for row `r` and column `c`
- `SGA` – (optional) a symmetric group algebra

EXAMPLES:

```
sage: from sage.combinat.specht_module import specht_module_spanning_set
sage: specht_module_spanning_set([(0,0), (1,1), (2,2)])
([1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1])
sage: specht_module_spanning_set([(0,0), (1,1), (2,1)])
([1, 2, 3] - [1, 3, 2], -[1, 2, 3] + [1, 3, 2], [2, 1, 3] - [3, 1, 2],
```

(continues on next page)

(continued from previous page)

```
 [2, 3, 1] - [3, 2, 1], -[2, 1, 3] + [3, 1, 2], -[2, 3, 1] + [3, 2, 1])

sage: SGA = SymmetricGroup(3).algebra(QQ)
sage: specht_module_spanning_set([(0,0), (1,1), (2,1)], SGA)
(() - (2,3), -(1,2) + (1,3,2), (1,2,3) - (1,3),
 -() + (2,3), -(1,2,3) + (1,3), (1,2) - (1,3,2))
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import specht_module_spanning_set
>>> specht_module_spanning_set([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(2))])
([1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1])
>>> specht_module_spanning_set([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(1))])
([1, 2, 3] - [1, 3, 2], -[1, 2, 3] + [1, 3, 2], [2, 1, 3] - [3, 1, 2],
 [2, 3, 1] - [3, 2, 1], -[2, 1, 3] + [3, 1, 2], -[2, 3, 1] + [3, 2, 1])

>>> SGA = SymmetricGroup(Integer(3)).algebra(QQ)
>>> specht_module_spanning_set([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(1))], SGA)
(() - (2,3), -(1,2) + (1,3,2), (1,2,3) - (1,3),
 -() + (2,3), -(1,2,3) + (1,3), (1,2) - (1,3,2))
```

sage.combinat.specht_module.**tabloid_gram_matrix**(*la*, *base_ring*)

Compute the Gram matrix of the bilinear form of a Specht module pulled back from the tabloid module.

For the module spanned by all tabloids, we define an bilinear form by having the tabloids be an orthonormal basis. We then pull this bilinear form back across the natural injection of the Specht module into the tabloid module.

EXAMPLES:

```
sage: from sage.combinat.specht_module import tabloid_gram_matrix
sage: tabloid_gram_matrix([3,2], GF(5))
[4 2 2 1 4]
[2 4 1 2 1]
[2 1 4 2 1]
[1 2 2 4 2]
[4 1 1 2 4]
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import tabloid_gram_matrix
>>> tabloid_gram_matrix([Integer(3),Integer(2)], GF(Integer(5)))
[4 2 2 1 4]
[2 4 1 2 1]
[2 1 4 2 1]
[1 2 2 4 2]
[4 1 1 2 4]
```

Steinhaus-Johnson-Trotter algorithm

The Steinhaus-Johnson-Trotter algorithm generates all permutations of a list in an order such that each permutation is obtained by transposing two adjacent elements from the previous permutation.

Each element of the list has a direction (initialized at -1) that changes at each permutation and that is used to determine which elements to transpose. Thus in addition to the permutation itself, the direction of each element is also stored.

Note that the permutations are not generated in lexicographic order.

AUTHORS:

- Martin Grenouilloux (2024-05-22): initial version

class sage.combinat.SJT.**SJT**(*l*, *directions=None*)

Bases: *CombinatorialElement*

A representation of a list permuted using the Steinhaus-Johnson-Trotter algorithm.

Each element of the list has a direction (initialized at -1) that changes at each permutation and that is used to determine which elements to transpose. The directions have three possible values:

- `-1`: element transposes to the left
- `1`: element transposes to the right
- `0`: element does not move

Thus in addition to the permutation itself, the direction of each element is also stored.

Note that the permutations are not generated in lexicographic order.

Warning

An `SJT` object should always be created with identity permutation for the algorithm to behave properly. If the identity permutation is not provided, it expects a coherent list of directions according to the provided input. This list is not checked.

Todo

Implement the previous permutation for the Steinhaus-Johnson-Trotter algorithm.

EXAMPLES:

```
sage: from sage.combinat.SJT import SJT
sage: s = SJT([1, 2, 3, 4]); s
[1, 2, 3, 4]
sage: s = s.next(); s
[1, 2, 4, 3]
sage: p = Permutation(s._list, algorithm='sjt', sjt=s)
sage: p
[1, 2, 4, 3]
sage: p.next()
[1, 4, 2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.SJT import SJT
```

(continues on next page)

(continued from previous page)

```
>>> s = SJT([Integer(1), Integer(2), Integer(3), Integer(4)]); s
[1, 2, 3, 4]
>>> s = s.next(); s
[1, 2, 4, 3]
>>> p = Permutation(s._list, algorithm='sjt', sjt=s)
>>> p
[1, 2, 4, 3]
>>> p.next()
[1, 4, 2, 3]
```

next()

Produce the next permutation of `self` following the Steinhaus-Johnson-Trotter algorithm.

OUTPUT: the list of the next permutation

EXAMPLES:

```
sage: from sage.combinat.SJT import SJT
sage: s = SJT([1, 2, 3, 4])
sage: s = s.next(); s
[1, 2, 4, 3]
sage: s = s.next(); s
[1, 4, 2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.SJT import SJT
>>> s = SJT([Integer(1), Integer(2), Integer(3), Integer(4)])
>>> s = s.next(); s
[1, 2, 4, 3]
>>> s = s.next(); s
[1, 4, 2, 3]
```

Strong and weak tableaux

There are two types of k-tableaux: strong k-tableaux and weak k-tableaux. Standard weak k-tableaux correspond to saturated chains in the weak order, whereas standard strong k-tableaux correspond to saturated chains in the strong Bruhat order. For semistandard tableaux, the notion of weak and strong horizontal strip is necessary. More information can be found in [LLMS2006] .

class sage.combinat.k_tableau.**StrongTableau**(*parent*, *T*)

Bases: `ClonableList`

A (standard) strong k-tableau is a (saturated) chain in Bruhat order.

Combinatorially, it is a sequence of embedded $k+1$-cores (subject to some conditions) together with a set of markings.

A strong cover in terms of cores corresponds to certain translated ribbons. A marking corresponds to the choice of one of the translated ribbons, which is indicated by marking the head (southeast most cell in French notation) of the chosen ribbon. For more information, see [LLMS2006] and [LLMSSZ2013].

In Sage, a strong k-tableau is created by specifying k, a standard strong tableau together with its markings, and a weight μ. Here the standard tableau is represented by a sequence of $k+1$-cores

$$\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(m)}$$

where each of the $\lambda^{(i)}$ is a $k+1$-core. The standard tableau is a filling of the diagram for the core $\lambda^{(m)}/\lambda^{(0)}$ where a strong cover is represented by letters $\pm i$ in the skew shape $\lambda^{(i)}/\lambda^{(i-1)}$. Each skew $(k+1)$-core $\lambda^{(i)}/\lambda^{(i-1)}$ is a ribbon or multiple copies of the same ribbon which are separated by $k+1$ diagonals. Precisely one of the copies of the ribbons will be marked in the largest diagonal of the connected component (the 'head' of the ribbon). The marked cells are indicated by negative signs.

The strong tableau is stored as a standard strong marked tableau (referred to as the standard part of the strong tableau) and a vector representing the weight.

EXAMPLES:

```
sage: StrongTableau( [[-1, -2, -3], [3]], 2, [3] )
[[-1, -1, -1], [1]]
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1])
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
```

```
>>> from sage.all import *
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],␣
↪Integer(2), [Integer(3)] )
[[-1, -1, -1], [1]]
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-Integer(3),
↪Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-Integer(5),-
↪Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),Integer(1)])
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
```

Alternatively, the strong k-tableau can also be entered directly in semistandard format and then the standard tableau and the weight are computed and stored:

```
sage: T = StrongTableau([[-1,-1,-1],[1]], 2); T
[[-1, -1, -1], [1]]
sage: T.to_standard_list()
[[-1, -2, -3], [3]]
sage: T.weight()
(3,)
sage: T = StrongTableau([[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]], 3);␣
↪T
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
sage: T.to_standard_list()
[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]]
sage: T.weight()
(2, 2, 3, 1)
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(1),-Integer(1)],[Integer(1)]],␣
↪Integer(2)); T
[[-1, -1, -1], [1]]
>>> T.to_standard_list()
[[-1, -2, -3], [3]]
>>> T.weight()
(3,)
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2), -Integer(3)], [-
↪Integer(2), Integer(3), -Integer(3), Integer(4)], [Integer(2), Integer(3)], [-
↪Integer(3), -Integer(4)]], Integer(3)); T
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
>>> T.to_standard_list()
[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]]
>>> T.weight()
(2, 2, 3, 1)
```

cell_of_highest_head(*v*)

Return the cell of the highest head of label `v` in the standard part of `self`.

Return the cell where the head of the ribbon in the highest row is located in the underlying standard tableau. If there is no cell with entry `v` then the cell returned is $(0, r)$ where r is the length of the first row.

This cell is calculated by iterating through the diagonals of the tableau.

INPUT:

- `v` – integer indicating the label in the standard tableau

OUTPUT: a pair of integers indicating the coordinates of the head of the highest ribbon with label `v`

EXAMPLES:

```
sage: T = StrongTableau([[-1,2,-3],[-2,3],[3]], 1)
sage: [T.cell_of_highest_head(v) for v in range(1,5)]
[(0, 0), (1, 0), (2, 0), (0, 3)]
sage: T = StrongTableau([[None,None,-3,4],[3,-4]],2)
sage: [T.cell_of_highest_head(v) for v in range(1,5)]
[(1, 0), (1, 1), (0, 4), (0, 4)]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),Integer(2),-Integer(3)],[-Integer(2),
↪Integer(3)]],[Integer(3)]], Integer(1))
>>> [T.cell_of_highest_head(v) for v in range(Integer(1),Integer(5))]
[(0, 0), (1, 0), (2, 0), (0, 3)]
>>> T = StrongTableau([[None,None,-Integer(3),Integer(4)],[Integer(3),-
↪Integer(4)]],Integer(2))
>>> [T.cell_of_highest_head(v) for v in range(Integer(1),Integer(5))]
[(1, 0), (1, 1), (0, 4), (0, 4)]
```

cell_of_marked_head(*v*)

Return location of marked head labeled by `v` in the standard part of `self`.

Return the coordinates of the `v`-th marked cell in the strong standard tableau `self`. If there is no mark, then the value returned is $(0, r)$ where r is the length of the first row.

INPUT:

- v – integer representing the label in the standard tableau

OUTPUT: a pair of the coordinates of the marked cell with entry v

EXAMPLES:

```
sage: T = StrongTableau([[-1, -3, 4, -5], [-2], [-4]], 3)
sage: [ T.cell_of_marked_head(i) for i in range(1,7)]
[(0, 0), (1, 0), (0, 1), (2, 0), (0, 3), (0, 4)]
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: [ T.cell_of_marked_head(i) for i in range(1,7)]
[(2, 0), (0, 2), (2, 1), (0, 3), (4, 0), (0, 4)]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(3), Integer(4), -Integer(5)], [-
↪Integer(2)], [-Integer(4)]], Integer(3))
>>> [ T.cell_of_marked_head(i) for i in range(Integer(1),Integer(7))]
[(0, 0), (1, 0), (0, 1), (2, 0), (0, 3), (0, 4)]
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> [ T.cell_of_marked_head(i) for i in range(Integer(1),Integer(7))]
[(2, 0), (0, 2), (2, 1), (0, 3), (4, 0), (0, 4)]
```

cells_head_dictionary()

Return a dictionary with the locations of the heads of all markings.

Return a dictionary of values and lists of cells where the heads with the values are located.

OUTPUT:

- a dictionary with keys the entries in the tableau and values are the coordinates of the heads with those entries

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,7],[-3,6,-6,8],[4,-7],[-5,-8]], 3)
sage: T.cells_head_dictionary()
{1: [(0, 0)],
 2: [(0, 1)],
 3: [(1, 0)],
 4: [(2, 0), (0, 2)],
 5: [(3, 0)],
 6: [(1, 2)],
 7: [(2, 1), (0, 3)],
 8: [(3, 1), (1, 3)]}
sage: T = StrongTableau([[None, 4, -4, -6, -7, 8, 8, -8], [None, -5, 8, 8, 8],
↪ [-3, 6]],3)
sage: T.cells_head_dictionary()
{1: [(2, 0)],
 2: [(0, 2)],
 3: [(1, 1)],
 4: [(2, 1), (0, 3)],
 5: [(0, 4)],
 6: [(1, 4), (0, 7)]}
```

(continues on next page)

(continued from previous page)

```
 sage: StrongTableau([[None, None], [None, -1]], 4).cells_head_dictionary()
 {1: [(1, 1)]}
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),-Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3))
>>> T.cells_head_dictionary()
{1: [(0, 0)],
 2: [(0, 1)],
 3: [(1, 0)],
 4: [(2, 0), (0, 2)],
 5: [(3, 0)],
 6: [(1, 2)],
 7: [(2, 1), (0, 3)],
 8: [(3, 1), (1, 3)]}
>>> T = StrongTableau([[None, Integer(4), -Integer(4), -Integer(6), -
↪Integer(7), Integer(8), Integer(8), -Integer(8)], [None, -Integer(5),␣
↪Integer(8), Integer(8), Integer(8)], [-Integer(3), Integer(6)]],Integer(3))
>>> T.cells_head_dictionary()
{1: [(2, 0)],
 2: [(0, 2)],
 3: [(1, 1)],
 4: [(2, 1), (0, 3)],
 5: [(0, 4)],
 6: [(1, 4), (0, 7)]}
>>> StrongTableau([[None, None], [None, -Integer(1)]], Integer(4)).cells_head_
↪dictionary()
 {1: [(1, 1)]}
```

cells_of_heads(*v*)

Return a list of cells of the heads with label `v` in the standard part of `self`.

A list of cells which are heads of the ribbons with label `v` in the standard part of the tableau `self`. If there is no cell labelled by `v` then return the empty list.

INPUT:

- `v` – integer label

OUTPUT: a list of pairs of integers of the coordinates of the heads of the ribbons with label `v`

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.cells_of_heads(1)
[(2, 0)]
sage: T.cells_of_heads(2)
[(3, 0), (0, 2)]
sage: T.cells_of_heads(3)
[(2, 1)]
sage: T.cells_of_heads(4)
[(3, 1), (0, 3)]
```

(continues on next page)

(continued from previous page)

```
sage: T.cells_of_heads(5)
[(4, 0)]
sage: T.cells_of_heads(6)
[]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.cells_of_heads(Integer(1))
[(2, 0)]
>>> T.cells_of_heads(Integer(2))
[(3, 0), (0, 2)]
>>> T.cells_of_heads(Integer(3))
[(2, 1)]
>>> T.cells_of_heads(Integer(4))
[(3, 1), (0, 3)]
>>> T.cells_of_heads(Integer(5))
[(4, 0)]
>>> T.cells_of_heads(Integer(6))
[]
```

cells_of_marked_ribbon(*v*)

Return a list of all cells the marked ribbon labeled by `v` in the standard part of `self`.

Return the list of coordinates of the cells which are in the marked ribbon with label `v` in the standard part of the tableau. Note that the result is independent of the weight of the tableau.

The cells are listed from largest content (where the mark is located) to the smallest. Hence, the first entry in this list will be the marked cell.

INPUT:

- `v` – the entry of the standard tableau

OUTPUT:

- a list of pairs representing the coordinates of the cells of the marked ribbon

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]],3)
sage: T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.cells_of_marked_ribbon(1)
[(0, 0)]
sage: T.cells_of_marked_ribbon(4)
[(0, 3)]
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3)
sage: T.cells_of_marked_ribbon(6)
[(1, 2), (1, 1)]
sage: T.cells_of_marked_ribbon(9)
[]
sage: T = StrongTableau([[None, None, -1, -1, 3], [1, -3], [-3]],3)
sage: T.to_standard_list()
```

(continues on next page)

(continued from previous page)

```
[[None, None, -1, -2, 4], [2, -4], [-3]]
sage: T.cells_of_marked_ribbon(1)
[(0, 2)]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2), -Integer(2),␣
↪Integer(3)], [Integer(2), -Integer(3)], [-Integer(3)]],Integer(3))
>>> T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
>>> T.cells_of_marked_ribbon(Integer(1))
[(0, 0)]
>>> T.cells_of_marked_ribbon(Integer(4))
[(0, 3)]
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3))
>>> T.cells_of_marked_ribbon(Integer(6))
[(1, 2), (1, 1)]
>>> T.cells_of_marked_ribbon(Integer(9))
[]
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(1), Integer(3)],␣
↪[Integer(1), -Integer(3)], [-Integer(3)]],Integer(3))
>>> T.to_standard_list()
[[None, None, -1, -2, 4], [2, -4], [-3]]
>>> T.cells_of_marked_ribbon(Integer(1))
[(0, 2)]
```

check()

Check that `self` is a valid strong k-tableau.

This function verifies that the outer and inner shape of the parent class is equal to the outer and inner shape of the tableau, that the tableau portion of `self` is a valid standard tableau, that the marks are placed correctly and that the size and weight agree.

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2], [2]], 2)
sage: T.check()
sage: T = StrongTableau([[None, None, 2, -4, -4], [-1, 4], [-2]], 3)
sage: T.check()
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2)], [Integer(2)]],
↪ Integer(2))
>>> T.check()
>>> T = StrongTableau([[None, None, Integer(2), -Integer(4), -Integer(4)], [-
↪Integer(1), Integer(4)], [-Integer(2)]], Integer(3))
>>> T.check()
```

content_of_highest_head(v)

Return the diagonal of the highest head of the cells labeled `v` in the standard part of `self`.

Return the content of the cell of the head in the highest row of all ribbons labeled by `v` of the underlying standard tableau. If there is no cell with entry `v` then the value returned is the length of the first row.

INPUT:

- v – integer representing the label in the standard tableau

OUTPUT: an integer representing the content of the head of the highest ribbon with label v

EXAMPLES:

```
sage: [StrongTableau([[-1,2,-3],[-2,3],[3]], 1).content_of_highest_head(v)␣
↪for v in range(1,5)]
[0, -1, -2, 3]
```

```
>>> from sage.all import *
>>> [StrongTableau([[-Integer(1),Integer(2),-Integer(3)],[-Integer(2),
↪Integer(3)],[Integer(3)]], Integer(1)).content_of_highest_head(v) for v in␣
↪range(Integer(1),Integer(5))]
[0, -1, -2, 3]
```

content_of_marked_head(*v*)

Return the diagonal of the marked label v in the standard part of self.

Return the content (the $j - i$ coordinate of the cell) of the v-th marked cell in the strong standard tableau self. If there is no mark, then the value returned is the size of first row.

INPUT:

- v – integer representing the label in the standard tableau

OUTPUT: integer representing the residue of the location of the mark

EXAMPLES:

```
sage: [ StrongTableau([[-1, -3, 4, -5], [-2], [-4]], 3).content_of_marked_
↪head(i) for i in range(1,7)]
[0, -1, 1, -2, 3, 4]
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: [ T.content_of_marked_head(i) for i in range(1,7)]
[-2, 2, -1, 3, -4, 4]
```

```
>>> from sage.all import *
>>> [ StrongTableau([[-Integer(1), -Integer(3), Integer(4), -Integer(5)], [-
↪Integer(2)], [-Integer(4)]], Integer(3)).content_of_marked_head(i) for i in␣
↪range(Integer(1),Integer(7))]
[0, -1, 1, -2, 3, 4]
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> [ T.content_of_marked_head(i) for i in range(Integer(1),Integer(7))]
[-2, 2, -1, 3, -4, 4]
```

contents_of_heads(*v*)

A list of contents of the cells which are heads of the ribbons with label v.

If there is no cell labelled by v then return the empty list.

INPUT:

- v – integer label

OUTPUT: list of integers of the content of the heads of the ribbons with label `v`

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.contents_of_heads(1)
[-2]
sage: T.contents_of_heads(2)
[-3, 2]
sage: T.contents_of_heads(3)
[-1]
sage: T.contents_of_heads(4)
[-2, 3]
sage: T.contents_of_heads(5)
[-4]
sage: T.contents_of_heads(6)
[]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.contents_of_heads(Integer(1))
[-2]
>>> T.contents_of_heads(Integer(2))
[-3, 2]
>>> T.contents_of_heads(Integer(3))
[-1]
>>> T.contents_of_heads(Integer(4))
[-2, 3]
>>> T.contents_of_heads(Integer(5))
[-4]
>>> T.contents_of_heads(Integer(6))
[]
```

entries_by_content (*diag*)

Return the entries on the diagonal of `self`.

Return the entries in the tableau that are in the cells (i, j) with $j - i$ equal to `diag` (that is, with content equal to `diag`).

INPUT:

- `diag` – integer indicating the diagonal

OUTPUT: list (perhaps empty) of labels on the diagonal `diag`

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.entries_by_content(0)
[]
sage: T.entries_by_content(1)
[]
```

(continues on next page)

(continued from previous page)

```
sage: T.entries_by_content(2)
[-1]
sage: T.entries_by_content(-2)
[-1, 2]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.entries_by_content(Integer(0))
[]
>>> T.entries_by_content(Integer(1))
[]
>>> T.entries_by_content(Integer(2))
[-1]
>>> T.entries_by_content(-Integer(2))
[-1, 2]
```

entries_by_content_standard(*diag*)

Return the entries on the diagonal of the standard part of `self`.

Return the entries in the tableau that are in the cells (i, j) with $j - i$ equal to `diag` (that is, with content equal to `diag`) in the standard tableau.

INPUT:

- `diag` – integer indicating the diagonal

OUTPUT: list (perhaps empty) of labels on the diagonal `diag`

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.entries_by_content_standard(0)
[]
sage: T.entries_by_content_standard(1)
[]
sage: T.entries_by_content_standard(2)
[-2]
sage: T.entries_by_content_standard(-2)
[-1, 4]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.entries_by_content_standard(Integer(0))
[]
>>> T.entries_by_content_standard(Integer(1))
[]
>>> T.entries_by_content_standard(Integer(2))
[-2]
```

(continues on next page)

(continued from previous page)

```
>>> T.entries_by_content_standard(-Integer(2))
[-1, 4]
```

follows_tableau()

Return a list of strong marked tableaux with length one longer than `self`.

Return list of all strong tableaux obtained from `self` by extending to a core which follows the shape of `self` in the strong order.

OUTPUT: list of strong tableaux which follow `self` in strong order

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,
↪1])
sage: T.follows_tableau()
[[[-1, -1, -2, -3, 5, 5, -5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, -5], [-3, -4], [5]],
 [[-1, -1, -2, -3, -5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [-5], [5], [5]]]
sage: StrongTableau([[-1,-2],[-3,-4]],3).follows_tableau()
[[[-1, -2, 5, 5, -5], [-3, -4]], [[-1, -2, 5], [-3, -4], [-5]],
 [[-1, -2, -5], [-3, -4], [5]], [[-1, -2], [-3, -4], [-5], [5], [5]]]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)])
>>> T.follows_tableau()
[[[-1, -1, -2, -3, 5, 5, -5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, -5], [-3, -4], [5]],
 [[-1, -1, -2, -3, -5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [-5], [5], [5]]]
>>> StrongTableau([[-Integer(1),-Integer(2)],[-Integer(3),-Integer(4)]],
↪Integer(3)).follows_tableau()
[[[-1, -2, 5, 5, -5], [-3, -4]], [[-1, -2, 5], [-3, -4], [-5]],
 [[-1, -2, -5], [-3, -4], [5]], [[-1, -2], [-3, -4], [-5], [5], [5]]]
```

height_of_ribbon(*v*)

The number of rows occupied by one of the ribbons with label `v`.

The number of rows occupied by the marked ribbon with label `v` (and by consequence the number of rows occupied by any ribbon with the same label) in the standard part of `self`.

INPUT:

- `v` – the label of the standard marked tableau

OUTPUT: nonnegative integer representing the number of rows occupied by the ribbon which is marked

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]],3)
sage: T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.height_of_ribbon(1)
1
sage: T.height_of_ribbon(4)
1
sage: T = StrongTableau([[None,None,1,-2],[None,-3,4,-5],[-1,3],[-4,5]], 3)
sage: T.height_of_ribbon(3)
2
sage: T.height_of_ribbon(6)
0
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2), -Integer(2),␣
↪Integer(3)], [Integer(2), -Integer(3)], [-Integer(3)]],Integer(3))
>>> T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
>>> T.height_of_ribbon(Integer(1))
1
>>> T.height_of_ribbon(Integer(4))
1
>>> T = StrongTableau([[None,None,Integer(1),-Integer(2)],[None,-Integer(3),
↪Integer(4),-Integer(5)],[-Integer(1),Integer(3)],[-Integer(4),Integer(5)]],␣
↪Integer(3))
>>> T.height_of_ribbon(Integer(3))
2
>>> T.height_of_ribbon(Integer(6))
0
```

inner_shape()

Return the inner shape of `self`.

If `self` is a strong skew tableau, then this method returns the inner shape (the shape of the cells labelled with `None`). If `self` is not skew, then the inner shape is empty.

OUTPUT:

- a $(k+1)$-core

EXAMPLES:

```
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).inner_shape()
[2, 2]
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).
↪inner_shape()
[]
```

```
>>> from sage.all import *
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).inner_shape()
[2, 2]
```

(continues on next page)

(continued from previous page)

```
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)]).inner_shape()
[]
```

intermediate_shapes()

Return the intermediate shapes of `self`.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the i-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$.

The output is the list of these shapes. The marked cells are ignored so to recover the strong tableau one would need the intermediate shapes and the *content_of_marked_head()* for each pair of adjacent shapes in the list.

OUTPUT: list of lists of integers representing $k+1$-cores

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,
↪1])
sage: T.intermediate_shapes()
[[], [2], [3, 1, 1], [4, 3, 2, 1], [4, 4, 2, 2]]
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.intermediate_shapes()
[[2, 2], [3, 2, 1, 1], [4, 2, 2, 2], [4, 2, 2, 2, 1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)])
>>> T.intermediate_shapes()
[[], [2], [3, 1, 1], [4, 3, 2, 1], [4, 4, 2, 2]]
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.intermediate_shapes()
[[2, 2], [3, 2, 1, 1], [4, 2, 2, 2], [4, 2, 2, 2, 1, 1, 1, 1]]
```

is_column_strict_with_weight(*mu*)

Test if `self` is a column strict tableau with respect to the weight `mu`.

INPUT:

- `mu` – a vector of weights

OUTPUT: boolean; `True` means the underlying column strict strong marked tableau is valid

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3], [3]], 2).is_column_strict_with_weight([3])
True
```

(continues on next page)

(continued from previous page)

```
sage: StrongTableau([[-1, -2, 3], [-3]], 2).is_column_strict_with_weight([3])
False
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],␣
↪Integer(2)).is_column_strict_with_weight([Integer(3)])
True
>>> StrongTableau([[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]],␣
↪Integer(2)).is_column_strict_with_weight([Integer(3)])
False
```

left_action(*tij*)

Action of transposition `tij` on `self` by adding marked ribbons.

Computes the left action of the transposition `tij` on the tableau. If `tij` acting on the element of the affine Grassmannian raises the length by 1, then this function will add a cell to the standard tableau.

INPUT:

- `tij` – a transposition represented as a pair (i, j)

OUTPUT: `self` after it has been modified by the action of the transposition `tij`

EXAMPLES:

```
sage: StrongTableau( [[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1] ).
↪left_action([0,1])
[[None, -1, -2, -3, 5], [3, -5], [-4]]
sage: StrongTableau( [[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1] ).
↪left_action([4,5])
[[None, -1, -2, -3, -5], [3, 5], [-4]]
sage: T = StrongTableau( [[None, -1, -2, -3], [3], [-4]], 3, weight=[1,1,1,1]␣
↪)
sage: T.left_action([-3,-2])
[[None, -1, -2, -3], [3], [-4], [-5]]
sage: T = StrongTableau( [[None, -1, -2, -3], [3], [-4]], 3, weight=[3,1] )
sage: T.left_action([-3,-2])
[[None, -1, -1, -1], [1], [-2], [-3]]
sage: T
[[None, -1, -1, -1], [1], [-2]]
sage: T.check()
sage: T.weight()
(3, 1)
```

```
>>> from sage.all import *
>>> StrongTableau( [[None, -Integer(1), -Integer(2), -Integer(3)],␣
↪[Integer(3)], [-Integer(4)]], Integer(3), weight=[Integer(1),Integer(1),
↪Integer(1),Integer(1)] ).left_action([Integer(0),Integer(1)])
[[None, -1, -2, -3, 5], [3, -5], [-4]]
>>> StrongTableau( [[None, -Integer(1), -Integer(2), -Integer(3)],␣
↪[Integer(3)], [-Integer(4)]], Integer(3), weight=[Integer(1),Integer(1),
↪Integer(1),Integer(1)] ).left_action([Integer(4),Integer(5)])
[[None, -1, -2, -3, -5], [3, 5], [-4]]
>>> T = StrongTableau( [[None, -Integer(1), -Integer(2), -Integer(3)],␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(3)], [-Integer(4)]], Integer(3), weight=[Integer(1),Integer(1),
↪Integer(1),Integer(1)] )
>>> T.left_action([-Integer(3),-Integer(2)])
[[None, -1, -2, -3], [3], [-4], [-5]]
>>> T = StrongTableau( [[None, -Integer(1), -Integer(2), -Integer(3)],␣
↪[Integer(3)], [-Integer(4)]], Integer(3), weight=[Integer(3),Integer(1)] )
>>> T.left_action([-Integer(3),-Integer(2)])
[[None, -1, -1, -1], [1], [-2], [-3]]
>>> T
[[None, -1, -1, -1], [1], [-2]]
>>> T.check()
>>> T.weight()
(3, 1)
```

number_of_connected_components(*v*)

Number of connected components of ribbons with label v in the standard part.

The number of connected components is calculated by finding the number of cells with label v in the standard part of the tableau and dividing by the number of cells in the ribbon.

INPUT:

- v – the label of the standard marked tableau

OUTPUT: nonnegative integer representing the number of connected components

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]],3)
sage: T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.number_of_connected_components(1)
1
sage: T.number_of_connected_components(4)
2
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3)
sage: T.number_of_connected_components(6)
1
sage: T.number_of_connected_components(9)
0
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2), -Integer(2),␣
↪Integer(3)], [Integer(2), -Integer(3)], [-Integer(3)]],Integer(3))
>>> T.to_standard_list()
[[-1, -2, -3, -4, 6], [4, -6], [-5]]
>>> T.number_of_connected_components(Integer(1))
1
>>> T.number_of_connected_components(Integer(4))
2
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3))
>>> T.number_of_connected_components(Integer(6))
```

(continues on next page)

(continued from previous page)

```
1
>>> T.number_of_connected_components(Integer(9))
0
```

outer_shape()

Return the outer shape of `self`.

This method returns the outer shape of `self` as viewed as a `Core`. The outer shape of a strong tableau is always a $(k+1)$-core.

OUTPUT:

- a $(k+1)$-core

EXAMPLES:

```
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).outer_shape()
[4, 2, 2, 2, 1, 1, 1, 1]
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).
↪outer_shape()
[4, 4, 2, 2]
```

```
>>> from sage.all import *
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).outer_shape()
[4, 2, 2, 2, 1, 1, 1, 1]
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),
↪Integer(1)]).outer_shape()
[4, 4, 2, 2]
```

pp()

Print the strong tableau `self` in pretty print format.

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,
↪1])
sage: T.pp()
-1 -1 -2 -3
-2  3 -3  4
 2  3
-3 -4
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.pp()
  .  . -1 -2
  .  .
 -1 -2
  1  2
 -3
```

(continues on next page)

(continued from previous page)

  .  .
  .  . -1 -2
>>> Tableaux.options(convention='English')
```

restrict(*r*)

Restrict the standard part of the tableau to the labels $1, 2, \ldots, r$.

Return the tableau consisting of the labels of the standard part of `self` restricted to the labels of 1 through

r. The result is another StrongTableau object.

INPUT:

- r – integer

OUTPUT: a strong tableau

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -4, 5, -5], [None, None], [-1, -3], [-
↪2], [2], [2], [3]], 4, weight=[1,1,1,1,1])
sage: T.restrict(3)
[[None, None], [None, None], [-1, -3], [-2], [2], [2], [3]]
sage: TT = T.restrict(0)
sage: TT
[[None, None], [None, None]]
sage: TT == StrongTableau( [[None, None], [None, None]], 4 )
True
sage: T.restrict(5) == T
True
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(4), Integer(5), -Integer(5)],␣
↪[None, None], [-Integer(1), -Integer(3)], [-Integer(2)], [Integer(2)],␣
↪[Integer(2)], [Integer(3)]], Integer(4), weight=[Integer(1),Integer(1),
↪Integer(1),Integer(1),Integer(1)])
>>> T.restrict(Integer(3))
[[None, None], [None, None], [-1, -3], [-2], [2], [2], [3]]
>>> TT = T.restrict(Integer(0))
>>> TT
[[None, None], [None, None]]
>>> TT == StrongTableau( [[None, None], [None, None]], Integer(4) )
True
>>> T.restrict(Integer(5)) == T
True
```

ribbons_above_marked(*v*)

Number of ribbons of label v higher than the marked ribbon in the standard part.

Return the number of copies of the ribbon with label v in the standard part of self which are in a higher row than the marked ribbon. Note that the result is independent of the weight of the tableau.

INPUT:

- v – the entry of the standard tableau

OUTPUT:

- an integer representing the number of copies of the ribbon above the marked ribbon

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3)
sage: T.ribbons_above_marked(4)
1
sage: T.ribbons_above_marked(6)
0
```

(continues on next page)

(continued from previous page)

```
sage: T.ribbons_above_marked(9)
0
sage: StrongTableau([[-1,-2,-3,-4],[2,3,4],[3,4],[4]], 1).ribbons_above_
↪marked(4)
3
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-
↪Integer(3),Integer(6),-Integer(6),Integer(8)],[Integer(4),Integer(7)],[-
↪Integer(5),-Integer(8)]], Integer(3))
>>> T.ribbons_above_marked(Integer(4))
1
>>> T.ribbons_above_marked(Integer(6))
0
>>> T.ribbons_above_marked(Integer(9))
0
>>> StrongTableau([[-Integer(1),-Integer(2),-Integer(3),-Integer(4)],
↪[Integer(2),Integer(3),Integer(4)],[Integer(3),Integer(4)],[Integer(4)]],␣
↪Integer(1)).ribbons_above_marked(Integer(4))
3
```

set_weight(*mu*)

Set a new weight `mu` for `self`.

This method first tests if the underlying standard tableau is column-strict with respect to the weight `mu`. If it is, then it changes the weight and returns the tableau; otherwise it raises an error.

INPUT:

- `mu` – list of nonnegative integers representing the new weight

EXAMPLES:

```
sage: StrongTableau( [[-1, -2, -3], [3]], 2 ).set_weight( [3] )
[[-1, -1, -1], [1]]
sage: StrongTableau( [[-1, -2, -3], [3]], 2 ).set_weight( [0,3] )
[[-2, -2, -2], [2]]
sage: StrongTableau( [[-1, -2, 3], [-3]], 2 ).set_weight( [2, 0, 1] )
[[-1, -1, 3], [-3]]
sage: StrongTableau( [[-1, -2, 3], [-3]], 2 ).set_weight( [3] )
Traceback (most recent call last):
...
ValueError: [[-1, -2, 3], [-3]] is not a semistandard strong tableau with␣
↪respect to the partition [3]
```

```
>>> from sage.all import *
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],␣
↪Integer(2) ).set_weight( [Integer(3)] )
[[-1, -1, -1], [1]]
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],␣
↪Integer(2) ).set_weight( [Integer(0),Integer(3)] )
[[-2, -2, -2], [2]]
>>> StrongTableau( [[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]],␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(2) ).set_weight( [Integer(2), Integer(0), Integer(1)] )
[[-1, -1, 3], [-3]]
>>> StrongTableau( [[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]],␣
↪Integer(2) ).set_weight( [Integer(3)] )
Traceback (most recent call last):
...
ValueError: [[-1, -2, 3], [-3]] is not a semistandard strong tableau with␣
↪respect to the partition [3]
```

shape()

Return the shape of `self`.

If `self` is a skew tableau then return a pair of $k+1$-cores consisting of the outer and the inner shape. If `self` is strong tableau with no inner shape then return a $k+1$-core.

INPUT:

- `form` – argument to indicate `'inner'`, `'outer'` or `'skew'` (default: `'outer'`)

OUTPUT: a $k+1$-core or a pair of $k+1$-cores if form is not `'inner'` or `'outer'`

EXAMPLES:

```
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
↪ [-3], [3], [3], [3]], 4)
sage: T.shape()
([4, 2, 2, 2, 1, 1, 1, 1], [2, 2])
sage: StrongTableau([[-1, -2, 3], [-3]], 2).shape()
[3, 1]
sage: type(StrongTableau([[-1, -2, 3], [-3]], 2).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
```

```
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],␣
↪[-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))
>>> T.shape()
([4, 2, 2, 2, 1, 1, 1, 1], [2, 2])
>>> StrongTableau([[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]],␣
↪Integer(2)).shape()
[3, 1]
>>> type(StrongTableau([[-Integer(1), -Integer(2), Integer(3)], [-
↪Integer(3)]], Integer(2)).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
```

size()

Return the size of the strong tableau.

The size of the strong tableau is the sum of the entries in the *weight()*. It will also be equal to the length of the outer shape (as a $k+1$-core) minus the length of the inner shape.

See also

sage.combinat.core.Core.length()

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3).size()
5
sage: StrongTableau([[None, None, -1, 2], [-2], [-3]], 3).size()
3
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3)).size()
5
>>> StrongTableau([[None, None, -Integer(1), Integer(2)], [-Integer(2)], [-
↪Integer(3)]], Integer(3)).size()
3
```

spin()

Return the spin statistic of the tableau `self`.

The spin is an integer statistic on a strong marked tableau. It is the sum of $(h-1)r$ plus the number of connected components above the marked one where h is the height of the marked ribbon and r is the number of connected components.

See also

height_of_ribbon(), *number_of_connected_components()*, *ribbons_above_marked()*

The k-Schur functions with a parameter t can be defined as

$$s_\lambda^{(k)}[X;t] = \sum_T t^{spin(T)} m_{weight(T)}[X]$$

where the sum is over all column strict marked strong k-tableaux of shape λ and partition content.

OUTPUT: integer value representing the spin

EXAMPLES:

```
sage: StrongTableau([[-1,-2,5,6],[-3,-4,-7,8],[-5,-6],[7,-8]], 3, [2,2,3,1]).
↪spin()
1
sage: StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).
↪spin()
2
sage: StrongTableau([[None,None,-1,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3).spin()
2
sage: ks3 = SymmetricFunctions(QQ['t'].fraction_field()).kschur(3)
sage: t = ks3.realization_of().t
sage: m = ks3.ambient().realization_of().m()
```

(continues on next page)

(continued from previous page)

```
sage: myks221 = sum(sum(t**T.spin() for T in StrongTableaux(3,[3,2,1],
↪weight=mu))*m(mu) for mu in Partitions(5, max_part=3))
sage: myks221 == m(ks3[2,2,1])
True
sage: h = ks3.ambient().realization_of().h()
sage: Core([4,4,2,2],4).to_bounded_partition()
[2, 2, 2, 2]

True
```

spin_of_ribbon(*v*)

Return the spin of the ribbon with label `v` in the standard part of `self`.

The spin of a ribbon is an integer statistic. It is the sum of $(h-1)r$ plus the number of connected components above the marked one where h is the height of the marked ribbon and r is the number of connected components.

See also

height_of_ribbon(), *number_of_connected_components()*, *ribbons_above_marked()*

INPUT:

- `v` – a label of the standard part of the tableau

OUTPUT: integer value representing the spin of the ribbon with label `v`

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,5,6],[-3,-4,-7,8],[-5,-6],[7,-8]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,9)]
[0, 0, 0, 0, 0, 0, 1, 0]
sage: T = StrongTableau([[None,None,-1,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,7)]
[0, 1, 0, 0, 1, 0]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1),-Integer(2),Integer(5),Integer(6)],[-
↪Integer(3),-Integer(4),-Integer(7),Integer(8)],[-Integer(5),-Integer(6)],
↪[Integer(7),-Integer(8)]], Integer(3))
>>> [T.spin_of_ribbon(v) for v in range(Integer(1),Integer(9))]
[0, 0, 0, 0, 0, 0, 1, 0]
>>> T = StrongTableau([[None,None,-Integer(1),-Integer(3)],[-Integer(2),
↪Integer(3),-Integer(3),Integer(4)],[Integer(2),Integer(3)],[-Integer(3),-
↪Integer(4)]], Integer(3))
>>> [T.spin_of_ribbon(v) for v in range(Integer(1),Integer(7))]
[0, 1, 0, 0, 1, 0]
```

to_list()

Return the marked column strict (possibly skew) tableau as a list of lists.

OUTPUT: list of lists of integers or `None`

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3).set_weight([2,1,1,1]).
↪to_list()
[[-1, -1, -2, 3], [-3], [-4]]
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_list()
[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_list()
[[-1, -1, -1, 2], [-2], [-3]]
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3)).set_weight([Integer(2),Integer(1),
↪Integer(1),Integer(1)]).to_list()
[[-1, -1, -2, 3], [-3], [-4]]
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_list()
[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),
↪Integer(1)]).to_list()
[[-1, -1, -1, 2], [-2], [-3]]
```

to_standard_list()

Return the underlying standard strong tableau as a list of lists.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part.

OUTPUT: list of lists of integers or `None`

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_standard_
↪list()
[[-1, -2, -3, 4], [-4], [-5]]
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_standard_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),
↪Integer(1)]).to_standard_list()
[[-1, -2, -3, 4], [-4], [-5]]
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_standard_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

to_standard_tableau()

Return the underlying standard strong tableau as a `StrongTableau` object.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part as a `StrongTableau`.

OUTPUT: a strong tableau with standard weight

EXAMPLES:

```
sage: T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
sage: T.to_standard_tableau()
[[-1, -2, -3, 4], [-4], [-5]]
sage: T.to_standard_tableau() == T.to_standard_list()
False
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_standard_tableau()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),Integer(1)])
>>> T.to_standard_tableau()
[[-1, -2, -3, 4], [-4], [-5]]
>>> T.to_standard_tableau() == T.to_standard_list()
False
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_standard_tableau()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

to_transposition_sequence()

Return a list of transpositions corresponding to `self`.

Given a strong column strict tableau `self` returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

OUTPUT: list of pairs of values `[i,j]` representing the transpositions t_{ij}

EXAMPLES:

```
sage: T = StrongTableau([[-1, -1, -1], [1]],2)
sage: T.to_transposition_sequence()
[[2, 3], [1, 2], [0, 1]]
sage: T = StrongTableau([[-1, -1, 2], [-2]],2)
sage: T.to_transposition_sequence()
[[-1, 0], [1, 2], [0, 1]]
sage: T = StrongTableau([[None, -1, 2, -3], [-2, 3]],2)
sage: T.to_transposition_sequence()
[[3, 4], [-1, 0], [1, 2]]
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(1)], [Integer(1)]],
↪Integer(2))
>>> T.to_transposition_sequence()
[[2, 3], [1, 2], [0, 1]]
>>> T = StrongTableau([[-Integer(1), -Integer(1), Integer(2)], [-Integer(2)]],
↪Integer(2))
>>> T.to_transposition_sequence()
[[-1, 0], [1, 2], [0, 1]]
>>> T = StrongTableau([[None, -Integer(1), Integer(2), -Integer(3)], [-
↪Integer(2), Integer(3)]],Integer(2))
>>> T.to_transposition_sequence()
[[3, 4], [-1, 0], [1, 2]]
```

to_unmarked_list()

Return the tableau as a list of lists with markings removed.

Return the list of lists of the rows of the tableau where the markings have been removed.

OUTPUT: list of lists of integers or `None`

EXAMPLES:

```
sage: T = StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
sage: T.to_unmarked_list()
[[1, 1, 1, 2], [2], [3]]
sage: TT = T.set_weight([2,1,1,1])
sage: TT.to_unmarked_list()
[[1, 1, 2, 3], [3], [4]]
sage: StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_unmarked_list()
[[None, None, 1, 2], [None, None], [1, 2], [1, 2], [3], [3], [3], [3]]
```

```
>>> from sage.all import *
>>> T = StrongTableau( [[-Integer(1), -Integer(2), -Integer(3), Integer(4)],␣
↪[-Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),
↪Integer(1)])
>>> T.to_unmarked_list()
[[1, 1, 1, 2], [2], [3]]
>>> TT = T.set_weight([Integer(2),Integer(1),Integer(1),Integer(1)])
>>> TT.to_unmarked_list()
[[1, 1, 2, 3], [3], [4]]
>>> StrongTableau( [[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_unmarked_list()
[[None, None, 1, 2], [None, None], [1, 2], [1, 2], [3], [3], [3], [3]]
```

to_unmarked_standard_list()

Return the standard part of the tableau as a list of lists with markings removed.

Return the list of lists of the rows of the tableau where the markings have been removed.

OUTPUT: list of lists of integers or `None`

EXAMPLES:

```
sage: StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1]).to_unmarked_
↪standard_list()
[[1, 2, 3, 4], [4], [5]]
sage: StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-
↪3], [3], [3], [3]], 4).to_unmarked_standard_list()
[[None, None, 2, 4], [None, None], [1, 3], [2, 4], [5], [5], [5], [5]]
```

```
>>> from sage.all import *
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),
↪Integer(1)]).to_unmarked_standard_list()
[[1, 2, 3, 4], [4], [5]]
>>> StrongTableau( [[None, None, -Integer(1), -Integer(2)], [None, None], [-
↪Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],␣
↪[Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_unmarked_standard_
↪list()
[[None, None, 2, 4], [None, None], [1, 3], [2, 4], [5], [5], [5], [5]]
```

weight()

Return the weight of the tableau.

The weight is a list of nonnegative integers indicating the number of 1s, number of 2s, number of 3s, etc.

OUTPUT: list of nonnegative integers

EXAMPLES:

```
sage: T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3); T.weight()
(1, 1, 1, 1, 1)
sage: T.set_weight([3,1,1]).weight()
(3, 1, 1)
sage: StrongTableau([[-1,-1,-2,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3).weight()
(2, 2, 3, 1)
```

```
>>> from sage.all import *
>>> T = StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-
↪Integer(4)], [-Integer(5)]], Integer(3)); T.weight()
(1, 1, 1, 1, 1)
>>> T.set_weight([Integer(3),Integer(1),Integer(1)]).weight()
(3, 1, 1)
>>> StrongTableau([[-Integer(1),-Integer(1),-Integer(2),-Integer(3)],[-
↪Integer(2),Integer(3),-Integer(3),Integer(4)],[Integer(2),Integer(3)],[-
↪Integer(3),-Integer(4)]], Integer(3)).weight()
(2, 2, 3, 1)
```

class sage.combinat.k_tableau.**StrongTableaux**(*k*, *shape*, *weight*)

Bases: UniqueRepresentation, Parent

Element

alias of *StrongTableau*

classmethod add_marking(*unmarkedT*, *marking*, *k*, *weight*)

Add markings to a partially marked strong tableau.

Given a partially marked standard tableau and a list of cells where the marks should be placed along with a weight, return the semi-standard marked strong tableau. The marking should complete the marking so that the result is a strong standard marked tableau.

INPUT:

- unmarkedT – list of lists which is a partially marked strong k-tableau
- marking – list of pairs of coordinates where cells are to be marked
- k – positive integer
- weight – tuple of the weight of the output tableau

OUTPUT: a StrongTableau object

EXAMPLES:

```
sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (1,0)], 2, [1,1])
[[None, -1, 2], [-2]]
sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (1,0)], 2, [2])
Traceback (most recent call last):
...
ValueError: The weight=(2,) and the markings on the standard tableau=[[None, -
↪1, 2], [-2]] do not agree.
sage: StrongTableaux.add_marking([[None,1,2],[2]], [(0,1), (0,2)], 2, [2])
[[None, -1, -1], [1]]
```

```
>>> from sage.all import *
>>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)],[Integer(2)]],␣
↪[(Integer(0),Integer(1)), (Integer(1),Integer(0))], Integer(2), [Integer(1),
↪Integer(1)])
[[None, -1, 2], [-2]]
>>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)],[Integer(2)]],␣
↪[(Integer(0),Integer(1)), (Integer(1),Integer(0))], Integer(2),␣
↪[Integer(2)])
Traceback (most recent call last):
...
ValueError: The weight=(2,) and the markings on the standard tableau=[[None, -
↪1, 2], [-2]] do not agree.
>>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)],[Integer(2)]],␣
↪[(Integer(0),Integer(1)), (Integer(0),Integer(2))], Integer(2),␣
↪[Integer(2)])
[[None, -1, -1], [1]]
```

classmethod cells_head_dictionary(*T*)

Return a dictionary with the locations of the heads of all markings.

Return a dictionary of values and lists of cells where the heads with the values are located in a strong standard unmarked tableau `T`.

INPUT:

- `T` – a strong standard unmarked tableau as a list of lists

OUTPUT:

- a dictionary with keys the entries in the tableau and values are the coordinates of the heads with those entries

EXAMPLES:

```
sage: StrongTableaux.cells_head_dictionary([[1,2,4,7],[3,6,6,8],[4,7],[5,8]])
{1: [(0, 0)],
 2: [(0, 1)],
 3: [(1, 0)],
 4: [(2, 0), (0, 2)],
 5: [(3, 0)],
 6: [(1, 2)],
 7: [(2, 1), (0, 3)],
 8: [(3, 1), (1, 3)]}
sage: StrongTableaux.cells_head_dictionary([[None, 2, 2, 4, 5, 6, 6, 6],␣
↪[None, 3, 6, 6, 6], [1, 4]])
{1: [(2, 0)],
 2: [(0, 2)],
 3: [(1, 1)],
 4: [(2, 1), (0, 3)],
 5: [(0, 4)],
 6: [(1, 4), (0, 7)]}
```

```
>>> from sage.all import *
>>> StrongTableaux.cells_head_dictionary([[Integer(1),Integer(2),Integer(4),
↪Integer(7)],[Integer(3),Integer(6),Integer(6),Integer(8)],[Integer(4),
```

(continues on next page)

(continued from previous page)

```
↪Integer(7)],[Integer(5),Integer(8)]])
{1: [(0, 0)],
 2: [(0, 1)],
 3: [(1, 0)],
 4: [(2, 0), (0, 2)],
 5: [(3, 0)],
 6: [(1, 2)],
 7: [(2, 1), (0, 3)],
 8: [(3, 1), (1, 3)]}
>>> StrongTableaux.cells_head_dictionary([[None, Integer(2), Integer(2),␣
↪Integer(4), Integer(5), Integer(6), Integer(6), Integer(6)], [None,␣
↪Integer(3), Integer(6), Integer(6), Integer(6)], [Integer(1), Integer(4)]])
{1: [(2, 0)],
 2: [(0, 2)],
 3: [(1, 1)],
 4: [(2, 1), (0, 3)],
 5: [(0, 4)],
 6: [(1, 4), (0, 7)]}
```

classmethod follows_tableau_unsigned_standard(*Tlist*, *k*)

Return a list of strong tableaux one longer in length than `Tlist`.

Return list of all standard strong tableaux obtained from `Tlist` by extending to a core which follows the shape of `Tlist` in the strong order. It does not put the markings on the last entry that it adds but it does keep the markings on all entries smaller. The objects returned are not `StrongTableau` objects (and cannot be) because the last entry will not properly marked.

INPUT:

- `Tlist` – a filling of a $k+1$-core as a list of lists
- `k` – integer

OUTPUT: list of strong tableaux which follow `Tlist` in strong order

EXAMPLES:

```
sage: StrongTableaux.follows_tableau_unsigned_standard([[-1, -1, -2, -3], [-2,
↪ 3, -3, 4], [2, 3], [-3, -4]], 3)
[[[-1, -1, -2, -3, 5, 5, 5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [5], [5], [5]]]
sage: StrongTableaux.follows_tableau_unsigned_standard([[None,-1],[-2,-3]],3)
[[[None, -1, 4, 4, 4], [-2, -3]], [[None, -1, 4], [-2, -3], [4]],
 [[None, -1], [-2, -3], [4], [4], [4]]]
```

```
>>> from sage.all import *
>>> StrongTableaux.follows_tableau_unsigned_standard([[-Integer(1), -
↪Integer(1), -Integer(2), -Integer(3)], [-Integer(2), Integer(3), -
↪Integer(3), Integer(4)], [Integer(2), Integer(3)], [-Integer(3), -
↪Integer(4)]], Integer(3))
[[[-1, -1, -2, -3, 5, 5, 5], [-2, 3, -3, 4], [2, 3], [-3, -4]],
 [[-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5]],
 [[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4], [5], [5], [5]]]
>>> StrongTableaux.follows_tableau_unsigned_standard([[None,-Integer(1)],[-
```

(continues on next page)

(continued from previous page)

```
↪Integer(2),-Integer(3)]],Integer(3))
[[[None, -1, 4, 4, 4], [-2, -3]], [[None, -1, 4], [-2, -3], [4]],
 [[None, -1], [-2, -3], [4], [4], [4]]]
```

inner_shape()

Return the inner shape of the class of strong tableaux.

OUTPUT: a $k+1$-core

EXAMPLES:

```
sage: StrongTableaux( 2, [3,1] ).inner_shape()
[]
sage: type(StrongTableaux( 2, [3,1] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).inner_shape()
[1]
```

```
>>> from sage.all import *
>>> StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).inner_shape()
[]
>>> type(StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
>>> StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).
↪inner_shape()
[1]
```

classmethod marked_CST_to_transposition_sequence(T, k)

Return a list of transpositions corresponding to `T`.

Given a strong column strict tableau `T` returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

INPUT:

- `T` – a non-empty column strict tableau as a list of lists
- `k` – positive integer

OUTPUT: list of pairs of values `[i,j]` representing the transpositions t_{ij}

EXAMPLES:

```
sage: CST_to_trans = StrongTableaux.marked_CST_to_transposition_sequence
sage: CST_to_trans([[-1, -1, -1], [1]], 2)
[[2, 3], [1, 2], [0, 1]]
sage: CST_to_trans([], 2)
[]
sage: CST_to_trans([[-2, -2, -2], [2]], 2)
[[2, 3], [1, 2], [0, 1]]
sage: CST_to_trans([[-1, -2, -2, -2, -2], [-2, 2], [2]], 3)
[[4, 5], [3, 4], [2, 3], [1, 2], [-1, 0], [0, 1]]
sage: CST_to_trans([[-1, -2, -5, 5, -5, 5, -5], [-3, -4, 5, 5], [5]],3)
[[5, 7], [3, 5], [2, 3], [0, 1], [-1, 0], [1, 2], [0, 1]]
sage: CST_to_trans([[-1, -2, -3, 4, -7], [-4, -6], [-5, 6]],3)
[[4, 5], [-1, 1], [-2, -1], [-1, 0], [2, 3], [1, 2], [0, 1]]
```

```
>>> from sage.all import *
>>> CST_to_trans = StrongTableaux.marked_CST_to_transposition_sequence
>>> CST_to_trans([[-Integer(1), -Integer(1), -Integer(1)], [Integer(1)]],␣
↪Integer(2))
[[2, 3], [1, 2], [0, 1]]
>>> CST_to_trans([], Integer(2))
[]
>>> CST_to_trans([[-Integer(2), -Integer(2), -Integer(2)], [Integer(2)]],␣
↪Integer(2))
[[2, 3], [1, 2], [0, 1]]
>>> CST_to_trans([[-Integer(1), -Integer(2), -Integer(2), -Integer(2), -
↪Integer(2)], [-Integer(2), Integer(2)], [Integer(2)]], Integer(3))
[[4, 5], [3, 4], [2, 3], [1, 2], [-1, 0], [0, 1]]
>>> CST_to_trans([[-Integer(1), -Integer(2), -Integer(5), Integer(5), -

↪Integer(7)], [-Integer(4), -Integer(6)], [-Integer(5), Integer(6)]],
↪Integer(3))
[[4, 5], [-1, 1], [-2, -1], [-1, 0], [2, 3], [1, 2], [0, 1]]
```

classmethod marked_given_unmarked_and_weight_iterator(*unmarkedT*, *k*, *weight*)

An iterator generating strong marked tableaux from an unmarked strong tableau.

Iterator which lists all marked tableaux of weight `weight` such that the standard unmarked part of the tableau is equal to `unmarkedT`.

INPUT:

- `unmarkedT` – list of lists representing a strong unmarked tableau
- `k` – positive integer
- `weight` – list of nonnegative integers indicating the weight

OUTPUT: an iterator that returns `StrongTableau` objects

EXAMPLES:

```
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
↪[3]], 2, [3])
sage: list(ST)
[[[-1, -1, -1], [1]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
↪[3]], 2, [0,3])
sage: list(ST)
[[[-2, -2, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
↪[3]], 2, [1,2])
sage: list(ST)
[[[-1, -2, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
↪[3]], 2, [2,1])
sage: list(ST)
[[[-1, -1, 2], [-2]], [[-1, -1, -2], [2]]]
```

(continues on next page)

(continued from previous page)

```
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,␣
↪None, 1, 2, 4], [2, 4], [3]], 3, [3,1])
sage: list(ST)
[]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,␣
↪None, 1, 2, 4], [2, 4], [3]], 3, [2,2])
sage: list(ST)
[[[None, None, -1, -1, 2], [1, -2], [-2]],
 [[None, None, -1, -1, -2], [1, 2], [-2]]]
```

```
>>> from sage.all import *
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_
↪iterator([[Integer(1),Integer(2),Integer(3)],[Integer(3)]], Integer(2),␣
↪[Integer(3)])
>>> list(ST)
[[[-1, -1, -1], [1]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_
↪iterator([[Integer(1),Integer(2),Integer(3)],[Integer(3)]], Integer(2),␣
↪[Integer(0),Integer(3)])
>>> list(ST)
[[[-2, -2, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_
↪iterator([[Integer(1),Integer(2),Integer(3)],[Integer(3)]], Integer(2),␣
↪[Integer(1),Integer(2)])
>>> list(ST)
[[[-1, -2, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_
↪iterator([[Integer(1),Integer(2),Integer(3)],[Integer(3)]], Integer(2),␣
↪[Integer(2),Integer(1)])
>>> list(ST)
[[[-1, -1, 2], [-2]], [[-1, -1, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,␣
↪None, Integer(1), Integer(2), Integer(4)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), [Integer(3),Integer(1)])
>>> list(ST)
[]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,␣
↪None, Integer(1), Integer(2), Integer(4)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), [Integer(2),Integer(2)])
>>> list(ST)
[[[None, None, -1, -1, 2], [1, -2], [-2]],
 [[None, None, -1, -1, -2], [1, 2], [-2]]]
```

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

outer_shape()

Return the outer shape of the class of strong tableaux.

OUTPUT: a $k+1$-core

EXAMPLES:

```
sage: StrongTableaux( 2, [3,1] ).outer_shape()
[3, 1]
sage: type(StrongTableaux( 2, [3,1] ).outer_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).outer_shape()
[2, 1]
```

```
>>> from sage.all import *
>>> StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).outer_shape()
[3, 1]
>>> type(StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).outer_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
>>> StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).
↪outer_shape()
[2, 1]
```

shape()

Return the shape of `self`.

If the `self` has an inner shape return a pair consisting of an inner and an outer shape. If the inner shape is empty then return only the outer shape.

OUTPUT: a $k+1$-core or a pair of $k+1$-cores

EXAMPLES:

```
sage: StrongTableaux( 2, [3,1] ).shape()
[3, 1]
sage: type(StrongTableaux( 2, [3,1] ).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).shape()
([2, 1], [1])
```

```
>>> from sage.all import *
>>> StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).shape()
[3, 1]
>>> type(StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
>>> StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).
↪shape()
([2, 1], [1])
```

classmethod standard_marked_iterator(*k*, *size*, *outer_shape=None*, *inner_shape=[]*)

An iterator for generating standard strong marked tableaux.

An iterator which generates all standard marked k-tableaux of a given `size` which are contained in `outer_shape` and contain the `inner_shape`. If `outer_shape` is `None` then there is no restriction on the shape of the tableaux which are created.

INPUT:

- `k` – positive integer
- `size` – positive integer
- `outer_shape` – list which is a $k+1$-core (default: `None`)

- `inner_shape` – list which is a $k+1$-core (default: `[]`)

OUTPUT:

- an iterator which returns the standard marked tableaux with `size` cells and that are contained in `outer_shape` and contain `inner_shape`

EXAMPLES:

```
sage: list(StrongTableaux.standard_marked_iterator(2, 3))
[[[-1, -2, 3], [-3]], [[-1, -2, -3], [3]], [[-1, -2], [-3], [3]], [[-1, 3, -
↪3], [-2]], [[-1, 3], [-2], [-3]], [[-1, -3], [-2], [3]]]
sage: list(StrongTableaux.standard_marked_iterator(2, 1, inner_shape=[1,1]))
[[[None, 1, -1], [None]], [[None, 1], [None], [-1]], [[None, -1], [None],␣
↪[1]]]
sage: len(list(StrongTableaux.standard_marked_iterator(4,4)))
10
sage: len(list(StrongTableaux.standard_marked_iterator(4,6)))
140
sage: len(list(StrongTableaux.standard_marked_iterator(4,4, inner_shape=[2,
↪2])))
200
sage: len(list(StrongTableaux.standard_marked_iterator(4,4, outer_shape=[5,2,
↪2,1], inner_shape=[2,2])))
24
```

```
>>> from sage.all import *
>>> list(StrongTableaux.standard_marked_iterator(Integer(2), Integer(3)))
[[[-1, -2, 3], [-3]], [[-1, -2, -3], [3]], [[-1, -2], [-3], [3]], [[-1, 3, -
↪3], [-2]], [[-1, 3], [-2], [-3]], [[-1, -3], [-2], [3]]]
>>> list(StrongTableaux.standard_marked_iterator(Integer(2), Integer(1),␣
↪inner_shape=[Integer(1),Integer(1)]))
[[[None, 1, -1], [None]], [[None, 1], [None], [-1]], [[None, -1], [None],␣
↪[1]]]
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4))))
10
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(6))))
140
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4),␣
↪inner_shape=[Integer(2),Integer(2)])))
200
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4),␣
↪outer_shape=[Integer(5),Integer(2),Integer(2),Integer(1)], inner_
↪shape=[Integer(2),Integer(2)])))
24
```

classmethod standard_unmarked_iterator(*k*, *size*, *outer_shape=None*, *inner_shape=[]*)

An iterator for standard unmarked strong tableaux.

An iterator which generates all unmarked tableaux of a given `size` which are contained in `outer_shape` and which contain the `inner_shape`.

These are built recursively by building all standard marked strong tableaux of size `size` -1 and adding all possible covers.

If `outer_shape` is `None` then there is no restriction on the shape of the tableaux which are created.

INPUT:

- `k`, `size` – positive integers
- `outer_shape` – list representing a $k+1$-core (default: `None`)
- `inner_shape` – list representing a $k+1$-core (default: `[]`)

OUTPUT:

- an iterator which lists all standard strong unmarked tableaux with `size` cells and which are contained in `outer_shape` and contain `inner_shape`

EXAMPLES:

```
sage: list(StrongTableaux.standard_unmarked_iterator(2, 3))
[[[1, 2, 3], [3]], [[1, 2], [3], [3]], [[1, 3, 3], [2]], [[1, 3], [2], [3]]]
sage: list(StrongTableaux.standard_unmarked_iterator(2, 1, inner_shape=[1,1]))
[[[None, 1, 1], [None]], [[None, 1], [None], [1]]]
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4)))
10
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,6)))
98
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, inner_shape=[2,
↪2])))
92
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, outer_shape=[5,
↪2,2,1], inner_shape=[2,2])))
10
```

```
>>> from sage.all import *
>>> list(StrongTableaux.standard_unmarked_iterator(Integer(2), Integer(3)))
[[[1, 2, 3], [3]], [[1, 2], [3], [3]], [[1, 3, 3], [2]], [[1, 3], [2], [3]]]
>>> list(StrongTableaux.standard_unmarked_iterator(Integer(2), Integer(1),␣
↪inner_shape=[Integer(1),Integer(1)]))
[[[None, 1, 1], [None]], [[None, 1], [None], [1]]]
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4),
↪Integer(4))))
10
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4),
↪Integer(6))))
98
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4),Integer(4),␣
↪inner_shape=[Integer(2),Integer(2)])))
92
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4),Integer(4),␣
↪outer_shape=[Integer(5),Integer(2),Integer(2),Integer(1)], inner_
↪shape=[Integer(2),Integer(2)])))
10
```

classmethod transpositions_to_standard_strong(*transeq*, *k*, *emptyTableau=[]*)

Return a strong tableau corresponding to a sequence of transpositions.

This method returns the action by left multiplication on the empty strong tableau by transpositions specified by `transeq`.

INPUT:

- `transeq` – a sequence of transpositions t_{ij} (a list of pairs)
- `emptyTableau` – (default: `[]`) an empty list or a skew strong tableau possibly consisting of `None` entries

OUTPUT: a `StrongTableau` object

EXAMPLES:

```
sage: StrongTableaux.transpositions_to_standard_strong([[0,1]], 2)
[[-1]]
sage: StrongTableaux.transpositions_to_standard_strong([[-2,-1], [2,3]], 2,␣
↪[[None, None]])
[[None, None, -1], [1], [-2]]
sage: StrongTableaux.transpositions_to_standard_strong([[2, 3], [1, 2], [0,␣
↪1]], 2)
[[-1, -2, -3], [3]]
sage: StrongTableaux.transpositions_to_standard_strong([[-1, 0], [1, 2], [0,␣
↪1]], 2)
[[-1, -2, 3], [-3]]
sage: StrongTableaux.transpositions_to_standard_strong([[3, 4], [-1, 0], [1,␣
↪2]], 2, [[None]])
[[None, -1, 2, -3], [-2, 3]]
```

```
>>> from sage.all import *
>>> StrongTableaux.transpositions_to_standard_strong([[Integer(0),
↪Integer(1)]], Integer(2))
[[-1]]
>>> StrongTableaux.transpositions_to_standard_strong([[-Integer(2),-
↪Integer(1)], [Integer(2),Integer(3)]], Integer(2), [[None, None]])
[[None, None, -1], [1], [-2]]
>>> StrongTableaux.transpositions_to_standard_strong([[Integer(2),␣
↪Integer(3)], [Integer(1), Integer(2)], [Integer(0), Integer(1)]],␣
↪Integer(2))
[[-1, -2, -3], [3]]
>>> StrongTableaux.transpositions_to_standard_strong([[-Integer(1),␣
↪Integer(0)], [Integer(1), Integer(2)], [Integer(0), Integer(1)]],␣
↪Integer(2))
[[-1, -2, 3], [-3]]
>>> StrongTableaux.transpositions_to_standard_strong([[Integer(3),␣
↪Integer(4)], [-Integer(1), Integer(0)], [Integer(1), Integer(2)]],␣
↪Integer(2), [[None]])
[[None, -1, 2, -3], [-2, 3]]
```

`sage.combinat.k_tableau.`**`WeakTableau`**(*t*, *k*, *inner_shape=[]*, *representation='core'*)

This is the dispatcher method for the element class of weak k-tableaux.

Standard weak k-tableaux correspond to saturated chains in the weak order. There are three formulations of weak tableaux, one in terms of cores, one in terms of k-bounded partitions, and one in terms of factorizations of affine Grassmannian elements. For semistandard weak k-tableaux, all letters of the same value have to satisfy the conditions of a horizontal strip. In the affine Grassmannian formulation this means that all factors are cyclically decreasing elements. For more information, see for example [LLMSSZ2013].

INPUT:

- `t` – a weak k-tableau in the specified representation:

  - for the 'core' representation `t` is a list of lists where each subtableaux should have a $k+1$-core shape; `None` is allowed as an entry for skew weak k-tableaux
  - for the 'bounded' representation `t` is a list of lists where each subtableaux should have a k-bounded shape; `None` is allowed as an entry for skew weak k-tableaux
  - for the 'factorized_permutation' representation `t` is either a list of cyclically decreasing Weyl group elements or a list of reduced words of cyclically decreasing Weyl group elements; to indicate a skew tableau in this representation, `inner_shape` should be the inner shape as a $(k+1)$-core

- `k` – positive integer
- `inner_shape` – this entry is only relevant for the 'factorized_permutation' representation and specifies the inner shape in case the tableau is skew (default: `[]`)
- `representation` – 'core', 'bounded', or 'factorized_permutation' (default: `'core'`)

EXAMPLES:

Here is an example of a weak 3-tableau in core representation:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t.weight()
(2, 2, 2)
sage: type(t)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)],
↪ [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.shape()
[5, 2, 1]
>>> t.weight()
(2, 2, 2)
>>> type(t)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

And now we give a skew weak 3-tableau in core representation:

```
sage: ts = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: ts.shape()
([5, 2, 1], [1, 1])
sage: ts.weight()
(2, 2)
sage: type(ts)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

```
>>> from sage.all import *
>>> ts = WeakTableau([[None, Integer(1), Integer(1), Integer(2), Integer(2)],␣
↪[None, Integer(2)], [Integer(1)]], Integer(3))
>>> ts.shape()
([5, 2, 1], [1, 1])
>>> ts.weight()
(2, 2)
```

(continues on next page)

(continued from previous page)

```
>>> type(ts)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

Next we create the analogue of the first example in bounded representation:

```
sage: tb = WeakTableau([[1,1,2],[2,3],[3]], 3, representation='bounded')
sage: tb.shape()
[3, 2, 1]
sage: tb.weight()
(2, 2, 2)
sage: type(tb)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
sage: tb.to_core_tableau()
[[1, 1, 2, 2, 3], [2, 3], [3]]
sage: t == tb.to_core_tableau()
True
```

```
>>> from sage.all import *
>>> tb = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),Integer(3)],
↪[Integer(3)]], Integer(3), representation='bounded')
>>> tb.shape()
[3, 2, 1]
>>> tb.weight()
(2, 2, 2)
>>> type(tb)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
>>> tb.to_core_tableau()
[[1, 1, 2, 2, 3], [2, 3], [3]]
>>> t == tb.to_core_tableau()
True
```

And the analogue of the skew example in bounded representation:

```
sage: tbs = WeakTableau([[None, 1, 2], [None, 2], [1]], 3, representation =
↪"bounded")
sage: tbs.shape()
([3, 2, 1], [1, 1])
sage: tbs.weight()
(2, 2)
sage: tbs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.to_bounded_tableau() == tbs
True
```

```
>>> from sage.all import *
>>> tbs = WeakTableau([[None, Integer(1), Integer(2)], [None, Integer(2)],␣
↪[Integer(1)]], Integer(3), representation = "bounded")
>>> tbs.shape()
([3, 2, 1], [1, 1])
>>> tbs.weight()
(2, 2)
>>> tbs.to_core_tableau()
```

(continues on next page)

(continued from previous page)

```
[[None, 1, 1, 2, 2], [None, 2], [1]]
>>> ts.to_bounded_tableau() == tbs
True
```

Finally we do the same examples for the factorized permutation representation:

```
sage: tf = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = "factorized_
↪permutation")
sage: tf.shape()
[5, 2, 1]
sage: tf.weight()
(2, 2, 2)
sage: type(tf)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.
↪element_class'>
sage: tf.to_core_tableau() == t
True

sage: tfs = WeakTableau([[0,3],[2,1]], 3, inner_shape = [1,1], representation =
↪'factorized_permutation')
sage: tfs.shape()
([5, 2, 1], [1, 1])
sage: tfs.weight()
(2, 2)
sage: type(tfs)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.
↪element_class'>
sage: tfs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
```

```
>>> from sage.all import *
>>> tf = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],[Integer(1),
↪Integer(0)]], Integer(3), representation = "factorized_permutation")
>>> tf.shape()
[5, 2, 1]
>>> tf.weight()
(2, 2, 2)
>>> type(tf)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.
↪element_class'>
>>> tf.to_core_tableau() == t
True

>>> tfs = WeakTableau([[Integer(0),Integer(3)],[Integer(2),Integer(1)]],␣
↪Integer(3), inner_shape = [Integer(1),Integer(1)], representation = 'factorized_
↪permutation')
>>> tfs.shape()
([5, 2, 1], [1, 1])
>>> tfs.weight()
(2, 2)
>>> type(tfs)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.
```

(continues on next page)

(continued from previous page)

```
↪element_class'>
>>> tfs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
```

Another way to pass from one representation to another is as follows:

```
sage: ts
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.parent()._representation
'core'
sage: ts.representation('bounded')
[[None, 1, 2], [None, 2], [1]]
```

```
>>> from sage.all import *
>>> ts
[[None, 1, 1, 2, 2], [None, 2], [1]]
>>> ts.parent()._representation
'core'
>>> ts.representation('bounded')
[[None, 1, 2], [None, 2], [1]]
```

To test whether a given semistandard tableau is a weak k-tableau in the bounded representation, one can ask:

```
sage: t = Tableau([[1,1,2],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 2], [None, 2], [1]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None, 1, 1], [None, 2], [2]])
sage: t.is_k_tableau(3)
False
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),Integer(3)],
↪[Integer(3)]])
>>> t.is_k_tableau(Integer(3))
True
>>> t = SkewTableau([[None, Integer(1), Integer(2)], [None, Integer(2)],␣
↪[Integer(1)]])
>>> t.is_k_tableau(Integer(3))
True
>>> t = SkewTableau([[None, Integer(1), Integer(1)], [None, Integer(2)],␣
↪[Integer(2)]])
>>> t.is_k_tableau(Integer(3))
False
```

class sage.combinat.k_tableau.**WeakTableau_abstract**

Bases: ClonableList

Abstract class for the various element classes of WeakTableau.

intermediate_shapes()

Return the intermediate shapes of `self`.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the i-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$. The output is the list of these shapes.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.intermediate_shapes()
[[], [2], [4, 1], [5, 2, 1]]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.intermediate_shapes()
[[], [3], [3, 2], [3, 2, 1]]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.intermediate_shapes()
[[2], [3], [3, 1], [3, 1, 1], [3, 2, 1]]

sage: t = WeakTableau([[0],[3],[2],[3]], 3, inner_shape = [2], representation␣
↪= 'factorized_permutation')
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.intermediate_shapes()
[[], [2], [4, 1], [5, 2, 1]]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.intermediate_shapes()
[[], [3], [3, 2], [3, 2, 1]]

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.intermediate_shapes()
[[2], [3], [3, 1], [3, 1, 1], [3, 2, 1]]

>>> t = WeakTableau([[Integer(0)],[Integer(3)],[Integer(2)],[Integer(3)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
```

(continues on next page)

(continued from previous page)

```
>>> t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

pp()

Return a pretty print string of the tableau.

EXAMPLES:

```
sage: t = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: t.pp()
.  1  1  2  2
.  2
1
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.pp()
[s2*s0, s3*s2]
```

```
>>> from sage.all import *
>>> t = WeakTableau([[None, Integer(1), Integer(1), Integer(2), Integer(2)],␣
↪[None, Integer(2)], [Integer(1)]], Integer(3))
>>> t.pp()
.  1  1  2  2
.  2
1
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.pp()
[s2*s0, s3*s2]
```

representation(*representation='core'*)

Return the analogue of `self` in the specified representation.

INPUT:

- `representation` – 'core', 'bounded', or 'factorized_permutation' (default: `'core'`)

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,␣
↪7], [5, 6], [6], [7]], 4)
sage: t.parent()._representation
'core'
sage: t.representation('bounded')
[[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]]
sage: t.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

sage: tb = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4,
↪ representation = 'bounded')
sage: tb.parent()._representation
'bounded'
sage: tb.representation('core') == t
```

(continues on next page)

(continued from previous page)

```
True
sage: tb.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

sage: tp = WeakTableau([[0],[3,1],[2,1],[0,4],[3,0],[4,2],[1,0]], 4,␣
↪representation = 'factorized_permutation')
sage: tp.parent()._representation
'factorized_permutation'
sage: tp.representation('core') == t
True
sage: tp.representation('bounded') == tb
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),␣
↪Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),␣
↪Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),␣
↪Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],␣
↪Integer(4))
>>> t.parent()._representation
'core'
>>> t.representation('bounded')
[[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]]
>>> t.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

>>> tb = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(4)],␣
↪[Integer(2), Integer(3), Integer(5)], [Integer(3), Integer(4)], [Integer(5),
↪ Integer(6)], [Integer(6)], [Integer(7)]], Integer(4), representation =
↪'bounded')
>>> tb.parent()._representation
'bounded'
>>> tb.representation('core') == t
True
>>> tb.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

>>> tp = WeakTableau([[Integer(0)],[Integer(3),Integer(1)],[Integer(2),
↪Integer(1)],[Integer(0),Integer(4)],[Integer(3),Integer(0)],[Integer(4),
↪Integer(2)],[Integer(1),Integer(0)]], Integer(4), representation =
↪'factorized_permutation')
>>> tp.parent()._representation
'factorized_permutation'
>>> tp.representation('core') == t
True
>>> tp.representation('bounded') == tb
True
```

shape()

Return the shape of `self`.

When the tableau is straight, the outer shape is returned. When the tableau is skew, the tuple of the outer and inner shape is returned.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape()
([5, 2, 1], [2])

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape()
[3, 2, 1]
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.shape()
([3, 2, 1], [2])

sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.shape()
[5, 2, 1]
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.shape()
([5, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.shape()
[5, 2, 1]
>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.shape()
([5, 2, 1], [2])

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape()
[3, 2, 1]
>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape()
([3, 2, 1], [2])

>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.shape()
[5, 2, 1]
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
```

(continues on next page)

(continued from previous page)

```
>>> t.shape()
([5, 2, 1], [2])
```

size()

Return the size of the shape of `self`.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

See also

sage.combinat.core.Core.length()

EXAMPLES:

```
sage: t = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: t.shape()
([5, 2, 1], [1, 1])
sage: t.size()
4
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation='bounded')
sage: t.shape()
[3, 2, 1]
sage: t.size()
6
```

```
>>> from sage.all import *
>>> t = WeakTableau([[None, Integer(1), Integer(1), Integer(2), Integer(2)],␣
↪[None, Integer(2)], [Integer(1)]], Integer(3))
>>> t.shape()
([5, 2, 1], [1, 1])
>>> t.size()
4
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),
↪Integer(3)],[Integer(3)]], Integer(3), representation='bounded')
>>> t.shape()
[3, 2, 1]
>>> t.size()
6
```

weight()

Return the weight of `self`.

The weight is a tuple whose i-th entry is the number of labels i in the bounded representation of `self`.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
```

(continues on next page)

(continued from previous page)

```
sage: t.weight()
(1, 1, 1, 1)
sage: t = WeakTableau([[None,2,3],[3]],2)
sage: t.weight()
(0, 1, 1)

sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation = 'bounded')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.weight()
(1, 1, 1, 1)

sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.weight()
(2, 2)
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.weight()
(2, 2, 2)
>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.weight()
(1, 1, 1, 1)
>>> t = WeakTableau([[None,Integer(2),Integer(3)],[Integer(3)]],Integer(2))
>>> t.weight()
(0, 1, 1)

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.weight()
(3, 2, 1)
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),
↪Integer(3)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.weight()
(2, 2, 2)
>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.weight()
(1, 1, 1, 1)

>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.weight()
(3, 2, 1)
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],
↪[Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.weight()
(2, 2, 2)
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.weight()
(2, 2)
```

class sage.combinat.k_tableau.**WeakTableau_bounded**(*parent*, *t*)

Bases: *WeakTableau_abstract*

A (skew) weak k-tableau represented in terms of k-bounded partitions.

check()

Check that `self` is a valid weak k-tableau.

EXAMPLES:

```
sage: t = WeakTableau([[1,1],[2]], 2, representation = 'bounded')
sage: t.check()

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.check()
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1)],[Integer(2)]], Integer(2),␣
↪representation = 'bounded')
>>> t.check()

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.check()
```

classmethod from_core_tableau(*t*, *k*)

Construct weak k-bounded tableau from in k-core tableau.

EXAMPLES:

```
sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: WeakTableau_bounded.from_core_tableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
```

(continues on next page)

(continued from previous page)

```
[[1, 1, 2], [2, 3], [3]]

sage: WeakTableau_bounded.from_core_tableau([[None, None, 2, 3, 4], [1, 4],␣
↪[2]], 3)
[[None, None, 3], [1, 4], [2]]

sage: WeakTableau_bounded.from_core_tableau([[None,2,3],[3]], 2)
[[None, 2], [3]]
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import WeakTableau_bounded
>>> WeakTableau_bounded.from_core_tableau([[Integer(1), Integer(1),␣
↪Integer(2), Integer(2), Integer(3)], [Integer(2), Integer(3)],␣
↪[Integer(3)]], Integer(3))
[[1, 1, 2], [2, 3], [3]]

>>> WeakTableau_bounded.from_core_tableau([[None, None, Integer(2),␣
↪Integer(3), Integer(4)], [Integer(1), Integer(4)], [Integer(2)]],␣
↪Integer(3))
[[None, None, 3], [1, 4], [2]]

>>> WeakTableau_bounded.from_core_tableau([[None,Integer(2),Integer(3)],
↪[Integer(3)]], Integer(2))
[[None, 2], [3]]
```

k_charge(*algorithm='I'*)

Return the k-charge of `self`.

INPUT:

- `algorithm` – (default: `'I'`) if "I", computes k-charge using the I algorithm, otherwise uses the J-algorithm

OUTPUT: nonnegative integer

For the definition of k-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2], [2, 3], [3]], 3, representation = 'bounded')
sage: t.k_charge()
2
sage: t = WeakTableau([[1, 3, 5], [2, 6], [4]], 3, representation = 'bounded')
sage: t.k_charge()
8
sage: t = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4,␣
↪representation = 'bounded')
sage: t.k_charge()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2)], [Integer(2),␣
↪Integer(3)], [Integer(3)]], Integer(3), representation = 'bounded')
>>> t.k_charge()
```

(continues on next page)

(continued from previous page)

```
2
>>> t = WeakTableau([[Integer(1), Integer(3), Integer(5)], [Integer(2),␣
↪Integer(6)], [Integer(4)]], Integer(3), representation = 'bounded')
>>> t.k_charge()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(4)],␣
↪[Integer(2), Integer(3), Integer(5)], [Integer(3), Integer(4)], [Integer(5),
↪ Integer(6)], [Integer(6)], [Integer(7)]], Integer(4), representation =
↪'bounded')
>>> t.k_charge()
12
```

shape_bounded()

Return the shape of `self` as k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

```
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape_bounded()
[3, 2, 1]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.shape_bounded()
([3, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape_bounded()
[3, 2, 1]

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape_bounded()
([3, 2, 1], [2])
```

shape_core()

Return the shape of `self` as $(k+1)$-core.

When the tableau is straight, the outer shape is returned as a $(k+1)$-core. When the tableau is skew, the tuple of the outer and inner shape is returned as $(k+1)$-cores.

EXAMPLES:

```
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape_core()
[5, 2, 1]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
```

(continues on next page)

(continued from previous page)

```
sage: t.shape_core()
([5, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape_core()
[5, 2, 1]

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.shape_core()
([5, 2, 1], [2])
```

to_core_tableau()

Return the weak k-tableau `self` where the shape of each restricted tableau is a $(k+1)$-core.

EXAMPLES:

```
sage: t = WeakTableau([[1,1,2,4],[2,3,5],[3,4],[5,6],[6],[7]], 4,␣
↪representation = 'bounded')
sage: c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class
↪'>
sage: t = WeakTableau([], 4, representation = 'bounded')
sage: t.to_core_tableau()
[]

sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: t = WeakTableau([[1,1,2],[2,3],[3]], 3, representation = 'bounded')
sage: WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
[[1, 1, 2], [2, 3], [3]]
sage: t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
True

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation =
↪'bounded')
sage: t.to_core_tableau()
[[None, None, 1, 2, 4], [2, 4], [3]]
sage: t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2),Integer(4)],
↪[Integer(2),Integer(3),Integer(5)],[Integer(3),Integer(4)],[Integer(5),
↪Integer(6)],[Integer(6)],[Integer(7)]], Integer(4), representation =
↪'bounded')
>>> c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
>>> type(c)
```

(continues on next page)

(continued from previous page)

```
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class
↪'>
>>> t = WeakTableau([], Integer(4), representation = 'bounded')
>>> t.to_core_tableau()
[]

>>> from sage.combinat.k_tableau import WeakTableau_bounded
>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),
↪Integer(3)],[Integer(3)]], Integer(3), representation = 'bounded')
>>> WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
[[1, 1, 2], [2, 3], [3]]
>>> t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
True

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3)]], Integer(3), representation = 'bounded')
>>> t.to_core_tableau()
[[None, None, 1, 2, 4], [2, 4], [3]]
>>> t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
True
```

class sage.combinat.k_tableau.**WeakTableau_core**(*parent*, *t*)

Bases: *WeakTableau_abstract*

A (skew) weak k-tableau represented in terms of $(k+1)$-cores.

check()

Check that `self` is a valid weak k-tableau.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2], [2]], 2)
sage: t.check()
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.check()
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2)], [Integer(2)]],␣
↪Integer(2))
>>> t.check()
>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.check()
```

dictionary_of_coordinates_at_residues(*v*)

Return a dictionary assigning to all residues of `self` with label `v` a list of cells with the given residue.

INPUT:

- `v` – a label of a cell in `self`

OUTPUT: dictionary assigning coordinates in `self` to residues

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.dictionary_of_coordinates_at_residues(3)
{0: [(0, 4), (1, 1)], 2: [(2, 0)]}

sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [3]], 3)
sage: t.dictionary_of_coordinates_at_residues(1)
{2: [(0, 2)], 3: [(0, 3), (1, 0)]}

sage: t = WeakTableau([], 3)
sage: t.dictionary_of_coordinates_at_residues(1)
{}
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(3))
{0: [(0, 4), (1, 1)], 2: [(2, 0)]}

>>> t = WeakTableau([[None, None, Integer(1), Integer(1), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(3)]], Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(1))
{2: [(0, 2)], 3: [(0, 3), (1, 0)]}

>>> t = WeakTableau([], Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(1))
{}
```

k_charge(*algorithm='I'*)

Return the k-charge of `self`.

INPUT:

- `algorithm` – (default: `'I'`) if "I", computes k-charge using the I algorithm, otherwise uses the J-algorithm

OUTPUT: nonnegative integer

For the definition of k-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

k_charge_I() and *k_charge_J()*

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,␣
↪7], [5, 6], [6], [7]], 4)
```

(continues on next page)

(continued from previous page)

```
sage: t.k_charge()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.k_charge()
2
>>> t = WeakTableau([[Integer(1), Integer(3), Integer(4), Integer(5),␣
↪Integer(6)], [Integer(2), Integer(6)], [Integer(4)]], Integer(3))
>>> t.k_charge()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),␣
↪Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),␣
↪Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),␣
↪Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],␣
↪Integer(4))
>>> t.k_charge()
12
```

k_charge_I()

Return the k-charge of `self` using the I-algorithm.

For the definition of k-charge and the I-algorithm see Section 3.3 of [LLMSSZ2013].

OUTPUT: nonnegative integer

See also

k_charge() and *k_charge_J()*

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge_I()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge_I()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,␣
↪7], [5, 6], [6], [7]], 4)
sage: t.k_charge_I()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.k_charge_I()
2
>>> t = WeakTableau([[Integer(1), Integer(3), Integer(4), Integer(5),␣
↪Integer(6)], [Integer(2), Integer(6)], [Integer(4)]], Integer(3))
```

(continues on next page)

(continued from previous page)

```
>>> t.k_charge_I()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),␣
↪Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),␣
↪Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),␣
↪Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],␣
↪Integer(4))
>>> t.k_charge_I()
12
```

k_charge_J()

Return the k-charge of `self` using the J-algorithm.

For the definition of k-charge and the J-algorithm see Section 3.3 of [LLMSSZ2013].

OUTPUT: nonnegative integer

See also

k_charge() and *k_charge_I()*

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge_J()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge_J()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,␣
↪7], [5, 6], [6], [7]], 4)
sage: t.k_charge_J()
12

>>> t = WeakTableau([[Integer(1), Integer(3), Integer(4), Integer(5),␣
↪Integer(6)], [Integer(2), Integer(6)], [Integer(4)]], Integer(3))
>>> t.k_charge_J()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),␣
↪Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),␣
↪Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),␣
↪Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],␣
↪Integer(4))
>>> t.k_charge_J()
12
```

list_of_standard_cells()

Return a list of lists of the coordinates of the standard cells of `self`.

INPUT:

- `self` – a weak k-tableau in core representation with partition weight

OUTPUT: list of lists of coordinates

> **Warning**
>
> This method currently only works for straight weak tableaux with partition weight.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.list_of_standard_cells()
[[(0, 1), (1, 0), (2, 0)], [(0, 0), (0, 2), (1, 1)]]
sage: t = WeakTableau([[1, 1, 1, 2], [2, 2, 3]], 5)
sage: t.list_of_standard_cells()
[[(0, 2), (1, 1), (1, 2)], [(0, 1), (1, 0)], [(0, 0), (0, 3)]]
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4,␣
↪7], [5, 6], [6], [7]], 4)
sage: t.list_of_standard_cells()
[[(0, 1), (1, 0), (2, 0), (0, 5), (3, 0), (4, 0), (5, 0)], [(0, 0), (0, 2),␣
↪(1, 1), (2, 1), (1, 2), (3, 1)]]
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.list_of_standard_cells()
[[(0, 1), (1, 0), (2, 0)], [(0, 0), (0, 2), (1, 1)]]
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(1), Integer(2)],␣
↪[Integer(2), Integer(2), Integer(3)]], Integer(5))
>>> t.list_of_standard_cells()
[[(0, 2), (1, 1), (1, 2)], [(0, 1), (1, 0)], [(0, 0), (0, 3)]]
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3),␣
↪Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2),␣
↪Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4),␣
↪Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]],␣
↪Integer(4))
>>> t.list_of_standard_cells()
[[(0, 1), (1, 0), (2, 0), (0, 5), (3, 0), (4, 0), (5, 0)], [(0, 0), (0, 2),␣
↪(1, 1), (2, 1), (1, 2), (3, 1)]]
```

residues_of_entries(*v*)

Return a list of residues of cells of weak k-tableau `self` labeled by `v`.

INPUT:

- `v` – a label of a cell in `self`

OUTPUT: list of residues

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.residues_of_entries(1)
[0, 1]

sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [3]], 3)
sage: t.residues_of_entries(1)
[2, 3]
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.residues_of_entries(Integer(1))
[0, 1]

>>> t = WeakTableau([[None, None, Integer(1), Integer(1), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(3)]], Integer(3))
>>> t.residues_of_entries(Integer(1))
[2, 3]
```

shape_bounded()

Return the shape of `self` as a k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.shape_bounded()
[3, 2, 1]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_bounded()
([3, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.shape_bounded()
[3, 2, 1]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.shape_bounded()
([3, 2, 1], [2])
```

shape_core()

Return the shape of `self` as a $(k+1)$-core.

When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: t.shape_core()
[5, 2, 1]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_core()
([5, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> t.shape_core()
[5, 2, 1]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.shape_core()
([5, 2, 1], [2])
```

to_bounded_tableau()

Return the bounded representation of the weak k-tableau `self`.

Each restricted subtableau of the output is a k-bounded partition.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_bounded_tableau(); c
[[1, 1, 2], [2, 3], [3]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_
↪class'>

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.to_bounded_tableau()
[[None, None, 3], [1, 4], [2]]
sage: t.to_bounded_tableau().to_core_tableau() == t
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> c = t.to_bounded_tableau(); c
[[1, 1, 2], [2, 3], [3]]
>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_
↪class'>

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> t.to_bounded_tableau()
[[None, None, 3], [1, 4], [2]]
>>> t.to_bounded_tableau().to_core_tableau() == t
```

(continues on next page)

(continued from previous page)

```
True
```

to_factorized_permutation_tableau()

Return the factorized permutation representation of the weak k-tableau `self`.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s2*s0, s3*s2, s1*s0]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_
↪category.element_class'>
sage: c.to_core_tableau() == t
True

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s0, s3, s2, s3]
sage: c._inner_shape
[2]
sage: c.to_core_tableau() == t
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),␣
↪Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> c = t.to_factorized_permutation_tableau(); c
[s2*s0, s3*s2, s1*s0]
>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_
↪category.element_class'>
>>> c.to_core_tableau() == t
True

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> c = t.to_factorized_permutation_tableau(); c
[s0, s3, s2, s3]
>>> c._inner_shape
[2]
>>> c.to_core_tableau() == t
True
```

class sage.combinat.k_tableau.**WeakTableau_factorized_permutation**(*parent*, *t*)

Bases: *WeakTableau_abstract*

A weak (skew) k-tableau represented in terms of factorizations of affine permutations into cyclically decreasing elements.

check()

Check that `self` is a valid weak k-tableau.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.check()
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.check()
```

classmethod from_core_tableau(*t*, *k*)

Construct weak factorized affine permutation tableau from a k-core tableau.

EXAMPLES:

```
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 2, 3],␣
↪[2, 3], [3]],3)
[s2*s0, s3*s2, s1*s0]
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 3, 4, 4,
↪ 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: WeakTableau_factorized_permutation.from_core_tableau([[None, 1, 1, 2,␣
↪2], [None, 2], [1]], 3)
[s0*s3, s2*s1]
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import WeakTableau_factorized_permutation
>>> WeakTableau_factorized_permutation.from_core_tableau([[Integer(1),␣
↪Integer(1), Integer(2), Integer(2), Integer(3)], [Integer(2), Integer(3)],␣
↪[Integer(3)]],Integer(3))
[s2*s0, s3*s2, s1*s0]
>>> WeakTableau_factorized_permutation.from_core_tableau([[Integer(1),␣
↪Integer(1), Integer(2), Integer(3), Integer(4), Integer(4), Integer(5),␣
↪Integer(5), Integer(6)], [Integer(2), Integer(3), Integer(5), Integer(5),␣
↪Integer(6)], [Integer(3), Integer(4), Integer(7)], [Integer(5), Integer(6)],
↪ [Integer(6)], [Integer(7)]], Integer(4))
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
>>> WeakTableau_factorized_permutation.from_core_tableau([[None, Integer(1),␣
↪Integer(1), Integer(2), Integer(2)], [None, Integer(2)], [Integer(1)]],␣
↪Integer(3))
[s0*s3, s2*s1]
```

k_charge(*algorithm='I'*)

Return the k-charge of `self`.

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.k_charge()
2
```

(continues on next page)

(continued from previous page)

```
sage: t = WeakTableau([[0],[3],[2],[1],[3],[0]], 3, representation =
↪'factorized_permutation')
sage: t.k_charge()
8
sage: t = WeakTableau([[0],[3,1],[2,1],[0,4],[3,0],[4,2],[1,0]], 4,␣
↪representation = 'factorized_permutation')
sage: t.k_charge()
12
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],
↪[Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.k_charge()
2
>>> t = WeakTableau([[Integer(0)],[Integer(3)],[Integer(2)],[Integer(1)],
↪[Integer(3)],[Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.k_charge()
8
>>> t = WeakTableau([[Integer(0)],[Integer(3),Integer(1)],[Integer(2),
↪Integer(1)],[Integer(0),Integer(4)],[Integer(3),Integer(0)],[Integer(4),
↪Integer(2)],[Integer(1),Integer(0)]], Integer(4), representation =
↪'factorized_permutation')
>>> t.k_charge()
12
```

shape_bounded()

Return the shape of `self` as a k-bounded partition.

When the tableau is straight, the outer shape is returned as a k-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as k-bounded partitions.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.shape_bounded()
[3, 2, 1]

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.shape_bounded()
([3, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.shape_bounded()
[3, 2, 1]
```

(continues on next page)

(continued from previous page)

```
>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.shape_bounded()
([3, 2, 1], [2])
```

shape_core()

Return the shape of `self` as a $(k+1)$-core.

When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

EXAMPLES:

```
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_
↪permutation')
sage: t.shape_core()
[5, 2, 1]

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.shape()
([5, 2, 1], [2])
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
↪Integer(1),Integer(0)]], Integer(3), representation = 'factorized_
↪permutation')
>>> t.shape_core()
[5, 2, 1]

>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],␣
↪Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
↪permutation')
>>> t.shape()
([5, 2, 1], [2])
```

static straighten_input(t, k)

Straightens input.

INPUT:

- `t` – list of reduced words or a list of elements in the Weyl group of type $A_k^{(1)}$
- `k` – positive integer

EXAMPLES:

```
sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.straighten_input([[2,0],[3,2],[1,0]],
↪ 3)
(s2*s0, s3*s2, s1*s0)
sage: W = WeylGroup(['A',4,1])
sage: WeakTableau_factorized_permutation.straighten_input([W.an_element(),W.
```

(continues on next page)

(continued from previous page)

```
↪an_element()], 4)
(s0*s1*s2*s3*s4, s0*s1*s2*s3*s4)
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import WeakTableau_factorized_permutation
>>> WeakTableau_factorized_permutation.straighten_input([[Integer(2),
↪Integer(0)],[Integer(3),Integer(2)],[Integer(1),Integer(0)]], Integer(3))
(s2*s0, s3*s2, s1*s0)
>>> W = WeylGroup(['A',Integer(4),Integer(1)])
>>> WeakTableau_factorized_permutation.straighten_input([W.an_element(),W.an_
↪element()], Integer(4))
(s0*s1*s2*s3*s4, s0*s1*s2*s3*s4)
```

to_core_tableau()

Return the weak k-tableau `self` where the shape of each restricted tableau is a $(k+1)$-core.

EXAMPLES:

```
sage: t = WeakTableau([[0], [3,1], [2,1], [0,4], [3,0], [4,2], [1,0]], 4,␣
↪representation = 'factorized_permutation'); t
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class
↪'>
sage: t = WeakTableau([[]], 4, representation = 'factorized_permutation'); t
[1]
sage: t.to_core_tableau()
[]

sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_
↪permutation')
sage: WeakTableau_factorized_permutation.from_core_tableau(t.to_core_
↪tableau(), 3)
[s2*s0, s3*s2, s1*s0]
sage: t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_
↪tableau(), 3)
True

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation =
↪'factorized_permutation')
sage: t.to_core_tableau()
[[None, None, 1, 1, 2], [1, 2], [2]]
sage: t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_
↪tableau(), 3)
True
```

```
>>> from sage.all import *
>>> t = WeakTableau([[Integer(0)], [Integer(3),Integer(1)], [Integer(2),
↪Integer(1)], [Integer(0),Integer(4)], [Integer(3),Integer(0)], [Integer(4),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2)], [Integer(1),Integer(0)]], Integer(4), representation =
↪'factorized_permutation'); t
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
>>> c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class
↪'>

```

`sage.combinat.k_tableau.`**`WeakTableaux`**(*k*, *shape*, *weight*, *representation='core'*)

This is the dispatcher method for the parent class of weak k-tableaux.

INPUT:

- `k` – positive integer
- `shape` – shape of the weak k-tableaux; for the 'core' and 'factorized_permutation' representation, the shape is inputted as a $(k+1)$-core; for the 'bounded' representation, the shape is inputted as a k-bounded partition; for skew tableaux, the shape is inputted as a tuple of the outer and inner shape
- `weight` – the weight of the weak k-tableaux as a list or tuple
- `representation` – `'core'`, `'bounded'`, or `'factorized_permutation'` (default: `'core'`)

EXAMPLES:

```
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T.list()
[[[1, 3, 4, 5, 6], [2, 6], [4]],
[[1, 2, 4, 5, 6], [3, 6], [4]],
```

(continues on next page)

(continued from previous page)

```

```

class sage.combinat.k_tableau.**WeakTableaux_abstract**

Bases: UniqueRepresentation, Parent

Abstract class for the various parent classes of WeakTableaux.

representation(*representation='core'*)

Return the analogue of `self` in the specified representation.

INPUT:

- `representation` – 'core', 'bounded', or 'factorized_permutation' (default: `'core'`)

EXAMPLES:

```
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1,1])
sage: T._representation
'core'
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1,␣
```

(continues on next page)

(continued from previous page)

```
↪1, 1, 1, 1)

Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight␣
↪(1, 1, 1, 1, 1, 1)
```

shape()

Return the shape of the tableaux of `self`.

When `self` is the class of straight tableaux, the outer shape is returned. When `self` is the class of skew tableaux, the tuple of the outer and inner shape is returned.

Note that in the 'core' and 'factorized_permutation' representation, the shapes are $(k+1)$-cores. In the 'bounded' representation, the shapes are k-bounded partitions.

If the user wants to access the skew shape (even if the inner shape is empty), please use `self._shape`.

EXAMPLES:

```
sage: T = WeakTableaux(3, [5,2,2], [2,2,2,1])
sage: T.shape()
[5, 2, 2]
sage: T._shape
([5, 2, 2], [])
sage: T = WeakTableaux(3, [[5,2,2], [1]], [2,1,2,1])
sage: T.shape()
([5, 2, 2], [1])

sage: T = WeakTableaux(3, [3,2,2], [2,2,2,1], representation = 'bounded')
sage: T.shape()
```

(continues on next page)

(continued from previous page)

```
[3, 2, 2]
sage: T._shape
([3, 2, 2], [])
sage: T = WeakTableaux(3, [[3,2,2], [1]], [2,1,2,1], representation = 'bounded
↪')
sage: T.shape()
([3, 2, 2], [1])

sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_
↪permutation')
sage: T.shape()
[4, 1]
sage: T._shape
([4, 1], [])
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation =
↪'factorized_permutation')
sage: T.shape()
([6, 2, 1], [2])
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(5),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(2),Integer(2),Integer(1)])
>>> T.shape()
[5, 2, 2]
>>> T._shape
([5, 2, 2], [])
>>> T = WeakTableaux(Integer(3), [[Integer(5),Integer(2),Integer(2)],␣
↪[Integer(1)]], [Integer(2),Integer(1),Integer(2),Integer(1)])
>>> T.shape()
([5, 2, 2], [1])

>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(2),Integer(2),Integer(1)], representation = 'bounded')
>>> T.shape()
[3, 2, 2]
>>> T._shape
([3, 2, 2], [])
>>> T = WeakTableaux(Integer(3), [[Integer(3),Integer(2),Integer(2)],␣
↪[Integer(1)]], [Integer(2),Integer(1),Integer(2),Integer(1)],␣
↪representation = 'bounded')
>>> T.shape()
([3, 2, 2], [1])

>>> T = WeakTableaux(Integer(3), [Integer(4),Integer(1)], [Integer(2),
↪Integer(2)], representation = 'factorized_permutation')
>>> T.shape()
[4, 1]
>>> T._shape
([4, 1], [])
>>> T = WeakTableaux(Integer(4), [[Integer(6),Integer(2),Integer(1)],␣
↪[Integer(2)]], [Integer(2),Integer(1),Integer(1),Integer(1)],␣
↪representation = 'factorized_permutation')
```

(continues on next page)

(continued from previous page)

```
>>> T.shape()
([6, 2, 1], [2])
```

size()

Return the size of the shape.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

EXAMPLES:

```
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T.size()
6
sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T.size()
6
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], 'factorized_permutation')
sage: T.size()
5
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(5),Integer(2),Integer(1)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)])
>>> T.size()
6
>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(2),Integer(1)],␣
↪[Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)],␣
↪representation = 'bounded')
>>> T.size()
6
>>> T = WeakTableaux(Integer(4), [[Integer(6),Integer(2),Integer(1)],␣
↪[Integer(2)]], [Integer(2),Integer(1),Integer(1),Integer(1)], 'factorized_
↪permutation')
>>> T.size()
5
```

class sage.combinat.k_tableau.**WeakTableaux_bounded**(*k*, *shape*, *weight*)

Bases: *WeakTableaux_abstract*

The class of (skew) weak k-tableaux in the bounded representation of shape `shape` (as k-bounded partition or tuple of k-bounded partitions in the skew case) and weight `weight`.

INPUT:

- `k` – positive integer
- `shape` – the shape of the k-tableaux represented as a k-bounded partition; if the tableaux are skew, the shape is a tuple of the outer and inner shape each represented as a k-bounded partition
- `weight` – the weight of the k-tableaux

EXAMPLES:

```
sage: T = WeakTableaux(3, [3,1], [2,2], representation = 'bounded')
sage: T.list()
[[[1, 1, 2], [2]]]

sage: T = WeakTableaux(3, [[3,2,1], [2]], [1,1,1,1], representation = 'bounded')
sage: T.list()
[[[None, None, 3], [1, 4], [2]],
[[None, None, 1], [2, 4], [3]],
[[None, None, 1], [2, 3], [4]]]
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(1)], [Integer(2),Integer(2)],
↪ representation = 'bounded')
>>> T.list()
[[[1, 1, 2], [2]]]

>>> T = WeakTableaux(Integer(3), [[Integer(3),Integer(2),Integer(1)],␣
↪[Integer(2)]], [Integer(1),Integer(1),Integer(1),Integer(1)], representation =
↪'bounded')
>>> T.list()
[[[None, None, 3], [1, 4], [2]],
[[None, None, 1], [2, 4], [3]],
[[None, None, 1], [2, 3], [4]]]
```

Element

alias of *WeakTableau_bounded*

class sage.combinat.k_tableau.**WeakTableaux_core**(*k*, *shape*, *weight*)

Bases: *WeakTableaux_abstract*

The class of (skew) weak k-tableaux in the core representation of shape `shape` (as $k+1$-core) and weight `weight`.

INPUT:

- `k` – positive integer
- `shape` – the shape of the k-tableaux represented as a $(k+1)$-core; if the tableaux are skew, the shape is a tuple of the outer and inner shape (both as $(k+1)$-cores)
- `weight` – the weight of the k-tableaux

EXAMPLES:

```
sage: T = WeakTableaux(3, [4,1], [2,2])
sage: T.list()
[[[1, 1, 2, 2], [2]]]

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1])
sage: T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
[[None, None, 1, 2, 4], [2, 4], [3]],
[[None, None, 1, 2, 3], [2, 3], [4]]]
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(4),Integer(1)], [Integer(2),Integer(2)])
```

(continues on next page)

(continued from previous page)

```
>>> T.list()
[[[1, 1, 2, 2], [2]]]

>>> T = WeakTableaux(Integer(3), [[Integer(5),Integer(2),Integer(1)],␣
↪[Integer(2)]], [Integer(1),Integer(1),Integer(1),Integer(1)])
>>> T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
[[None, None, 1, 2, 4], [2, 4], [3]],
[[None, None, 1, 2, 3], [2, 3], [4]]]
```

Element

alias of *WeakTableau_core*

circular_distance(*cr*, *r*)

Return the shortest counterclockwise distance between `cr` and `r` modulo $k+1$.

INPUT:

- `cr`, `r` – nonnegative integers between 0 and k

OUTPUT: positive integer

EXAMPLES:

```
sage: T = WeakTableaux(10, [], [])
sage: T.circular_distance(8, 6)
2
sage: T.circular_distance(8, 8)
0
sage: T.circular_distance(8, 9)
10
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(10), [], [])
>>> T.circular_distance(Integer(8), Integer(6))
2
>>> T.circular_distance(Integer(8), Integer(8))
0
>>> T.circular_distance(Integer(8), Integer(9))
10
```

diag(*c*, *ha*)

Return the number of diagonals strictly between cells `c` and `ha` of the same residue as `c`.

INPUT:

- `c` – a cell in the lattice
- `ha` – another cell in the lattice with bigger row and smaller column than c

OUTPUT: nonnegative integer

EXAMPLES:

```
sage: T = WeakTableaux(4, [5,2,2], [2,2,2,1])
sage: T.diag((1,2),(4,0))
0
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(4), [Integer(5),Integer(2),Integer(2)],␣
↪[Integer(2),Integer(2),Integer(2),Integer(1)])
>>> T.diag((Integer(1),Integer(2)),(Integer(4),Integer(0)))
0
```

class sage.combinat.k_tableau.**WeakTableaux_factorized_permutation**(k, *shape*, *weight*)

Bases: *WeakTableaux_abstract*

The class of (skew) weak k-tableaux in the factorized permutation representation of shape `shape` (as $k+1$-core or tuple of $(k+1)$-cores in the skew case) and weight `weight`.

INPUT:

- `k` – positive integer
- `shape` – the shape of the k-tableaux represented as a $(k+1)$-core; in the skew case the shape is a tuple of the outer and inner shape both as $(k+1)$-cores
- `weight` – the weight of the k-tableaux

EXAMPLES:

```
sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_permutation')
sage: T.list()
[[s3*s2, s1*s0]]

sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation = 'factorized_
↪permutation')
sage: T.list()
[[s0, s4, s3, s4*s2], [s0, s3, s4, s3*s2], [s3, s0, s4, s3*s2]]
```

```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(4),Integer(1)], [Integer(2),Integer(2)],
↪ representation = 'factorized_permutation')
>>> T.list()
[[s3*s2, s1*s0]]

>>> T = WeakTableaux(Integer(4), [[Integer(6),Integer(2),Integer(1)],␣
↪[Integer(2)]], [Integer(2),Integer(1),Integer(1),Integer(1)], representation =
↪'factorized_permutation')
>>> T.list()
[[s0, s4, s3, s4*s2], [s0, s3, s4, s3*s2], [s3, s0, s4, s3*s2]]
```

Element

alias of *WeakTableau_factorized_permutation*

sage.combinat.k_tableau.**intermediate_shapes**(t)

Return the intermediate shapes of tableau `t`.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the i-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$. The output is the list of these shapes.

OUTPUT: list of lists representing partitions

EXAMPLES:

```
sage: from sage.combinat.k_tableau import intermediate_shapes
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]],3)
sage: intermediate_shapes(t)
[[], [2], [4, 1], [5, 2, 1]]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: intermediate_shapes(t)
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import intermediate_shapes
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)],
↪ [Integer(2), Integer(3)], [Integer(3)]],Integer(3))
>>> intermediate_shapes(t)
[[], [2], [4, 1], [5, 2, 1]]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],␣
↪[Integer(1), Integer(4)], [Integer(2)]], Integer(3))
>>> intermediate_shapes(t)
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

sage.combinat.k_tableau.**nabs**(*v*)

Return the absolute value of `v` or `None`.

INPUT:

- `v` – either an integer or `None`

OUTPUT: either a nonnegative integer or `None`

EXAMPLES:

```
sage: from sage.combinat.k_tableau import nabs
sage: nabs(None)
sage: nabs(-3)
3
sage: nabs(None)
```

```
>>> from sage.all import *
>>> from sage.combinat.k_tableau import nabs
>>> nabs(None)
>>> nabs(-Integer(3))
3
>>> nabs(None)
```

Subsets

The set of subsets of a finite set. The set can be given as a list or a `sage.sets.set.Set()` or else as an integer n which encodes the set $\{1, 2, ..., n\}$. See *Subsets* for more information and examples.

class sage.combinat.subset.**SubMultiset_s**(*s*)

Bases: Parent

The combinatorial class of the sub multisets of s.

EXAMPLES:

```
sage: S = Subsets([1,2,2,3], submultiset=True)
sage: S.cardinality()
12
sage: S.list()
[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 2],
 [2, 3],
 [1, 2, 2],
 [1, 2, 3],
 [2, 2, 3],
 [1, 2, 2, 3]]
sage: S.first()
[]
sage: S.last()
[1, 2, 2, 3]
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(2),Integer(3)], submultiset=True)
>>> S.cardinality()
12
>>> S.list()
[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 2],
 [2, 3],
 [1, 2, 2],
 [1, 2, 3],
 [2, 2, 3],
 [1, 2, 2, 3]]
>>> S.first()
[]
>>> S.last()
[1, 2, 2, 3]
```

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: S = Subsets([1,1,2,3],submultiset=True)
sage: S.cardinality()
12
sage: len(S.list())
12

sage: S = Subsets([1,1,2,2,3],submultiset=True)
sage: S.cardinality()
18
sage: len(S.list())
18

sage: S = Subsets([1,1,1,2,2,3],submultiset=True)
sage: S.cardinality()
24
sage: len(S.list())
24
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(3)],
↪submultiset=True)
>>> S.cardinality()
12
>>> len(S.list())
12

>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(2),Integer(3)],
↪submultiset=True)
>>> S.cardinality()
18
>>> len(S.list())
18

>>> S = Subsets([Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3)],submultiset=True)
>>> S.cardinality()
24
>>> len(S.list())
24
```

element_class

alias of `list`

generating_serie(*variable='x'*)

Return the polynomial associated to the counting of the elements of `self` weighted by the number of element they contain.

EXAMPLES:

```
sage: Subsets([1,1],submultiset=True).generating_serie()
x^2 + x + 1
sage: Subsets([1,1,2,3],submultiset=True).generating_serie()
x^4 + 3*x^3 + 4*x^2 + 3*x + 1
```

(continues on next page)

(continued from previous page)

```
sage: Subsets([1,1,1,2,2,3,3,4],submultiset=True).generating_serie()
x^8 + 4*x^7 + 9*x^6 + 14*x^5 + 16*x^4 + 14*x^3 + 9*x^2 + 4*x + 1

sage: S = Subsets([1,1,1,2,2,3,3,4],submultiset=True)
sage: S.cardinality()
72
sage: sum(S.generating_serie())
72
```

```
>>> from sage.all import *
>>> Subsets([Integer(1),Integer(1)],submultiset=True).generating_serie()
x^2 + x + 1
>>> Subsets([Integer(1),Integer(1),Integer(2),Integer(3)],submultiset=True).
↪generating_serie()
x^4 + 3*x^3 + 4*x^2 + 3*x + 1
>>> Subsets([Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3),Integer(4)],submultiset=True).generating_serie()
x^8 + 4*x^7 + 9*x^6 + 14*x^5 + 16*x^4 + 14*x^3 + 9*x^2 + 4*x + 1

>>> S = Subsets([Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3),Integer(4)],submultiset=True)
>>> S.cardinality()
72
>>> sum(S.generating_serie())
72
```

random_element()

Return a random element of `self` with uniform law.

EXAMPLES:

```
sage: S = Subsets([1,1,2,3], submultiset=True)
sage: s = S.random_element()
sage: s in S
True
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(3)],␣
↪submultiset=True)
>>> s = S.random_element()
>>> s in S
True
```

class sage.combinat.subset.**SubMultiset_sk**(s, k)

Bases: *SubMultiset_s*

The combinatorial class of the subsets of size `k` of a multiset `s`. Note that each subset is represented by a list of the elements rather than a set since we can have multiplicities (no multiset data structure yet in sage).

EXAMPLES:

```
sage: S = Subsets([1,2,3,3],2,submultiset=True)
sage: S._k
```

(continues on next page)

(continued from previous page)

```
2
sage: S.cardinality()
4
sage: S.first()
[1, 2]
sage: S.last()
[3, 3]
sage: [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(3),Integer(3)],Integer(2),
↪submultiset=True)
>>> S._k
2
>>> S.cardinality()
4
>>> S.first()
[1, 2]
>>> S.last()
[3, 3]
>>> [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: S = Subsets([1,2,2,3,3,3],4,submultiset=True)
sage: S.cardinality()
5
sage: len(list(S))
5

sage: S = Subsets([1,2,2,3,3,3],3,submultiset=True)
sage: S.cardinality()
6
sage: len(list(S))
6
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(2),Integer(3),Integer(3),
↪Integer(3)],Integer(4),submultiset=True)
>>> S.cardinality()
5
>>> len(list(S))
5

>>> S = Subsets([Integer(1),Integer(2),Integer(2),Integer(3),Integer(3),
↪Integer(3)],Integer(3),submultiset=True)
>>> S.cardinality()
```

(continues on next page)

(continued from previous page)

```
6
>>> len(list(S))
6
```

generating_serie(*variable='x'*)

Return the polynomial associated to the counting of the elements of `self` weighted by the number of elements they contains

EXAMPLES:

```
sage: x = ZZ['x'].gen()
sage: l = [1,1,1,1,2,2,3]
sage: for k in range(len(l)):
....:     S = Subsets(l,k,submultiset=True)
....:     print(S.generating_serie('x') == S.cardinality()*x**k)
True
True
True
True
True
True
True
```

```
>>> from sage.all import *
>>> x = ZZ['x'].gen()
>>> l = [Integer(1),Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3)]
>>> for k in range(len(l)):
...     S = Subsets(l,k,submultiset=True)
...     print(S.generating_serie('x') == S.cardinality()*x**k)
True
True
True
True
True
True
True
```

random_element()

Return a random submultiset of given length.

EXAMPLES:

```
sage: s = Subsets(7,3).random_element()
sage: s in Subsets(7,3)
True

sage: s = Subsets(7,5).random_element()
sage: s in Subsets(7,5)
True
```

```
>>> from sage.all import *
>>> s = Subsets(Integer(7),Integer(3)).random_element()
```

(continues on next page)

(continued from previous page)

```
>>> s in Subsets(Integer(7),Integer(3))
True

>>> s = Subsets(Integer(7),Integer(5)).random_element()
>>> s in Subsets(Integer(7),Integer(5))
True
```
